| <code>list</code>                                                               | Print all commands available. No explanation is given.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>load</code>                                                               | <code>[message] file</code> The specified message is replaced by the message in the named file. <code>file</code> should contain a single mail message including mail headers (as saved by the <i>save</i> command).                                                                                                                                                                                                                                              |
| <code>mail recipient...</code>                                                  | Mail a message to the specified recipients.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>Mail recipient</code>                                                     | Mail a message to the specified recipients, and record it in a file whose name is derived from the author of the message. Overrides the <i>record</i> variable, if set. See also the <i>Save</i> and <i>Copy</i> commands and <i>outfolder</i> in <i>Internal Variables</i> .                                                                                                                                                                                     |

mbox [*message-list*]

Arrange for the given messages to end up in the standard mbox save file when mailx terminates normally. See MBOX in ENVIRONMENT VARIABLES for a description of this file. See also the exit and quit commands.

more [*message-list*]

page [*message-list*]

Print the specified messages. If crt is set, the messages longer than the number of lines specified by the crt variable are paged through the command specified by the PAGER variable. The default command is [pg\(1\)](#) or if the bsdcompat variable is set, the default is [more\(1\)](#). See ENVIRONMENT VARIABLES. Same as the print and type commands.

More [*message-list*]

Page [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ignore command. Same as the Print and Type commands.

new [*message-list*]

New [*message-list*]

unread [*message-list*]

Unread

[*message-list*] Take a message list and mark each message as *not* having been read.

next [*message*]

Go to the next message matching *message*. If message is not supplied, this command finds the next message that was not deleted or saved. A *message-list* may be specified, but in this case the first valid message in the list is the only one used. This is useful for jumping to the next message from a specific user, since the name would be taken as a command in the absence of a real command. See

```
pipe [message-list] [shell-command]
| [message-list] [shell-command]
```

the discussion of *message-list* above for a description of possible message specifications.

Pipe the message through the given *shell-command*. The message is treated as if it were read. If no arguments are given, the current message is piped through the command specified by the value of the `cmd` variable. If the `page` variable is set, a form feed character is inserted after each message (see `Internal Variables`).

```
preserve [message-list]
hold [message-list]
```

Preserve the specified messages in the mailbox.

```
print [message-list]
type [message-list]
```

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See `ENVIRONMENT VARIABLES`. Same as the `more` and `page` commands.

```
Print [message-list]
Type [message-list]
```

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `More` and `Page` commands.

```
put [file]
put [message-list] file
```

Save the specified message in the given file. Use the same conventions as the `print` command for which header fields are ignored.

Put [*file*]

Put [*message-list*] *file*

Save the specified message in the given file. Overrides suppression of fields by the ignore command.

quit

Exit from mailx, storing messages that were read in mbox and unread messages in the mailbox. Messages that have been explicitly saved in a file are deleted unless the keepsave variable is set.

reply [*message-list*]

respond [*message-list*]

replysender [*message-list*]

Send a response to the author of each message in the *message-list*. The subject line is taken from the first message. If record is set to a file, a copy of the reply is added to that file. If the replyall variable is set, the actions of Reply/Respond and reply/respond are reversed. The replysender command is not affected by the replyall variable, but sends each reply only to the sender of each message. See the Starting Mail section in USAGE above.

Reply [*message*]

Respond [*message*]

replyall [*message*]

Reply to the specified message, including all other recipients of that message. If the variable record is set to a file, a copy of the reply added to that file. If the replyall variable is set, the actions of Reply/Respond and reply/respond are reversed. The replyall command is not affected by the replyall variable, but always sends the reply to all recipients of the message. See the Starting Mail section in USAGE above.

retain

Add the list of header fields named to the *retained list*. Only the header fields in the retain list are shown on your terminal when you print a message. All

Save [*message-list*]

save [*file*]  
save [*message-list*] *file*

set  
set *variable*  
set *variable*=*string*  
set *variable*=*number*

other header fields are suppressed. The set of retained fields specified by the retain command overrides any list of ignored fields specified by the ignore command. The Type and Print commands can be used to print a message in its entirety. If retain is executed with no arguments, it lists the current set of retained fields.

Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author's name with all network addressing stripped off. See also the Copy, followup, and Followup commands and outfolder in Internal Variables.

Save the specified messages in the given file. The file is created if it does not exist. The file defaults to mbox. The message is deleted from the mailbox when mailx terminates unless keepsave is set (see also Internal Variables and the exit and quit commands).

Define a *variable*. To assign a *value* to *variable*, separate the variable name from the value by an '=' (there must be no space before or after the '='). A variable may be given a null, string, or numeric *value*. To embed SPACE characters within a *value*, enclose it in quotes.

With no arguments, set displays all defined variables and any values they might have. See Internal Variables for a description of all predefined mail variables.

|                                                               |                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shell                                                         | Invoke an interactive shell. See also SHELL in ENVIRONMENT VARIABLES.                                                                                                                                                                                            |
| size [ <i>message-list</i> ]                                  | Print the size in characters of the specified messages.                                                                                                                                                                                                          |
| source <i>file</i>                                            | Read commands from the given file and return to command mode.                                                                                                                                                                                                    |
| top [ <i>message-list</i> ]                                   | Print the top few lines of the specified messages. If the topLines variable is set, it is taken as the number of lines to print (see Internal Variables). The default is 5.                                                                                      |
| touch [ <i>message-list</i> ]                                 | Touch the specified messages. If any message in <i>message-list</i> is not specifically saved in a file, it is placed in the mbox, or the file specified in the MBOX environment variable, upon normal termination. See exit and quit.                           |
| Type [ <i>message-list</i> ]<br>Print [ <i>message-list</i> ] | Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ignore command.                                                                                                                                  |
| type [ <i>message-list</i> ]<br>print [ <i>message-list</i> ] | Print the specified messages. If crt is set, the messages longer than the number of lines specified by the crt variable are paged through the command specified by the PAGER variable. The default command is <a href="#">pg(1)</a> . See ENVIRONMENT VARIABLES. |
| unalias [ <i>alias</i> ] ...<br>ungroup [ <i>alias</i> ] ...  | Remove the definitions of the specified aliases.                                                                                                                                                                                                                 |
| undelete [ <i>message-list</i> ]                              | Restore the specified deleted messages. Will only restore messages deleted in the current mail session. If autoprint is set, the last message of those restored is printed (see Internal Variables).                                                             |

|                                                                                                |                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>undiscard [<i>header-field</i> . . .]<br/> unignore [<i>header-field</i> . . .]</p>         | <p>Remove the specified header fields from the list being ignored. If no header fields are specified, all header fields are removed from the list being ignored.</p>                                                                          |
| <p>unretain [<i>header-field</i> . . .]</p>                                                    | <p>Remove the specified header fields from the list being retained. If no header fields are specified, all header fields are removed from the list being retained.</p>                                                                        |
| <p>unread [<i>message-list</i>]<br/> Unread [<i>message-list</i>] Same as the new command.</p> |                                                                                                                                                                                                                                               |
| <p>unset <i>variable</i> . . .</p>                                                             | <p>Erase the specified variables. If the variable was imported from the environment (that is, an environment variable or exported shell variable), it cannot be unset from within mailx.</p>                                                  |
| <p>version</p>                                                                                 | <p>Print the current version and release date of the mailx utility.</p>                                                                                                                                                                       |
| <p>visual [<i>message-list</i>]</p>                                                            | <p>Edit the given messages with a screen editor. Each messages is placed in a temporary file and the program named by the VISUAL variable is invoked to edit it (see ENVIRONMENT VARIABLES). Notice that the default visual editor is vi.</p> |
| <p>write [<i>message-list</i>] <i>file</i></p>                                                 | <p>Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the save command.</p>                                                                                                    |
| <p>xit<br/> exit</p>                                                                           | <p>Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).</p>                                                                                                                                      |
| <p>z[+   -]</p>                                                                                | <p>Scroll the header display forward or backward one screen–full. The number of headers displayed is set by the screen variable (see Internal Variables).</p>                                                                                 |

**Tilde Escapes** The following tilde escape commands can be used when composing mail to send. These may be entered only from *input mode*, by beginning a line with the tilde escape character (~). See *escape* in *Internal Variables* for changing this special character. The escape character can be entered as text by typing it twice.

|                            |                                                                                                                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ~ ! <i>shell-command</i>   | Escape to the shell. If present, run <i>shell-command</i> .                                                                                                                                                          |
| ~.                         | Simulate end of file (terminate message input).                                                                                                                                                                      |
| ~ : <i>mail-command</i>    |                                                                                                                                                                                                                      |
| ~_ <i>mail-command</i>     | Perform the command-level request. Valid only when sending a message while reading mail.                                                                                                                             |
| ~?                         | Print a summary of tilde escapes.                                                                                                                                                                                    |
| ~A                         | Insert the autograph string <i>Sign</i> into the message (see <i>Internal Variables</i> ).                                                                                                                           |
| ~a                         | Insert the autograph string <i>sign</i> into the message (see <i>Internal Variables</i> ).                                                                                                                           |
| ~b <i>name</i> . . .       | Add the <i>names</i> to the blind carbon copy (Bcc) list. This is like the carbon copy (Cc) list, except that the names in the Bcc list are not shown in the header of the mail message.                             |
| ~c <i>name</i> . . .       | Add the <i>names</i> to the carbon copy (Cc) list.                                                                                                                                                                   |
| ~d                         | Read in the <i>dead-letter</i> file. See <i>DEAD</i> in <i>ENVIRONMENT VARIABLES</i> for a description of this file.                                                                                                 |
| ~e                         | Invoke the editor on the partial message. See also <i>EDITOR</i> in <i>ENVIRONMENT VARIABLES</i> .                                                                                                                   |
| ~f [ <i>message-list</i> ] | Forward the specified message, or the current message being read. Valid only when sending a message while reading mail. The messages are inserted into the message without alteration (as opposed to the ~m escape). |
| ~F [ <i>message-list</i> ] | Forward the specified message, or the current message being read, including all header fields. Overrides the suppression of fields by the <i>ignore</i> command.                                                     |
| ~h                         | Prompt for <i>Subject</i> line and <i>To</i> , <i>Cc</i> , and <i>Bcc</i> lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.                                      |
| ~i <i>variable</i>         | Insert the value of the named variable into the text of the message. For example, ~A is equivalent to '~i <i>Sign</i> .' Environment variables set and exported in the shell are also accessible by ~i.              |

---

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>~m [message-list]</code>     | Insert the listed messages, or the current message being read into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line.                                                                                                       |
| <code>~M [message-list]</code>     | Insert the listed messages, or the current message being read, including the header fields, into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line. Overrides the suppression of fields by the <code>ignore</code> command. |
| <code>~p</code>                    | Print the message being entered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>~q</code>                    | Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in <code>dead-letter</code> . See <code>DEAD</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file.                                                                                                                                                                                                                                                          |
| <code>~R</code>                    | Mark message for return receipt.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>~r file</code>               | Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message.                                                                                                                                                                                                                                                                                     |
| <code>~&lt; file</code>            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>~&lt; ! shell-command</code> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>~s string . . .</code>       | Set the subject line to <i>string</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>~t name . . .</code>         | Add the given <i>names</i> to the To list.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>~v</code>                    | Invoke a preferred screen editor on the partial message. The default visual editor is <code>vi(1)</code> . See also <code>VISUAL</code> in <code>ENVIRONMENT VARIABLES</code> .                                                                                                                                                                                                                                                                                                                          |
| <code>~w file</code>               | Write the message into the given file, without the header.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>~x</code>                    | Exit as with <code>~q</code> except the message is not saved in <code>dead-letter</code> .                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>~  shell-command</code>      | Pipe the body of the message through the given <i>shell-command</i> . If the <i>shell-command</i> returns a successful exit status, the output of the command replaces the message.                                                                                                                                                                                                                                                                                                                      |

**Internal Variables** The following variables are internal variables. They may be imported from the execution environment or set using the `set` command at any time. The `unset` command may be used to erase variables.

|                  |                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allnet           | All network names whose last component (login name) match are treated as identical. This causes the <i>message-list</i> message specifications to behave similarly. Disabled by default. See also the <code>alternates</code> command and the <code>metoo</code> and <code>fuzzymatch</code> variables.                                                                                      |
| alwaysignore     | Ignore header fields with <code>ignore</code> everywhere, not just during print or type. Affects the <code>save</code> , <code>Save</code> , <code>copy</code> , <code>Copy</code> , <code>top</code> , <code>pipe</code> , and <code>write</code> commands, and the <code>~m</code> and <code>~f</code> tilde escapes. Enabled by default.                                                  |
| append           | Upon termination, append messages to the end of the <code>mbox</code> file instead of prepending them. Although disabled by default, <code>append</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).                                                                                                                           |
| appenddeadletter | Append to the deadletter file rather than overwrite it. Although disabled by default, <code>appenddeadletter</code> is frequently set in the system startup file. See <code>Starting Mail</code> in <code>USAGE</code> above.                                                                                                                                                                |
| askbcc           | Prompt for the Bcc list after the Subject is entered if it is not specified on the command line with the <code>-b</code> option. Disabled by default.                                                                                                                                                                                                                                        |
| askcc            | Prompt for the Cc list after the Subject is entered if it is not specified on the command line with the <code>-c</code> option. Disabled by default.                                                                                                                                                                                                                                         |
| asksub           | Prompt for subject if it is not specified on the command line with the <code>-s</code> option. Enabled by default.                                                                                                                                                                                                                                                                           |
| autoinc          | Automatically incorporate new messages into the current session as they arrive. This has an affect similar to issuing the <code>inc</code> command every time the command prompt is displayed. Disabled by default, but <code>autoinc</code> is set in the default system startup file for <code>mailx</code> ; it is not set for <code>/usr/ucb/mail</code> or <code>/usr/ucb/Mail</code> . |
| autoprint        | Enable automatic printing of messages after delete and undelete commands. Disabled by default.                                                                                                                                                                                                                                                                                               |
| bang             | Enable the special-casing of exclamation points (!) in shell escape command lines as in <code>vi(1)</code> . Disabled by default.                                                                                                                                                                                                                                                            |
| bsdcompat        | Set automatically if <code>mailx</code> is invoked as <code>mail</code> or <code>Mail</code> . Causes <code>mailx</code> to use <code>/etc/mail/Mail.rc</code> as the system startup file. Changes the default pager to <code>more(1)</code> .                                                                                                                                               |

---

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cmd=shell-command</code> | Set the default command for the pipe command. No default value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>conv=conversion</code>   | Convert uucp addresses to the specified address style, which can be either: <ul style="list-style-type: none"> <li><code>internet</code> This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.</li> <li><code>optimize</code> Remove loops in <code>uucp(1C)</code> address paths (typically generated by the reply command). No rerouting is performed; <code>mail</code> has no knowledge of UUCP routes or connections.</li> </ul> <p>Conversion is disabled by default. See also <code>sendmail(1M)</code> and the <code>-U</code> command-line option.</p> |
| <code>crt[=number]</code>      | Pipe messages having more than <i>number</i> lines through the command specified by the value of the PAGER variable ( <code>pg(1)</code> or <code>more(1)</code> by default). If <i>number</i> is not specified, the current window size is used. Disabled by default.                                                                                                                                                                                                                                                                                                                                            |
| <code>debug</code>             | Enable verbose diagnostics for debugging. Messages are not delivered. Disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>dot</code>               | Take a period on a line by itself, or EOF during input from a terminal as end-of-file. Disabled by default, but <code>dot</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).                                                                                                                                                                                                                                                                                                                                                                        |
| <code>fcc</code>               | By default, <code>mailx</code> will treat any address containing a slash (/) character as a local send to file address. By unsetting this option, this behavior is disabled. Enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>flipr</code>             | Reverse the effect of the <code>followup/Followup</code> and <code>reply/Reply</code> command pairs. If both <code>flipr</code> and <code>replyall</code> are set, the effect is as if neither was set.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>from</code>              | Extract the author listed in the header summary from the <code>From:</code> header instead of the UNIX <code>From</code> line. Enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>fuzzymatch</code>        | The <code>from</code> command searches for messages from the indicated sender. By default, the full sender address must be specified. By setting this option, only a sub-string of the sender address need be specified. Disabled by default.                                                                                                                                                                                                                                                                                                                                                                     |

|                             |                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| escape= <i>c</i>            | Substitute <i>c</i> for the ~ escape character. Takes effect with next message sent.                                                                                                                                                                                                                                                                     |
| folder= <i>directory</i>    | The directory for saving standard mail files. User-specified file names beginning with a plus (+) are expanded by preceding the file name with this directory name to obtain the real file name. If <i>directory</i> does not start with a slash (/), \$HOME is prepended to it. There is no default for the folder variable. See also out folder below. |
| header                      | Enable printing of the header summary when entering mailx. Enabled by default.                                                                                                                                                                                                                                                                           |
| hold                        | Preserve all messages that are read in the mailbox instead of putting them in the standard mbox save file. Disabled by default.                                                                                                                                                                                                                          |
| ignore                      | Ignore interrupts while entering messages. Handy for noisy dial-up lines. Disabled by default.                                                                                                                                                                                                                                                           |
| ignoreeof                   | Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the ~. command. See also dot above. Disabled by default.                                                                                                                                                                                     |
| indentprefix= <i>string</i> | When indentprefix is set, <i>string</i> is used to mark indented lines from messages included with ~m. The default is a TAB character.                                                                                                                                                                                                                   |
| keep                        | When the mailbox is empty, truncate it to zero length instead of removing it. Disabled by default.                                                                                                                                                                                                                                                       |
| iprompt= <i>string</i>      | The specified prompt string is displayed before each line on input is requested when sending a message.                                                                                                                                                                                                                                                  |
| keepsave                    | Keep messages that have been saved in other files in the mailbox instead of deleting them. Disabled by default.                                                                                                                                                                                                                                          |
| makeremote                  | When replying to all recipients of a message, if an address does not include a machine name, it is assumed to be relative to the sender of the message. Normally not needed when dealing with hosts that support RFC822.                                                                                                                                 |
| metoo                       | If your login appears as a recipient, do not delete it from the list. Disabled by default.                                                                                                                                                                                                                                                               |
| mustbang                    | Force all mail addresses to be in bang format.                                                                                                                                                                                                                                                                                                           |
| onehop                      | When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients'                                                                                                     |

---

|                           |                                                                                                                                                                                                                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). Disabled by default.                                                                                                                                                               |
| outfolder                 | Locate the files used to record outgoing messages in the directory specified by the <code>folder</code> variable unless the path name is absolute. Disabled by default. See <code>folder</code> above and the <code>Save</code> , <code>Copy</code> , <code>followup</code> , and <code>Followup</code> commands.   |
| page                      | Used with the <code>pipe</code> command to insert a form feed after each message sent through the pipe. Disabled by default.                                                                                                                                                                                        |
| pipeignore                | Omit ignored header when outputting to the <code>pipe</code> command. Although disabled by default, <code>pipeignore</code> is frequently set in the system startup file. See <code>Starting Mail</code> in <code>USAGE</code> above.                                                                               |
| postmark                  | Your real name to be included in the <code>From</code> line of messages you send. By default this is derived from the <code>comment</code> field in your <code>passwd(4)</code> file entry.                                                                                                                         |
| prompt= <i>string</i>     | Set the <i>command mode</i> prompt to <i>string</i> . Default is “?” , unless the <code>bsdcompat</code> variable is set, then the default is “&”.                                                                                                                                                                  |
| quiet                     | Refrain from printing the opening message and version when entering <code>mailx</code> . Disabled by default.                                                                                                                                                                                                       |
| record= <i>file</i>       | Record all outgoing mail in <i>file</i> . Disabled by default. See also <code>outfolder</code> above.                                                                                                                                                                                                               |
| replyall                  | Reverse the effect of the <code>reply</code> and <code>Reply</code> and <code>followup</code> and <code>Followup</code> commands. Although set by default, <code>replyall</code> is frequently unset in the system startup file. See <code>flipr</code> and <code>Starting Mail</code> in <code>USAGE</code> above. |
| returnaddr= <i>string</i> | The default sender address is that of the current user. This variable can be used to set the sender address to any arbitrary value. Set with caution.                                                                                                                                                               |
| save                      | Enable saving of messages in dead-letter on interrupt or delivery error. See <code>DEAD</code> for a description of this file. Enabled by default.                                                                                                                                                                  |
| screen= <i>number</i>     | Sets the number of lines in a screen-full of headers for the <code>headers</code> command. <i>number</i> must be a positive number.<br><br>The default is set according to baud rate or window size. With a baud rate less than 1200, <i>number</i> defaults to 5, if baud rate is                                  |

exactly 1200, it defaults to 10. If you are in a window, *number* defaults to the default window size minus 4. Otherwise, the default is 20.

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sendmail=shell-command</code> | Alternate command for delivering messages. <i>Note:</i> In addition to the expected list of recipients, <code>mail</code> also passes the <code>-i</code> and <code>-m</code> , flags to the command. Since these flags are not appropriate to other commands, you may have to use a shell script that strips them from the arguments list before invoking the desired command. Default is <code>/usr/bin/rmail</code> .                                                                                                                                                                                                                                                                            |
| <code>sendwait</code>               | Wait for background mailer to finish before returning. Disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>showname</code>               | Causes the message header display to show the sender's real name (if known) rather than their mail address. Disabled by default, but <code>showname</code> is set in the <code>/etc/mail/mailx.rc</code> system startup file for <code>mailx</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>showto</code>                 | When displaying the header summary and the message is from you, print the recipient's name instead of the author's name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>sign=string</code>            | The variable inserted into the text of a message when the <code>~a</code> (autograph) command is given. No default (see also <code>~i</code> in Tilde Escapes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>Sign=string</code>            | The variable inserted into the text of a message when the <code>~A</code> command is given. No default (see also <code>~i</code> in Tilde Escapes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>toplines=number</code>        | The number of lines of header to print with the <code>top</code> command. Default is 5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>verbose</code>                | Invoke <code>sendmail(IM)</code> with the <code>-v</code> flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>translate</code>              | The name of a program to translate mail addresses. The program receives mail addresses as arguments. The program produces, on the standard output, lines containing the following data, in this order: <ul style="list-style-type: none"><li>▪ the postmark for the sender (see the <code>postmark</code> variable)</li><li>▪ translated mail addresses, one per line, corresponding to the program's arguments. Each translated address will replace the corresponding address in the mail message being sent.</li><li>▪ a line containing only <code>y</code> or <code>n</code>. if the line contains <code>y</code> the user will be asked to confirm that the message should be sent.</li></ul> |

The translate program will be invoked for each mail message to be sent. If the program exits with a non-zero exit status, or fails to produce enough output, the message is not sent.

**Large File Behavior** See [largefile\(5\)](#) for the description of the behavior of mailx when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of mailx: HOME, LANG, LC\_CTYPE, LC\_TIME, LC\_MESSAGES, NLSPATH, and TERM.

|            |                                                                                                                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEAD       | The name of the file in which to save partial letters in case of untimely interrupt. Default is \$HOME/dead.letter.                                                                                                                                                      |
| EDITOR     | The command to run when the edit or ~e command is used. Default is <a href="#">ed(1)</a> .                                                                                                                                                                               |
| LISTER     | The command (and options) to use when listing the contents of the folder directory. The default is <a href="#">ls(1)</a> .                                                                                                                                               |
| MAIL       | The name of the initial mailbox file to read (in lieu of the standard system mailbox). The default is /var/mail/username .                                                                                                                                               |
| MAILRC     | The name of the startup file. Default is \$HOME/.mailrc.                                                                                                                                                                                                                 |
| MAILX_HEAD | The specified string is included at the beginning of the body of each message that is sent.                                                                                                                                                                              |
| MAILX_TAIL | The specified string is included at the end of the body of each message that is sent.                                                                                                                                                                                    |
| MBOX       | The name of the file to save messages which have been read. The exit command overrides this function, as does saving the message explicitly in another file. Default is \$HOME/mbox.                                                                                     |
| PAGER      | The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is <a href="#">pg(1)</a> , or if the bsdcompat variable is set, the default is <a href="#">more(1)</a> . See <a href="#">Internal Variables</a> . |
| SHELL      | The name of a preferred command interpreter. Default is <a href="#">sh(1)</a> .                                                                                                                                                                                          |
| VISUAL     | The name of a preferred screen editor. Default is <a href="#">vi(1)</a> .                                                                                                                                                                                                |

**Exit Status** When the -e option is specified, the following exit values are returned:

- 0 Mail was found.
- >0 Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

- 0 Successful completion. Notice that this status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*.

>0 An error occurred

|              | /var/mail/*                      | post office directory                                                          |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [biff\(1B\)](#), [echo\(1\)](#), [ed\(1\)](#), [ex\(1\)](#), [fmt\(1\)](#), [ls\(1\)](#), [mail\(1\)](#), [mail\(1B\)](#), [mailcompat\(1\)](#), [more\(1\)](#), [pg\(1\)](#), [sh\(1\)](#), [uucp\(1C\)](#), [vacation\(1\)](#), [vi\(1\)](#), [newaliases\(1M\)](#), [sendmail\(1M\)](#), [aliases\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** Where *shell-command* is shown as valid, arguments are not always allowed. Experimentation is recommended.

Internal variables imported from the execution environment cannot be unset.

The full internet addressing is not fully supported by mailx. The new standards need some time to settle down.

Replies do not always generate correct return addresses. Try resending the errant reply with `onehop` set.

mailx does not lock your record file. So, if you use a record file and send two or more messages simultaneously, lines from the messages may be interleaved in the record file.

The format for the `alias` command is a space-separated list of recipients, while the format for an alias in either the `.forward` or `/etc/aliases` is a comma-separated list.

To read mail on a workstation running Solaris 1.x when your mail server is running Solaris 2.x, first execute the `mailcompat(1)` program.

**Name** make – maintain, update, and regenerate related programs and files

**Synopsis** /usr/bin/make [-d] [-dd] [-D] [-DD] [-e] [-i] [-k] [-n]  
 [-p] [-P] [-q] [-r] [-s] [-S] [-t] [-u][-w] [-V]  
 [-f *makefile*]... [-K *statefile*]... [*target*]...  
 [*macro* = *value*...]  
 /usr/xpg4/bin/make [-d] [-dd] [-D] [-DD] [-e] [-i] [-k]  
 [-n] [-p] [-P] [-q] [-r] [-s] [-S] [-t] [-u][-w] [-V]  
 [-f *makefile*]... [*target*]... [*macro* = *value*...]

**Description** The make utility executes a list of shell commands associated with each *target*, typically to create or update a file of the same name. *makefile* contains entries that describe how to bring a target up to date with respect to those on which it depends, which are called *dependencies*. Since each dependency is a target, it can have dependencies of its own. Targets, dependencies, and sub-dependencies comprise a tree structure that make traces when deciding whether or not to rebuild a *target*.

The make utility recursively checks each *target* against its dependencies, beginning with the first target entry in *makefile* if no *target* argument is supplied on the command line. If, after processing all of its dependencies, a target file is found either to be missing, or to be older than any of its dependencies, make rebuilds it. Optionally with this version of make, a target can be treated as out-of-date when the commands used to generate it have changed since the last time the target was built.

To build a given target, make executes the list of commands, called a *rule*. This rule can be listed explicitly in the target's makefile entry, or it can be supplied implicitly by make.

If no *target* is specified on the command line, make uses the first target defined in *makefile*.

If a *target* has no makefile entry, or if its entry has no rule, make attempts to derive a rule by each of the following methods, in turn, until a suitable rule is found. Each method is described under [Usage](#) below.

- Pattern matching rules.
- Implicit rules, read in from a user-supplied makefile.
- Standard implicit rules (also known as suffix rules), typically read in from the file `/usr/share/lib/make/make.rules`.
- SCCS retrieval. make retrieves the most recent version from the SCCS history file (if any). See the description of the `.SCCS_GET`: special-function target for details.
- The rule from the `.DEFAULT`: target entry, if there is such an entry in the makefile.

If there is no makefile entry for a *target*, if no rule can be derived for building it, and if no file by that name is present, make issues an error message and halts.

**Options** The following options are supported:

- d Displays the reasons why `make` chooses to rebuild a target. `make` displays any and all dependencies that are newer. In addition, `make` displays options read in from the `MAKEFLAGS` environment variable.
- dd Displays the dependency check and processing in vast detail.
- D Displays the text of the makefiles read in.
- DD Displays the text of the makefiles, `make.rules` file, the state file, and all hidden-dependency reports.
- e Environment variables override assignments within makefiles.
- f *makefile* Uses the description file *makefile*. A – as the *makefile* argument denotes the standard input. The contents of *makefile*, when present, override the standard set of implicit rules and predefined macros. When more than one -f *makefile* argument pair appears, `make` uses the concatenation of those files, in order of appearance.

When no *makefile* is specified, `/usr/bin/make` tries the following in sequence, except when in POSIX mode (see `.POSIX` in [Usage](#)):

- If there is a file named `makefile` in the working directory, `make` uses that file. If, however, there is an SCCS history file (`SCCS/s.makefile`) which is newer, `make` attempts to retrieve and use the most recent version.
- In the absence of the above file(s), if a file named `Makefile` is present in the working directory, `make` attempts to use it. If there is an SCCS history file (`SCCS/s.Makefile`) that is newer, `make` attempts to retrieve and use the most recent version.

When no *makefile* is specified, `/usr/bin/make` in POSIX mode and `/usr/xpg4/bin/make` try the following files in sequence:

- `./makefile`, `./Makefile`
  - `s.makefile`, `SCCS/s.makefile`
  - `s.Makefile`, `SCCS/s.Makefile`
- i Ignores error codes returned by commands. Equivalent to the special-function target `.IGNORE:.`
  - k When a nonzero error status is returned by a rule, or when `make` cannot find a rule, abandons work on the current target, but continues with other dependency branches that do not depend on it.
  - K *statefile* Uses the state file *statefile*. A – as the *statefile* argument denotes the standard input. The contents of *statefile*, when present, override the standard set of implicit rules and predefined macros. When more than one -K *statefile*

argument pair appears, make uses the concatenation of those files, in order of appearance. (See also `.KEEP_STATE` and `.KEEP_STATE_FILE` in the [Special-Function Targets](#) section).

- n No execution mode. Prints commands, but does not execute them. Even lines beginning with an @ are printed. However, if a command line contains a reference to the `$(MAKE)` macro, that line is always executed (see the discussion of `MAKEFLAGS` in [Reading Makefiles and the Environment](#)). When in POSIX mode, lines beginning with a “+” are executed.
- p Prints out the complete set of macro definitions and target descriptions.
- P Merely reports dependencies, rather than building them.
- q Question mode. make returns a zero or nonzero status code depending on whether or not the target file is up to date. When in POSIX mode, lines beginning with a “+” are executed.
- r Does not read in the default makefile `/usr/share/lib/make/make.rules`.
- s Silent mode. Does not print command lines before executing them. Equivalent to the special-function target `.SILENT:`.
- S Undoes the effect of the `-k` option. Stops processing when a non-zero exit status is returned by a command.
- t Touches the target files (bringing them up to date) rather than performing their rules. *Warning:* This can be *dangerous* when files are maintained by more than one person. When the `.KEEP_STATE:` target appears in the makefile, this option updates the state file just as if the rules had been performed. When in POSIX mode, lines beginning with a “+” are executed.
- u Unconditional build of targets. Even if a target is up to date, it is rebuilt. This might be useful for rebuilding all targets without cleaning.
- V Puts make into SysV mode. Refer to [sysv-make\(1\)](#) for respective details.
- w Print a message containing the working directory before and after other processing. This can be useful for tracking down errors from complicated nests of recursive make commands.
- x Puts make into the specified compatibility mode. The following compatibility modes are supported:
  1. Compatibility with POSIX:
    - x `SUN_MAKE_COMPAT_MODE=POSIX`
  2. Compatibility with SUN make:
    - x `SUN_MAKE_COMPAT_MODE=SUN`

### 3. Compatibility with GNU make (partially supported):

```
-x SUN_MAKE_COMPAT_MODE=GNU
```

### 4. Compatibility with `/usr/lib/svr4.make`:

```
-x SUN_MAKE_COMPAT_MODE=SVR4
```

**Operands** The following operands are supported:

*target* Target names, as defined in [Usage](#).

*macro=value* Macro definition. This definition overrides any regular definition for the specified macro within the makefile itself, or in the environment. However, this definition can still be overridden by conditional macro assignments.

**Usage** The usage of make is described below:

#### Reading Makefiles and the Environment

When make first starts, it reads the MAKEFLAGS environment variable to obtain any of the following options specified present in its value: `-d`, `-D`, `-e`, `-i`, `-k`, `-n`, `-p`, `-q`, `-r`, `-s`, `-S`, or `-t`. Due to the implementation of POSIX.2 (see [POSIX.2\(5\)](#)), the MAKEFLAGS values contains a leading `-` character. The make utility then reads the command line for additional options, which also take effect.

Next, make reads in a default makefile that typically contains predefined macro definitions, target entries for implicit rules, and additional rules, such as the rule for retrieving SCCS files. If present, make uses the file `make.rules` in the current directory; otherwise it reads the file `/usr/share/lib/make/make.rules`, which contains the standard definitions and rules. Use the directive:

```
include /usr/share/lib/make/make.rules
```

in your local `make.rules` file to include them.

Next, make imports variables from the environment (unless the `-e` option is in effect), and treats them as defined macros. Because make uses the most recent definition it encounters, a macro definition in the makefile normally overrides an environment variable of the same name. When `-e` is in effect, however, environment variables are read *after* all makefiles have been read. In that case, the environment variables take precedence over definitions in the makefile.

Next, make reads any makefiles you specify with `-f`, or one of `makefile` or `Makefile` as described above and then the state file, in the local directory if it exists. If the makefile contains a `.KEEP_STATE_FILE` target, then it reads the state file that follows the target. Refer to special target `.KEEP_STATE_FILE` for details.

Next (after reading the environment if `-e` is in effect), make reads in any macro definitions supplied as command line arguments. These override macro definitions in the makefile and the environment both, but only for the make command itself.

make exports environment variables, using the most recently defined value. Macro definitions supplied on the command line are not normally exported, unless the macro is also an environment variable.

make does not export macros defined in the makefile. If an environment variable is set, and a macro with the same name is defined on the command line, make exports its value as defined on the command line. Unless -e is in effect, macro definitions within the makefile take precedence over those imported from the environment.

The macros MAKEFLAGS, MAKE, SHELL, HOST\_ARCH, HOST\_MACH, and TARGET\_MACH are special cases. See [Special-Purpose Macros](#) below for details.

**Makefile Target Entries** A target entry has the following format:

```
target [:::] [dependency] ... [; command] ... [command] ...
```

The first line contains the name of a target, or a space-separated list of target names, terminated with a colon or double colon. If a list of targets is given, this is equivalent to having a separate entry of the same form for each target. The colon(s) can be followed by a *dependency*, or a dependency list. make checks this list before building the target. The dependency list can be terminated with a semicolon (;), which in turn can be followed by a single Bourne shell command. Subsequent lines in the target entry begin with a TAB and contain Bourne shell commands. These commands comprise the rule for building the target.

Shell commands can be continued across input lines by escaping the NEWLINE with a backslash (\). The continuing line must also start with a TAB.

To rebuild a target, make expands macros, strips off initial TAB characters and either executes the command directly (if it contains no shell metacharacters), or passes each command line to a Bourne shell for execution.

The first *non-empty* line that does not begin with a TAB or # begins another target or macro definition.

**Special Characters** Special characters are defined below.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Global</i> #         | Start a comment. The comment ends at the next NEWLINE. If the # follows the TAB in a command line, that line is passed to the shell (which also treats # as the start of a comment).                                                                                                                                                                                                                                             |
| include <i>filename</i> | If the word include appears as the first seven letters of a line and is followed by a SPACE or TAB, the string that follows is taken as a filename to interpolate at that line.<br><br>include files can be nested to a depth of no more than about 16. If <i>filename</i> is a macro reference, it is expanded. If <i>filename</i> is surrounded by double quotes, make searches for a <i>filename</i> with relation to current |

---

|                                 |                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                                          | makefile path. If not, make is supposed to find it with relation to <i>path</i> where make was launched.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>Targets and Dependencies</i> | :                                        | Target list terminator. Words following the colon are added to the dependency list for the target or targets. If a target is named in more than one colon-terminated target entry, the dependencies for all its entries are added to form that target's complete dependency list.                                                                                                                                                                                                                                                                                                                               |
|                                 | ::                                       | Target terminator for alternate dependencies. When used in place of a : the double-colon allows a target to be checked and updated with respect to alternate dependency lists. When the target is out-of-date with respect to dependencies listed in the first alternate, it is built according to the rule for that entry. When out-of-date with respect to dependencies in another alternate, it is built according the rule in that other entry. Implicit rules do not apply to double-colon targets; you must supply a rule for each entry. If no dependencies are specified, the rule is always performed. |
|                                 | <i>target</i> [+ <i>target</i> . . . ] : | Target group. The rule in the target entry builds all the indicated targets as a group. It is normally performed only once per make run, but is checked for command dependencies every time a target in the group is encountered in the dependency scan.                                                                                                                                                                                                                                                                                                                                                        |
|                                 | %                                        | Pattern matching wild card metacharacter. Like the * shell wild card, % matches any string of zero or more characters in a target name or dependency, in the target portion of a conditional macro definition, or within a pattern replacement macro reference. Notice that only one % can appear in a target, dependency-name, or pattern-replacement macro reference.                                                                                                                                                                                                                                         |
|                                 | ./ <i>pathname</i>                       | make ignores the leading ./ characters from targets with names given as pathnames relative to “dot,” the working directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>Macros</i>                   | =                                        | Macro definition. The word to the left of this character is the macro name; words to the right comprise its value. Leading and trailing white space characters are stripped from the value. A word break following the = is implied.                                                                                                                                                                                                                                                                                                                                                                            |
|                                 | \$                                       | Macro reference. The following character, or the parenthesized or bracketed string, is interpreted as a macro reference: make expands the reference (including the \$) by replacing it with the macro's value.                                                                                                                                                                                                                                                                                                                                                                                                  |
|                                 | ( )                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                 | { }                                      | Macro-reference name delimiters. A parenthesized or bracketed word appended to a \$ is taken as the name of the macro being referred to. Without the delimiters, make recognizes only the first character as the macro name.                                                                                                                                                                                                                                                                                                                                                                                    |
|                                 | \$\$                                     | A reference to the dollar-sign macro, the value of which is the character \$. Used to pass variable expressions beginning with \$ to the shell, to refer to environment                                                                                                                                                                                                                                                                                                                                                                                                                                         |

variables which are expanded by the shell, or to delay processing of dynamic macros within the dependency list of a target, until that target is actually processed.

- \\$ Escaped dollar-sign character. Interpreted as a literal dollar sign within a rule.
- += When used in place of =, appends a string to a macro definition (must be surrounded by white space, unlike =).
- := Conditional macro assignment. When preceded by a list of targets with explicit target entries, the macro definition that follows takes effect when processing only those targets, and their dependencies.
- :sh = Define the value of a macro to be the output of a command (see [Command Substitutions](#) below).
- :sh In a macro reference, execute the command stored in the macro, and replace the reference with the output of that command (see [Command Substitutions](#) below).

- Rules*
- + make always executes the commands preceded by a “+”, even when -n is specified.
  - make ignores any nonzero error code returned by a command line for which the first non-TAB character is a -. This character is not passed to the shell as part of the command line. make normally terminates when a command returns nonzero status, unless the -i or -k options, or the .IGNORE: special-function target is in effect.
  - @ If the first non-TAB character is a @, make does not print the command line before executing it. This character is not passed to the shell.
  - ? Escape command-dependency checking. Command lines starting with this character are not subject to command dependency checking.
  - ! Force command-dependency checking. Command-dependency checking is applied to command lines for which it would otherwise be suppressed. This checking is normally suppressed for lines that contain references to the ? dynamic macro (for example, \$?).

When any combination of +, -, @, ?, or ! appear as the first characters after the TAB, all that are present apply. None are passed to the shell.

**Special-Function Targets** When incorporated in a makefile, the following target names perform special-functions:

- .DEFAULT: If it has an entry in the makefile, the rule for this target is used to process a target when there is no other entry for it, no rule for building it, and no SCCS history file from which to retrieve a current version. make ignores any dependencies for this target.
- .DONE: If defined in the makefile, make processes this target and its dependencies after all other targets are built. This target is also performed when make halts with an error, unless the .FAILED target is defined.

---

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>.FAILED:</code>          | This target, along with its dependencies, is performed instead of <code>.DONE</code> when defined in the makefile and <code>make</code> halts with an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>.GET_POSIX:</code>       | This target contains the rule for retrieving the current version of an SCCS file from its history file in the current working directory. <code>make</code> uses this rule when it is running in POSIX mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>.IGNORE:</code>          | Ignore errors. When this target appears in the makefile, <code>make</code> ignores non-zero error codes returned from commands. When used in POSIX mode, <code>.IGNORE</code> could be followed by target names only, for which the errors is ignored.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>.INIT:</code>            | If defined in the makefile, this target and its dependencies are built before any other targets are processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>.KEEP_STATE:</code>      | If this target is in effect, <code>make</code> updates the state file, <code>.make.state</code> , in the current directory. This target also activates command dependencies, and hidden dependency checks. If either the <code>.KEEP_STATE:</code> target appears in the makefile, or the environment variable <code>KEEP_STATE</code> is set ( <code>setenv KEEP_STATE</code> ), <code>make</code> rebuilds everything in order to collect dependency information, even if all the targets were up to date due to previous <code>make</code> runs. See also the <a href="#">Environment Variables</a> section. This target has no effect if used in POSIX mode. |
| <code>.KEEP_STATE_FILE:</code> | This target has no effect if used in POSIX mode. This target implies <code>.KEEP_STATE</code> . If the target is followed by a filename, <code>make</code> uses it as the state file. If the target is followed by a directory name, <code>make</code> looks for a <code>.make.state</code> file in that directory. If the target is not followed by any name, <code>make</code> looks for <code>.make.state</code> file in the current working directory.                                                                                                                                                                                                       |
| <code>.MAKE_VERSION:</code>    | A target-entry of the form:<br><code>.MAKE_VERSION: VERSION-number</code><br>enables version checking. If the version of <code>make</code> differs from the version indicated by a string like <code>VERSION-1.0</code> , <code>make</code> issues a warning message.                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>.NO_PARALLEL:</code>     | Currently, this target has no effect, it is, however, reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>.PARALLEL:</code>        | Currently of no effect, but reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>.POSIX:</code>           | This target enables POSIX mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>.PRECIOUS:</code>        | List of files not to delete. <code>make</code> does not remove any of the files listed as dependencies for this target when interrupted. <code>make</code> normally                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

removes the current target when it receives an interrupt. When used in POSIX mode, if the target is not followed by a list of files, all the file are assumed precious.

**.SCCS\_GET:** This target contains the rule for retrieving the current version of an SCCS file from its history file. To suppress automatic retrieval, add an entry for this target with an empty rule to your makefile.

**.SCCS\_GET\_POSIX:** This target contains the rule for retrieving the current version of an SCCS file from its history file. `make` uses this rule when it is running in POSIX mode.

**.SILENT:** Run silently. When this target appears in the makefile, `make` does not echo commands before executing them. When used in POSIX mode, it could be followed by target names, and only those are executed silently.

**.SUFFIXES:** The suffixes list for selecting implicit rules (see [The Suffixes List](#)).

**.WAIT:** Currently of no effect, but reserved for future use.

*Clearing Special Targets* In this version of `make`, you can clear the definition of the following special targets by supplying entries for them with no dependencies and no rule:

**.DEFAULT**, **.SCCS\_GET**, and **.SUFFIXES**

**Command Dependencies** When the **.KEEP\_STATE:** target is effective, `make` checks the command for building a target against the state file. If the command has changed since the last `make` run, `make` rebuilds the target.

**Hidden Dependencies** When the **.KEEP\_STATE:** target is effective, `make` reads reports from [cpp\(1\)](#) and other compilation processors for any “hidden” files, such as `#include` files. If the target is out of date with respect to any of these files, `make` rebuilds it.

**Macros** Entries of the form

*macro=value*

define macros. *macro* is the name of the macro, and *value*, which consists of all characters up to a comment character or unescaped `NEWLINE`, is the value. `make` strips both leading and trailing white space in accepting the value.

Subsequent references to the macro, of the forms: `$(name)` or `${name}` are replaced by *value*. The parentheses or brackets can be omitted in a reference to a macro with a single-character name.

Macro references can contain references to other macros, in which case nested references are expanded first.

*Suffix Replacement  
Macro References* Substitutions within macros can be made as follows:

```
$(name:string1=string2)
```

where *string1* is either a suffix, or a word to be replaced in the macro definition, and *string2* is the replacement suffix or word. Words in a macro value are separated by SPACE, TAB, and escaped NEWLINE characters.

*Pattern Replacement  
Macro References* Pattern matching replacements can also be applied to macros, with a reference of the form:

```
$(name: op%os= np%ns)
```

where *op* is the existing (old) prefix and *os* is the existing (old) suffix, *np* and *ns* are the new prefix and new suffix, respectively, and the pattern matched by % (a string of zero or more characters), is carried forward from the value being replaced. For example:

```
PROGRAM=fabricate
DEBUG= $(PROGRAM:%=tmp/%-g)
```

sets the value of DEBUG to tmp/fabricate-g.

Notice that pattern replacement macro references cannot be used in the dependency list of a pattern matching rule; the % characters are not evaluated independently. Also, any number of % metacharacters can appear after the equal-sign.

*Appending to a Macro* Words can be appended to macro values as follows:

```
macro += word . . .
```

*Special-Purpose  
Macros* When the MAKEFLAGS variable is present in the environment, make takes options from it, in combination with options entered on the command line. make retains this combined value as the MAKEFLAGS macro, and exports it automatically to each command or shell it invokes.

Notice that flags passed by way of MAKEFLAGS are only displayed when the -d, or -dd options are in effect.

The MAKE macro is another special case. It has the value make by default, and temporarily overrides the -n option for any line in which it is referred to. This allows nested invocations of make written as:

```
$(MAKE) . . .
```

to run recursively, with the -n flag in effect for all commands but make. This lets you use make -n to test an entire hierarchy of makefiles.

For compatibility with the 4.2 BSD make, the MFLAGS macro is set from the MAKEFLAGS variable by prepending a -. MFLAGS is not exported automatically.

The SHELL macro, when set to a single-word value such as `/usr/bin/csh`, indicates the name of an alternate shell to use. The default is `/bin/sh`. Notice that `make` executes commands that contain no shell metacharacters itself. Built-in commands, such as `dirs` in the C shell, are not recognized unless the command line includes a metacharacter (for instance, a semicolon). This macro is neither imported from, nor exported to the environment, regardless of `-e`. To be sure it is set properly, you must define this macro within every makefile that requires it.

The syntax of the VPATH macro is:

```
VPATH = [pathname [: pathname] ...]
```

VPATH specifies a list of directories to search for the files, which are targets or dependencies, when `make` is executed. VPATH is also used in order to search for the `include` files mentioned in the particular makefile.

When processing a target or a dependency or an include directive, `make` checks the existence of the file with the same name in the current directory. If the file is found to be missing, `make` searches for this file in the list of directories presented in VPATH (like the PATH variable in the shell). Unlike the PATH variable, VPATH is used in order to search for the files with relative pathnames. When `make` attempts to apply implicit rules to the target, it also searches for the dependency files using VPATH.

When the file is found using VPATH, internal macros `$(`, `$(<`, `$(?`, `$(*`, and their alternative forms (with `D` or `F` appended) are set in accordance with the name derived from VPATH. For instance, if the target `subdir/foo.o` is found in the directory `/aaa/bbb` using VPATH, then the value of the internal macro `$(` for this target is `/aaa/bbb/subdir/foo.o`.

If a target or a dependency file is found using VPATH, then any occurrences of the word that is the same as the target name in the subsequent rules are replaced with the actual name of the target derived from VPATH.

For example:

```
VPATH=./subdir
file.o : file.c
 cc -c file.c -o file.o
```

If `file.c` is found in `./subdir`, then the command

```
cc -c ./subdir/file.c -o file.o
```

are executed.

The following macros are provided for use with cross-compilation:

|           |                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HOST_ARCH | The processor type of the host system. By default, this is the output of the <code>mach(1)</code> command, prepended with <code>-</code> . Under normal circumstances, this value should never be altered by the user. |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`HOST_MACH`      The machine architecture of the host system. By default, this is the output of the `arch(1)` command, prepended with `-`. Under normal circumstances, this value should never be altered by the user.

`TARGET_ARCH`    The processor type of the target system. By default, the output of `mach`, prepended with `-`.

Dynamic Macros    There are several dynamically maintained macros that are useful as abbreviations within rules. They are shown here as references; if you were to define them, `make` would simply override the definition.

`$$*`      The basename of the current target, derived as if selected for use with an implicit rule.

`$$<`      The name of a dependency file, derived as if selected for use with an implicit rule.

`$$@`      The name of the current target. This is the only dynamic macro whose value is strictly determined when used in a dependency list. (In which case it takes the form `$$@`.)

`$$?`      The list of dependencies that are newer than the target. Command-dependency checking is automatically suppressed for lines that contain this macro, just as if the command had been prefixed with a `?`. See the description of `?`, under *Special Character Rules* above. You can force this check with the `!` command-line prefix.

`$$%`      The name of the library member being processed. (See *Library Maintenance* below.)

To refer to the `$$@` dynamic macro within a dependency list, precede the reference with an additional `$` character (as in, `$$$@`). Because `make` assigns `$$<` and `$$*` as it would for implicit rules (according to the suffixes list and the directory contents), they can be unreliable when used within explicit target entries.

These macros can be modified to apply either to the filename part, or the directory part of the strings they stand for, by adding an upper case `F` or `D`, respectively (and enclosing the resulting name in parentheses or braces). Thus, `$(@D)` refers to the directory part of the string `$$@`; if there is no directory part, `.` is assigned. `$(@F)` refers to the filename part.

Conditional Macro Definitions    A macro definition of the form:

```
target-list := macro = value
```

indicates that when processing any of the targets listed *and their dependencies*, *macro* is to be set to the *value* supplied. Notice that if a conditional macro is referred to in a dependency list, the `$` must be delayed (use `$$` instead). Also, *target-list* can contain a `%` pattern, in which case the macro is conditionally defined for all targets encountered that match the pattern. A pattern replacement reference can be used within the *value*.

You can temporarily append to a macros value with a conditional definition of the form:

```
target-list := macro += value
```

Predefined Macros `make` supplies the macros shown in the table that follows for compilers and their options, host architectures, and other commands. Unless these macros are read in as environment variables, their values are not exported by `make`. If you run `make` with any of these set in the environment, it is a good idea to add commentary to the makefile to indicate what value each is expected to take. If `-r` is in effect, `make` does not read the default makefile (`./make.rules` or `/usr/share/lib/make/make.rules`) in which these macro definitions are supplied.

**Implicit Rules** When a target has no entry in the makefile, `make` attempts to determine its class (if any) and apply the rule for that class. An implicit rule describes how to build any target of a given class, from an associated dependency file. The class of a target can be determined either by a pattern, or by a suffix; the corresponding dependency file (with the same basename) from which such a target might be built. In addition to a predefined set of implicit rules, `make` allows you to define your own, either by pattern, or by suffix.

**Pattern Matching Rules** A target entry of the form:

```
tp%ts: dp%ds
 rule
```

is a pattern matching rule, in which *tp* is a target prefix, *ts* is a target suffix, *dp* is a dependency prefix, and *ds* is a dependency suffix (any of which can be null). The % stands for a basename of zero or more characters that is matched in the target, and is used to construct the name of a dependency. When `make` encounters a match in its search for an implicit rule, it uses the rule in that target entry to build the target from the dependency file. Pattern-matching implicit rules typically make use of the `$(` and `$(` dynamic macros as placeholders for the target and dependency names. Other, regular dependencies can occur in the dependency list; however, none of the regular dependencies can contain %. An entry of the form:

```
tp%ts: [dependency...] dp%ds [dependency...]
 rule
```

is a valid pattern matching rule.

**Suffix Rules** When no pattern matching rule applies, `make` checks the target name to see if it ends with a suffix in the known suffixes list. If so, `make` checks for any suffix rules, as well as a dependency file with same root and another recognized suffix, from which to build it.

The target entry for a suffix rule takes the form:

```
DsTs: rule
```

where *Ts* is the suffix of the target, *Ds* is the suffix of the dependency file, and *rule* is the rule for building a target in the class. Both *Ds* and *Ts* must appear in the suffixes list. (A suffix need not begin with a . to be recognized.)

A suffix rule with only one suffix describes how to build a target having a null (or no) suffix from a dependency file with the indicated suffix. For instance, the `.c` rule could be used to build an executable program named `file` from a C source file named `file.c`. If a target with a null suffix has an explicit dependency, `make` omits the search for a suffix rule.

Table of Standard Implicit (Suffix) Rules for Assembly Files

| Implicit Rule Name | Command Line                             |
|--------------------|------------------------------------------|
| <code>.s.o</code>  | <code>\$(COMPILE.s) -o \$@ \$&lt;</code> |

make reads in the standard set of implicit rules from the file `/usr/share/lib/make/make.rules`, unless `-r` is in effect, or there is a `make.rules` file in the local directory that does not include that file.

**The Suffixes List** The suffixes list is given as the list of dependencies for the `.SUFFIXES:` special-function target. The default list is contained in the `SUFFIXES` macro (See *Table of Predefined Macros* for the standard list of suffixes). You can define additional `.SUFFIXES:` targets; a `.SUFFIXES` target with no dependencies clears the list of suffixes. Order is significant within the list; make selects a rule that corresponds to the target's suffix and the first dependency-file suffix found in the list. To place suffixes at the head of the list, clear the list and replace it with the new suffixes, followed by the default list:

```
.SUFFIXES:
.SUFFIXES: suffixes $(SUFFIXES)
```

A tilde (~) indicates that if a dependency file with the indicated suffix (minus the ~) is under SCCS its most recent version should be retrieved, if necessary, before the target is processed.

**Library Maintenance** A target name of the form:

```
lib(member ...)
```

refers to a member, or a space-separated list of members, in an `ar(1)` library.

The dependency of the library member on the corresponding file must be given as an explicit entry in the makefile. This can be handled by a pattern matching rule of the form:

```
lib(%.s): %.s
```

where `.s` is the suffix of the member; this suffix is typically `.o` for object libraries.

A target name of the form:

```
lib((symbol))
```

refers to the member of a randomized object library that defines the entry point named *symbol*.

**Command Execution** Command lines are executed one at a time, *each by its own process or shell*. Shell commands, notably `cd`, are ineffectual across an unescaped `NEWLINE` in the makefile. A line is printed (after macro expansion) just before being executed. This is suppressed if it starts with a `@`, if there is a `.SILENT` entry in the makefile, or if `make` is run with the `-s` option. Although the `-n` option specifies printing without execution, lines containing the macro `$(MAKE)` are executed regardless, and lines containing the `@` special character are printed. The `-t` (`touch`) option updates the modification date of a file without executing any rules. This can be dangerous when sources are maintained by more than one person.

`make` invokes the shell with the `-e` (`exit-on-errors`) argument. Thus, with semicolon-separated command sequences, execution of the later commands depends on the success of the former. This behavior can be overridden by starting the command line with a `-`, or by writing a shell script that returns a non-zero status only as it finds appropriate.

**Bourne Shell Constructs** To use the Bourne shell `if` control structure for branching, use a command line of the form:

```
if expression ; \
then command ; \
 ... ; \
else command; \
 ... ; \
fi
```

Although composed of several input lines, the escaped `NEWLINE` characters insure that `make` treats them all as one (shell) command line.

To use the Bourne shell `for` control structure for loops, use a command line of the form:

```
for var in list ; \
do command; \
 ... ; \done
```

To refer to a shell variable, use a double-dollar-sign (`$$`). This prevents expansion of the dollar-sign by `make`.

**Command Substitutions** To incorporate the standard output of a shell command in a macro, use a definition of the form:

```
MACRO :sh =command
```

The command is executed only once, standard error output is discarded, and `NEWLINE` characters are replaced with `SPACES`. If the command has a non-zero exit status, `make` halts with an error.

To capture the output of a shell command in a macro reference, use a reference of the form:

```
$(MACRO :sh)
```

where *MACRO* is the name of a macro containing a valid Bourne shell command line. In this case, the command is executed whenever the reference is evaluated. As with shell command substitutions, the reference is replaced with the standard output of the command. If the command has a non-zero exit status, *make* halts with an error.

In contrast to commands in rules, the command is not subject for macro substitution; therefore, a dollar sign (\$) need not be replaced with a double dollar sign (\$\$).

*Signals* INT, SIGTERM, and QUIT signals received from the keyboard halt *make* and remove the target file being processed unless that target is in the dependency list for `.PRECIOUS:`.

*Compatibility with GNU make* The compatibility mode with GNU *make* changes Oracle Solaris *make*'s behavior with respect to the dynamic macro `$<`. By default the Oracle Solaris *make* treats this macro as the name of a dependency file, derived as if selected for use with an implicit rule.

GNU *make* treats this macro as the name of a dependency, even if it is not a file. If the `-x SUN_MAKE_COMPAT_MODE=GNU` option is passed to the Oracle Solaris *make*, it behaves as GNU *make* in this particular case.

### Examples **EXAMPLE 1** Defining dependencies

This makefile says that `pgm` depends on two files `a.o` and `b.o`, and that they in turn depend on their corresponding source files (`a.c` and `b.c`) along with a common file `incl.h`:

```
pgm: a.o b.o
 $(LINK.c) -o $@a.o b.o
a.o: incl.h a.c
 cc -c a.c
b.o: incl.h b.c
 cc -c b.c
```

### **EXAMPLE 2** Using implicit rules

The following makefile uses implicit rules to express the same dependencies:

```
pgm: a.o b.o
 cc a.o b.o -o pgm
a.o b.o: incl.h
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of *make*: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**KEEP\_STATE** This environment variable has the same effect as the `.KEEP_STATE`: special-function target. It enables command dependencies, hidden dependencies and writing of the state file.

**USE\_SVR4\_MAKE** This environment variable causes *make* to invoke the generic System V version of *make* (`/usr/lib/svr4.make`). See [sysV-make\(1\)](#).

---

**MAKEFLAGS**

This variable is interpreted as a character string representing a series of option characters to be used as the default options. The implementation accepts both of the following formats (but need not accept them when intermixed):

1. The characters are option letters without the leading hyphens or blank character separation used on a command line.
2. The characters are formatted in a manner similar to a portion of the `make` command line: options are preceded by hyphens and blank-character-separated. The `macro=name` macro definition operands can also be included. The difference between the contents of `MAKEFLAGS` and the command line is that the contents of the variable is not subjected to the word expansions associated with parsing the command line values. See [wordexp\(3C\)](#).

When the command-line options `-f` or `-p` are used, they take effect regardless of whether they also appear in `MAKEFLAGS`. If they otherwise appear in `MAKEFLAGS`, the result is undefined.

The `MAKEFLAGS` variable is accessed from the environment before the makefile is read. At that time, all of the options (except `-f` and `-p`) and command-line macros not already included in `MAKEFLAGS` are added to the `MAKEFLAGS` macro. The `MAKEFLAGS` macro is passed into the environment as an environment variable for all child processes. If the `MAKEFLAGS` macro is subsequently set by the makefile, it replaces the `MAKEFLAGS` variable currently found in the environment.

**PROJECTDIR**

Provides a directory to be used to search for SCCS files not found in the current directory. In all of the following cases, the search for SCCS files is made in the directory `SCCS` in the identified directory. If the value of `PROJECTDIR` begins with a slash, it shall be considered an absolute pathname. Otherwise, the value of `PROJECTDIR` is treated as a user name and that user's initial working directory shall be examined for a subdirectory `src` or `source`. If such a directory is found, it shall be used. Otherwise, the value is used as a relative pathname.

If `PROJECTDIR` is not set or has a null value, the search for SCCS files shall be made in the directory `SCCS` in the current directory. The setting of `PROJECTDIR` affects all files listed in the remainder of this utility description for files with a component named `SCCS`.

`SUN_MAKE_COMPAT_MODE` Causes make to change behavior according to the specified compatibility mode. Examples:

```
SUN_MAKE_COMPAT_MODE="POSIX"
 Support POSIX makefiles and compatibility with
 /usr/xpg4/bin/make

SUN_MAKE_COMPAT_MODE="SUN"
 Support Sun makefiles and compatibility with Oracle Solaris
 /usr/bin/make

SUN_MAKE_COMPAT_MODE="GNU"
 Support GNU makefiles and GNU make behavior (partially
 supported)

SUN_MAKE_COMPAT_MODE="SVR4"
 Support SVR4 makefiles and compatibility with
 /usr/lib/svr4.make
```

**Exit Status** When the `-q` option is specified, the make utility exits with one of the following values:

```
0 Successful completion.
1 The target was not up-to-date.
>1 An error occurred.
```

When the `-q` option is not specified, the make utility exits with one of the following values:

```
0 Successful completion
>0 An error occurred
```

**Files**

|                                             |                                                                                          |

*Solaris Advanced User's Guide*

**Diagnostics** Don't know how to make target *target*

There is no makefile entry for *target*, and none of make's implicit rules apply (there is no dependency file with a suffix in the suffixes list, or the target's suffix is not in the list).

\*\*\* *target* removed.

make was interrupted while building *target*. Rather than leaving a partially-completed version that is newer than its dependencies, make removes the file named *target*.

\*\*\* *target* not removed.

make was interrupted while building *target* and *target* was not present in the directory.

\*\*\* *target* could not be removed, *reason*

make was interrupted while building *target*, which was not removed for the indicated reason.

Read of include file *file* failed

The makefile indicated in an include directive was not found, or was inaccessible.

Loop detected when expanding macro value *macro*'

A reference to the macro being defined was found in the definition.

Could not write state file *file*

You used the .KEEP\_STATE: target, but do not have write permission on the state file.

\*\*\*Error code *n*

The previous shell command returned a nonzero error code.

\*\*\* *signal message*

The previous shell command was aborted due to a signal. If – core dumped appears after the message, a core file was created.

Conditional macro conflict encountered

Displayed only when `-d` is in effect, this message indicates that two or more parallel targets currently being processed depend on a target which is built differently for each by virtue of conditional macros. Since the target cannot simultaneously satisfy both dependency relationships, it is conflicted.

**Bugs** Some commands return nonzero status inappropriately; to overcome this difficulty, prefix the offending command line in the rule with a `–`.

Filenames with the characters `=`, `:`, or `@`, do not work.

You cannot build `file.o` from `lib(file.o)`.

Options supplied by `MAKEFLAGS` should be reported for nested `make` commands. Use the `-d` option to find out what options the nested command picks up from `MAKEFLAGS`.

This version of `make` is incompatible in certain respects with previous versions:

- The `-d` option output is much briefer in this version. `–dd` now produces the equivalent voluminous output.
- `make` attempts to derive values for the dynamic macros `$$*`, `$$<`, and `$$?`, while processing explicit targets. It uses the same method as for implicit rules; in some cases this can lead either to unexpected values, or to an empty value being assigned. (Actually, this was true for earlier versions as well, even though the documentation stated otherwise.)
- `make` no longer searches for SCCS history (`s.`) files.
- Suffix replacement in macro references are now applied after the macro is expanded.

There is no guarantee that makefiles created for this version of `make` works with earlier versions.

If there is no `make.rules` file in the current directory, and the file `/usr/share/lib/make/make.rules` is missing, `make` stops before processing any targets. To force `make` to run anyway, create an empty `make.rules` file in the current directory.

Once a dependency is made, `make` assumes the dependency file is present for the remainder of the run. If a rule subsequently removes that file and future targets depend on its existence, unexpected errors can result.

When hidden dependency checking is in effect, the `$$?` macro's value includes the names of hidden dependencies. This can lead to improper filename arguments to commands when `$$?` is used in a rule.

Pattern replacement macro references cannot be used in the dependency list of a pattern matching rule.

Unlike previous versions, this version of `make` strips a leading `./` from the value of the `$$@` dynamic macro.

With automatic SCCS retrieval, this version of `make` does not support tilde suffix rules.

The only dynamic macro whose value is strictly determined when used in a dependency list is `$$` (takes the form `$$@`).

`make` invokes the shell with the `-e` argument. This cannot be inferred from the syntax of the rule alone.

**Name** makekey – generate encryption key

**Synopsis** /usr/lib/makekey

**Description** makekey improves the usefulness of encryption schemes that depend on a key by increasing the amount of time required to search the key space. It attempts to read 8 bytes for its *key* (the first eight input bytes), then it attempts to read 2 bytes for its *salt* (the last two input bytes). The output depends on the input in a way intended to be difficult to compute (that is, to require a substantial fraction of a second).

The first eight input bytes (the *input key*) can be arbitrary ASCII characters. The last two (the *salt*) are best chosen from the set of digits, ., /, upper- and lower-case letters. The salt characters are repeated as the first two characters of the output. The remaining 11 output characters are chosen from the same set as the *salt* and constitute the *output key*.

The transformation performed is essentially the following: the *salt* is used to select one of 4,096 cryptographic machines all based on the National Bureau of Standards DES algorithm, but broken in 4,096 different ways. Using the *input key* as key, a constant string is fed into the machine and recirculated a number of times. The 64 bits that come out are distributed into the 66 *output key* bits in the result.

makekey is intended for programs that perform encryption. Usually, its input and output will be pipes.

**See Also** [ed\(1\)](#), [vi\(1\)](#), [passwd\(4\)](#)

**Notes** makekey can produce different results depending upon whether the input is typed at the terminal or redirected from a file.

- 
- Name** man – find and display reference manual pages
- Synopsis** man [-] [-adFlrt] [-M *path*] [-T *macro-package*] [-s *section*] *name*...  
 man [-M *path*] [-s *section*] -k *query*...  
 man [-M *path*] -f *file*...  
 man [-M *path*] [-s *section*] -K *query*...
- Description** The man command displays information from the reference manuals. It displays complete manual pages that you select by *name*, or one-line summaries selected either by *query* (-k or -K), or by the name of an associated file (-f). If no manual page is located, man prints an error message.
- Source Format** Reference Manual pages are marked up with either nroff (see [nroff\(1\)](#)) or SGML (Standard Generalized Markup Language) tags (see [sgml\(5\)](#)). The man command recognizes the type of markup and processes the file accordingly. The various source files are kept in separate directories depending on the type of markup.
- Location of Manual Pages** The online Reference Manual page directories are conventionally located in /usr/share/man. The nroff sources are located in the /usr/share/man/man\* directories. The SGML sources are located in the /usr/share/man/sman\* directories. Each directory corresponds to a section of the manual. Since these directories are optionally installed, they might not reside on your host. You might have to mount /usr/share/man from a host on which they do reside.
- If there are preformatted, up-to-date versions in the corresponding cat\* or fmt\* directories, man simply displays or prints those versions. If the preformatted version of interest is out of date or missing, man reformats it prior to display and stores the preformatted version if cat\* or fmt\* is writable. The index files are not updated. See [catman\(1M\)](#). If directories for the preformatted versions are not provided, man reformats a page whenever it is requested. man uses a temporary file to store the formatted text during display.
- If the standard output is not a terminal, or if the '-l' flag is given, man pipes its output through [cat\(1\)](#). Otherwise, man pipes its output through [more\(1\)](#) to handle paging and underlining on the screen.
- Query Strings** Using -k or -K options, manual pages can be searched with *query*, one or more terms or phrases. It supports index-file-based, full text searching, stemming, and section matching. For information regarding how to generate the index files, refer to [catman\(1M\)](#) and [man\(5\)](#).
- Stemming for English, for example, identifies the string cats, catlike, catty, and so forth, based on the root cat. It identifies stemmer, stemming, and stemmed based on stem. A stemming algorithm reduces the words fishing, fished, fish, and fisherto the root word, fish.
- Matching is done in case-insensitive manner. Stemming is done for English manual pages only.

Matched manual pages are sorted and presented based on the score of the query matches in ascending order.

Oracle Solaris manual pages are divided into sections such as NAME, SYNOPSIS, DESCRIPTION, and so forth. Users can specify the scope of search into a section as details described in the -K option.

**Options** The following options are supported:

- a  
Shows all manual pages matching *name* within the MANPATH search path. Manual pages are displayed in the order found.
- d  
Debugs. Displays what a section-specifier evaluates to, method used for searching, and paths searched by man.
- f *file* ...  
man attempts to locate manual pages related to any of the given *files*. It strips the leading path name components from each *file*, and then prints one-line summaries containing the resulting basename or names.

This option uses the index files. Refer to [catman\(1M\)](#) and [man\(5\)](#) for details on how index files are generated.

- F  
Forces man to search all directories specified by MANPATH or the man.cf file, rather than using the index lookup files. This option is useful if the index files are not up to date and they have been made the default behavior of the man command. The option therefore does not have to be invoked and is documented here for reference only.
- k *query* ...  
Prints out one-line summaries from the index files.

See the -K option for information regarding how the index files are generated. If there are no index files, manual page files are directly looked up, therefore yielding slower response time than cases where index files exist.

- K *query* ...  
Search for the specified query from the index files. If there are no index files, search is directly done on the manual pages, which causes a much slower search.

If you supply a section name ending with a colon (:) at the query option argument as the first text from left, just as *section name: query*, the search for the query string is done on the specified section only. If the specified section name does not exist, it will list all the supported section name for users.

The index files in /usr/share/man and /usr/gnu/share/man used by -f, -k, and -K are automatically generated when man pages in those directories are installed or updated and

the packages delivering them have tagged the files with `restart_fmri=svc:/application/man-index:default` as specified in [pkg\(5\)](#). They may also be generated by running `svcadm restart application/man-index` manually, or running [catman\(1M\)](#) with the `-w`.

`-l`

Lists all manual pages found matching *name* within the search path.

`-M path`

Specifies an alternate search path for manual pages. *path* is a colon-separated list of directories that contain manual page directory subtrees. For example, if *path* is `/usr/share/man:/usr/local/man`, `man` searches for *name* in the standard location, and then `/usr/local/man`. When used with the `-f`, `-k` or `-K` options, the `-M` option must appear first. Each directory in the *path* is assumed to contain subdirectories of the form `man*` or `sman*`, one for each section. This option overrides the `MANPATH` environment variable.

`-r`

Reformats the manual page, but does not display it. This replaces the `man -t name` combination.

`-s section ...`

Specifies sections of the manual for `man` to search. The directories searched for *name* are limited to those specified by *section*. *section* can be a numerical digit, perhaps followed by one or more letters to match the desired section of the manual, for example, “3lib”. Also, *section* can be a word, for example, `local`, `new`, `old`, `public`. *section* can also be a letter. To specify multiple sections, separate each section with a comma. This option overrides the `MANPATH` environment variable and the `man.cf` file. See Search Path below for an explanation of how `man` conducts its search.

`-t`

`man` arranges for the specified manual pages to be troffed to a suitable raster output device (see [troff\(1\)](#)). If both the `-` and `-t` flags are given, `man` updates the troffed versions of each named *name* (if necessary), but does not display them.

`-T macro-package`

Formats manual pages using *macro-package* rather than the standard `-man` macros defined in `/usr/share/lib/tmac/an`. See Search Path under USAGE for a complete explanation of the default search path order.

**Operands** The following operand is supported:

*name*

The name of a standard utility or a keyword.

**Usage** The usage of `man` is described below:

**Manual Page Sections** Entries in the reference manuals are organized into *sections*. A section name consists of a major section name, typically a single digit, optionally followed by a subsection name, typically one or more letters. An unadorned major section name, for example, “9”, does not act as an abbreviation for the subsections of that name, such as “9e”, “9f”, or “9s”. That is, each subsection must be searched separately by `man -s`. Each section contains descriptions apropos to a particular reference category, with subsections refining these distinctions. See the `intro` manual pages for an explanation of the classification used in this release.

The following contains a brief description of each manual page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9E describes the DDI (Device Driver Interface)/DKI (Driver/Kernel Interface), DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

**Search Path** Before searching for a given *name*, `man` constructs a list of candidate directories and sections. `man` searches for *name* in the directories specified by the `MANPATH` environment variable.

In the absence of `MANPATH`, `man` constructs its search path based upon the `PATH` environment variable, primarily by substituting `man` for the last component of the `PATH` element. Special provisions are added to account for unique characteristics of directories such as `/sbin`, `/usr/ucb`, `/usr/xpg4/bin`, and others. If the file argument contains a `/` character, the *dirname* portion of the argument is used in place of `PATH` elements to construct the search path.

Within the manual page directories, `man` confines its search to the sections specified in the following order:

- *sections* specified on the command line with the `-s` option

- *sections* embedded in the MANPATH environment variable
- *sections* specified in the man.cf file for each directory specified in the MANPATH environment variable

If none of the above exist, man searches each directory in the manual page path, and displays the first matching manual page found.

The man.cf file has the following format:

```
MANSECTS=section[,section] . . .
```

Lines beginning with '#' and blank lines are considered comments, and are ignored. Each directory specified in MANPATH can contain a manual page configuration file, specifying the default search order for that directory.

### Formatting Manual Pages

Manual pages are marked up in `nroff(1)` or `sgml(5)`. `nroff` manual pages are processed by `nroff(1)` or `troff(1)` with the `-man` macro package. Please refer to `man(5)` for information on macro usage. SGML—tagged manual pages are processed by an SGML parser and passed to the formatter.

### Preprocessing `nroff` Manual Pages

When formatting an `nroff` manual page, man examines the first line to determine whether it requires special processing. If the first line is a string of the form:

```
'\ " X
```

where *X* is separated from the "" by a single SPACE and consists of any combination of characters in the following list, man pipes its input to `troff(1)` or `nroff(1)` through the corresponding preprocessors.

e

`eqn(1)`, or `neqn` for `nroff`

r

`refer(1)`

t

`tbl(1)`

v

`vgrind(1)`

If `eqn` or `neqn` is invoked, it automatically reads the file `/usr/pub/eqnchar` (see `eqnchar(5)`). If `nroff(1)` is invoked, `col(1)` is automatically used.

### Referring to Other `nroff` Manual Pages

If the first line of the `nroff` manual page is a reference to another manual page entry fitting the pattern:

```
.so man*/sourcefile
```

man processes the indicated file in place of the current one. The reference must be expressed as a path name relative to the root of the manual page directory subtree.

When the second or any subsequent line starts with `.so`, `man` ignores it; `troff(1)` or `nroff(1)` processes the request in the usual manner.

**Processing SGML Manual Pages** Manual pages are identified as being marked up in SGML by the presence of the string `<!DOCTYPE`. If the file also contains the string `SHADOW_PAGE`, the file refers to another manual page for the content. The reference is made with a file entity reference to the manual page that contains the text. This is similar to the `.so` mechanism used in the `nroff` formatted manual pages.

**Environment Variables** See `environ(5)` for descriptions of the following environment variables that affect the execution of `man`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

#### MANPATH

A colon-separated list of directories; each directory can be followed by a comma-separated list of sections. If set, its value overrides `/usr/share/man` as the default directory search path, and the `man.cf` file as the default section search path. The `-M` and `-s` flags, in turn, override these values.)

#### PAGER

A program to use for interactively delivering `man`'s output to the screen. If not set, `'more -s'` is used. See `more(1)`.

#### TCAT

The name of the program to use to display `troffed` manual pages.

#### TROFF

The name of the formatter to use when the `-t` flag is given. If not set, `troff(1)` is used.

### Examples

**EXAMPLE 1** Creating a Text Version of a Manual Page

The following example creates the `pipe(2)` manual page in `ascii` text:

```
% man pipe.2 | col -x -b > pipe.text
```

This is an alternative to using `man -t`, which sends the manual page to the default printer, if the user wants a text file version of the manual page.

**EXAMPLE 2** Getting a List of Manual Pages that Match One or More Terms

The following example gets a list of manual pages that match for the term `zfs` or `create`:

```
% man -K zfs create
```

**EXAMPLE 3** Getting a List of Manual Pages that Match One or More Phrases

The following example gets a list of manual pages that match for the quote-enclosed phrases, `"zfs create"` or `"storage pool"`.

```
% man -K 'zfs create' "storage pool"
```

**EXAMPLE 4** Getting a List of Manual Pages that Match Terms or Phrases in a Section

The following example gets a list of manual pages that have the term `zfs` in the `SEE ALSO` section:

```
% man -K see also: zfs
```

The following example gets a list of manual pages that have the phrase “`zfs create`” in the `Examples` section:

```
% man -K examples: "zfs create"
```

**Exit Status** The following exit values are returned:

```
0
 Successful completion.
>0
 An error occurred.
```

**Files** `/usr/share/man`  
 Root of the standard manual page directory subtree

`/usr/share/man/man?/*`  
 Unformatted `nroff` manual entries

`/usr/share/man/man_index/*`  
 Table of Contents and keyword database.

Generated files include:

- `/usr/share/man/man-index/man.idx`
- `/usr/share/man/man-index/man.dic`
- `/usr/share/man/man-index/man.req`
- `/usr/share/man/man-index/man.pos`
- `/usr/share/man/man-index/man.doc`

`/usr/share/man/sman?/*`  
 Unformatted SGML manual entries

`/usr/share/man/cat?/*`  
`nroffed` manual entries

`/usr/share/man/fmt?/*`  
`troffed` manual entries

`/usr/share/lib/tmac/an`  
 Standard `–man` macro package

`/usr/share/lib/sgml/locale/C/dtd/*`  
 SGML document type definition files

`/usr/share/lib/sgml/locale/C/solbook/*`  
 SGML style sheet and entity definitions directories

`/usr/share/lib/pub/eqnchar`  
 Standard definitions for eqn and neqn

`man.cf`  
 Default search order by section

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | text/doctools                      |
| CSI                 | Enabled, see NOTES.                |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [apropos\(1\)](#), [cat\(1\)](#), [col\(1\)](#), [eqn\(1\)](#), [more\(1\)](#), [nroff\(1\)](#), [refer\(1\)](#), [tbl\(1\)](#), [ttr\(1\)](#), [vgrind\(1\)](#), [whatis\(1\)](#), [catman\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [eqnchar\(5\)](#), [man\(5\)](#), [sgml\(5\)](#), [standards\(5\)](#)

**Notes** The `-f`, `-k`, and `-K` options use the index files which are created by the SMF service as specified in [man\(5\)](#), or by manually using [catman\(1M\)](#) with the `-w` option.

The `windex` database file is no longer used. The `windex` database file has replaced with the new index files.

The `man` command is CSI-capable. However, some utilities invoked by the `man` command, namely, `ttr`, `eqn`, `neqn`, `refer`, `tbl`, and `vgrind`, are not verified to be CSI-capable. Because of this, the `man` command with the `-t` option can not handle non-EUC data. Also, using the `man` command to display manual pages that require special processing through `eqn`, `neqn`, `refer`, `tbl`, or `vgrind` can not be CSI-capable.

**Bugs** The manual is supposed to be reproducible either on a phototypesetter or on an ASCII terminal. However, on a terminal some information (indicated by font changes, for instance) is lost.

Some dumb terminals cannot process the vertical motions produced by the `e` (see [eqn\(1\)](#)) preprocessing flag. To prevent garbled output on these terminals, when you use `e`, also use `t`, to invoke [col\(1\)](#) implicitly. This workaround has the disadvantage of eliminating superscripts and subscripts, even on those terminals that can display them. Control-q clears a terminal that gets confused by [eqn\(1\)](#) output.

**Name** mconnect – connect to SMTP mail server socket

**Synopsis** mconnect [-p *port*] [-r] [*hostname*]

**Description** The mconnect utility opens a connection to the mail server on a given host, so that it can be tested independently of all other mail software. If no host is given, the connection is made to the local host. Servers expect to speak the Simple Mail Transfer Protocol (SMTP) on this connection. Exit by typing the `quit` command. Typing EOF sends an end of file to the server. An interrupt closes the connection immediately and exits.

**Options** The following options are supported:

- p*port* Specify the port number instead of the default SMTP port (number 25) as the next argument.
- r Raw mode: disable the default line buffering and input handling. This produces an effect similar to [telnet\(1\)](#) to port number 25.

**Operands** The following operand is supported:

*hostname* The name of a given host.

**Usage** The mconnect command is IPv6-enabled. See [ip6\(7P\)](#).

**Files** /etc/mail/sendmail.hf Help file for SMTP commands

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE               |
|----------------|-------------------------------|
| Availability   | service/network/smtp/sendmail |

**See Also** [telnet\(1\)](#), [sendmail\(1M\)](#), [attributes\(5\)](#), [ip6\(7P\)](#)

Postel, Jonathan B., *RFC 821, Simple Mail Transfer Protocol*, Information Sciences Institute, University of Southern California, August 1982.

**Name** mcs – manipulate the comment section of an object file

**Synopsis** mcs [-cdHpVz] [-A *file*] [-a *string*][-n *name*] *file*...

**Description** The `mcs` command is used to display, compress, or append content to comment sections in an ELF object file. It can also be used to delete comment or non-comment sections, and to zero `SHT_PROGBITS` sections. Unless otherwise specified, the section named `.comment` is manipulated. `mcs` cannot modify or delete a section that is contained within a segment.

If the input file is an archive (see [ar.h\(3HEAD\)](#)), the archive is treated as a set of individual files. For example, if the `-a` option is specified, the string is appended to the comment section of each object file in the archive; if the archive member is not an object file, then it is left unchanged.

`mcs` must be given one or more of the options described below. It applies each option, in the order given, to each file.

For append operations, if the object does not already contain a section with the specified name, `mcs` will create a new empty section with that name before performing the append operation.

**Options** The following options are supported:

- A *file* Appends the contents of the given file to the comment section of the object files.
- a *string* Appends *string* to the comment section of the object files.
- c Compresses the contents of the comment section of the object files. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.
- d Deletes the specified section from the object files.
- H When `-p` is used, suppress the output of the name of the file, as well as any blank lines normally inserted between the output for each file.
- n *name* Specifies the name of the section to access if other than `.comment`. By default, `mcs` deals with the section named `.comment`. `mcs` can take multiple `-n` options to allow for specification of multiple sections. `mcs` always manipulations sections assuming that they have the format of a comment section.
- p Prints the contents of the comment section on the standard output. Unless used with `-H`, each section printed is prefixed with the name of the file from which it was extracted, using the format *file*[*member\_name*] : for archive files and *file*: for other files.
- V Prints a message on standard error giving information about the version of `mcs`.
- z Replaces any `SHT_PROGBITS` sections with zeros while retaining the original attributes of the sections.

**Examples** **EXAMPLE 1** Printing a file's comment section

The following entry

```
example% mcs -p elf.file
```

prints the comment section of the file `elf.file`.

**EXAMPLE 2** Appending a string to a comment section

The following entry

```
example% mcs -a xyz elf.file
```

appends string `xyz` to `elf.file`'s comment section.

**EXAMPLE 3** Stripping a specified non-allocable section

Although used primarily with comment sections, `mcs` can operate on any non-allocable section. In contrast to the `strip` command, which removes a predefined selection of non-allocable sections, `mcs` can be used to delete a specific section. The following entry

```
example% mcs -d -n .annotate elf.file
```

removes the section named `.annotate` from the file `elf.file`.

**Files** `/tmp/mcs*` temporary files

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE                     |
|---------------------|------------------------------------|
| Availability        | developer/base-developer-utilities |
| Interface Stability | Committed                          |

**See Also** [ar\(1\)](#), [as\(1\)](#), [ld\(1\)](#), [strip\(1\)](#), [ar.h\(3HEAD\)](#), [elf\(3ELF\)](#), [a.out\(4\)](#), [attributes\(5\)](#)

**Notes** When `mcs` deletes a section using the `-d` option, it tries to bind together sections of type `SHT_REL` and target sections pointed to by the `sh_info` section header field. If one is to be deleted, `mcs` attempts to delete the other of the pair.

The `-z` option removes the contents of `SHT_PROGBITS` sections while retaining the original ELF structure of the object. The need for use of the `-z` option is limited. However, the option can be used to deliver an object file when the contents of `SHT_PROGBITS` sections are not relevant.

**Name** mdb – modular debugger

**Synopsis** mdb [-fkmuwyAFKMSUW] [ $\pm$ o *option*] [-p *pid*] [-s *distance*]  
[-I *path*] [-L *path*] [-P *prompt*] [-R *root*]  
[-V *dis-version*] [object [core] | core | suffix]

## Description

**Introduction** The `mdb` utility is an extensible utility for low-level debugging and editing of the live operating system, operating system crash dumps, user processes, user process core dumps, and object files. For a more detailed description of `mdb` features, refer to the manual, [Oracle Solaris Modular Debugger Guide](#).

Debugging is the process of analyzing the execution and state of a software program in order to remove defects. Traditional debugging tools provide facilities for execution control so that programmers can re-execute programs in a controlled environment and display the current state of program data or evaluate expressions in the source language used to develop the program.

Unfortunately, these techniques are often inappropriate for debugging complex software systems such as an operating system, where bugs might not be reproducible and program state is massive and distributed, for programs that are highly optimized, have had their debug information removed, or are themselves low-level debugging tools, or for customer situations where the developer can only access post-mortem information.

`mdb` provides a completely customizable environment for debugging these programs and scenarios, including a dynamic module facility that programmers can use to implement their own debugging commands to perform program-specific analysis. Each `mdb` module can be used to examine the program in several different contexts, including live and post-mortem.

**Definitions** The *target* is the program being inspected by the debugger. `mdb` currently provides support for the following types of targets: user processes, user process core files, the live operating system (via `/dev/kmem` and `/dev/ksyms`), operating system crash dumps, user process images recorded inside an operating system crash dump, ELF object files, and raw binary files. Each target exports a standard set of properties, including one or more address spaces, one or more symbol tables, a set of load objects, and a set of threads that can be examined using the debugger commands described below.

A debugger command, or *dcmd* (pronounced dee-command) in `mdb` terminology, is a routine in the debugger that can access any of the properties of the current target. `mdb` parses commands from standard input, and then executes the corresponding `dcmds`. Each `dcmd` can also accept a list of string or numerical arguments, as shown in the syntax description below. `mdb` contains a set of built-in `dcmds`, described below, that are always available. You can also extend the capabilities of `mdb` itself by writing your own `dcmds`, as described in the [Oracle Solaris Modular Debugger Guide](#).

A *walker* is a set of routines that describe how to walk, or iterate, through the elements of a particular program data structure. A walker encapsulates the data structure's implementation from dcmds and from mdb itself. You can use walkers interactively, or use them as a primitive to build other dcmds or walkers. As with dcmds, you can extend mdb by implementing your own walkers as part of a debugger module.

A debugger module, or *dmod* (pronounced dee-mod), is a dynamically loaded library containing a set of dcmds and walkers. During initialization, mdb attempts to load dmods corresponding to the load objects present in the target. You can subsequently load or unload dmods at any time while running mdb. mdb ships with a set of standard dmods for debugging the Solaris kernel. The *Oracle Solaris Modular Debugger Guide* contains more information on developing your own debugger modules.

A *macro file* is a text file containing a set of commands to execute. Macro files are typically used to automate the process of displaying a simple data structure. mdb provides complete backward compatibility for the execution of macro files written for [adb\(1\)](#), and the Solaris installation includes a set of macro files for debugging the Solaris kernel that can be used with either tool.

**Syntax** The debugger processes commands from standard input. If standard input is a terminal, mdb provides terminal editing capabilities. mdb can also process commands from macro files and from dcmd pipelines, described below. The language syntax is designed around the concept of computing the value of an expression (typically a memory address in the target), and then applying a dcmd to that address. The current address location is referred to as *dot*, and its value is referenced using ".".

A *metacharacter* is one of the following characters:

```
[] | ! / \ ? = > $: ;
 NEWLINE SPACE TAB
```

A *blank* is a TAB or a SPACE. A *word* is a sequence of characters separated by one or more non-quoted metacharacters. Some of the metacharacters only function as delimiters in certain contexts, as described below. An *identifier* is a sequence of letters, digits, underscores, periods, or backquotes beginning with a letter, underscore, or period. Identifiers are used as the names of symbols, variables, dcmds, and walkers. Commands are delimited by a NEWLINE or semicolon ( ; ).

A dcmd is denoted by one of the following words or metacharacters:

```
/ \ ? = > $character :character ::identifier
```

dcmds named by metacharacters or prefixed by a single \$ or : are provided as built-in operators, and implement complete compatibility with the command set of the legacy [adb\(1\)](#) utility. Once a dcmd has been parsed, the /, \, ?, =, >, \$, and : characters are no longer recognized as metacharacters until the termination of the argument list.

A *simple-command* is a dcmd followed by a sequence of zero or more blank-separated words. The words are passed as arguments to the invoked dcmd, except as specified under `Quoting` and `Arithmetic Expansion` below. Each dcmd returns an exit status that indicates it was either successful, failed, or was invoked with invalid arguments.

A *pipeline* is a sequence of one or more simple commands separated by `|`. Unlike the shell, dcmds in mdb pipelines are not executed as separate processes. After the pipeline has been parsed, each dcmd is invoked in order from left to right. Each dcmd's output is processed and stored as described under `dcmd Pipelines` below. Once the left-hand dcmd is complete, its processed output is used as input for the next dcmd in the pipeline. If any dcmd does not return a successful exit status, the pipeline is aborted.

An *expression* is a sequence of words that is evaluated to compute a 64-bit unsigned integer value. The words are evaluated using the rules described under `Arithmetic Expansion` below.

Commands A *command* is one of the following:

*pipeline* [*! word . .*] [*;*]

A simple-command or pipeline can be optionally suffixed with the `!` character, indicating that the debugger should open a `pipe(2)` and send the standard output of the last dcmd in the mdb pipeline to an external process created by executing `$SHELL -c` followed by the string formed by concatenating the words after the `!` character. For more details, refer to `Shell Escapes` below.

*expression pipeline* [*! word . .*] [*;*]

A simple-command or pipeline can be prefixed with an expression. Before execution of the pipeline, the value of dot (the variable denoted by `."`) is set to the value of the expression.

*expression , expression pipeline* [*! word . .*] [*;*]

A simple-command or pipeline can be prefixed with two expressions. The first is evaluated to determine the new value of dot, and the second is evaluated to determine a repeat count for the first dcmd in the pipeline. This dcmd is executed *count* times before the next dcmd in the pipeline is executed. The repeat count only applies to the first dcmd in the pipeline.

*, expression pipeline* [*! word . .*] [*;*]

If the initial expression is omitted, dot is not modified but the first dcmd in the pipeline is repeated according to the value of the expression.

*expression* [*! word . .*] [*;*]

A command can consist only of an arithmetic expression. The expression is evaluated and the dot variable is set to its value, and then the previous dcmd and arguments are executed using the new value of dot.

*expression , expression* [*! word . .*] [*;*]

A command can consist only of a dot expression and repeat count expression. After dot is set to the value of the first expression, the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the second expression.

, *expression* [! *word* . . . ] [ ; ]

If the initial expression is omitted, dot is not modified but the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the count expression.

! *word* . . . [ ; ]

If the command begins with the ! character, no dcmds are executed and the debugger simply executes \$SHELL -c followed by the string formed by concatenating the words after the ! character.

Comments A word beginning with // causes that word and all the subsequent characters up to a NEWLINE to be ignored.

Arithmetic Expansion Arithmetic expansion is performed when an mdb command is preceded by an optional expression representing a start address, or a start address and a repeat count. Arithmetic expansion can also be performed to compute a numerical argument for a dcmd. An arithmetic expression can appear in an argument list enclosed in square brackets preceded by a dollar sign (\$[ *expression* ]), and is replaced by the value of the expression.

Expressions can contain any of the following special words:

*integer*

The specified integer value. Integer values can be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default).

0[tT][0-9]+.[0-9]+

The specified decimal floating point value, converted to its IEEE double-precision floating point representation.

'ccccccc'

The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters can be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte.

<*identifier*

The value of the variable named by *identifier*.

*identifier*

The value of the symbol named by *identifier*.

(*expression*)

The value of *expression*.

.

The value of dot.

&

The most recent value of dot used to execute a dcmd.

**+**  
The value of dot incremented by the current increment.

**^**  
The value of dot decremented by the current increment.

The increment is a global variable that stores the total bytes read by the last formatting dcmd. For more information on the increment, refer to the discussion of `Formatting dcmds` below.

Unary operators are right associative and have higher precedence than binary operators. The unary operators are:

**#*expression***  
Logical negation.

**~*expression***  
Bitwise complement.

**-*expression***  
Integer negation.

**%*expression***  
The value of a pointer-sized quantity at the object file location corresponding to virtual address *expression* in the target's virtual address space.

**%[*csil*]/*expression***  
The value of a char, short, int, or long-sized quantity at the object file location corresponding to virtual address *expression* in the target's virtual address space.

**%[1248]/*expression***  
The value of a one, two, four, or eight-byte quantity at the object file location corresponding to virtual address *expression* in the target's virtual address space.

**\**expression***  
The value of a pointer-sized quantity at virtual address *expression* in the target's virtual address space.

**\*[*csil*]/*expression***  
The value of a char, short, int, or long-sized quantity at virtual address *expression* in the target's virtual address space.

**\*[1248]/*expression***  
The value of a one, two, four, or eight-byte quantity at virtual address *expression* in the target's virtual address space.

Binary operators are left associative and have lower precedence than unary operators. The binary operators, in order of precedence from highest to lowest, are:

**\***  
Integer multiplication.

---

|    |                                                                |
|----|----------------------------------------------------------------|
| %  | Integer division.                                              |
| #  | Left-hand side rounded up to next multiple of right-hand side. |
| +  | Integer addition.                                              |
| -  | Integer subtraction.                                           |
| << | Bitwise shift left.                                            |
| >> | Bitwise shift right.                                           |
| == | Logical equality.                                              |
| != | Logical inequality.                                            |
| &  | Bitwise AND.                                                   |
| ^  | Bitwise exclusive OR.                                          |
|    | Bitwise inclusive OR.                                          |

**Quoting** Each metacharacter described above (see `Syntax`) terminates a word unless quoted. Characters can be quoted (forcing `mdb` to interpret each character as itself without any special significance) by enclosing them in a pair of single ( `' '` ) or double ( `" "` ) quote marks. A single quote cannot appear within single quotes. Inside double quotes, `mdb` recognizes the C programming language character escape sequences.

**Shell Escapes** The `!` character can be used to create a pipeline between an `mdb` command and the user's shell. If the `$SHELL` environment variable is set, `mdb` forks and execs this program for shell escapes; otherwise `/bin/sh` is used. The shell is invoked with the `-c` option followed by a string formed by concatenating the words after the `!` character. The `!` character takes precedence over all other metacharacters, except semicolon (`;`) and `NEWLINE`. Once a shell escape is detected, the remaining characters up to the next semicolon or `NEWLINE` are passed as is to the shell. The output of shell commands can not be piped to `mdb` dcmds. Commands executed by a shell escape have their output sent directly to the terminal, not to `mdb`.

**Variables** A *variable* is a variable name, a corresponding integer value, and a set of attributes. A variable name is a sequence of letters, digits, underscores, or periods. A variable can be assigned a value using the `> dcmd` or `:: typeset dcmd`, and its attributes can be manipulated using the `:: typeset dcmd`. Each variable's value is represented as a 64-bit unsigned integer. A variable can have one or more of the following attributes: read-only (cannot be modified by the user), persistent (cannot be unset by the user), and tagged (user-defined indicator).

The following variables are defined as persistent:

0

The most recent value printed using the `/`, `\`, `?`, or `=` dcmd.

9

The most recent count used with the `$<` dcmd.

b

The virtual address of the base of the data section.

d

The size of the data section in bytes.

e

The virtual address of the entry point.

m

The initial bytes (magic number) of the target's primary object file, or zero if no object file has been read yet.

t

The size of the text section in bytes.

hits

The count of the number of times the matched software event specifier has been matched. See `Event Cal lbacks`, below.

thread

The thread identifier of the current representative thread. The value of the identifier depends on the threading model used by the current target. See `Thread Support`, below.

In addition, the `mdb` kernel and process targets export the current values of the representative thread's register set as named variables. The names of these variables depend on the target's platform and instruction set architecture.

**Symbol Name  
Resolution**

As explained in the `Syntax` description above, a symbol identifier present in an expression context evaluates to the value of this symbol. The value typically denotes the virtual address of the storage associated with the symbol in the target's virtual address space. A target can support multiple symbol tables including, but not limited to, a primary executable symbol table, a primary dynamic symbol table, a run-time link-editor symbol table, and standard and dynamic symbol tables for each of a number of load objects (such as shared libraries in a user process, or kernel modules in the Solaris kernel). The target typically searches the primary

executable's symbol tables first, and then one or more of the other symbol tables. Notice that ELF symbol tables only contain entries for external, global, and static symbols; automatic symbols do not appear in the symbol tables processed by `mdb`.

Additionally, `mdb` provides a private user-defined symbol table that is searched prior to any of the target symbol tables. The private symbol table is initially empty, and can be manipulated using the `::nmadd` and `::nmdelete` commands. The `::nm -P` option can be used to display the contents of the private symbol table. The private symbol table allows the user to create symbol definitions for program functions or data that were either missing from the original program or stripped out. These definitions are then used whenever `mdb` converts a symbolic name to an address, or an address to the nearest symbol.

As targets contain multiple symbol tables, and each symbol table can include symbols from multiple object files, different symbols with the same name can exist. `mdb` uses the backquote (‘) character as a symbol name scoping operator to allow the programmer to obtain the value of the desired symbol in this situation. The programmer can specify the scope used to resolve a symbol name as either: *object' name*, or *file' name*, or *object'file' name*. The object identifier refers to the name of a load object. The file identifier refers to the basename of a source file that has a symbol of type `STT_FILE` in the specified object's symbol table. The object identifier's interpretation depends on the target type.

The `mdb` kernel target expects *object* to specify the basename of a loaded kernel module. For example, the symbol name

```
specfs'_init
```

evaluates to the value of the `_init` symbol in the `specfs` kernel module.

The `mdb` process target expects *object* to specify the name of the executable or of a loaded shared library. It can take any of the following forms:

1. An exact match (that is, a full pathname): `/usr/lib/libc.so.1`
2. An exact basename match: `libc.so.1`
3. An initial basename match up to a `."` suffix: `libc.so` or `libc`
4. The literal string `a.out` is accepted as an alias for the executable.

The process target also accepts any of the four forms described above preceded by an optional link-map id (`lmid`). The `lmid` prefix is specified by an initial `"LM"` followed by the link-map id in hexadecimal followed by an additional backquote. For example, the symbol name

```
LM0'libc.so.1'_init
```

evaluates to the value of the `_init` symbol in the `libc.so.1` library that is loaded on link-map 0 (`LM_ID_BASE`). The link-map specifier can be necessary to resolve symbol naming conflicts in the event that the same library is loaded on more than one link map. For more information on link maps, refer to the [Linker and Libraries Guide](#) and `dlopen(3C)`. Link-map identifiers are displayed when symbols are printed according to the setting of the `showlmid` option, as described under `OPTIONS`.

In the case of a naming conflict between symbols and hexadecimal integer values, `mdb` attempts to evaluate an ambiguous token as a symbol first, before evaluating it as an integer value. For example, the token `f` can either refer to the decimal integer value 15 specified in hexadecimal (the default base), or to a global variable named `f` in the target's symbol table. If a symbol with an ambiguous name is present, the integer value can be specified by using an explicit `0x` or `0X` prefix.

**dcmd and Walker Name Resolution** As described earlier, each `mdb` dmod provides a set of dcmds and walkers. dcmds and walkers are tracked in two distinct, global namespaces. `mdb` also keeps track of a dcmd and walker namespace associated with each dmod. Identically named dcmds or walkers within a given dmod are not allowed: a dmod with this type of naming conflict fails to load. Name conflicts between dcmds or walkers from different dmods are allowed in the global namespace. In the case of a conflict, the first dcmd or walker with that particular name to be loaded is given precedence in the global namespace. Alternate definitions are kept in a list in load order. The backquote character (```) can be used in a dcmd or walker name as a scoping operator to select an alternate definition. For example, if dmods `m1` and `m2` each provide a dcmd `d`, and `m1` is loaded prior to `m2`, then:

```

: : d
 Executes m1's definition of d.

: : m1'd
 Executes m1's definition of d.

: : m2'd
 Executes m2's definition of d.
```

If module `m1` were now unloaded, the next dcmd on the global definition list (`m2'd`) would be promoted to global visibility. The current definition of a dcmd or walker can be determined using the `: which dcmd`, described below. The global definition list can be displayed using the `: which -v` option.

**dcmd Pipelines** dcmds can be composed into a pipeline using the `|` operator. The purpose of a pipeline is to pass a list of values, typically virtual addresses, from one dcmd or walker to another. Pipeline stages might be used to map a pointer from one type of data structure to a pointer to a corresponding data structure, to sort a list of addresses, or to select the addresses of structures with certain properties.

`mdb` executes each dcmd in the pipeline in order from left to right. The leftmost dcmd is executed using the current value of `dot`, or using the value specified by an explicit expression at the start of the command. When a `|` operator is encountered, `mdb` creates a pipe (a shared buffer) between the output of the dcmd to its left and the `mdb` parser, and an empty list of values. As the dcmd executes, its standard output is placed in the pipe and then consumed and evaluated by the parser, as if `mdb` were reading this data from standard input. Each line must consist of an arithmetic expression terminated by a `NEWLINE` or semicolon (`;`). The value of the expression is appended to the list of values associated with the pipe. If a syntax error is detected, the pipeline is aborted.

When the dcmd to the left of a | operator completes, the list of values associated with the pipe is then used to invoke the dcmd to the right of the | operator. For each value in the list, dot is set to this value and the right-hand dcmd is executed. Only the rightmost dcmd in the pipeline has its output printed to standard output. If any dcmd in the pipeline produces output to standard error, these messages are printed directly to standard error and are not processed as part of the pipeline.

- Signal Handling** The debugger ignores the PIPE and QUIT signals. The INT signal aborts the command that is currently executing. The debugger intercepts and provides special handling for the ILL, TRAP, EMT, FPE, BUS, and SEGV signals. If any of these signals are generated asynchronously (that is, delivered from another process using `kill(2)`), mdb restores the signal to its default disposition and dump core. However, if any of these signals are generated synchronously by the debugger process itself and a dcmd from an externally loaded dmod is currently executing, and standard input is a terminal, mdb provides a menu of choices allowing the user to force a core dump, quit without producing a core dump, stop for attach by a debugger, or attempt to resume. The resume option aborts all active commands and unload the dmod whose dcmd was active at the time the fault occurred. It can then be subsequently re-loaded by the user. The resume option provides limited protection against buggy dcmds. Refer to WARNINGS, Use of the Error Recovery Mechanism, below for information about the risks associated with the resume option.
- Command Re-entry** The text of the last HISTSIZE (default 128) commands entered from a terminal device are saved in memory. The in-line editing facility, described next, provides key mappings for searching and fetching elements from the history list.
- In-line Editing** If standard input is a terminal device, mdb provides some simple emacs-style facilities for editing the command line. The search, previous, and next commands in edit mode provide access to the history list. Only strings, not patterns, are matched when searching. In the table below, the notation for control characters is caret (^) followed by a character shown in upper case. The notation for escape sequences is M- followed by a character. For example, M-f (pronounced meta-eff) is entered by depressing ESC followed by 'f', or by depressing Meta followed by 'f' on keyboards that support a Meta key. A command line is committed and executed using RETURN or NEWLINE. The edit commands are:
- `^F`  
Move cursor forward (right) one character.
  - `M-f`  
Move cursor forward one word.
  - `^B`  
Move cursor backward (left) one character.
  - `M-b`  
Move cursor backward one word.
  - `^A`  
Move cursor to start of line.

**^E**

Move cursor to end of line.

**^D**

Delete current character, if the current line is not empty. If the current line is empty, **^D** denotes EOF and the debugger exits.

**M-^H**

(Meta-backspace) Delete previous word.

**^K**

Delete from the cursor to the end of the line.

**^L**

Clear the screen and reprint the current line.

**^T**

Transpose current character with next character.

**^N**

Fetch the next command from the history. Each time **^N** is entered, the next command forward in time is retrieved.

**^P**

Fetch the previous command from the history. Each time **^P** is entered, the next command backward in time is retrieved.

**^R***[string]*

Search backward in the history for a previous command line containing *string*. The string should be terminated by a RETURN or NEWLINE. If *string* is omitted, the previous history element containing the most recent string is retrieved.

The editing mode also interprets the following user-defined sequences as editing commands. User defined sequences can be read or modified using the `stty(1)` command.

**erase**

User defined erase character (usually **^H** or **^?**). Delete previous character.

**intr**

User defined interrupt character (usually **^C**). Abort the current command and print a new prompt.

**kill**

User defined kill character (usually **^U**). Kill the entire current command line.

**quit**

User defined quit character (usually **^\**). Quit the debugger.

**suspend**

User defined suspend character (usually **^Z**). Suspend the debugger.

werase

User defined word erase character (usually ^W). Erase the preceding word.

On keyboards that support an extended keypad with arrow keys, mdb interprets these keystrokes as editing commands:

up-arrow

Fetch the previous command from the history (same as ^P).

down-arrow

Fetch the next command from the history (same as ^N).

left-arrow

Move cursor backward one character (same as ^B).

right-arrow

Move cursor forward one character (same as ^F).

**Output Pager** mdb provides a built-in output pager. The output pager is enabled if the debugger's standard output is a terminal device. Each time a command is executed, mdb pauses after one screenful of output is produced and displays a pager prompt:

```
>> More [<space>, <cr>, q, n, c, a] ?
```

The following key sequences are recognized by the pager:

SPACE

Display the next screenful of output.

a, A

Abort the current top-level command and return to the prompt.

c, C

Continue displaying output without pausing at each screenful until the current top-level command is complete.

n, N, NEWLINE, RETURN

Display the next line of output.

q, Q, ^C, ^\

Quit (abort) the current dcmd only.

**Formatting dcmds** The /, \, ?, and = metacharacters are used to denote the special output formatting dcmds. Each of these dcmds accepts an argument list consisting of one or more format characters, repeat counts, or quoted strings. A format character is one of the ASCII characters shown in the table below. Format characters are used to read and format data from the target. A repeat count is a positive integer preceding the format character that is always interpreted in base 10 (decimal). A repeat count can also be specified as an expression enclosed in square brackets preceded by a dollar sign (\$ [ 1]). A string argument must be enclosed in double-quotes (" "). No blanks are necessary between format arguments.

The formatting dcmts are:

/

Display data from the target's virtual address space starting at the virtual address specified by dot.

\

Display data from the target's physical address space starting at the physical address specified by dot.

?

Display data from the target's primary object file starting at the object file location corresponding to the virtual address specified by dot.

=

Display the value of dot itself in each of the specified data formats. The = dcmd is therefore useful for converting between bases and performing arithmetic.

In addition to dot, mdb keeps track of another global value called the *increment*. The increment represents the distance between dot and the address following all the data read by the last formatting dcmd. For example, if a formatting dcmd is executed with dot equal to address A, and displays a 4-byte integer, then after this dcmd completes, dot is still A, but the increment is set to 4. The + character (described under *Arithmetic Expansion* above) would now evaluate to the value A + 4, and could be used to reset dot to the address of the next data object for a subsequent dcmd.

Most format characters increase the value of the increment by the number of bytes corresponding to the size of the data format, shown in the table. The table of format characters can be displayed from within mdb using the ::formats dcmd. The format characters are:

|   |                                                      |
|---|------------------------------------------------------|
| + | increment dot by the count (variable size)           |
| - | decrement dot by the count (variable size)           |
| B | hexadecimal int (1 byte)                             |
| C | character using C character notation (1 byte)        |
| D | decimal signed int (4 bytes)                         |
| E | decimal unsigned long long (8 bytes)                 |
| F | double (8 bytes)                                     |
| G | octal unsigned long long (8 bytes)                   |
| H | swap bytes and shorts (4 bytes)                      |
| I | address and disassembled instruction (variable size) |
| J | hexadecimal long long (8 bytes)                      |

---

|   |                                                    |
|---|----------------------------------------------------|
| K | hexadecimal uintptr_t (4 or 8 bytes)               |
| N | newline                                            |
| O | octal unsigned int (4 bytes)                       |
| P | symbol (4 or 8 bytes)                              |
| Q | octal signed int (4 bytes)                         |
| R | binary int (8 bytes)                               |
| S | string using C string notation (variable size)     |
| T | horizontal tab                                     |
| U | decimal unsigned int (4 bytes)                     |
| V | decimal unsigned int (1 byte)                      |
| W | default radix unsigned int (4 bytes)               |
| X | hexadecimal int (4 bytes)                          |
| Y | decoded time32_t (4 bytes)                         |
| Z | hexadecimal long long (8 bytes)                    |
| ^ | decrement dot by increment * count (variable size) |
| a | dot as symbol+offset                               |
| b | octal unsigned int (1 byte)                        |
| c | character (1 byte)                                 |
| d | decimal signed short (2 bytes)                     |
| e | decimal signed long long (8 bytes)                 |
| f | float (4 bytes)                                    |
| g | octal signed long long (8 bytes)                   |
| h | swap bytes (2 bytes)                               |
| i | disassembled instruction (variable size)           |
| n | newline                                            |
| o | octal unsigned short (2 bytes)                     |
| p | symbol (4 or 8 bytes)                              |
| q | octal signed short (2 bytes)                       |
| r | whitespace                                         |

|   |                                        |
|---|----------------------------------------|
| s | raw string (variable size)             |
| t | horizontal tab                         |
| u | decimal unsigned short (2 bytes)       |
| v | decimal signed int (1 byte)            |
| w | default radix unsigned short (2 bytes) |
| x | hexadecimal short (2 bytes)            |
| y | decoded time64_t (8 bytes)             |

The /, \, and ? formatting dcmds can also be used to write to the target's virtual address space, physical address space, or object file by specifying one of the following modifiers as the first format character, and then specifying a list of words that are either immediate values or expressions enclosed in square brackets preceded by a dollar sign (\$[ ]).

The write modifiers are:

- v  
Write the lowest byte of the value of each expression to the target beginning at the location specified by dot.
- w  
Write the lowest two bytes of the value of each expression to the target beginning at the location specified by dot.
- W  
Write the lowest 4 bytes of the value of each expression to the target beginning at the location specified by dot.
- Z  
Write the complete 8 bytes of the value of each expression to the target beginning at the location specified by dot.

The /, \, and ? formatting dcmds can also be used to search for a particular integer value in the target's virtual address space, physical address space, and object file, respectively, by specifying one of the following modifiers as the first format character, and then specifying a value and optional mask. The value and mask are each specified as either immediate values or expressions enclosed in square brackets preceded by a dollar sign. If only a value is specified, mdb reads integers of the appropriate size and stops at the address containing the matching value. If a value *V* and mask *M* are specified, mdb reads integers of the appropriate size and stops at the address containing a value *X* where  $(X \& M) == V$ . At the completion of the dcmd, dot is updated to the address containing the match. If no match is found, dot is left at the last address that was read.

The search modifiers are:

---

|   |                                        |
|---|----------------------------------------|
| I | Search for the specified 2-byte value. |
| L | Search for the specified 4-byte value. |
| M | Search for the specified 8-byte value. |

Notice that for both user and kernel targets, an address space is typically composed of a set of discontinuous segments. It is not legal to read from an address that does not have a corresponding segment. If a search reaches a segment boundary without finding a match, it aborts when the read past the end of the segment boundary fails.

**Execution Control** mdb provides facilities for controlling and tracing the execution of a live running program. Currently, only the user process target provides support for execution control. mdb provides a simple model of execution control: a target process can be started from within the debugger using `::run`, or mdb can attach to an existing process using `:A, ::attach`, or the `-p` command-line option, as described below. A list of traced software events can be specified by the user. Each time a traced event occurs in the target process, all threads in the target stop, the thread that triggered the event is chosen as the representative thread, and control returns to the debugger. Once the target program is set running, control can be asynchronously returned to the debugger by typing the user-defined interrupt character (typically `^C`).

A *software event* is a state transition in the target program that is observed by the debugger. For example, the debugger can observe the transition of a program counter register to a value of interest (a breakpoint) or the delivery of a particular signal.

A *software event specifier* is a description of a class of software events that is used by the debugger to instrument the target program in order to observe these events. The `::events dcmd` is used to list the software event specifiers. A set of standard properties is associated with each event specifier, as described under `::events`, below.

The debugger can observe a variety of different software events, including breakpoints, watchpoints, signals, machine faults, and system calls. New specifiers can be created using `::bp`, `::fltp`, `::sigbp`, `::sysbp`, or `::wp`. Each specifier has an associated callback (an mdb command string to execute as if it had been typed at the command prompt) and a set of properties, as described below. Any number of specifiers for the same event can be created, each with different callbacks and properties. The current list of traced events and the properties of the corresponding event specifiers can be displayed using the `::events dcmd`. The event specifier properties are defined as part of the description of the `::events` and `::evset dcmds`, below.

The execution control built-in dcmds, described below, are always available, but issues an error message indicating they are not supported if applied to a target that does not support execution control. For more information about the interaction of `exec`, `attach`, `release`, and `job control` with debugger execution control, refer to NOTES, below.

**Event Callbacks** The `::evset dcmd` and event tracing `dcmds` allow you to associate an event callback (using the `-c` option) with each event specifier. The event callbacks are strings that represent `mdb` commands to execute when the corresponding event occurs in the target. These commands are executed as if they had been typed at the command prompt. Before executing each callback, the `dot` variable is set to the value of the representative thread's program counter and the `"hits"` variable is set to the number of times this specifier has been matched, including the current match.

If the event callbacks themselves contain one or more commands to continue the target (for example, `::cont` or `::step`), these commands do not immediately continue the target and wait for it to stop again. Instead, inside of an event callback, the continue `dcmds` note that a continue operation is now pending, and then return immediately. Therefore, if multiple `dcmds` are included in an event callback, the `step` or `continue dcmd` should be the last command specified. Following the execution of *all* event callbacks, the target immediately resumes execution if *all* matching event callbacks requested a continue. If conflicting continue operations are requested, the operation with the highest precedence determines what type of continue occurs. The order of precedence from highest to lowest is: `step`, `step-over (next)`, `step-out`, `continue`.

**Thread Support** `mdb` provides facilities to examine the stacks and registers of each thread associated with the target. The persistent `"thread"` variable contains the current representative thread identifier. The format of the thread identifier depends on the target. The `::regs` and `::fregs` `dcmds` can be used to examine the register set of the representative thread, or of another thread if its register set is currently available. In addition, the register set of the representative thread is exported as a set of named variables. The user can modify the value of one or more registers by applying the `>` `dcmd` to the corresponding named variable.

The `mdb` kernel target exports the virtual address of the corresponding internal thread structure as the identifier for a given thread. The *Oracle Solaris Modular Debugger Guide* provides more information on debugging support for threads in the Solaris kernel. The `mdb` process target provides proper support for examination of multi-threaded user processes that use the native `lwp_*` interfaces, `/usr/lib/libthread.so` or `/usr/lib/lwp/libthread.so`. When debugging a live user process, `mdb` detects if a single threaded process `dlopens` or closes `libthread` and automatically adjusts its view of the threading model on-the-fly. The process target thread identifiers corresponds to either the `lwpid_t`, `thread_t`, or `pthread_t` of the representative, depending on the threading model used by the application.

If `mdb` is debugging a user process target and the target makes use of compiler-supported thread-local storage, `mdb` automatically evaluates symbol names referring to thread-local storage to the address of the storage corresponding to the current representative thread. The `::tls` built-in `dcmd` can be used to display the value of the symbol for threads other than the representative thread.

Built-in dcmds `mdb` provides a set of built-in dcmds that are always defined. Some of these dcmds are only applicable to certain targets: if a dcmd is not applicable to the current target, it fails and prints a message indicating “command is not supported by current target”. In many cases, `mdb` provides a mnemonic equivalent (`::identifier`) for the legacy `adb(1)` dcmd names. For example, `::quit` is provided as the equivalent of `$q`. Programmers who are experienced with `adb(1)` or who appreciate brevity or arcana can prefer the `$` or `:` forms of the built-ins. Programmers who are new to `mdb` might prefer the more verbose `::` form. The built-ins are shown in alphabetical order. If a `$` or `:` form has a `::identifier` equivalent, it is shown underneath the `::identifier` form. The built-in dcmds are:

`> variable-name`

`>/modifier/variable-name`

Assign the value of dot to the specified named variable. Some variables are read-only and can not be modified. If the `>` is followed by a modifier character surrounded by `/ /`, then the value is modified as part of the assignment. The modifier characters are:

`c`

unsigned char quantity (1-byte)

`s`

unsigned short quantity (2-byte)

`i`

unsigned int quantity (4-byte)

`l`

unsigned long quantity (4-byte in 32-bit, 8-byte in 64-bit)

Notice that these operators do not perform a cast. Instead, they fetch the specified number of low-order bytes (on little-endian architectures) or high-order bytes (big-endian architectures). Modifiers are provided for backwards compatibility; the `mdb */modifier/` and `%/modifier/` syntax should be used instead.

`$< macro-name`

Read and execute commands from the specified macro file. The filename can be given as an absolute or relative path. If the filename is a simple name (that is, if it does not contain a `'/'`), `mdb` searches for it in the macro file include path. If another macro file is currently being processed, this file is closed and replaced with the new file.

`$<< macro-name`

Read and execute commands from the specified macro file (as with `$<`), but do not close the current open macro file.

`$?`

Print the process-ID and current signal of the target if it is a user process or core file, and then print the general register set of the representative thread.

[ *address* ] \$C [ *count* ]

Print a C stack backtrace, including stack frame pointer information. If the *dcmd* is preceded by an explicit *address*, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than *count* arguments are displayed for each stack frame in the output.

[ *base* ] \$d

Get or set the default output radix. If the *dcmd* is preceded by an explicit expression, the default output radix is set to the given *base*; otherwise the current radix is printed in base 10 (decimal). The default radix is base 16 (hexadecimal).

\$e

Print a list of all known external (global) symbols of type object or function, the value of the symbol, and the first 4 (32-bit *mdb*) or 8 (64-bit *mdb*) bytes stored at this location in the target's virtual address space. The `::nm` *dcmd* provides more flexible options for displaying symbol tables.

\$P *prompt-string*

Set the prompt to the specified *prompt-string*. The default prompt is '>'. The prompt can also be set using `::set -P` or the `-P` command-line option.

*distance* \$s

Get or set the symbol matching *distance* for address-to-symbol-name conversions. The symbol matching distance modes are discussed along with the `-s` command-line option under `OPTIONS`. The symbol matching distance can also be modified using the `::set -s` option. If no distance is specified, the current setting is displayed.

\$v

Print a list of the named variables that have non-zero values. The `::vars` *dcmd* provides other options for listing variables.

*width* \$w

Set the output page *width* to the specified value. Typically, this command is not necessary as *mdb* queries the terminal for its width and handles resize events.

\$W

Re-open the target for writing, as if *mdb* had been executed with the `-w` option on the command line. Write mode can also be enabled with the `::set -w` option.

[ *pid* ] ::attach [ *core* | *pid* ]

[ *pid* ] :A [ *core* | *pid* ]

If the user process target is active, attach to and debug the specified process-ID or *core* file. The core file pathname should be specified as a string argument. The process-ID can be specified as the string argument, or as the value of the expression preceding the *dcmd*. Recall that the default base is hexadecimal, so decimal PIDs obtained using `pgrep(1)` or `ps(1)` should be preceded with “0t” when specified as expressions.

`[address] :: bp [-/ -dDesT] [-c cmd] [-n count] sym ...`

`address : b [cmd ...]`

Set a breakpoint at the specified locations. The `:: bp dcmd` sets a breakpoint at each address or symbol specified, including an optional address specified by an explicit expression preceding the `dcmd`, and each string or immediate value following the `dcmd`. The arguments can either be symbol names or immediate values denoting a particular virtual address of interest. If a symbol name is specified, it can refer to a symbol that cannot yet be evaluated in the target process. That is, it can consist of an object name and function name in a load object that has not yet been opened. In this case, the breakpoint is deferred and is not active in the target until an object matching the given name is loaded. The breakpoint is automatically enabled when the load object is opened. Breakpoints on symbols defined in a shared library should always be set using a symbol name and not using an address expression, as the address can refer to the corresponding Procedure Linkage Table (PLT) entry instead of the actual symbol definition. Breakpoints set on PLT entries can be overwritten by the run-time link-editor when the PLT entry is subsequently resolved to the actual symbol definition. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `:: evset dcmd`, as described below. If the `: b` form of the `dcmd` is used, a breakpoint is only set at the virtual address specified by the expression preceding the `dcmd`. The arguments following the `: b dcmd` are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

`:: cat filename ...`

Concatenate and display files. Each filename can be specified as a relative or absolute pathname. The file contents are printed to standard output, but are not passed to the output pager. This `dcmd` is intended to be used with the `|` operator; the programmer can initiate a pipeline using a list of addresses stored in an external file.

`:: cont [ SIG ]`

`:c [ SIG ]`

Suspend the debugger, continue the target program, and wait for it to terminate or stop following a software event of interest. If the target is already running because the debugger was attached to a running program with the `-o nostop` option enabled, this `dcmd` simply waits for the target to terminate or stop after an event of interest. If an optional signal name or number (see [signal.h\(3HEAD\)](#)) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the `SIGINT` signal is traced, control can be asynchronously returned to the debugger by typing the user-defined interrupt character (usually `^C`). This `SIGINT` signal is automatically cleared and is not observed by the target the next time it is continued. If no target program is currently running, `:: cont` starts a new program running as if by `:: run`.

`address :: context`

`address $p`

Context switch to the specified process. A context switch operation is only valid when using the kernel target. The process context is specified using the *address* of its proc structure in the kernel's virtual address space. The special context address `"0"` is used to denote the context of the kernel itself. `mdb` can only perform a context switch when

examining a crash dump if the dump contains the physical memory pages of the specified user process (as opposed to just kernel pages). The kernel crash dump facility can be configured to dump all pages or the pages of the current user process using `dumpadm(1M)`. The `::status dcmd` can be used to display the contents of the current crash dump.

When the user requests a context switch from the kernel target, `mdb` constructs a new target representing the specified user process. Once the switch occurs, the new target interposes its `dcmds` at the global level: thus the `/ dcmd` now formats and displays data from the virtual address space of the user process, the `::mappings dcmd` displays the mappings in the address space of the user process, and so on. The kernel target can be restored by executing `0::context`.

`::dcmds`

List the available `dcmds` and print a brief description for each one.

`[ address ] ::delete [ id | all ]`

`[ address ] :d [ id | all ]`

Delete the event specifiers with the given `id` number. The `id` number argument is interpreted in decimal by default. If an optional address is specified preceding the `dcmd`, all event specifiers that are associated with the given virtual address are deleted (for example, all breakpoints or watchpoints affecting that address). If the special argument “`all`” is given, all event specifiers are deleted, except those that are marked sticky (`T` flag). The `::events dcmd` displays the current list of event specifiers.

`[ address ] ::dis [ -fw ] [ -n count ] [ address ]`

Disassemble starting at or around the `address` specified by the final argument, or the current value of `dot`. If the address matches the start of a known function, the entire function is disassembled. Otherwise, a “window” of instructions before and after the specified address is printed in order to provide context. By default, instructions are read from the target’s virtual address space. If the `-f` option is present, instructions are read from the target’s object file instead. The `-f` option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump. The `-w` option can be used to force “window”-mode, even if the address is the start of a known function. The size of the window defaults to ten instructions; the number of instructions can be specified explicitly using the `-n` option.

`::disasms`

List the available disassembler modes. When a target is initialized, `mdb` attempts to select the appropriate disassembler mode. The user can change the mode to any of the modes listed using the `::dismode dcmd`.

`::dismode [ mode ]`

`$V [ mode ]`

Get or set the disassembler mode. If no argument is specified, print the current disassembler mode. If a `mode` argument is specified, switch the disassembler to the specified mode. The list of available disassemblers can be displayed using the `::disasms dcmd`.

`::dmods [ -l ] [ module-name ]`

List the loaded debugger modules. If the `-l` option is specified, the list of the `dcmds` and `walkers` associated with each `dmod` is printed below its name. The output can be restricted to a particular `dmod` by specifying its name as an additional argument.

`[ address ] ::dump [ -eqrstu ] [ -f|-p ]`

`[ -g bytes ] [ -w paragraphs ]`

Print a hexadecimal and ASCII memory dump of the 16-byte aligned region of memory containing the address specified by `dot`. If a repeat count is specified for `::dump`, this is interpreted as a number of bytes to dump rather than a number of iterations. The `::dump` `dcmd` also recognizes the following options:

`-e`

Adjusts for endian-ness. The `-e` option assumes 4-byte words. The `-g` option can be used to change the default word size.

`-f`

Reads data from the object file location corresponding to the given virtual address instead of from the target's virtual address space. The `-f` option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump.

`-g bytes`

Displays bytes in groups of *bytes*. The default group size is 4 bytes. The group size must be a power of two that divides the line width.

`-p`

Interprets *address* as a physical address location in the target's address space instead of a virtual address.

`-q`

Does not print an ASCII decoding of the data.

`-r`

Numbers lines relative to the start address instead of with the explicit address of each line. This option implies the `-u` option.

`-s`

Elides repeated lines.

`-t`

Only reads from and displays the contents of the specified addresses, instead of reading and printing entire lines.

`-u`

Unaligns output instead of aligning the output at a paragraph boundary.

`-w paragraphs`

Displays paragraphs at 16-byte paragraphs per line. The default number of *paragraphs* is one. The maximum value accepted for `-w` is 16.

`::echo [ string | value ...]`

Print the arguments separated by blanks and terminated by a NEWLINE to standard output. Expressions enclosed in `$[ ]` is evaluated to a value and printed in the default base.

`::eval command`

Evaluate and execute the specified string as a command. If the command contains metacharacters or whitespace, it should be enclosed in double or single quotes.

`::events [ -av ]`

`$b [ -av ]`

Display the list of software event specifiers. Each event specifier is assigned a unique ID number that can be used to delete or modify it at a later time. The debugger can also have its own internal events enabled for tracing. These events are only be displayed if the `-a` option is present. If the `-v` option is present, a more verbose display, including the reason for any specifier inactivity, are shown. Here is some sample output:

```
> ::events
 ID S TA HT LM Description Action

[1] - T 1 0 stop on SIGINT -
[2] - T 0 0 stop on SIGQUIT -
[3] - T 0 0 stop on SIGILL -
...
[11] - T 0 0 stop on SIGXCPU -
[12] - T 0 0 stop on SIGXFSZ -
[13] - 2 0 stop at libc'printf ::echo printf
>
```

The following table explains the meaning of each column. A summary of this information is available using `::help events`.

ID

The event specifier identifier. The identifier is shown in square brackets `[ ]` if the specifier is enabled, in parentheses `( )` if the specifier is disabled, or in angle brackets `< >` if the target program is currently stopped on an event that matches the given specifier.

S

The event specifier state. The state is one of the following symbols:

-

The event specifier is idle. When no target program is running, all specifiers are idle. When the target program is running, a specifier can be idle if it cannot be evaluated (for example, a deferred breakpoint in a shared object that is not yet loaded).

+

The event specifier is active. When the target is continued, events of this type is detected by the debugger.

\*  
The event specifier is armed. This state means that the target is currently running with instrumentation for this type of event. This state is only visible if the debugger is attached to a running program with the `-o nos top` option.

!  
The event specifier was not armed due to an operating system error. The `::events -v` option can be used to display more information about the reason the instrumentation failed.

#### TA

The Temporary, Sticky, and Automatic event specifier properties. One or more of the following symbols can be shown:

t  
The event specifier is temporary, and is deleted the next time the target stops, regardless of whether it is matched.

T  
The event specifier is sticky, and is not be deleted by `::delete all` or `::z`. The specifier can be deleted by explicitly specifying its id number to `::delete`.

d  
The event specifier is automatically disabled when the hit count is equal to the hit limit.

D  
The event specifier is automatically deleted when the hit count is equal to the hit limit.

s  
The target automatically stops when the hit count is equal to the hit limit.

#### HT

The current hit count. This column displays the number of times the corresponding software event has occurred in the target since the creation of this event specifier.

#### LM

The current hit limit. This column displays the limit on the hit count at which the auto-disable, auto-delete, or auto-stop behavior takes effect. These behaviors can be configured using the `::evset dcmd`, described below.

#### Description

A description of the type of software event that is matched by the given specifier.

#### Action

The callback string to execute when the corresponding software event occurs. This callback is executed as if it had been typed at the command prompt.

`[id] :: evset [-/-dDestT] [-c cmd] [-n count] id ...`

Modify the properties of one or more software event specifiers. The properties are set for each specifier identified by the optional expression preceding the `dcmd` and an optional list of arguments following the `dcmd`. The argument list is interpreted as a list of decimal integers, unless an explicit radix is specified. The `:: evset dcmd` recognizes the following options:

-d

Disables the event specifier when the hit count reaches the hit limit. If the -d form of the option is given, this behavior is disabled. Once an event specifier is disabled, the debugger removes any corresponding instrumentation and ignores the corresponding software events until the specifier is subsequently re-enabled. If the -n option is not present, the specifier is disabled immediately.

-D

Deletes the event specifier when the hit count reaches the hit limit. If the -D form of the option is given, this behavior is disabled. The -D option takes precedence over the -d option. The hit limit can be configured using the -n option.

-e

Enables the event specifier. If the -e form of the option is given, the specifier is disabled.

-s

Stops the target program when the hit count reaches the hit limit. If the -s form of the option is given, this behavior is disabled. The -s behavior tells the debugger to act as if the `:: cont` were issued following each execution of the specifier's callback, except for the *N*th execution, where *N* is the current value of the specifier's hit limit. The -s option takes precedence over both the -D option and the -d option.

-t

Marks the event specifier as temporary. Temporary specifiers are automatically deleted the next time the target stops, regardless of whether it stopped as the result of a software event corresponding to the given specifier. If the -t form of the option is given, the temporary marker is removed. The -t option takes precedence over the -T option.

-T

Marks the event specifier as sticky. Sticky specifiers are not deleted by `:: delete all` or `:: z`. They can be deleted by specifying the corresponding specifier ID as an explicit argument to `:: delete`. If the -T form of the option is given, the sticky property is removed. The default set of event specifiers are all initially marked sticky.

-c

Executes the specified *cmd* string each time the corresponding software event occurs in the target program. The current callback string can be displayed using `:: events`.

-n

Sets the current value of the hit limit to *count*. If no hit limit is currently set and the -n option does not accompany -s or D, the hit limit is set to one.

A summary of this information is available using `::help evset`.

`::files`

`$f`

Print a list of the known source files (symbols of type `STT_FILE` present in the various target symbol tables).

`[flt] :: fltbp [-/-dDestT] [-c cmd] [-n count] flt ...`

Trace the specified machine faults. The faults are identified using an optional fault number preceding the `dcmd`, or a list of fault names or numbers (see `<sys/fault.h>`) following the `dcmd`. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset dcmd`.

`[thread] :: fpregs`

`[thread] $x, $X, $y, $Y`

Print the floating-point register set of the representative thread. If a thread is specified, the floating point registers of that thread are displayed. The thread expression should be one of the thread identifiers described under `Thread Support`, above.

`::formats`

List the available output format characters for use with the `/`, `\`, `?`, and `=` formatting `dcmds`. The formats and their use is described under `Formatting dcmds`, above.

`::grep command`

Evaluate the specified command string, and then print the old value of `dot` if the new value of `dot` is non-zero. If the `command` contains whitespace or metacharacters, it must be quoted. The `::grep dcmd` can be used in pipelines to filter a list of addresses.

`::help [ dcmd-name ]`

With no arguments, the `::help dcmd` prints a brief overview of the help facilities available in `mdb`. If a `dcmd-name` is specified, `mdb` prints a usage summary for that `dcmd`.

`signal : i`

If the target is a live user process, ignore the specified signal and allow it to be delivered transparently to the target. All event specifiers that are tracing delivery of the specified signal is deleted from the list of traced events. By default, the set of ignored signals is initialized to the complement of the set of signals that cause a process to dump core by default (see `signal.h(3HEAD)`), except for `SIGINT`, which is traced by default.

`$i`

Display the list of signals that are ignored by the debugger and that is handled directly by the target. More information on traced signals can be obtained using the `::events dcmd`.

`[address] :: if [-p] {type member tests} [type] [at off] test}`

Evaluate the tests and then print the old value of `dot` if the tests are true.

`-p`

Use physical rather than virtual addresses.

There are two kinds of tests. The first allows you to test the value of a member of a structure or union. The second allows you to test an offset from dot. These tests can then be joined with AND or OR to build more complex tests.

Start with an example of testing a member of a structure:

```
::if "struct foo" namep <> 0
```

This statement would print the old value of dot if the element namep in structure foo were not 0.

```
::if "struct foo" namep <> 0 AND namep->name <> 0 AND
namep->name streq "bar"
```

The preceding statement would print the old value of dot if the element name in structure pointed to by namep in foo were not 0 and pointed to a string that contained the string bar.

```
::if "struct foo" name <> 0 AND name streq "bar" and value = 0x123
```

The preceding statement would print only if the name were bar and value was 0x123.

The second form tests to see if the type at the given offset has the given value. Here is an example:

```
::if uint_t at 0x34 = 0x123
```

This will print if the value of an uint\_t at offset 0x34 is 0x123. Again this can be joined with other tests using AND or OR. With this form, ::if has a number of built-in types that are internal that can be used even when there is no symbolic type information. These types are:

```
char, uchar, short, ushort, int, uint, long, ulong,
longlong, ulonglong, pointer, addr
```

If the type is addr, then, rather than the value at that address, the actual address is tested. So, the statement:

```
::if addr at 0x34 = 0x100034
```

...would report the value of dot only if dot+0x34 was 0x100034, whereas:

```
::if pointer at 0x34 = 0x100034
```

...would print only if the value at dot+0x34.

More usefully, the statement:

```
::if "char *" at 0x34 streq "foo"
```

...will print the old value of dot if the string pointed to at offset 0x34 is foo.

Possible tests are:

```
= - True if the values are equal.
<> - True if the values are not equal.
< - True if the value is less than the right hand value.
```

---

```

<= - True if the value is less than or equal to the right
 hand value.
> - True if the value is greater than the right hand value.
>= - True if the value is greater than or equal to the right
 hand value.
& - True if the values ANDed together are non zero.
^ - True if the values XORed together are non zero.
streq - True if the strings exactly match.
strneq - True if the strings don't match.
strcaseeq - True if the strings match case insensitively.
strncaseeq - True if the strings do not match case insensitively.
strleneq - True if the string is this length.
strlneq - True if the string is not this length.
strlengt - True if the string is longer than this.
strlenlt - True if the string is shorter than this.
strlengt - True if the string is this long or longer.
strlenle - True if the string is this long or shorter

```

The right hand side of a test can be any one of the following:

- An element in the structure or union.
- The value from a symbol.
- An absolute value.
- `<var` — the value of the variable `var`.
- `$expr` - the value of dot after `mdb` expression `expr` is evaluated. This must be quoted using double quotation marks ("`\"`"). For example:

```
"$<var=J"
```

...would get the value of variable `var`.

```
::kill
```

```
:k
```

Forcibly terminate the target if it is a live user process. The target is also forcibly terminated when the debugger exits if it was created by the debugger using `::run`.

```
$l
```

Print the LWPID of the representative thread, if the target is a user process.

```
$L
```

Print the LWPIDs of each LWP in the target, if the target is a user process.

```
[address] ::list [-b back_member][-p][-L] [type] member [variable-name]
```

Walk through the elements of a linked list data structure and print the address of each element in the list. The address of the first element in the list can be specified using an optional address. Otherwise, the list is assumed to start at the current value of dot. The type parameter must name a C struct or union type and is used to describe the type of the list elements so that `mdb` can read in objects of the appropriate size. If `::list` can determine the type then `type` can be omitted. The `member` parameter is used to name the member of `type`

that contains a pointer to the next list element. The `::list dcmd` continues iterating until a NULL pointer is encountered, the first element is reached again (a circular list), a loop is detected, a loop is detected, back member checking is enabled (`-b`) and a bad back pointer is detected, or an error occurs while reading an element. If the optional *variable-name* is specified, the specified variable is assigned the value returned at each step of the walk when `mdb` invokes the next stage of a pipeline.

`-b` *back\_member*

Verify that *back\_member* points to the previous member of the list. The first member of the list is allowed to have a NULL back pointer.

`-L`

Check for loops in the list. Will print every element in the list once.

`-p`

Read from physical rather than virtual addresses.

The `::list dcmd` can only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to NOTES, “Symbolic Debugging Information,” below for more information.

`::load [ -s ] module-name`

Load the specified `dmod`. The module name can be given as an absolute or relative path. If *module-name* is a simple name (that is, does not contain a `'/'`), `mdb` searches for it in the module library path. Modules with conflicting names can not be loaded; the existing module must be unloaded first. If the `-s` option is present, `mdb` remains silent and not issue any error messages if the module is not found or could not be loaded.

`::log [ -d | [ -e ] filename ]`

`$> [ filename ]`

Enable or disable the output log. `mdb` provides an interactive logging facility where both the input commands and standard output can be logged to a file while still interacting with the user. The `-e` option enables logging to the specified file, or re-enables logging to the previous log file if no filename is given. The `-d` option disables logging. If the `$>` `dcmd` is used, logging is enabled if a filename argument is specified; otherwise, logging is disabled. If the specified log file already exists, `mdb` appends any new log output to the file.

`::map command`

Map the value of `dot` to a corresponding value using the *command* specified as a string argument, and then print the new value of `dot`. If the command contains whitespace or metacharacters, it must be quoted. The `::map dcmd` can be used in pipelines to transform the list of addresses into a new list of addresses.

`[ address ] : mappings [ name ]`

`[ address ] $m [ name ]`

Print a list of each mapping in the target's virtual address space, including the address, size, and description of each mapping. If the `dcmd` is preceded by an *address*, `mdb` only shows the

mapping that contains the given address. If a string *name* argument is given, mdb only shows the mapping matching that description.

::next [ *SIG* ]

:e [ *SIG* ]

Step the target program one instruction, but step over subroutine calls. If an optional signal name or number (see [signal.h\(3HEAD\)](#)) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If no target program is currently running, ::next starts a new program running as if by ::run and stop at the first instruction.

[ *address* ] ::nm [ -DPdghnopuvx ] [ -t *types* ]

[ -f *format* ] [ *object* ]

Print the symbol tables associated with the current target. If an optional address preceding the dcmd is specified, only the symbol table entry for the symbol corresponding to *address* is displayed. If an *object* is specified, only the symbol table for this load object is displayed. The ::nm dcmd also recognizes the following options:

-D

Prints .dynam (dynamic symbol table) instead of .symtab.

-P

Prints the private symbol table instead of .symtab.

-d

Prints value and size fields in decimal.

-g

Prints only global symbols.

-h

Suppresses the header line.

-n

Sorts symbols by name.

-o

Prints value and size fields in octal.

-p

Prints symbols as a series of ::nmadd commands. This option can be used with -P to produce a macro file that can be subsequently read into the debugger with \$<.

-u

Prints only undefined symbols.

-v

Sorts symbols by value.

-x

Prints value and size fields in hexadecimal.

`-t type[,type ... ]`

Prints only symbols of the specified type(s). The valid *type* argument strings are:

`noty`

`STT_NOTYPE`

`objt`

`STT_OBJECT`

`func`

`STT_FUNC`

`sect`

`STT_SECTION`

`file`

`STT_FILE`

`comm`

`STT_COMMON`

`tls`

`STT_TLS`

`regi`

`STT_SPARC_REGISTER`

`-f format[,format ... ]`

Prints only the specified symbol information. The valid *format* argument strings are:

`ndx`

symbol table index

`val`

symbol value

`size`

size in bytes

`type`

symbol type

`bind`

binding

`oth`

other

`shndx`

section index

`name`

symbol name

`ctype`  
C type for symbol (if known)

`obj`  
object which defines symbol

`value :: nmadd [ -fo ] [ -e end ] [ -s size ] name`

Add the specified symbol *name* to the private symbol table. `mdb` provides a private, configurable symbol table that can be used to interpose on the target's symbol table, as described under `Symbol Name Resolution` above. The `::nmadd` cmd also recognizes the following options:

`-e`  
Sets the size of the symbol to *end - value*.

`-f`  
Sets the type of the symbol to `STT_FUNC`.

`-o`  
Sets the type of the symbol to `STT_OBJECT`.

`-s`  
Sets the size of the symbol to *size*.

`::nmde1 name`

Delete the specified symbol *name* from the private symbol table.

`::objects [ -v ]`

Print a map of the target's virtual address space, showing only those mappings that correspond to the primary mapping (usually the text section) of each of the known load objects. The `-v` option displays the version of each load object. Version information is not available for all load objects. Load objects without version information is listed as having a version of "Unknown" in the output for the `-v` option.

`::offsetof member`

Print the offset of the specified member of the specified type. The type should be the name of a C structure. If no member is specified all the members for this type are reported.

The offset is printed in bytes, unless the member is a bit-field, in which case the offset can be printed in bits. The output is always suffixed with the appropriate units for clarity. The type name can use the backquote (‘) scoping operator described under `Symbol Name Resolution`, above. The `::offsetof` cmd can only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to `NOTES, Symbolic Debugging Information`, below for more information.

`address :: print [ -aCdiLptx ] [ -c lim ]`

`[ -l lim ] [ type [ member ... ] ]`

Print the data structure at the specified virtual *address* using the given *type* information. The *type* parameter can name a C struct, union, enum, fundamental integer type, or a pointer to any of these types. If the type name contains whitespace (for example, "struct

foo”), it must be enclosed in single or double quotes. The type name can use the backquote (‘) scoping operator described under Symbol Name Resolution, above. If the type is a structured type, the `::print` cmd recursively prints each member of the struct or union. If the *type* argument is not present and a static or global `STT_OBJECT` symbol matches the address, `::print` infers the appropriate type automatically. If the *type* argument is specified, it can be followed by an optional list of *member* expressions, in which case only those members and submembers of the specified *type* are displayed. If *type* contains other structured types, each member string can refer to a sub-structure element by forming a list of member names separated by period (‘.’) delimiters. The `::print` cmd can only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to NOTES, Symbolic Debugging Information, below for more information. After displaying the data structure, `::print` increments dot by the size of *type* in bytes.

If the `-a` option is present, the address of each member is displayed. If the `-p` option is present, `::print` interprets *address* as a physical memory address instead of a virtual memory address. If the `-t` option is present, the type of each member is displayed. If the `-d` or `-x` options are present, all integers are displayed in decimal (`-d`) or hexadecimal (`-x`). By default, a heuristic is used to determine if the value should be displayed in decimal or hexadecimal. The number of characters in a character array that is read and displayed as a string can be limited with the `-c` option. If the `-C` option is present, no limit is enforced. The number of elements in a standard array that is read and displayed can be limited with the `-l` option. If the `-L` option is present, no limit is enforced and all array elements are shown. The default values for `-c` and `-l` can be modified using `::set` or the `-o` command-line option as described under OPTIONS.

If the `-i` option is specified, the address value is interpreted as an immediate value to be printed. You must give a type with which to interpret the value. If the type is smaller than 64 bits, the immediate value is interpreted as if it were the size of the type. The `-i` option cannot be used in conjunction with the `-p` option. If the `-a` option is given, the addresses shown are byte offsets starting at zero.

```
::quit
```

```
$q
```

Quit the debugger.

```
[thread] ::regs
```

```
[thread] $r
```

Print the general purpose register set of the representative thread. If a thread is specified, the general purpose register set of that thread is displayed. The thread expression should be one of the thread identifiers described under Thread Support, above.

```
::release [-a]
```

```
:R [-a]
```

Release the previously attached process or core file. If the `-a` option is present, the process is released and left stopped and abandoned. It can subsequently be continued by `prun(1)` (see [proc\(1\)](#)) or it can be resumed by applying `mdb` or another debugger. By default, a released

process is forcibly terminated if it was created by mdb using `::run`, or it is released and set running if it was attached to by mdb using the `-p` option or using the `::attach` or `:A dcmds`.

`::run [ args... ]`

`:r [ args... ]`

Start a new target program running with the specified arguments and attach to it. The arguments are not interpreted by the shell. If the debugger is already examining a live running program, it first detaches from this program as if by `::release`.

`::set [ -wF ] [ -/-o option ] [ -s distance ] [ -I path ]`

`[ -L path ] [ -P prompt ]`

Get or set miscellaneous debugger properties. If no options are specified, the current set of debugger properties is displayed. The `::set` dcmd recognizes the following options:

`-F`

Forcibly takes over the next user process that `::attach` is applied to, as if mdb had been executed with the `-F` option on the command line.

`-I`

Sets the default path for locating macro files. The path argument can contain any of the special tokens described for the `-I` command-line option under OPTIONS.

`-L`

Sets the default path for locating debugger modules. The path argument can contain any of the special tokens described for the `-I` command-line option under OPTIONS.

`-o`

Enables the specified debugger option. If the `-o` form is used, the option is disabled. The option strings are described along with the `-o` command-line option under OPTIONS.

`-P`

Sets the command prompt to the specified prompt string.

`-s`

Sets the symbol matching distance to the specified distance. Refer to the description of the `-s` command-line option under OPTIONS for more information.

`-w`

Re-opens the target for writing, as if mdb had been executed with the `-w` option on the command line.

`::showrev [ -pv ]`

Display revision information for the hardware and software. With no options specified, general system information is displayed. The `-v` option displays version information for all load objects, whereas the `-p` option displays the version information only for the load objects that have been installed on the system as part of a patch. Version information is not available for all load objects. Load objects without version information is omitted from the output for the `-p` option and is listed as having a version of “Unknown” in the output for the `-v` option.

`[signal] :: sigbp [-/ -dDestT] [-c cmd] [-n count] SIG ...`

`[signal] :t [-/ -dDestT] [-c cmd] [-n count] SIG ...`

Trace delivery of the specified signals. The signals are identified using an optional signal number preceding the `cmd`, or a list of signal names or numbers (see [signal.h\(3HEAD\)](#)) following the `cmd`. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset cmd`. Initially, the set of signals that cause the process to dump core by default (see [signal.h\(3HEAD\)](#)) and `SIGINT` are traced.

`::sizeof [-s size] [-r min max] [type [member ...]]`

Options are as follows:

`-s size`

Show types for entries of this size.

`-r min max`

Show types for entries in range of sizes.

Print the size of the specified `type` in bytes. The `type` parameter can name a C struct, union, enum, fundamental integer type, or a pointer to any of these types. The type name can use the backquote (‘) scoping operator described under `Symbol Name Resolution`, above. `member` can be specified with standard C syntax using the array indexing operator “[`index`]”, structure member operator “.”.

The `::sizeof cmd` can only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to `NOTES, Symbolic Debugging Information`, below for more information.

`[ address ] :: stack [ count ]`

`[ address ] $c [ count ]`

Print a C stack backtrace. If the `cmd` is preceded by an explicit `address`, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than `count` arguments are displayed for each stack frame in the output.

`::status`

Print a summary of information related to the current target.

`::step [ over | out ] [ SIG ]`

`:s [ SIG ]`

`:u [ SIG ]`

Step the target program one instruction. If an optional signal name or number (see [signal.h\(3HEAD\)](#)) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the optional “over” argument is specified, `::step` steps over subroutine calls. The `::step over` argument is the same as the `::next cmd`. If the optional “out” argument is specified, the target program continues until the representative thread returns from the current function. If no target program is currently running, `::step out` starts a new program running as if by `::run` and stop at the first instruction. The `:s cmd` is the same as `::step`. The `:u cmd` is the same as `::step out`.

`[ syscall ] :: sysbp [ -/ -dDestT ] [ -io ] [ -c cmd ]  
[ -n count ] syscall...`

Trace entry to or exit from the specified system calls. The system calls are identified using an optional system call number preceding the dcmd, or a list of system call names or numbers (see <sys/syscall.h>) following the dcmd. If the `-i` option is specified (the default), the event specifiers trigger on entry into the kernel for each system call. If the `-o` option is specified, the event specifiers trigger on exit out from the kernel. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset` dcmd.

`thread :: tls symbol`

Print the address of the storage for the specified thread-local storage (TLS) symbol in the context of the specified thread. The thread expression should be one of the thread identifiers described under Thread Support, above. The symbol name can use any of the scoping operators described under Symbol Name Resolution, above.

`:: typeset [ -/ -t ] variable-name ...`

Set attributes for named variables. If one or more variable names are specified, they are defined and set to the value of dot. If the `-t` option is present, the user-defined tag associated with each variable is set. If the `-t` option is present, the tag is cleared. If no variable names are specified, the list of variables and their values is printed.

`:: unload module-name`

Unload the specified dmod. The list of active dmods can be printed using the `::dmods` dcmd. Built-in modules can not be unloaded. Modules that are busy (that is, provide dcmds that are currently executing) can not be unloaded.

`:: unset variable-name ...`

Unset (remove) the specified variable(s) from the list of defined variables. Some variables exported by mdb are marked as persistent, and can not be unset by the user.

`:: vars [ -npt ]`

Print a listing of named variables. If the `-n` option is present, the output is restricted to variables that currently have non-zero values. If the `-p` option is present, the variables are printed in a form suitable for re-processing by the debugger using the `$<` dcmd. This option can be used to record the variables to a macro file and then restore these values later. If the `-t` option is present, only the tagged variables are printed. Variables can be tagged using the `-t` option of the `::typeset` dcmd.

`:: version`

Print the debugger version number.

`address :: vtop [ -a as ]`

Print the physical address mapping for the specified virtual address, if possible. The `::vtop` dcmd is only available when examining a kernel target, or when examining a user process inside a kernel crash dump (after a `::context` dcmd has been issued).

When examining a kernel target from the kernel context, the `-a` option can be used to specify the address (*as*) of an alternate address space structure that should be used for the

virtual to physical translation. By default, the kernel's address space is used for translation. This option is available for active address spaces even when the dump content only contains kernel pages.

[ *address* ] : :walk *walker-name* [ *variable-name* ]

Walk through the elements of a data structure using the specified walker. The available walkers can be listed using the : :walkers dcmd. Some walkers operate on a global data structure and do not require a starting address. For example, walk the list of proc structures in the kernel. Other walkers operate on a specific data structure whose address must be specified explicitly. For example, given a pointer to an address space, walk the list of segments. When used interactively, the : :walk dcmd prints the address of each element of the data structure in the default base. The dcmd can also be used to provide a list of addresses for a pipeline. The walker name can use the backquote (‘) scoping operator described under dcmd and Walker Name Resolution, above. If the optional *variable-name* is specified, the specified variable is assigned the value returned at each step of the walk when mdb invokes the next stage of the pipeline.

: :walkers

List the available walkers and print a brief description for each one.

: :whence [ -v ] *name* ...

: :which [ -v ] *name* ...

Print the dmod that exports the specified dcmds and walkers. These dcmds can be used to determine which dmod is currently providing the global definition of the given dcmd or walker. Refer to the section on dcmd and Walker Name Resolution above for more information on global name resolution. The -v option causes the dcmd to print the alternate definitions of each dcmd and walker in order of precedence.

*addr* [ ,*len* ] : :wp [ -/ -dDestT ] [ -rwx ] [ -c *cmd* ]  
[ -n *count* ]

*addr* [ ,*len* ] : a [ *cmd* ... ]

*addr* [ ,*len* ] : p [ *cmd* ... ]

*addr* [ ,*len* ] : w [ *cmd* ... ]

Set a watchpoint at the specified address. The length in bytes of the watched region can be set by specifying an optional repeat count preceding the dcmd. If no length is explicitly set, the default is one byte. The : :wp dcmd allows the watchpoint to be configured to trigger on any combination of read (-r option), write (-w option), or execute (-x option) access. The -d, -D, -e, -s, -t, -T, -c, and -n options have the same meaning as they do for the : :evset dcmd. The : a dcmd sets a read access watchpoint at the specified address. The : p dcmd sets an execute access watchpoint at the specified address. The : w dcmd sets a write access watchpoint at the specified address. The arguments following the : a, : p, and : w dcmds are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

: :xdata

List the external data buffers exported by the current target. External data buffers represent information associated with the target that can not be accessed through standard target

facilities (that is, an address space, symbol table, or register set). These buffers can be consumed by dcmds; for more information, refer to the *Oracle Solaris Modular Debugger Guide*.

:z

Delete all event specifiers from the list of traced software events. Event specifiers can also be deleted using `::delete`.

**Options** The following options are supported:

-A

Disables automatic loading of mdb modules. By default, mdb attempts to load debugger modules corresponding to the active shared libraries in a user process or core file, or to the loaded kernel modules in the live operating system or an operating system crash dump.

-f

Forces raw file debugging mode. By default, mdb attempts to infer whether the object and core file operands refer to a user executable and core dump or to a pair of operating system crash dump files. If the file type cannot be inferred, the debugger defaults to examining the files as plain binary data. The `-f` option forces mdb to interpret the arguments as a set of raw files to examine.

-F

Forcibly takes over the specified user process, if necessary. By default, mdb refuses to attach to a user process that is already under the control of another debugging tool, such as [truss\(1\)](#). With the `-F` option, mdb attaches to these processes anyway. This can produce unexpected interactions between mdb and the other tools attempting to control the process.

-I *path*

Sets default path for locating macro files. Macro files are read using the `$<` or `$<<` dcmds. The path is a sequence of directory names delimited by colon (`:`) characters. The `-I include path` and `-L library path` (see below) can also contain any of the following tokens:

%i

Expands to the current instruction set architecture (ISA) name ('sparc', 'sparcv9', or 'i386').

%o

Expands to the old value of the path being modified. This is useful for appending or prepending directories to an existing path.

%p

Expands to the current platform string (either `uname -i` or the platform string stored in the process core file or crash dump).

%r

Expands to the pathname of the root directory. An alternate root directory can be specified using the `-R` option. If no `-R` option is present, the root directory is derived

dynamically from the path to the `mdb` executable itself. For example, if `/bin/mdb` is executed, the root directory is `.`. If `/net/hostname/bin/mdb` were executed, the root directory would be derived as `/net/hostname`.

`%t`

Expands to the name of the current target. This is either be the literal string 'proc' (a user process or user process core file), 'kvm' (a kernel crash dump or the live operating system), or 'raw' (a raw file).

The default include path for 32-bit `mdb` is:

```
%r/usr/platform/%p/lib/adb:%r/usr/lib/adb
```

The default include path for 64-bit `mdb` is:

```
%r/usr/platform/%p/lib/adb/%i:%r/usr/lib/adb/%i
```

`-k`

Forces kernel debugging mode. By default, `mdb` attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The `-k` option forces `mdb` to assume these files are operating system crash dump files. If no object or core operand is specified, but the `-k` option is specified, `mdb` defaults to an object file of `/dev/ksyms` and a core file of `/dev/kmem`. Read access to `/dev/kmem` is restricted to group `sys`. Write access requires ALL privileges.

`-K`

Load `kmdb`, stop the live running operating system kernel, and proceed to the `kmdb` debugger prompt. This option should only be used on the system console, as the subsequent `kmdb` prompt appears on the system console.

`-L path`

Sets default path for locating debugger modules. Modules are loaded automatically on startup or using the `: load dcmd`. The path is a sequence of directory names delimited by colon (`:`) characters. The `-L` library path can also contain any of the tokens shown for `-I` above.

`-m`

Disables demand-loading of kernel module symbols. By default, `mdb` processes the list of loaded kernel modules and performs demand loading of per-module symbol tables. If the `-m` option is specified, `mdb` does not attempt to process the kernel module list or provide per-module symbol tables. As a result, `mdb` modules corresponding to active kernel modules are not loaded on startup.

`-M`

Preloads all kernel module symbols. By default, `mdb` performs demand-loading for kernel module symbols: the complete symbol table for a module is read when an address is that module's text or data section is referenced. With the `-M` option, `mdb` loads the complete symbol table of all kernel modules during startup.

---

**-o *option***

Enables the specified debugger option. If the `-o` form of the option is used, the specified *option* is disabled. Unless noted below, each option is off by default. `mdb` recognizes the following *option* arguments:

**adb**

Enables stricter [adb\(1\)](#) compatibility. The prompt is set to the empty string and many `mdb` features, such as the output pager, is disabled.

**array\_mem\_limit=*limit***

Sets the default limit on the number of array members that `:::print` displays. If *limit* is the special token `none`, all array members are displayed by default.

**array\_str\_limit=*limit***

Sets the default limit on the number of characters that `:::print` attempts to display as an ASCII string when printing a char array. If *limit* is the special token `none`, the entire char array is displayed as a string by default.

**follow\_exec\_mode=*mode***

Sets the debugger behavior for following an [exec\(2\)](#) system call. The *mode* should be one of the following named constants:

**ask**

If `stdout` is a terminal device, the debugger stops after the `exec(2)` system call has returned and then prompts the user to decide whether to follow the `exec` or stop. If `stdout` is not a terminal device, the `ask` mode defaults to `stop`.

**follow**

The debugger follows the `exec` by automatically continuing the target process and resetting all of its mappings and symbol tables based on the new executable. The `follow` behavior is discussed in more detail under [NOTES, Interaction with Exec](#), below.

**stop**

The debugger stops following return from the `exec` system call. The `stop` behavior is discussed in more detail under [NOTES, Interaction with Exec](#), below.

**follow\_fork\_mode=*mode***

Sets the debugger behavior for following a [fork\(2\)](#), [fork1\(2\)](#), or [vfork\(2\)](#) system call. The *mode* should be one of the following named constants:

**ask**

If `stdout` is a terminal device, the debugger stops after the `fork(2)` system call has returned and then prompts the user to decide whether to follow the parent or child. If `stdout` is not a terminal device, the `ask` mode defaults to `parent`.

**parent**

The debugger follows the parent process, and detaches from the child process and sets it running.

**child**

The debugger follows the child process, and detaches from the parent process and sets it running.

**ignoreeof**

The debugger does not exit when an EOF sequence (^D) is entered at the terminal. The `::quit` dcmd must be used to quit.

**nostop**

Does not stop a user process when attaching to it when the `-p` option is specified or when the `::attach` or `:A` dcmds are applied. The `nostop` behavior is described in more detail under NOTES, Process Attach and Release, below.

**pager**

Enables the output pager (default).

**repeatlast**

If a NEWLINE is entered as the complete command at the terminal, mdb repeats the previous command with the current value of dot. This option is implied by `-o adb`.

**showlmid**

`mdb` provides support for symbol naming and identification in user applications that make use of link maps other than `LM_ID_BASE` and `LM_ID_LDSO`, as described in Symbol Name Resolution, above. Symbols on link maps other than `LM_ID_BASE` or `LM_ID_LDSO` is shown as `LMlmid'library'symbol`, where `lmid` is the link-map ID in the default output radix (16). The user can optionally configure `mdb` to show the link-map ID scope of all symbols and objects, including those associated with `LM_ID_BASE` and `LM_ID_LDSO`, by enabling the `showlmid` option. Built-in dcmds that deal with object file names displays link-map IDs according to the value of `showlmid` above, including `::nm`, `::mappings`, `$m`, and `::objects`.

**-p pid**

Attaches to and stops the specified process-id. `mdb` uses the `/proc/pid/object/a.out` file as the executable file pathname.

**-P prompt**

Sets the command prompt. The default prompt is `'>'`.

**-R root**

Sets root directory for pathname expansion. By default, the root directory is derived from the pathname of the `mdb` executable itself. The root directory is substituted in place of the `%r` token during pathname expansion.

**-s distance**

Sets the symbol matching distance for address-to-symbol-name conversions to the specified *distance*. By default, `mdb` sets the distance to zero, which enables a smart-matching mode. Each ELF symbol table entry includes a value `V` and size `S`, representing the size of the function or data object in bytes. In smart mode, `mdb` matches an address `A` with the

given symbol if A is in the range [ V, V + S ). If any non-zero distance is specified, the same algorithm is used, but S in the expression above is always the specified absolute distance and the symbol size is ignored.

- S  
Suppresses processing of the user's `~/ .mdbrc` file. By default, `mdb` reads and processes the macro file `.mdbrc` if one is present in the user's home directory, as defined by `$HOME`. If the `-S` option is present, this file is not read.
- u  
Forces user debugging mode. By default, `mdb` attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The `-u` option forces `mdb` to assume these files are not operating system crash dump files.
- U  
Unload `kmdb` if it is loaded. You should unload `kmdb` when it is not in use to release the memory used by the kernel debugger back to the free memory available to the operating system.
- V *version*  
Sets disassembler version. By default, `mdb` attempts to infer the appropriate disassembler version for the debug target. The disassembler can be set explicitly using the `-V` option. The `::disasms dcmd` lists the available disassembler versions.
- w  
Opens the specified object and core files for writing.
- W  
Permit access to memory addresses that are mapped to I/O devices. By default, `mdb` does not allow such access because many devices do not provide hardware protection against invalid software manipulations. Use this option only when debugging device drivers and with caution.
- y  
Sends explicit terminal initialization sequences for tty mode. Some terminals, such as `cmdtool(1)`, require explicit initialization sequences to switch into a tty mode. Without this initialization sequence, terminal features such as standout mode can not be available to `mdb`.

**Operands** The following operands are supported:

*object*

Specifies an ELF format object file to examine. `mdb` provides the ability to examine and edit ELF format executables (`ET_EXEC`), ELF dynamic library files (`ET_DYN`), ELF relocatable object files (`ET_REL`), and operating system `unix.X` symbol table files.

*core*

Specifies an ELF process core file (ET\_CORE), or an operating system crash dump vmcore.X file. If an ELF core file operand is provided without a corresponding object file, mdb attempts to infer the name of the executable file that produced the core using several different algorithms. If no executable is found, mdb still executes, but some symbol information can be unavailable.

*suffix*

Specifies the numerical suffix representing a pair of operating system crash dump files. For example, if the suffix is '3', mdb infers that it should examine the files 'unix.3' and 'vmcore.3'. If these files do not exist, but 'vmdump.3' does exist, then a message is printed indicating that `savecore -f vmdump.3` must be run first in order to uncompress the dump file. The string of digits are not interpreted as a suffix if an actual file of the same name is present in the current directory.

**Usage** mdb processes all input files (including scripts, object files, core files, and raw data files) in a large file aware fashion. See [largefile\(5\)](#) for more information about the processing of large files, which are files greater than or equal to 2 Gbytes ( $2^{31}$  bytes).

**Exit Status** The following exit values are returned:

- 0  
Debugger completed execution successfully.
- 1  
A fatal error occurred.
- 2  
Invalid command line options were specified.

**Environment Variables**

**HISTSIZE**  
This variable is used to determine the maximum length of the command history list. If this variable is not present, the default length is 128.

**HOME**  
This variable is used to determine the pathname of the user's home directory, where a `.mdbrc` file can reside. If this variable is not present, no `.mdbrc` processing occurs.

**SHELL**  
This variable is used to determine the pathname of the shell used to process shell escapes requested using the `!` meta-character. If this variable is not present, `/bin/sh` is used.

**Files** `$HOME/.mdbrc`  
User mdb initialization file. The `.mdbrc` file, if present, is processed after the debug target has been initialized, but before module auto-loading is performed or any commands have been read from standard input.

`/dev/kmem`  
Kernel virtual memory image device. This device special file is used as the core file when examining the live operating system.

`/dev/ksyms`

Kernel symbol table device. This device special file is used as the object file when examining the live operating system.

`/proc/pid/*`

Process information files that are read when examining and controlling user processes.

`/usr/lib/adb`

`/usr/platform/platform-name/lib/adb`

Default directories for macro files that are read with the `$<` and `$<<` dcmds. *platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see [uname\(1\)](#)).

`/usr/lib/mdb`

`/usr/platform/platform-name/lib/mdb`

Default directories for debugger modules that are loaded using the `::load` dcmd. *platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see [uname\(1\)](#)).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE     |
|---------------------|---------------------|
| Availability        | developer/debug/mdb |

*Linker and Libraries Guide*

*Oracle Solaris Modular Debugger Guide*

## Warnings

### Use of the Error Recovery Mechanism

The debugger and its dmods execute in the same address space, and thus it is quite possible that a buggy dmod can cause `mdb` to dump core or otherwise misbehave. The `mdb resume` capability, described above under [Signal Handling](#), provides a limited recovery mechanism for these situations. However, it is not possible for `mdb` to know definitively whether the dmod in question has corrupted only its own state, or the debugger's global state. Therefore a resume operation cannot be guaranteed to be safe, or to prevent a subsequent crash of the debugger. The safest course of action following a resume is to save any important debug information, and then quit and restart the debugger.

Use of the Debugger to Modify the Live Operating System The use of the debugger to modify (that is, write to) the address space of live running operating system is extremely dangerous, and can result in a system panic in the event the user damages a kernel data structure.

### Notes

- Limitations on Examining Process Core Files mdb does not provide support for examining process core files that were generated by a release of Solaris preceding Solaris 2.6. When debugging core files generated by a release of Solaris 9 or an earlier release, symbol information might not be available. Since the text section and read-only data is not present in those core files, the symbol information might not match the data present in the process at the time it dumped core. In releases later than Solaris 9, text sections and read-only data are included in core files by default. Users can configure their processes to exclude that information from core files using `coreadm(1M)`. Thus, the information presented by mdb for those core files can not match the data that was present at the time the process dumped core. Core files from Solaris x86 systems can not be examined on Solaris SPARC systems, and vice-versa.
- Limitations on Examining Crash Dump Files Crash dumps from Solaris 7 and earlier releases can only be examined with the aid of the libkvm from the corresponding operating system release. If a crash dump from one operating system release is examined using the dmods from a different operating system release, changes in the kernel implementation can prevent some dcmds or walkers from working properly. mdb issues a warning message if it detects this condition. Crash dumps from Solaris x86 systems can not be examined on Solaris SPARC systems, and vice-versa.
- Relationship Between 32-bit and 64-bit Debugger mdb provides support for debugging both 32-bit and 64-bit programs. Once it has examined the target and determined its data model, mdb automatically re-executes the mdb binary that has the same data model as the target, if necessary. This approach simplifies the task of writing debugger modules, because the modules that are loaded use the same data model as the primary target. Only the 64-bit debugger can be used to debug 64-bit target programs. The 64-bit debugger can only be used on a system that is running the 64-bit operating environment.
- The debugger can also need to re-execute itself when debugging a 32-bit process that execs a 64-bit process, or vice-versa. The handling of this situation is discussed in more detail under Interaction with Exec, below.
- Interaction with Exec When a controlled process performs a successful `exec(2)`, the behavior of the debugger is controlled by the `::set -o follow_exec_mode` option, as described above. If the debugger and victim process have the same data model, then the “stop” and “follow” modes determine whether mdb automatically continues the target or returns to the debugger prompt following the exec. If the debugger and victim process have a different data model, then the “follow” behavior causes mdb to automatically re-exec the mdb binary with the appropriate data model and to re-attach to the process, still stopped on return from the exec. Not all debugger state is preserved across this re-exec.

If a 32-bit victim process execs a 64-bit program, then “stop” returns to the command prompt, but the debugger is no longer able to examine the process because it is now using the 64-bit data model. To resume debugging, execute the `::release -a` dcmd, quit mdb, and then execute `mdb -p pid` to re-attach the 64-bit debugger to the process.

If a 64-bit victim process execs a 32-bit program, then “stop” returns to the command prompt, but the debugger only provides limited capabilities for examining the new process. All built-in dcmds work as advertised, but loadable dcmds do not since they do not perform data model conversion of structures. The user should release and re-attach the debugger to the process as described above in order to restore full debugging capabilities.

- |                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interaction with Job Control   | <p>If the debugger is attached to a process that is stopped by job control (that is, it stopped in response to SIGTSTP, SIGTTIN, or SIGTTOU), the process can not be able to be set running again when it is continued by a continue dcmd. If the victim process is a member of the same session (that is, it shares the same controlling terminal as mdb), mdb attempts to bring the associated process group to the foreground and to continue the process with SIGCONT to resume it from job control stop. When mdb is detached from such a process, it restores the process group to the background before exiting. If the victim process is not a member of the same session, mdb cannot safely bring the process group to the foreground, so it continues the process with respect to the debugger, but the process remains stopped by job control. mdb prints a warning in this case, and the user must issue an “fg” command from the appropriate shell in order to resume the process.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Process Attach and Release     | <p>When mdb attaches to a running process, the process is stopped and remains stopped until one of the continue dcmds is applied, or the debugger quits. If the <code>-o nostop</code> option is enabled prior to attaching the debugger to a process with <code>-p</code>, or prior to issuing an <code>::attach</code> or <code>:A</code> command, mdb attaches to the process but does not stop it. While the process is still running, it can be inspected as usual (albeit with inconsistent results) and breakpoints or other tracing flags might be enabled. If the <code>:c</code> or <code>::cont</code> dcmds are executed while the process is running, the debugger waits for the process to stop. If no traced software events occur, the user can send an interrupt (^C) after <code>:c</code> or <code>::cont</code> to force the process to stop and return control to the debugger.</p> <p>mdb releases the current running process (if any) when the <code>:R</code>, <code>::release</code>, <code>:r</code>, <code>::run</code>, <code>\$q</code>, or <code>::quit</code> dcmds are executed, or when the debugger terminates as the result of an EOF or signal. If the process was originally created by the debugger using <code>:r</code> or <code>::run</code>, it is forcibly terminated as if by SIGKILL when it is released. If the process was already running prior to attaching mdb to it, it is set running again when it is released. A process can be released and left stopped and abandoned using the <code>::release -a</code> option.</p> |
| Symbolic Debugging Information | <p>The <code>::list</code>, <code>::offsetof</code>, <code>::print</code>, and <code>::sizeof</code> dcmds require that one or more load objects contain compressed symbolic debugging information suitable for use with mdb. This information is currently only available for certain Solaris kernel modules.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Developer Information The *Oracle Solaris Modular Debugger Guide* provides a more detailed description of mdb features, as well as information for debugger module developers.

The header file `<sys/mdb_modapi.h>` contains prototypes for the functions in the MDB Module API, and the `/source/demo/mdb-examples` package provides source code for an example module in the directory `/usr/demo/mdb`.

**Name** mesg – permit or deny messages

**Synopsis** mesg [-n | -y | n | y]

**Description** The mesg utility will control whether other users are allowed to send messages via [write\(1\)](#), [talk\(1\)](#), or other utilities to a terminal device. The terminal device affected is determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, mesg reports the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.

**Options** The following options are supported:

- n|n Denies permission to other users to send message to the terminal. See [write\(1\)](#).
- y|y Grants permission to other users to send messages to the terminal.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of mesg: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 if messages are receivable.
- 1 if messages are not receivable.
- 2 on error.

**Files** /dev/tty\* terminal devices  
/dev/pts/\* terminal devices

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [talk\(1\)](#), [write\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** mkdir – make directories

**Synopsis** /usr/bin/mkdir [-m *mode*] [-p] *dir*...

**Description** The `mkdir` command creates the named directories in mode 777 (possibly altered by the file mode creation mask `umask(1)`).

Standard entries in a directory (for instance, the files “.”, for the directory itself, and “..”, for its parent) are made automatically. `mkdir` cannot create these entries by name. Creation of a directory requires write permission in the parent directory.

The owner-ID and group-ID of the new directories are set to the process's effective user-ID and group-ID, respectively. `mkdir` calls the `mkdir(2)` system call.

`setgid` and `mkdir` To change the `setgid` bit on a newly created directory, you must use `chmod g+s` or `chmod g-s` after executing `mkdir`.

The `setgid` bit setting is inherited from the parent directory.

**Options** The following options are supported:

-m *mode* This option allows users to specify the mode to be used for new directories. Choices for modes can be found in `chmod(1)`.

-p With this option, `mkdir` creates *dir* by creating all the non-existing parent directories first. The mode given to intermediate directories is the difference between 777 and the bits set in the file mode creation mask. The difference, however, must be at least 300 (write and execute permission for the user).

**Operands** The following operand is supported:

*dir* A path name of a directory to be created.

**Usage** See `largefile(5)` for the description of the behavior of `mkdir` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** EXAMPLE 1 Using `mkdir`

The following example:

```
example% mkdir -p ltr/jd/jan
```

creates the subdirectory structure `ltr/jd/jan`.

**Environment Variables** See `environ(5)` for descriptions of the following environment variables that affect the execution of `mkdir`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

0 All the specified directories were created successfully or the `-p` option was specified and all the specified directories now exist.

---

>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE                     |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| CSI                 | Enabled                            |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [chmod\(1\)](#), [rm\(1\)](#), [sh\(1\)](#), [umask\(1\)](#), [Intro\(2\)](#), [mkdir\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Name** mkmsgs – create message files for use by gettext

**Synopsis** mkmsgs [-o] [-i *locale*] *inputstrings* *msgfile*

**Description** The mkmsgs utility is used to create a file of text strings that can be accessed using the text retrieval tools (see [gettext\(1\)](#), [srchtxt\(1\)](#), [exstr\(1\)](#), and [gettext\(3C\)](#)). It will take as input a file of text strings for a particular geographic locale (see [setlocale\(3C\)](#)) and create a file of text strings in a format that can be retrieved by both [gettext\(1\)](#) and [gettext\(3C\)](#). By using the `-i` option, you can install the created file under the `/usr/lib/locale/locale/LC_MESSAGES` directory (`locale` corresponds to the language in which the text strings are written).

*inputstrings* is the name of the file that contains the original text strings. *msgfile* is the name of the output file where mkmsgs writes the strings in a format that is readable by [gettext\(1\)](#) and [gettext\(3C\)](#). The name of *msgfile* can be up to 14 characters in length, but may not contain either `\0` (null) or the ASCII code for `/` (slash) or `:` (colon).

The input file contains a set of text strings for the particular geographic locale. Text strings are separated by a newline character. Nongraphic characters must be represented as alphabetic escape sequences. Messages are transformed and copied sequentially from *inputstrings* to *msgfile*. To generate an empty message in *msgfile*, leave an empty line at the correct place in *inputstrings*.

Strings can be changed simply by editing the file *inputstrings*. New strings must be added only at the end of the file; then a new *msgfile* file must be created and installed in the correct place. If this procedure is not followed, the retrieval function will retrieve the wrong string and software compatibility will be broken.

**Options** The following options are supported:

- `-o` Overwrite *msgfile*, if it exists.
- `-i locale` Install *msgfile* in the `/usr/lib/locale/locale/LC_MESSAGES` directory. Only someone who is super user or a member of group `bin` can create or overwrite files in this directory. Directories under `/usr/lib/locale` will be created if they do not exist.

**Examples** **EXAMPLE 1** Using the mkmsgs command.

The following example shows an input message source file `C.st r`:

```
File %s:\t cannot be opened\n
%s: Bad directory\n
.
.
.
write error\n
.
.
```

**EXAMPLE 2** Using Input Strings From C.str to Create Text Strings in a File

The following command uses the input strings from C.str to create text strings in the appropriate format in the file UX in the current directory:

```
example% mkmsgs C.str UX
```

**EXAMPLE 3** Using Input Strings From FR.str to Create Text Strings in a File

The following command uses the input strings from FR.str to create text strings in the appropriate format in the file UX in the directory /usr/lib/locale/fr/LC\_MESSAGES:

```
example% mkmsgs -i fr FR.str UX
```

These text strings would be accessed if you had set the environment variable LC\_MESSAGES=fr and then invoked one of the text retrieval tools listed at the beginning of the DESCRIPTION section.

**Files** /usr/lib/locale/locale/LC\_MESSAGES/\* message files created by mkmsgs

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | text/locale     |

**See Also** [exstr\(1\)](#), [gettxt\(1\)](#), [srchtxt\(1\)](#), [gettxt\(3C\)](#), [setlocale\(3C\)](#), [attributes\(5\)](#)

**Name** mkstr – create an error message file by massaging C source files

**Synopsis** /usr/ucb/mkstr [-] *messagefile prefix filename...*

**Description** The `mkstr` utility creates files of error messages. You can use `mkstr` to make programs with large numbers of error diagnostics much smaller, and to reduce system overhead in running the program — as the error messages do not have to be constantly swapped in and out.

`mkstr` processes each of the specified *filenames*, placing a massaged version of the input file in a file with a name consisting of the specified *prefix* and the original source file name. A typical example of using `mkstr` would be:

```
mkstr pistrings processed *.c
```

This command would cause all the error messages from the C source files in the current directory to be placed in the file `pistrings` and processed copies of the source for these files to be placed in files whose names are prefixed with *processed*.

To process the error messages in the source to the message file, `mkstr` keys on the string `'error('` in the input stream. Each time it occurs, the C string starting at the `'` is placed in the message file followed by a null character and a NEWLINE character; the null character terminates the message so it can be easily used when retrieved, the NEWLINE character makes it possible to sensibly `cat` the error message file to see its contents. The massaged copy of the input file then contains a `lseek` pointer into the file which can be used to retrieve the message, that is:

```
char efilename[] = "/usr/lib/pi_strings";
int efil = -1;

error(a1, a2, a3, a4)
{

 char
 buf[256];
 if (efil < 0) {

 efil = open(efilename, 0);
 if (efil < 0) {
oops:
 perror (efilename);
 exit (1);
 }
 }
 if (lseek(efil, (long) a1, 0) || read(efil, buf, 256) <= 0)
 goto oops;
 printf(buf, a2, a3, a4);
}
```

**Options** – Place error messages at the end of the specified message file for recompiling part of a large `mkstred` program.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | compatibility/ucb |

**Name** mktemp – make temporary filename

**Synopsis** mktemp [-dtqu] [--directory] [--quiet] [--dry-run] [-p *directory*]  
          [--suffix=*suff*] [--tmpdir[=*dir*]] [*template*]

**Description** The `mktemp` utility makes a temporary filename. To do this, `mktemp` takes the specified filename template and overwrites a portion of it to create a unique filename. See OPERANDS.

The template is converted to a path name using the `mktemp(3C)`, `mkdtemp(3C)`, `mkstemp(3C)`, and `mkstemp(3C)` library functions.

If `mktemp` can successfully generate a unique filename, the file (or directory) is created with file permissions such that it is only readable and writable by its owner (unless the `-u` flag is given) and the filename is printed to standard output.

`mktemp` allows shell scripts to safely use temporary files. Traditionally, many shell scripts take the name of the program with the PID as a suffix and used that as a temporary filename. This kind of naming scheme is predictable and the race condition it creates is easy for an attacker to win. A safer, though still inferior approach is to make a temporary directory using the same naming scheme. While this guarantees that a temporary file is not subverted, it still allows a simple denial of service attack. Use `mktemp` instead.

**Options** The following options are supported:

`-d, --directory`

Make a directory instead of a file.

`-p directory`

Use the specified directory as a prefix when generating the temporary filename. The directory is overridden by the user's `TMPDIR` environment variable if it is set. This option implies the `-t` flag.

`-q, --quiet`

Fail silently if an error occurs. This is useful if a script does not want error output to go to standard error.

`--suffix=suff`

Append *suff* to the template. *suff* must not contain a slash (/). This option is implied when the template ends in characters other than replaceable X characters, and does not remove the requirement to include such X characters.

`--tmpdir[=dir]`

'template' is relative to *dir*. If *dir* is not specified, the user's environment variable `TMPDIR` is used if set, else `/tmp` is used. This option does not support a template with an absolute name and unlike with the use of `-t`, a template may contain slashes.

`-t`

Generate a path rooted in a temporary directory. This directory is chosen as follows: If the user's `TMPDIR` environment variable is set, the directory contained therein is used.

Otherwise, if the `-p` flag was given the specified directory is used. If none of the above apply, `/tmp` is used. In this mode, the template (if specified) should be a directory component (as opposed to a full path) and thus should not contain any forward slashes.

`-u, --dry-run`

Operate in unsafe mode. The temp file is unlinked before `mktemp` exits. This is slightly better than `mktemp(3C)`, but still introduces a race condition. Use of this option is discouraged.

**Operands** The following operands are supported:

*template* *template* can be any filename with three to six Xs included in it, for example `/tmp/tfile.XXXXXX`.

If *template* is not specified, a default of `tmp.XXXXXX` is used and the `-t` flag is implied.

If *template* has multiple series of Xs, the final series is used for the replacement text, unless `--suffix` specifies otherwise.

If *template* has characters after the final set of Xs, then the `--suffix` option is implied to be all such characters, unless explicitly specified.

**Examples** EXAMPLE 1 Using `mktemp`

The following example illustrates a simple use of `mktemp` in a `sh(1)` script. In this example, the script quits if it cannot get a safe temporary file.

```
TMPFILE='mktemp /tmp/example.XXXXXX'
if [-z "$TMPFILE"]; then exit 1; fi
echo "program output" >> $TMPFILE
```

EXAMPLE 2 Using `mktemp` to Support `TMPDIR`

The following example uses `mktemp` to support for a user's `TMPDIR` environment variable:

```
TMPFILE='mktemp -t example.XXXXXX'
if [-z "$TMPFILE"]; then exit 1; fi
echo "program output" >> $TMPFILE
```

EXAMPLE 3 Using `mktemp` Without Specifying the Name of the Temporary File

The following example uses `mktemp` without specifying the name of the temporary file. In this case the `-t` flag is implied.

```
TMPFILE='mktemp'
if [-z "$TMPFILE"]; then exit 1; fi
echo "program output" >> $TMPFILE
```

**EXAMPLE 4** Using `mktemp` with a Default Temporary Directory Other than `/tmp`

The following example creates the temporary file in `/extra/tmp` unless the user's `TMPDIR` environment variable specifies otherwise:

```
TMPFILE='mktemp -p /extra/tmp example.XXXXXX'
if [-z "$TMPFILE"]; then exit 1; fi
echo "program output" >> $TMPFILE
```

**EXAMPLE 5** Using `mktemp` to Remove a File

The following example attempts to create two temporary files. If creation of the second temporary file fails, `mktemp` removes the first file before exiting:

```
TMP1='mktemp -t example.1.XXXXXX'
if [-z "$TMP1"]; then exit 1; fi
TMP2='mktemp -t example.2.XXXXXX'
if [-z "$TMP2"]; then
 rm -f $TMP1
 exit 1
fi
```

**EXAMPLE 6** Using `mktemp`

The following example does not exit if `mktemp` is unable to create the file. That part of the script has been protected.

```
TMPFILE='mktemp -q -t example.XXXXXX'
if [! -z "$TMPFILE"]
then
 # Safe to use $TMPFILE in this block
 echo data > $TMPFILE
 ...
 rm -f $TMPFILE
fi
```

**EXAMPLE 7** Using `mktemp` with Suffix Option

The following command illustrates the use of the suffix option. The effect of this command is to create the temporary file `ex.q5N.SUFF`.

```
mktemp --suffix=.SUFF ex.XXXXXX
ex.q5Ngid.SUFF
```

**EXAMPLE 8** Using Suffix and `Tmpdir` Options

The following command illustrates the use of the suffix and `tmpdir` options.

```
mktemp --tmpdir=$HOME --suffix=.bar foo.XXXXXX
/root/foo.7Za0_N.bar
```

**EXAMPLE 9** Using Directory and Suffix Options

The following command uses both the directory and suffix options.

```
mktemp --directory --suffix=.bar foo.XXXXXX
foo.GSa03d.bar
ls -l
drwx----- 2 root staff 512 Mar 19 2012 foo.GSa0.bar
```

**EXAMPLE 10** Supporting a Template with Non-Trailing Xs

The following command shows the use of the directory option with non-trailing X characters. In this command, the `--suffix=suff` option is implied, where `bar` is used as the suffix.

```
mktemp XXfooXXXXXXbar
XXfoaFY0N6bar
```

**EXAMPLE 11** Using the Quiet and Tmpdir Options

The following command illustrates the use of the quiet and tmpdir options.

```
mktemp --quiet --tmpdir=/tmp foo
[No diagnostic message is returned]
```

**EXAMPLE 12** Using mktemp with Multiple Options

The following command combines the use of the dry-run, tmpdir, and suffix options.

```
mktemp --dry-run --tmpdir=$HOME --suffix=SUFF
/root/tmp.qdaGcOSUFF
ls -l /root/tmp.qdaGcOSUFF
/root/tmp.qdaGcOSUFF: No such file or directory
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `mktemp` with the `-t` option: `TMPDIR`.

**TMPDIR** Name a directory used for creating temporary files to override system default; used by `mktemp`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Committed       |

**See Also** [sh\(1\)](#), [mkdtemp\(3C\)](#), [mkstemp\(3C\)](#), [mkstemp\(3C\)](#), [mktemp\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** The `mktemp` utility appeared in OpenBSD 2.1. The Solaris implementation uses only as many 'Xs' as are significant for [mktemp\(3C\)](#), [mkstemp\(3C\)](#), and [mkstemp\(3C\)](#).

**Name** moe – manifest the optimal expansion of a pathname

**Synopsis** moe [-c] [-32 | -64] [-s | -v] *path*

**Description** The moe utility manifests the optimal expansion of a pathname containing reserved runtime linker tokens. These tokens can be used to define dependencies, filtees and runpaths within dynamic objects. The expansion of these tokens at runtime, provides a flexible mechanism for selecting objects and search paths that perform best on this machine. See [ld.so.1\(1\)](#).

For example, the token \$HWCAP can be employed to represent filters and dependencies. The runtime interpretation of this token can result in a family of objects that are analyzed to determine their applicability for loading with a process. The objects are sorted based on the hardware capabilities that each object requires to execute. moe returns the name of the object optimally suited for execution on the current platform.

moe analyzes a pathname by passing the supplied *path* to [dlopen\(3C\)](#), together with the RTLD\_FIRST flag. Reserved token expansion is therefore carried out by [ld.so.1](#) as the expansion would occur in an executing process. Although multiple objects can be analyzed as a result of the [dlopen\(\)](#) call, the RTLD\_FIRST flag insures only the optimal object is processed.

By default, moe analyzes the specified *path* twice. The first analysis looks for 32-bit objects. The second analysis, if applicable, looks for 64-bit objects. Typically, 32-bit objects and 64-bit objects are isolated to different directories. These directories are frequently named to reflect the class of object the directory contains. The multiple passes of moe catch any instances where 32-bit objects and 64-bit objects occupy the same directory. Multiple passes also provide flexibility when the pathname that is specified does not convey to the user the class of object the directory might contain.

For a complete description of the reserved token expansion carried out by the runtime linker, refer to the [Linker and Libraries Guide](#).

**Options** The following options are supported:

- 32 Only analyze 32-bit objects.
- 64 Only analyze 64-bit objects.
- c Prefix each pathname with the class of the object.
- s Silent. No optimal name, or error diagnostics are displayed. Only an error return is made available. This option is only meaningful with the -32 and -64 options. The -s option can not be used with the -v option.
- v Verbose. If no optimal expansion name can be determined, an error diagnostic is written to standard error. The -v option can not be used with the -s option.

**Operands** The following operand is supported:

*path* The pathname to be expanded.

**Examples** The following example uses `moe` to display the optimal expansion of objects in the directory `/usr/lib/libc`. This directory contains a family of Intel objects that are built to use various hardware capabilities.

```
% moe '/usr/lib/libc/$HWCAP'
/usr/lib/libc/libc_hwcap.so.1
```

The `-c` option can be used to clarify the class of the optimal object.

```
% moe -c '/usr/lib/libc/$HWCAP'
32-bit: /usr/lib/libc/libc_hwcap.so.1
```

The following example uses `moe` to display the optimal expansion of objects under the `/opt/ISV/cpu` directory hierarchy. These directories contain a family of SPARC objects that are built for various platforms.

```
% moe -c -64 '/opt/ISV/$ISALIST/isa.so.1'
64-bit: /opt/ISV/sparcv9/isa.so.1
```

The `-v` can be used to diagnose the instance where an optimal name is not returned. An attempt to inspect the previous pathname as a 32-bit object, would result in the following diagnostic being produced.

```
% moe -c -v -32 '/opt/ISV/$ISALIST/isa.so.1'
32-bit: /opt/ISV/sparcv9/isa.so.1: wrong ELF class: ELFCLASS64
```

**Exit Status** When the `-32` or `-64` options are in effect, a successful optimal expansion returns `0`, otherwise non-zero. Without the `-32` or `-64` options in effect, the return value is always `0`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | system/linker   |
| Interface Stability | Committed       |

*Linker and Libraries Guide*

**Name** more, page – browse or page through a text file

**Synopsis** `/usr/bin/more [-cdfllrsuw] [-lines] [+ linenumber]  
 [+/ pattern] [file]...`

`/usr/bin/page [-cdfllrsuw] [-lines] [+ linenumber]  
 [+/ pattern] [file]...`

`/usr/xpg4/bin/more [-cdeisu] [-n number] [-p command]  
 [-t tagstring] [file]...`

`/usr/xpg4/bin/more [-cdeisu] [-n number] [+ command]  
 [-t tagstring] [file]...`

**Description** The more utility is a filter that displays the contents of a text file on the terminal, one screenful at a time. It normally pauses after each screenful. `/usr/bin/more` then prints `--More--` and `/usr/xpg4/bin/more` then prints *file* at the bottom of the screen. If more is reading from a file rather than a pipe, the percentage of characters displayed so far is also shown.

The more utility scrolls up to display one more line in response to a RETURN character. more displays another screenful in response to a SPACE character. Other commands are listed below.

The page utility clears the screen before displaying the next screenful of text. page only provides a one-line overlap between screens.

The more utility sets the terminal to NOECHO mode, so that the output can be continuous. Commands that you type do not normally show up on your terminal, except for the / and ! commands.

The `/usr/bin/more` utility exits after displaying the last specified file. `/usr/xpg4/bin/more` prompts for a command at the last line of the last specified file.

If the standard output is not a terminal, more acts just like `cat(1)`, except that a header is printed before each file in a series.

**Options** The following options are supported for both `/usr/bin/more` and `/usr/xpg4/bin/more`:

- c Clears before displaying. Redraws the screen instead of scrolling for faster displays. This option is ignored if the terminal does not have the ability to clear to the end of a line.
- d Displays error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.
- s Squeeze. Replaces multiple blank lines with a single blank line. This is helpful when viewing `nroff(1)` output on the screen.

`/usr/bin/more` The following options are supported for `/usr/bin/more` only:

- f Does not fold long lines. This is useful when lines contain nonprinting characters or escape sequences, such as those generated when `nroff(1)` output is piped through `ul(1)`.

- l Does not treat FORMFEED characters (Control-l) as page breaks. If -l is not used, more pauses to accept commands after any line containing a ^L character (Control-l). Also, if a file begins with a FORMFEED, the screen is cleared before the file is printed.
- r Normally, more ignores control characters that it does not interpret in some way. The -r option causes these to be displayed as ^C where C stands for any such control character.
- u Suppresses generation of underlining escape sequences. Normally, more handles underlining, such as that produced by `nroff(1)`, in a manner appropriate to the terminal. If the terminal can perform underlining or has a stand-out mode, more supplies appropriate escape sequences as called for in the text file.
- w Normally, more exits when it comes to the end of its input. With -w, however, more prompts and waits for any key to be struck before exiting.
- lines Displays the indicated number of *lines* in each screenful, rather than the default (the number of lines in the terminal screen less two).
- +linenumber Start up at *linenumber*.
- +/pattern Start up two lines above the line containing the regular expression *pattern*.  
*Note:* Unlike editors, this construct should *not* end with a '/'. If it does, then the trailing slash is taken as a character in the search pattern.

/usr/xpg4/bin/more The following options are supported for /usr/xpg4/bin/more only:

- e Exits immediately after writing the last line of the last file in the argument list.
- i Performs pattern matching in searches without regard to case.
- n *number* Specifies the number of lines per screenful. The *number* argument is a positive decimal integer. The -n option overrides any values obtained from the environment.
- p *command*  
+*command* For each file examined, initially executes the more command in the *command* argument. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands:  
  

```
more -p 1000j file
more -p 1000G file
```

are equivalent and start the display with the current position at line 1000, bypassing the lines that j would write and scroll off the screen if it had been

issued during the file examination. If the positioning command is unsuccessful, the first line in the file will be the current position.

- t *tagstring* Writes the screenful of the file containing the tag named by the *tagstring* argument. See the [ctags\(1\)](#) utility.
- u Treats a backspace character as a printable control character, displayed as a ^H (Control-h), suppressing backspacing and the special handling that produces underlined or standout-mode text on some terminal types. Also, does not ignore a carriage-return character at the end of a line.

If both the -t *tagstring* and -p *command* (or the obsolescent +*command*) options are given, the -t *tagstring* is processed first.

## Usage

Environment `more` uses the terminal's [terminfo\(4\)](#) entry to determine its display characteristics.

`more` looks in the environment variable `MORE` for any preset options. For instance, to page through files using the -c mode by default, set the value of this variable to -c. (Normally, the command sequence to set up this environment variable is placed in the `.login` or `.profile` file).

Commands The commands take effect immediately. It is not necessary to type a carriage return unless the command requires a *file*, *command*, *tagstring*, or *pattern*. Up to the time when the command character itself is given, the user may type the line kill character to cancel the numerical argument being formed. In addition, the user may type the erase character to redisplay the `' -More - - (xx%)'` or *file* message.

In the following commands, *i* is a numerical argument (1 by default).

*i*SPACE Display another screenful, or *i* more lines if *i* is specified.

*i*RETURN Display another line, or *i* more lines, if specified.

*i*b

*i*^B (Control-b) Skip back *i* screenfuls and then print a screenful.

*i*d

*i*^D (Control-d) Scroll forward one half screenful or *i* more lines. If *i* is specified, the count becomes the default for subsequent d and u commands.

*i*f Skip *i* screens full and then print a screenful.

h Help. Give a description of all the `more` commands.

^L (Control-l) Refresh.

*i*n Search for the *i* th occurrence of the last *pattern* entered.

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| q                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Q                | Exit from more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| is               | Skip <i>i</i> lines and then print a screenful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| v                | Drop into the vi editor at the current line of the current file.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| iz               | Same as SPACE, except that <i>i</i> , if present, becomes the new default number of lines per screenful.                                                                                                                                                                                                                                                                                                                                                                                                         |
| =                | Display the current line number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>i/pattern</i> | Search forward for the <i>i</i> th occurrence of the regular expression <i>pattern</i> . Display the screenful starting two lines before the line that contains the <i>i</i> th match for the regular expression <i>pattern</i> , or the end of a pipe, whichever comes first. If more is displaying a file and there is no match, its position in the file remains unchanged. Regular expressions can be edited using erase and kill characters. Erasing back past the first column cancels the search command. |
| ! <i>command</i> | Invoke a shell to execute <i>command</i> . The characters % and !, when used within <i>command</i> are replaced with the current filename and the previous shell command, respectively. If there is no current filename, % is not expanded. Prepend a backslash to these characters to escape expansion.                                                                                                                                                                                                         |
| :f               | Display the current filename and line number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| :n               | Skip to the <i>i</i> th next filename given in the command line, or to the last filename in the list if <i>i</i> is out of range.                                                                                                                                                                                                                                                                                                                                                                                |
| :p               | Skip to the <i>i</i> th previous filename given in the command line, or to the first filename if <i>i</i> is out of range. If given while more is positioned within a file, go to the beginning of the file. If more is reading from a pipe, more simply rings the terminal bell.                                                                                                                                                                                                                                |
| :q               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| :Q               | Exit from more (same as q or Q).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

*/usr/bin/more* The following commands are available only in */usr/bin/more*:

|     |                                                                                                                                                         |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| '   | Single quote. Go to the point from which the last search started. If no search has been performed in the current file, go to the beginning of the file. |
| .   | Dot. Repeat the previous command.                                                                                                                       |
| ^ \ | Halt a partial display of text. more stops sending output, and displays the usual -More- prompt. Some output is lost as a result.                       |

*/usr/xpg4/bin/more* The following commands are available only in */usr/xpg4/bin/more*:

|             |                                                                                     |
|-------------|-------------------------------------------------------------------------------------|
| <i>i</i> ^F | (Control-f) Skip <i>i</i> screens full and print a screenful. (Same as <i>if</i> .) |
|-------------|-------------------------------------------------------------------------------------|

---

|                                 |                                                                                                                                                                                                                                                                                                                                                      |

| <code>ik</code>                 | Scroll backwards one or <i>i</i> lines, if specified.                                                                                                                                                                                                                                                                                                |
| <code>mletter</code>            | Mark the current position with the name <i>letter</i> .                                                                                                                                                                                                                                                                                              |
| <code>N</code>                  | Reverse direction of search.                                                                                                                                                                                                                                                                                                                         |
| <code>r</code>                  | Refresh the screen.                                                                                                                                                                                                                                                                                                                                  |
| <code>R</code>                  | Refresh the screen, discarding any buffered input.                                                                                                                                                                                                                                                                                                   |
| <code>iu</code>                 |                                                                                                                                                                                                                                                                                                                                                      |
| <code>i^U</code>                | (Control-u) Scroll backwards one half a screen of <i>i</i> lines, if specified. If <i>i</i> is specified, the count becomes the new default for subsequent <code>d</code> and <code>u</code> commands.                                                                                                                                               |
| <code>ZZ</code>                 | Exit from <code>more</code> (same as <code>q</code> ).                                                                                                                                                                                                                                                                                               |
| <code>:e file</code>            | Examine (display) a new file. If no <i>file</i> is specified, the current file is redisplayed.                                                                                                                                                                                                                                                       |
| <code>:t tagstring</code>       | Go to the tag named by the <i>tagstring</i> argument and scroll/rewrite the screen with the tagged line in the current position. See the <code>ctags</code> utility.                                                                                                                                                                                 |
| <code>'letter</code>            | Return to the position that was previously marked with the name <i>letter</i> .                                                                                                                                                                                                                                                                      |
| <code>''</code>                 | Return to the position from which the last move of more than a screenful was made. Defaults to the beginning of the file.                                                                                                                                                                                                                            |
| <code>i?[!]pattern</code>       | Search backward in the file for the <i>i</i> th line containing the <i>pattern</i> . The <i>!</i> specifies to search backward for the <i>i</i> th line that does not contain the <i>pattern</i> .                                                                                                                                                   |
| <code>i/!pattern</code>         | Search forward in the file for the <i>i</i> th line that does not contain the <i>pattern</i> .                                                                                                                                                                                                                                                       |
| <code>![command]</code>         | Invoke a shell or the specified command.                                                                                                                                                                                                                                                                                                             |
| Large File Behavior             | See <a href="#">largefile(5)</a> for the description of the behavior of <code>more</code> and <code>page</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                          |
| Environment Variables           | See <a href="#">environ(5)</a> for descriptions of the following environment variables that affect the execution of <code>more</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_COLLATE</code> ( <code>/usr/xpg4/bin/more</code> only), <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , <code>NLSPATH</code> , and <code>TERM</code> . |
| <code>/usr/xpg4/bin/more</code> | The following environment variables also affect the execution of <code>/usr/xpg4/bin/more</code> :<br><code>COLUMNS</code> Overrides the system selected horizontal screen size.                                                                                                                                                                     |

**EDITOR** Used by the `v` command to select an editor.

**LINES** Overrides the system selected vertical screen size. The `-n` option has precedence over **LINES** in determining the number of lines in a screen.

**MORE** A string specifying options as described in the **OPTIONS** section, above. As in a command line, The options must be separated by blank characters and each option specification must start with a `-`. Any command line options are processed after those specified in **MORE** as though the command line were: `more $MORE options operands`

**Exit Status** The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

**Files** `/usr/lib/more.help` help file for `/usr/bin/more` and `/usr/bin/page` only.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

|                                                          | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------------------------------------------------|----------------|-----------------|
| <code>/usr/bin/more</code><br><code>/usr/bin/page</code> | Availability   | system/core-os  |
|                                                          | CSI            | Not enabled     |

|                                 | ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |

## Notes

`/usr/bin/more` Skipping backwards is too slow on large files.

`/usr/xpg4/bin/more` This utility will not behave correctly if the terminal is not set up properly.

**Name** mp – text to PDL (Page Description Language) pretty print filter

**Synopsis** mp [-A4] [-C] [-D *target\_printer\_name*] [-F] [-L *localename*]  
 [-P *target\_spool\_printer*] [-PS] [-US] [-a] [-c *chars*]  
 [-d] [-e] [-ff] [-fp] [-l] [-ll] [-m] [-M] [-n] [-o]  
 [-p *prologue*] [-s *subject*] [-tm] [-ts]  
 [-u *config\_file\_path*] [-v] [-w *words*] [-z *point\_size*]  
 [-?] [*filename*]. . .

**Description** The mp program, when called without the -D or -P option, reads each *filename* in sequence and generates a prettified version of the contents in PostScript™ format, sent to standard output. If no filename argument is provided, mp reads the standard input. If the standard input is a terminal, input is terminated by an EOF signal, usually Control-d.

The -D and -P options require the target printer name as an argument and produce the Page Description Language (PDL) of the target printer. The -D option causes the PDL to output to stdout and the -P option causes the PDL to be directly spooled to the printer. In the absence of these options, mp will product default PostScript output.

The mp program accepts international text files of various Solaris locales and produces output which is proper for the specified locale. The output will also contain proper text layout. For instance, the output will contain bidirectional text rendering, and also shaping, since the complex text layout (CTL) is supported in mp.

Mail items, news articles, ordinary ASCII files, complete mail folders, and digests are all acceptable input formats for mp. The output format includes grayscale lozenges, or the outline of the same dimensions as the lozenges, containing banner information at the top and bottom of every page.

**Options** The following options are supported:

- a                      Formats the file as a news article. The top banner contains the text: "Article from *newsgroup*", where *newsgroup* is the first news group found on the "Newsgroups:" line.
- A4                     Uses A4 paper size (8.26 x 11.69 inches).
- c *chars*             The maximum number of characters to extract from the gecos field of the user's /etc/passwd entry. The default is 18.
- C                      Instead of using "\nFrom" to denote the start of new mail messages, mp will look for (and use) the value of the Content-Length: mail header. If the Content-Length doesn't take you to the next "\nFrom", then it is wrong, and mp falls back to looking for the next "\nFrom" in the mail folder.
- d                      Formats the file as a digest.

- 
- D** *target\_printer\_name* Produces the PDL for the target printer. Requires X Print Server connection. *target\_printer\_name* can be either *printer\_name@machine[:display\_number]* or just *printer\_name*. In the first form, mp tries to connect to the X Print Server display *machine[:display\_number]* with the target printer as *printer\_name*.
- e** Assumes the ELM mail frontend intermediate file format. Used when printing messages from within ELM (using the "p" command), especially for printing tagged messages. This option must be specified in your ELM option setup.
- ff** Formats the file for use with a Filofax personal organizer.
- fp** Formats the file for use with a Franklin Planner personal organizer.
- F** Instead of printing who the mail article is *for*, the top header will contain who the mail article is *from*. A useful option for people with their own personal printer.
- l** Formats output in landscape mode. Two pages of text will be printed per sheet of paper.
- ll** Formats output in landscape mode. One page of text will be printed per sheet of paper. This is useful for printing files with longer than normal lines.
- L** *localename* Provides the locale of the file to be printed. If this command line option is not present, then mp looks for the MP\_LANG environment variable. If that is not present, the LANG environment variable is used. If none of these options are present, mp tries to determine the locale it is running in. If it cannot determine the locale, mp assumes it is running in the C locale.
- m** Formats the file as a mail folder, printing multiple messages.
- M** Forces mp to use the mp.conf file for printing output even if a prolog.ps file exists for that locale. Useful when printing to non-native PostScript printers.
- n** Turns off the gray bars and associated information from header and footer. Used to get output similar to output of '*lp filename*'.
- o** Formats the file as an ordinary ASCII file.
- p** *prologue* Employs the file *prologue* as the PostScript/Xprt prologue file, overriding any previously defined file names. This file specifies the format of the print output. For PostScript output, the *prologue* file

will have a .ps extension. For Xprt clients (when the -D option is specified), this file will have an .xpr extension. These files are defined in the SUPPLIED PROLOGUE FILES section below.

- P *target\_spool\_printer* Spools the PDL to the target printer. No output is sent to stdout. Requires X Print Server connection. *target\_spool\_printer* can be either *printer\_name@machine[:display\_number]* or just *printer\_name*. In the first form, mp tries to connect to the display *machine[:display\_number]* with the target printer as *printer\_name*.
- PS If the mail or digest message just has PostScript as the text of the message, this is normally just passed straight through. Specifying this option causes PostScript to be printed as text.
- s *subject* Uses *subject* as the new subject for the printout. If you are printing ordinary ASCII files that have been specified on the command line, the subject will default to the name of each of these files.
- tm Formats the file for use with the Time Manager personal organizer.
- ts Formats the file for use with the Time/System International personal organizer.
- US Uses US paper size (8.5 x 11 inches). This is the default paper size.
- u *config\_file\_path* Specifies an alternate configuration file to the default file `/usr/lib/lp/locale/locale_name/mp/mp.conf`. The absolute file path name must be used.
- v Prints the version number of this release of mp.
- w *words* The maximum number of words to extract from the gecost field of the user's `/etc/passwd` entry. The default is 3.
- z *point\_size* Prints the output text in the point size specified by *point\_size*. The internal default is 12 points for portrait printing and 9 points for landscape printing.
- ? Prints the usage line for mp. Notice that the ? character must be escaped if using `cs(1)`.

**Operands** The following operand is supported:

*filename* The name of the file to be read.

**Examples** The mp print filter can be used to print files in any locale that is installed in the user's machine.

**EXAMPLE 1** Printing Japanese text files

Japanese text files encoded in the euc codeset can be printed in any non-Japanese PostScript printers by entering:

```
example% mp -L ja_JP.eucJP -M ja_JP_eucJP.txt | lp
```

Here, the `-L` option specifies the locale and the `-M` option invokes the `mp.conf` configuration file instead of the default `prolog.ps` file. In the case of `ja_JP.eucJP`, both `/usr/lib/lp/locale/ja_JP.eucJP/mp/mp.conf` and `/usr/openwin/lib/locale/ja_JP.eucJP/print/prolog.ps` files are present. Therefore, the `-M` option is used to override the precedence of the default `prolog.ps` file. Using `mp.conf` as the configuration file makes it possible to print to any PostScript printer.

The encoding of the locale specified by the `-L` option and that of the text file to be printed have to be the same. In the above Japanese file example, if the text file is encoded in `Shift-JIS`, use the following command, since the locale `ja_JP.PCK` is encoded in `SJIS`:

```
example% mp -L ja_JP.PCK -M SJIS.txt | lp
```

**EXAMPLE 2** Running in Xprt mode

If an X Print Server daemon (`/usr/openwin/bin/Xprt`) is running in any system in the network, `mp` can be invoked as follows, enabling it to output in any Page Description Language supported by `Xprt` (the default value of `display_number` is 2100):

```
example% setenv XPSERVERLIST "machine1[:display_number1] \
machine2[:display_number2] machine3[:display_number3]"
```

or

```
example% setenv XPDISPLAY machine_name[:display_number]
```

Using the options `-D printer_name[@machine[:display_number]]` or `-P printer_name[@machine[:display_number]]` gives the greatest precedence and `mp` tries to connect to `Xprt` running on `machine[:display_number]` with `printer_name`. When not specified, the default `display_number` value is 2100. If this fails, `printer_name` is tried with an `Xprt` display obtained from the following logic. The following is also valid if you enter only `-D printer_name` or `-P printer_name` on the command line.

`mp` checks `XPSERVERLIST` for a list of space-separated `Xprt` servers until it finds one which supports the `printer_name` argument. If none is found, `mp` checks the `XPDISPLAY` environment variable, which is of the form `machine[:display_number]`. If that is also not set or not valid, `mp` tries to connect to the default display, `:2100`. If that is also not successful, `mp` exits with an error message.

To pipe the data to the target printer when `XPSERVERLIST` or `XPDISPLAY` is set, enter:

EXAMPLE 2 Running in Xprt mode (Continued)

```
example% mp -D printer_name -L ja_JP.eucJP \
-M ja_JP_eucJP.txt | lp -d printer_name
```

For direct spooling when working in Xprt client mode, use the -P option:

```
example% mp -P printer_name -L ja_JP.eucJP -M ja_JP_eucJP.txt
```

EXAMPLE 3 Turning off the header and footer

Use the -n option to turn off the mp header and footer:

```
example% mp -n mytext.txt | lp
```

EXAMPLE 4 Printing long text lines

Use the -ll option to print text files with longer than 80 column lines in landscape mode:

```
example% mp -ll mytext.txt | lp
```

EXAMPLE 5 Specifying print point size

Use the -z option to specify any point size, in this case, 20 points:

```
example% mp -z 20 mytext.txt | lp
```

## Environment Variables

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XPSEVERLIST | <p>If the arguments to -D or -P is of the form <i>printer_name@machine[:display_number]</i>, XPSEVERLIST is used only if the <i>machine[:display_number]</i> does not support <i>printer_name</i>.</p> <p>XPSEVERLIST contains a space-separated list of Xprt displays to which to connect the printer. mp goes through the list sequentially to get an Xprt server that can support the given printer, exiting at the first instance where mp finds a display to which to connect. If this is not set, the environment variable XPDISPLAY is used instead.</p>                                                                                                                       |
| XPDISPLAY   | <p>If the -D or -P option is specified in the command line with just the <i>printer_name</i> argument and no XPSEVERLIST variable is set in the environment, the XPDISPLAY variable is used to determine the <i>machine[:display_number]</i> running the X Print Server to connect the client. If XPDISPLAY is also not set, the print server startup script starts an Xprt server at port 2100 of the machine in which the client is running. The script terminates the print server once the job is over. If XPDISPLAY is set, the mp client tries to contact the print server running at XPDISPLAY. In this case, no attempt is made to start the server if it is not running.</p> |
| MP_PROLOGUE | <p>Used to determine the directory where the page formatting files (.xpr or .ps) are kept. These files determine page decorations, number of logical</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

pages per physical page, landscape or portrait format, and so forth. In the absence of `MP_PROLOGUE`, the default location of the directory is `/usr/lib/lp/locale/C/mp`.

`MP_LANG`  
`LANG`

If neither of the `-D` or `-P` options is specified, a prologue file is prepended to the output to be printed. The prologue file is called `/usr/openwin/lib/locale/localename/print/prolog.ps` or `/usr/lib/lp/locale/localename/mp/prolog.ps`, where *localename* is the value of the `MP_LANG` or `LANG` environment variable, if present. If both variables are present, the file `/usr/openwin/lib/locale/localename/print/prolog.ps` is given preference due to backward compatibility reasons. If either of these files are not present, and the `-D` option is not specified, a configuration file of the locale called `/usr/lib/lp/locale/localename/mp/mp.conf` is used as the source of the configuration information that substitutes the prologue information for printing. The presence of `prolog.ps` disables `mp.conf` for backward compatibility.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**Supplied Prologue Files** The following prologue files are provided. Files with `.ps` extensions are for the PostScript output. Files with `.xpr` extensions are for the Print Server client. `.xpr` files are created for 300dpi printers and will scale to other resolution values.

- `mp.common.ps` Common prologue file for all other `.ps` files in this directory.
- `mp.pro.ps`
- `mp.pro.xpr` Used by default.
- `mp.pro.ff.ps`
- `mp.pro.ff.xpr` Used if the `-ff` option is in effect.
- `mp.pro.fp.ps`
- `mp.pro.fp.xpr` Used if the `-fp` option is in effect.
- `mp.pro.tm.ps`
- `mp.pro.tm.xpr` Used if the `-tm` option is in effect.
- `mp.pro.ts.ps`
- `mp.pro.ts.xpr` Used if the `-ts` option is in effect.
- `mp.pro.alt.ps`
- `mp.pro.alt.xpr` An alternative modification of the default prologue file which outputs the page number in the right corner of the bottom banner.

`mp.pro.l.ps`  
`mp.pro.l.xpr` Prologue file used for landscape outputs.

`mp.pro.ll.ps`  
`mp.pro.ll.xpr` Prologue file used for landscape outputs, when printing files with longer than normal lines.

`mp.pro.altl.ps`  
`mp.pro.altl.xpr` Alternate prologue file used for landscape outputs.

**Files** `.cshrc`

Initialization file for [csh\(1\)](#).

`.mailrc`

Initialization file for [mail\(1\)](#).

`/usr/bin/mp`

Executable.

`/usr/lib/lp/locale/C/mp/mp.conf`

Default configuration file.

`/usr/lib/lp/locale/C/mp/mp.common.ps`

Common prologue file for all other `.ps` files in this directory. Not for `.xpr` files.

`/usr/lib/lp/locale/C/mp/mp.pro.ps`

`/usr/lib/lp/locale/C/mp/mp.pro.xpr`

Default prologue files for mail printing.

`/usr/lib/lp/locale/C/mp/mp.pro.l.ps`

`/usr/lib/lp/locale/C/mp/mp.pro.l.xpr`

Default prologue files for landscape format.

`/usr/lib/lp/locale/C/mp/mp.pro.ll.ps`

`/usr/lib/lp/locale/C/mp/mp.pro.ll.xpr`

Default prologue files for landscape format with one column per page. Useful when printing files with long lines.

`/usr/lib/lp/locale/C/mp/mp.pro.altl.ps`

`/usr/lib/lp/locale/C/mp/mp.pro.altl.xpr`

Alternate prologue files for landscape format.

`/usr/lib/lp/locale/C/mp/mp.pro.alt.ps`

`/usr/lib/lp/locale/C/mp/mp.pro.alt.xpr`

Alternative "default" prologue files. Insert page numbers in the bottom right corner of each page.

`/usr/lib/lp/locale/C/mp/mp.pro.ff.ps`

`/usr/lib/lp/locale/C/mp/mp.pro.ff.xpr`

Default prologue files for Filofax format.

/usr/lib/lp/locale/C/mp/mp.pro.fp.ps  
 /usr/lib/lp/locale/C/mp/mp.pro.fp.xpr  
 Default prologue files for Franklin Planner format.

/usr/lib/lp/locale/C/mp/mp.pro.tm.ps  
 /usr/lib/lp/locale/C/mp/mp.pro.tm.xpr  
 Default prologue files for Time Manager format.

/usr/lib/lp/locale/C/mp/mp.pro.ts.ps  
 /usr/lib/lp/locale/C/mp/mp.pro.ts.xpr  
 Default prologue files for Time/System International format.

/usr/openwin/lib/locale/localename/print/prolog.ps  
 /usr/lib/lp/locale/localename/mp/prolog.ps  
 Default locale-specific prologued file as an alternative to the mp.conf file. See ENVIRONMENT VARIABLES for more detail on the relationship.

The structure and format for mp.conf and .xpr files are documented in the *International Language Environments Guide*. Refer to this document if you need to use alternate fonts, including Printer Resident Fonts, or if you want to make changes to output format.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

**See Also** [csh\(1\)](#), [mail\(1\)](#), [mailtool\(1\)](#), [attributes\(5\)](#)

*International Language Environments Guide*

**Name** mpss.so.1 – shared object for setting preferred page size

**Synopsis** mpss.so.1

**Description** The mpss.so.1 shared object provides a means by which the preferred stack and/or heap page size can be selectively configured for launched processes and their descendants. To enable mpss.so.1, the following string needs to be present in the environment (see [ld.so.1\(1\)](#)) along with one or more MPSS (Multiple Page Size Support) environment variables:

**LD\_PRELOAD=\$LD\_PRELOAD:mpss.so.1**

**Environment Variables** Once preloaded, the mpss.so.1 shared object reads the following environment variables to determine any preferred page size requirements and any processes these may be specific to.

MPSSHEAP=*size*

MPSSSTACK=*size*

MPSSHEAP and MPSSSTACK specify the preferred page sizes for the heap and stack, respectively. The specified page size(s) are applied to all created processes.

*size* must be a supported page size (see [pagesize\(1\)](#)) or 0, in which case the system will select an appropriate page size (see [memcntl\(2\)](#)).

*size* can be qualified with K, M, G, or T to specify Kilobytes, Megabytes, Gigabytes, or Terabytes respectively.

MPSSCFGFILE=*config-file*

*config-file* is a text file which contains one or more mpss configuration entries of the form:

*exec-name exec-args:heap-size:stack-size*

*exec-name* specifies the name of an application or executable. The corresponding preferred page size(s) are set for newly created processes (see [getexecname\(3C\)](#)) that match the first *exec-name* found in the file.

*exec-name* can be a full pathname, a base name or a pattern string. See File Name Generation in [sh\(1\)](#) for a discussion of pattern matching.

*exec-args* is an optionally specified pattern string to match against arguments. Preferred page size(s) are set only if *exec-args* is not specified or occurs within the arguments to *exec-name*.

If *heap-size* and/or *stack-size* are not specified, the corresponding preferred page size(s) will not be set.

MPSSCFGFILE takes precedence over MPSSHEAP and MPSSSTACK. When MPSSCFGFILE is not set, preferred page size settings are taken from file `/etc/mpss.conf` if it exists.

`MPSSERRFILE=pathname` By default, error messages are logged via `syslog(3C)` using level `LOG_ERR` and facility `LOG_USER`. If `MPSSERRFILE` contains a valid *pathname* (such as `/dev/stderr`), error messages will be logged there instead.

### Examples EXAMPLE 1 Configuring the Preferred Page Sizes Using MPSSCFGFILE

The following Bourne shell commands (see [sh\(1\)](#)) configure the preferred page sizes to a select set of applications with exec names that begin with `foo`, using the `MPSSCFGFILE` environment variable. The MPSS configuration file, `mpsscfcg`, is assumed to have been previously created via a text editor like [vi\(1\)](#). The `cat(1)` command is only dumping out the contents.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSCFGFILE=mpsscfcg
example$ export LD_PRELOAD MPSSCFGFILE
example$ cat $MPSSCFGFILE
foo*:512K:64K
```

Once the application has been started, `pmap` (see [proc\(1\)](#)) can be used to view the actual page sizes configured:

```
example$ foobar &
example$ pmap -s 'pgrep foobar'
```

If the desired page size is not configured (shown in the `pmap` output), it may be due to errors in the MPSS configuration file or environment variables. Check the error log (by default: `/var/adm/messages`) for errors.

If no errors can be found, resource or alignment constraints may be responsible. See the NOTES section.

### EXAMPLE 2 Configuring the Preferred Page Sizes Using MPSSHEAP and MPSSSTACK

The following Bourne shell commands configure 512K heap and 64K stack preferred page sizes for all applications using the `MPSSHEAP` and `MPSSSTACK` environment variables.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSHEAP=512K
example$ MPSSSTACK=64K
example$ export LD_PRELOAD MPSSHEAP MPSSSTACK
```

### EXAMPLE 3 Precedence Rules (a continuation of Example 2)

The preferred page size configuration in `MPSSCFGFILE` overrides `MPSSHEAP` and `MPSSSTACK`. Appending the following commands to those in Example 2 would mean that all applications

**EXAMPLE 3** Precedence Rules (a continuation of Example 2) *(Continued)*

will be configured with 512K heap and 64K stack preferred page sizes with the exception of those applications, the `ls` command, and all applications beginning with `ora` that have `ora1` as an argument, in the configuration file.

```
example$ MPSSCFGFILE=mpsscfig2
example$ export MPSSCFGFILE
example$ cat $MPSSCFGFILE
ls:
ora* ora1:4m:4m
```

**Files** `/usr/lib/ld/map.bssalign` A template link-editor map file for aligning bss (see NOTES).  
`/etc/mpss.conf` Configuration file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                  |
|---------------------|----------------------------------|
| Availability        | system/extended-system-utilities |
| Interface Stability | Committed                        |

**See Also** [cat\(1\)](#), [ld\(1\)](#), [ld.so.1\(1\)](#), [pagesize\(1\)](#), [ppgsz\(1\)](#), [proc\(1\)](#), [sh\(1\)](#), [vi\(1\)](#), [exec\(2\)](#), [fork\(2\)](#), [memcntl\(2\)](#), [getexecname\(3C\)](#), [getpagesize\(3C\)](#), [syslog\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#)

**Notes** The heap and stack preferred page sizes are inherited. A child process has the same preferred page sizes as its parent. On [exec\(2\)](#), the preferred page sizes are set back to the default system page size unless a preferred page size has been configured via the `mpss` shared object.

[ppgsz\(1\)](#), a `proc` tool, can also be used to set the preferred stack and/or heap page sizes. It cannot selectively configure the page size for descendants based on name matches.

See also NOTES under [ppgsz\(1\)](#).

**Name** msgcc – C language message catalog compiler

**Synopsis** msgcc [-M-*option*] [cc-*optionsoption*] *file*...

**Description** msgcc is a C language message catalog compiler. It accepts cc style options and arguments.

A [msgcpp\(1\)](#) .msg file is generated for each input .c file. If the -c option is not specified then a [gencat\(1\)](#) format .msg file is generated from the input .mso and .msg files. If -c is not specified then a .msg suffix is appended to the -o file if it doesn't already have a suffix. The default output is a.out.msg if -c and -o are not specified.

If -M-new is not specified then messages are merged with those in the pre-existing -o file.

**Options** The following options are supported:

*cc-options* Specify cc style options and arguments.

-M-*option* Set a msgcc option.

Specify option as one of the following:

*mkmsgs* The -o file is assumed to be in [mkmsgs\(1\)](#) format.

*new* Create a new -o file.

*preserve* Messages in the -o file that are not in new .msg file arguments are preserved. The default is to either reuse the message numbers with new message text that is similar to the old or to delete the message text, leaving an unused message number.

*set=number* Set the message set number to *number*. The default is 1.

*similar=number* The message text similarity message threshold. The similarity measure between old and new message text is:

$$100 * (2 * \text{gzip}(\text{old} + \text{new}) \backslash \\ / (\text{gzip}(\text{old}) + \text{gzip}(\text{new})) - 1)$$

where  $\text{gzip}(x)$  is the size of text  $x$  when compressed by gzip. The default threshold is `$_similar_$.A` threshold of 0 turns off message replacement, but unused old messages are still deleted. Use -M-preserve to preserve all old messages.

*verbose* Trace similar message replacements on the standard error.

**Operands** The following operands are supported:

*file* Specifies the name of the file on which msgcc operates.

**Exit Status** 0 Successful completion.  
>0 An error occurred.

**Examples** EXAMPLE 1 Using msgcc

The following example uses msgcc to extract localizable strings from the file `hello.c`, marked using `ERROR_dictionary()`, writes them to the file `hello.mso`, and creates a gencat format `xxx.msg` file:

```
example% cat hello.c

#include <stdio.h>
#include <stdlib.h>

/*
 * dummy macro to avoid including
 * libast headers
 */
#define ERROR_dictionary(x) x

int main(int ac, char *av[])
{
 puts(ERROR_dictionary("hello world"));
 return(EXIT_SUCCESS);
}

example% msgcc -o xxx -D__STDC__ -D__i386 hello.c

example% cat hello.mso
str "hello world"

example% cat xxx.msg
$ xxx message catalog
$translation msgcc 2007-09-25
$set 1
$quote "
1 "hello world"
```

**Authors** Glenn Fowler, [gsf@research.att.com](mailto:gsf@research.att.com)

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE  |
|---------------------|------------------|
| Availability        | developer/astdev |
| Interface Stability | Volatile         |

**See Also** [cpp\(1\)](#), [gencat\(1\)](#), [mkmsgs\(1\)](#), [msggen\(1\)](#), [msgcpp\(1\)](#), [msgcvt\(1\)](#), [attributes\(5\)](#)

**Name** msgcpp – C language message catalog preprocessor

**Synopsis** msgcpp [-ACEHMPVX] [-D *name*[=*value*]] [-I *directory*] [-U *name*]  
[-T[*length*]] [-Y *directory*] [*input* [*output*]

**Description** msgcpp is a C language message catalog preprocessor. It accepts [cpp\(1\)](#) style options and arguments. msgcpp preprocesses an input C source file and emits keyed lines to the output, usually for further processing by [msgcc\(1\)](#). msgcc output is in the [gencat\(1\)](#) syntax. Candidate message text is determined by arguments to the last `<error.h>` and `<option.h>` functions. The msgcpp keyed output lines are:

`cmd command`      *command* is a candidate for `--??keys` option string generation. This is triggered by `b_command(int argc, in the input.`

`def name string`      *name* is a candidate variable with *string* value string.

`str string`            *string* should be entered into the catalog.

`var name`              If `def name` occurs then its string value should be entered into the catalog.

The input source file is preprocessed with the `pp:allpossible` option on. This enables non-C semantics. All source should first be compiled error-free with a real compiler before running msgcpp. The following changes are enabled for the top level files. Included file behavior is not affected.

1. All `#if`, `#ifdef` and `#ifndef` branches are enabled.
2. The first definition for a macro is retained, even when subsequent `#define` statements would normally redefine the macro. `#undef` must be used to redefine a macro.
3. Macro calls with an improper number of arguments are silently ignored.
4. `#include` on non-existent headers are silently ignored.
5. Invalid C source characters are silently ignored.

`msgcat.h` is included if it exists. This file may contain macro definitions for functions that translate string arguments. If `foo` is a function that translates its string arguments then include the line `#define foo _TRANSLATE_` in `msgcat.h`, or specify the option `-Dfoo=_TRANSLATE_`. If `bar` is a function that translates string arguments if the first argument is `stderr`, then use either `#define bar _STDIO_` or `-Dbar=_STDIO_`.

The macro `_BLD_msgcat` is defined to be 1. As an alternative to `msgcat.h`, `_TRANSLATE_` definitions could be placed inside `#ifdef _BLD_msgcat ... #endif`.

**Options** The following options are supported:

`-A`

`--assert=assertion`      Enter the assertion using `#assert` for system V compatibility.

`-C`

`--comments`              Pass comments to the output.

Comments are omitted by default.

-D

--define=*name*[=*value*]

Define the macro *name* to have *value*. This is the only portable way to pass options through cc to [cpp\(1\)](#).

- If *=value* is omitted, *value* is assumed to be 1.
- If *name* begins with :, then it is interpreted as a libpp #pragma pp: statement.
- If *name* begins with %, it is interpreted as a libpp # directive statement.
- If name begins with a - or a +, it is interpreted as a libpp option.

- turns the option on, + turns it off.

- Most options have a #pragma counterpart that is listed with the option definition.

-D-C

pp:compatibility

Preprocess for K&R C compatibility.

-D-Dlevel

pp:debug level *level*

Set the debug trace level.

Specify *level* as a number greater than or equal to 0. Higher levels produce more output. Levels higher than 3 can only be enabled in the -g compiled versions.

-D-Fname

Set the main input file name to *name*. This only affects the error messages and the line sync output.

-D-H

pp:hosted

All directories are hosted. Compatibility warning messages from the hosted directory headers are suppressed.

-D-I

pp:cdir

All directories contain C headers. This option is only used only with -D-+.

-D-K

pp:keyargs

Enable the non-standard *name=value* macro argument mode.

-D-L[*id*]

pp:lineid [*id*]

Set the line sync directive id to *id*. If *id* is not specified, set to null.

-D-M

pp:nomultiple

Disable multiple include detection.

-D-P

pp:passthrough

Enable the non-standard passthrough mode. This can be useful for processing non-C input.

-D-Q

pp:dump

Dump macro definitions to the output so that the output may be passed through cpp again. This is used for generating precompiled headers.

-D-R

pp:transition

Enable the transition preprocessing mode. This is used for compilers that cannot make up their semantics between K&R and ISO C.

-D-S

pp:strict

Enable strict preprocessing semantics and warnings. This works with any mode (compatibility, transition, or the default ISO).

-D-Ttest

pp:test *test*

Enable implementation specific test code according to *test*.

-D-W

pp:warn

Enable pedantic warnings in non-hosted files.

-D-X[*cc*]

Preprocess for the *cc* compiler, which must be an executable path or an executable on \$PATH.

-D-Z

pp:pool

Enable pool mode.

---

| --preprocess                   | Ignored; for compatibility with very old compilers.                                                                |
| -H                             |                                                                                                                    |
| --include-reference            | Emit <code>#include</code> file paths on the standard error, one per line, indented to show nesting.               |
| -I                             |                                                                                                                    |
| --include[= <i>directory</i> ] | Append <i>directory</i> to the list of directories searched for <code>#include</code> files.                       |
|                                | If <i>directory</i> is -:                                                                                          |
|                                | 1. -I <i>directories</i> before -I- are searched only for ". . ." include files                                    |
|                                | 2. -I <i>directories</i> after -I- are searched for ". . ." and "<". . .">" include files                          |
|                                | 3. the <i>directory</i> . is searched only if it is explicitly specified by an -I option                           |
| -I-C <i>directory</i>          |                                                                                                                    |
| pp:cdir <i>directory</i>       | Mark <i>directory</i> as a C header directory. This option is used with pp:plusplus.                               |
| -I-D[ <i>file</i> ]            | Read the default probe definitions from <i>file</i> , or ignore the default definitions if <i>file</i> is omitted. |
| -I-H <i>directory</i>          |                                                                                                                    |
| pp:hostdir <i>directory</i>    | Mark <i>directory</i> as a hosted directory. Headers from hosted directories have compatibility warnings disabled. |
| -I-I <i>header</i>             |                                                                                                                    |
| pp:ignore <i>header</i>        | Add <i>header</i> to the list of ignored headers.                                                                  |

**-I -Mfile**  
*file* contains a sequence of header [= "map" ] lines, where header is either <name> or "name", and "map" is an explicit binding for header. header is ignored if "map" is omitted.

**-I -Rfile**  
Include *file* but do not emit text or line syncs.

**-I -Sdirectory**  
Add *directory* to the default standard include directory list.

**-I -Tfile**  
Include *file* and emit text to the output file. The option value can be omitted.

**-M**

**--dependencies**

Generate **make(1S)** dependencies. This option is not needed with **nmake**.

The **-M** option can be followed by optional flags to change the dependency output styles.

The following optional flags are supported:

**D** Generate dependencies in a separate `.d` file. Preprocessed output is still written to output, or the standard output if output is omitted.

**G** Also generate missing dependencies.

**M** Only generate local header dependencies. Hosted headers are omitted. Hosted headers are determined by the **-I-H** option and the `--pp:hosted` and `pp:hostdir` pragmas. No special distinction is made between the "" and <> include styles.

**-P**

**--sync**

Emit line syncs.

Line sync is turned on by default. **-P** means `--nosync`.

**-T[length]**

If not **gcc**, truncate identifiers to *length* characters for compatibility with old AT&T compilers.

**-U**

**--undefine=name**

Remove the definition for the macro *name*.

**-V**

**--version**

Emit the **libpp** version.

---

```

-X
--argmode Enable name=value macro arguments for ease1 compatibility.
-Y
--standard=directory Add directory to the list searched for #include <...> files.

```

**Operands** The following operands are supported:

```

input Specifies C source file to preprocess.
output Specifies output file.

```

**Exit Status** 0 Successful completion.  
>0 An error occurred.

**Examples** EXAMPLE 1 Using msgcpp to Extract Localizable Strings

The following example uses msgcpp to extract localizable strings from the file `hello.c`, marked using the `ERROR_dictionary()`, and writes them to the file `hello.mso`:

```
example% cat hello.c
```

```

#include <stdio.h>
#include <stdlib.h>

/*
 * dummy macro to avoid including
 * libast headers
 */
#define ERROR_dictionary(x) x

int main(int ac, char *av[])
{
 puts(ERROR_dictionary("hello world"));
 puts(ERROR_dictionary("hello all"));
 return(EXIT_SUCCESS);
}

```

```
example% msgcpp -D__STDC__ -D__i386 hello.c hello.mso
```

```
example% cat hello.mso
str "hello world"
str "hello all"

```

**Name** msgcvt – convert message file to and from HTML

**Synopsis** msgcvt [-hmr]

**Description** msgcvt reads a [gencat\(1\)](#) format file on the standard input and converts it to HTML on the standard output. The input file must contain the control statement `$quote "` and use the `"` character to quote message text. The output is in a form suitable for automatic translation by web sites such as <http://babelfish.yahoo.com>.

**Options** The following options are supported:

-h

--html Generate HTML from [gencat\(1\)](#) input.

This is the default.

-m

--msg Generate a [gencat\(1\)](#) message file from (presumably translated) HTML. Wide characters are UTF-8 encoded.

-r

--raw The message file is raw message text, one message per line, with no quoting or line numbering.

**Exit Status** 0 Successful completion.

>0 One or more specified jobs does not exist.

**Examples** EXAMPLE 1 Generating a gencat Message Catalog File

The following example generates a [gencat\(1\)](#) message catalog file from an HTML file:

```
example% cat example.html | msgcvt -m > examplecat
```

**Authors** Glenn Fowler, [gsf@research.att.com](mailto:gsf@research.att.com)

**Name** msgfmt – create a message object from a message file

**Synopsis** msgfmt [-D *dir* | --directory=*dir*]  
[-f | --use-fuzzy] [-g]  
[-o *output-file* | --output-file=*output-file*]  
[-s] [--strict] [-v] [--verbose] *filename.po*...

**Description** The msgfmt utility creates message object files from portable object files (*filename.po*), without changing the portable object files.

The .po file contains messages displayed to users by system commands or by application programs. .po files can be edited. The messages in these files can be rewritten in any language supported by the system.

The [xgettext\(1\)](#) command can be used to create .po files from script or programs.

msgfmt interprets data as characters according to the current setting of the LC\_CTYPE locale category or according to the codeset specified in the .po file.

**Options** The following options are supported:

|                              |                                                                                                                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -D <i>dir</i>                |                                                                                                                                                                                           |
| --directory= <i>dir</i>      | Adds <i>dir</i> to the list for input files search.                                                                                                                                       |
| -f                           |                                                                                                                                                                                           |
| --use-fuzzy                  | Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.       |
| -g                           | Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.                                                              |
| -o <i>output-file</i>        |                                                                                                                                                                                           |
| --output= <i>output-file</i> | Specifies the output file name as <i>output-file</i> . All domain directives and duplicate msgids in the .po file are ignored.                                                            |
| -s                           | Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.                                                                     |
| --strict                     | Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed. |
| -v                           |                                                                                                                                                                                           |
| --verbose                    | Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.                                                           |

If GNU-compatible message files are processed, this option detects and diagnoses input file anomalies which might represent translation errors. The msgid and msgstr strings are studied and

compared. It is considered abnormal if one string starts or ends with a newline while the other does not. Also, if the string represents a format string used in a printf-like function, both strings should have the same number of % format specifiers, with matching types. If the flag `c` - format appears in the special comment '#' for this entry, a check is performed.

**Usage** The format of portable object files (.po files) is defined as follows. Each .po file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a pound sign (#) and end with the newline character. All comments (except special comments described later) and empty lines are ignored. The format of a statement is:

*directive*      *value*

Each *directive* starts at the beginning of the line and is separated from *value* by white space (such as one or more space or tab characters). *value* consists of one or more quoted strings separated by white space. Use any of the following types of directives for the Solaris message file:

```
domain domainname
msgid message_identifier
msgstr message_string
```

For a GNU-compatible message file, use any of the following types of directives:

```
domain domainname
msgid message_identifier
msgid_plural untranslated_string_plural
msgstr message_string
msgstr[n] message_string
```

The behavior of the `domain` directive is affected by the options used. See `OPTIONS` for the behavior when the `-o` or `--output-file` options are specified. If the `-o` or `--output-file` options are not specified, the behavior of the `domain` directive is as follows:

- All msgids from the beginning of each .po file to the first `domain` directive are put into a default message object file. The default message object file is named `messages.mo`, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the default message object file is named `messages`.
- When `msgfmt` encounters a `domain domainname` directive in the .po file, all following msgids until the next `domain` directive are put into the message object file, named `domainname.mo`, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the msgids are put into the message object file named `domainname`.
- Duplicate msgids are defined in the scope of each domain. That is, a msgid is considered a duplicate only if the identical msgid exists in the same domain.

- All duplicate msgids are ignored.

The `msgid` directive specifies the value of a message identifier associated with the directive that follows it. The `msgid_plural` directive specifies the plural form message specified to the plural message handling functions `ngettext()`, `dngettext()`, or `dcngettext()`. The *message\_identifier* string identifies a target string to be used at retrieval time. Each statement containing a `msgid` directive must be followed by a statement containing a `msgstr` directive or `msgstr[n]` directives.

The `msgstr` directive specifies the target string associated with the *message\_identifier* string declared in the immediately preceding `msgid` directive.

The directive `msgstr[n]` (where  $n = 0, 1, 2, \dots$ ) specifies the target string to be used with plural form handling functions `ngettext()`, `dngettext()`, and `dcngettext()`.

Message strings can contain the escape sequences `\n` for newline, `\t` for tab, `\v` for vertical tab, `\b` for backspace, `\r` for carriage return, `\f` for formfeed, `\\` for backslash, `\"` for double quote, `\bso\`; a for alarm, `\ddd` for octal bit pattern, and `\xDD` for hexadecimal bit pattern.

Comments for a GNU-compatible message file should be in one of the following formats (the `msgfmt` utility will ignore these comments when processing Solaris message files):

```
translator-comments
. automatic-comments
#: reference..
#, flag
```

The `'#:'` comments indicate the location of the `msgid` string in the source files in *filename:line* format. The `'#'`, `'#.'`, and `'#:'` comments are informative only and are silently ignored by the `msgfmt` utility. The `'#,'` comments require one or more flags separated by the comma character. The following *flags* can be specified:

**fuzzy** This flag can be inserted by the translator. It shows that the `msgstr` string might not be a correct translation (anymore). Only the translator can judge if the translation requires further modification or is acceptable as is. Once satisfied with the translation, the translator removes this fuzzy flag. If this flag is specified, the `msgfmt` utility will not generate the entry for the immediately following `msgid` in the output message catalog.

**c-format**

**no-c-format** The `c-format` flag indicates that the `msgid` string is used as a format string by `printf`-like functions. In case the `c-format` flag is given for a string, the `msgfmt` utility does some more tests to check the validity of the translation.

In the GNU-compatible message file, the `msgid` entry with empty string (`""`) is called the header entry and treated specially. If the message string for the header entry contains `np\lurals=value`, the value indicates the number of plural forms. For example, if `np\lurals=4`,

there are four plural forms. If `nplurals` is defined, the same line should contain `plural=expression`, separated by a semicolon character. The *expression* is a C language expression to determine which version of `msgstr[n]` is to be used based on the value of *n*, the last argument of `ngettext()`, `dngettext()`, or `dcngettext()`. For example,

```
nplurals=2; plural= n == 1 ? 0 : 1
```

indicates that there are two plural forms in the language. `msgstr[0]` is used if `n == 1`, otherwise `msgstr[1]` is used. For another example:

```
nplurals=3; plural= n == 1 ? 0 : n == 2 ? 1 : 2
```

indicates that there are three plural forms in the language. `msgstr[0]` is used if `n == 1`, `msgstr[1]` is used if `n == 2`, otherwise `msgstr[2]` is used.

If the header entry contains a `charset=codeset` string, the *codeset* is used to indicate the codeset to be used to encode the message strings. If the output string's codeset is different from the message string's codeset, codeset conversion from the message string's codeset to the output string's codeset will be performed upon the call of `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, and `dcngettext()` for the GNU-compatible message catalogs. The output string's codeset is determined by the current locale's codeset (the return value of `ngettext(CODESET)`) by default, and can be changed by the call of `bind_textdomain_codeset()`.

#### Message catalog file format

The `msgfmt` utility can generate the message object both in Solaris message catalog file format and in GNU-compatible message catalog file format. If the `-s` option is specified and the input file is a Solaris `.po` file, the `msgfmt` utility generates the message object in Solaris message catalog file format. If the `-g` option is specified and the input file is a GNU `.po` file, the `msgfmt` utility generates the message object in GNU-compatible message catalog file format. If neither the `-s` nor `-g` option is specified, the `msgfmt` utility determines the message catalog file format as follows:

- If the `.po` file contains a valid GNU header entry (having an empty string for `msgid`), the `msgfmt` utility uses the GNU-compatible message catalog file format.
- Otherwise, the `msgfmt` utility uses the Solaris message catalog file format.

If the `msgfmt` utility determined that the Solaris message catalog file format is used, as above, but found the `.po` file contains directives that are specific to the GNU-compatible message catalog file format, such as `msgid_plural` and `msgstr[n]`, the `msgfmt` utility handles those directives as invalid specifications.

#### Examples EXAMPLE 1 Creating message objects from message files

In this example, `module1.po` and `module2.po` are portable message objects files.

```
example% cat module1.po
default domain "messages.mo"
```

**EXAMPLE 1** Creating message objects from message files (Continued)

```

msgid "msg 1"
msgstr "msg 1 translation"
#
domain "help_domain"
msgid "help 2"
msgstr "help 2 translation"
#
domain "error_domain"
msgid "error 3"
msgstr "error 3 translation"
example% cat module2.po
default domain "messages.mo"
msgid "mesg 4"
msgstr "mesg 4 translation"
#
domain "error_domain"
msgid "error 5"
msgstr "error 5 translation"
#
domain "window_domain"
msgid "window 6"
msgstr "window 6 translation"

```

The following command will produce the output files `messages.mo`, `help_domain.mo`, and `error_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po
```

The following command will produce the output files `messages.mo`, `help_domain.mo`, `error_domain.mo`, and `window_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po module2.po
```

The following command will produce the output file `hello.mo` in Solaris message catalog file format:

```
example% msgfmt -o hello.mo module1.po module2.po
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environmental variables that affect the execution of `msgfmt`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | text/locale     |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| CSI            | Enabled         |

**See Also** [xgettext\(1\)](#), [gettext\(3C\)](#), [setlocale\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.

**Name** msggen – generate a machine independent formatted message catalog

**Synopsis** msggen [-fls] *catfile* [*msgfile*]

**Description** msggen merges the message text source file *msgfile* into a machine independent formatted message catalog *catfile*. The file *catfile* is created if it does not already exist. If *catfile* does exist, its messages are included in the new *catfile*. If set and message numbers collide, the new message text defined in *msgfile* replaces the old message text currently contained in *catfile*.

Non-ASCII characters must be UTF-8 encoded. [iconv\(1\)](#) can be used to convert to/from UTF-8.

**Options** The following options are supported:

-f

--format List the [printf\(3C\)](#) format signature for each message in *catfile*. A format signature is one line containing one character for each format specification:

|   |             |
|---|-------------|
| c | char        |
| d | double      |
| D | long double |
| f | float       |
| h | short       |
| i | int         |
| j | long long   |
| l | long        |
| p | void*       |
| s | string      |
| t | ptrdiff_t   |
| z | size_t      |
| ? | unknown     |

-l

--list List *catfile* in UTF-8 msgfile form.

-s

--set Convert the *catfile* to a message set number and print the number on the standard output.

**Operands** The following operands are supported:

*catfile* Machine independent formatted message catalog file.

*msgfile* Message text source file.

**Usage** Message text source files are in `genocat(1)` format, defined as follows. The fields of a message text source line are separated by a single blank character. Any other blank characters are considered to be part of the subsequent field. The `NL_*` constants are defined in one or both of `<limits.h>` and `<nل_types.h>`.

`$comment`

A line beginning with a `$` followed by a blank character is treated as a comment.

`$delset n comment`

This line deletes message set *n* from an existing message catalog. *n* denotes the set number [1, `NL_SETMAX`]. Any text following the set number is treated as a comment.

`$quote c`

This line specifies an optional quote character *c*, which can be used to surround message-text so that trailing spaces or empty messages are visible in a message source line. By default, or if an empty `$quote` directive is supplied, no quoting of message-text is recognized.

`$set n comment`

This line specifies the set identifier of the following messages until the next `$set` or end-of-file (EOF) appears. *n* denotes the set identifier, which is defined as a number in the range [1, `NL_SETMAX`]. Set numbers need not be contiguous. Any text following the set identifier is treated as a comment. If no `$set` directive is specified in a message text source file, all messages are located in message set 1.

`$translation identification YYYY-MM-DD[ , . . . ]`

Append translation information to the message catalog header. Only the newest date for a given identification is retained in the catalog. Multiple translation lines are combined into a single, comma-separated list.

`m message-text`

*m* denotes the message identifier, which is defined as a number in the range [1, `NL_MSGMAX`]. The message-text is stored in the message catalogue with the set identifier specified by the last `$set` directive, and with message identifier *m*. If the message-text is empty, and a blank character field separator is present, an empty string is stored in the message catalogue. If a message source line has a message number, but neither a field separator nor message-text, the existing message with that number (if any) is deleted from the catalogue. Message identifiers need not be contiguous. There are no *message-text* length restrictions.

**Exit Status** 0 Successful completion.  
>0 One or more specified jobs does not exist.

**Examples** EXAMPLE 1 Using msggen

The following example generates a message catalog xxx from the message file xxx.msg:

```
example% msggen xxx xxx.msg
```

**Authors** Glenn Fowler, [gsf@research.att.com](mailto:gsf@research.att.com)

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE  |
|---------------------|------------------|
| Availability        | developer/astdev |

**Name** msgget – get a message from a message catalog

**Synopsis** msgget *locale* [*command*:]*catalog* [*set*.]*number* [*text*]

**Description** msgget gets the message corresponding to the parameters. See OPERANDS.

**Operands** The following operands are supported:

*catalog* Specifies the message catalog name.

*command* Specifies command-specific message.

*locale* Specifies the locale. If *locale* is - then the current locale is used.

[*set*] . *number* Identifies the message by message number and an optional message set. If specified as - , the message set and number are determined by looking up text in the corresponding C locale message catalog.

*text* Specifies the text of the message to be output upon error.

**Exit Status** 0 Successful completion.

>0 An error occurred.

**Examples** EXAMPLE 1 Getting a Message in the Current Locale

The following example gets msg 1 in the current locale from message catalog hello:

```
example% msgget - hello 1
hello world
```

**Authors** Glenn Fowler, gsf@research.att.com

**Name** mt – magnetic tape control

**Synopsis** mt [-f *tapename*] *command*... [*count*]

**Description** The `mt` utility sends commands to a magnetic tape drive. If -f *tapename* is not specified, the environment variable `TAPE` is used. If `TAPE` does not exist, `mt` uses the device `/dev/rmt/0n`.

**Options** The following options are supported:

-f *tapename* Specifies the raw tape device.

**Operands** The following operands are supported:

*count* The number of times that the requested operation is to be performed. By default, `mt` performs *command* once. Multiple operations of *command* can be performed by specifying *count*.

*command* The following available commands that can be sent to a magnetic tape drive are supported. Only as many characters as are required to uniquely identify a *command* need be specified.

`asf` Specifies absolute space to *count* file number. This is equivalent to a `rewind` followed by a `fsf count`.

`bsf` Back spaces over *count* EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark.

`bsr` Back spaces *count* records.

`bssf` Back spaces over the requested number of sequential file marks. Sequential file marks are where the file marks are one right after the other with no other blocks of any kind between the file marks. The number argument specifies how many sequential file marks to which to space. For example, `bssf 4` searches backwards to the first place where there are 4 sequential file marks and positions to the BOP side of the 4th file mark.

This command is not supported by all drives.

`eof`  
`weof` Writes *count* EOF marks at the current position on the tape.

`fsf` Forward spaces over *count* EOF marks. The tape is positioned on the first block of the file.

`fsr` Forward spaces *count* records.

`fssf` Forward spaces the over requested number of sequential file marks. Sequential file marks are where the file marks are one right after the other with no other blocks of any kind between the file marks. The number argument specifies how many sequential file marks to

which to space. For example, `fsf 4` searches forwards to the first place where there are 4 sequential file marks and positions after the 4th file mark.

This command is not supported by all drives.

|                     |                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>load</code>   | Requests drive load and thread current media. Not supported by all drives.                                                                                                       |
| <code>lock</code>   | Prevents media removal.                                                                                                                                                          |
| <code>nbsf</code>   | Back spaces <i>count</i> files. The tape is positioned on the first block of the file. This is equivalent to <i>count+1</i> <code>bsfs</code> followed by one <code>fsf</code> . |
| <code>seek</code>   | Positions to requested logical tape position.                                                                                                                                    |
| <code>tell</code>   | Gets and prints current logical tape position.                                                                                                                                   |
| <code>unlock</code> | Allows media removal.                                                                                                                                                            |

If *count* is specified with any of the following commands, the *count* is ignored and the command is performed only once.

|                                              |                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>config</code>                          | Reads the drives current configuration from the driver and displays it in <code>st.conf</code> format. See <a href="#">st(7D)</a> for definition of fields and there meanings.                                                                                                                                    |
| <code>eom</code>                             | Spaces to the end of recorded media on the tape. This is useful for appending files onto previously written tapes.                                                                                                                                                                                                |
| <code>erase</code>                           | Erases the entire tape.<br><br>Some tape drives have option settings where only portions of the tape can be erased. Be sure to select the correct setting to erase the whole tape. Erasing a tape can take a long time depending on the device and/or tape. Refer to the device specific manual for time details. |
| <code>forcereserve</code>                    | Attempts to break a SCSI II reserve issued by another initiator. When this command completes, the drive is not reserved for the current initiator, but is available for use. This command can be only be executed by those with super-user privileges.                                                            |
| <code>offline</code><br><code>rewoffl</code> | Rewinds the tape and, if appropriate, takes the drive unit off-line by unloading the tape.                                                                                                                                                                                                                        |
| <code>release</code>                         | Re-establishes the default behavior of releasing at close.                                                                                                                                                                                                                                                        |

|           |                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| reserve   | Allows the tape drive to remain reserved after closing the device. The drive must then be explicitly released.                                |
| retension | Rewinds the cartridge tape completely, then winds it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension. |
| rewind    | Rewinds the tape.                                                                                                                             |
| status    | Prints status information about the tape unit.                                                                                                |

Status information can include the sense key reported by the drive, the residual and retries for the last operation, the current tape position reported in file number, and the number of blocks from the beginning of that file. It might also report that WORM media is loaded in that drive.

- Exit Status**
- 0 All operations were successful.
  - 1 Command was unrecognized or mt was unable to open the specified tape drive.
  - 2 An operation failed.

**Files** /dev/rmt/\* magnetic tape interface

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [tar\(1\)](#), [tcopy\(1\)](#), [ar.h\(3HEAD\)](#), [attributes\(5\)](#), [mtio\(7I\)](#), [st\(7D\)](#)

**Bugs** Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page.

mt is architecture sensitive. Heterogeneous operation (that is, SPARC to x86 or the reverse) is not supported.

**Name** mv – move files

**Synopsis** /usr/bin/mv [-fi] *source target\_file*  
/usr/bin/mv [-fi] *source... target\_dir*  
/usr/xpg4/bin/mv [-fi] *source target\_file*  
/usr/xpg4/bin/mv [-fi] *source... target\_dir*

**Description** In the first synopsis form, the mv utility moves the file named by the *source* operand to the destination specified by the *target\_file*. *source* and *target\_file* can not have the same name. If *target\_file* does not exist, mv creates a file named *target\_file*. If *target\_file* exists, its contents are overwritten. This first synopsis form is assumed when the final operand does not name an existing directory.

In the second synopsis form, mv moves each file named by a *source* operand to a destination file in the existing directory named by the *target\_dir* operand. The destination path for each *source* is the concatenation of the target directory, a single slash character (/), and the last path name component of the *source*. This second form is assumed when the final operand names an existing directory.

If mv determines that the mode of *target\_file* forbids writing, it prints the mode (see [chmod\(2\)](#)), ask for a response, and read the standard input for one line. If the response is affirmative, the mv occurs, if permissible; otherwise, the command exits. Notice that the mode displayed can not fully represent the access permission if *target* is associated with an ACL. When the parent directory of *source* is writable and has the sticky bit set, one or more of the following conditions must be true:

- the user must own the file
- the user must own the directory
- the file must be writable by the user
- the user must be a privileged user

If *source* is a file and *target\_file* is a link to another file with links, the other links remain and *target\_file* becomes a new file.

If *source* and *target\_file/target\_dir* are on different file systems, mv copies the source and deletes the original. Any hard links to other files are lost. mv attempts to duplicate the source file characteristics to the target, that is, the owner and group id, permission modes, modification and access times, ACLs, and extended attributes, if applicable. For symbolic links, mv preserves only the owner and group of the link itself.

If unable to preserve owner and group id, mv clears S\_ISUID and S\_ISGID bits in the target. mv prints a diagnostic message to stderr if unable to clear these bits, though the exit code is not affected. mv might be unable to preserve extended attributes if the target file system does not have extended attribute support. /usr/xpg4/bin/mv prints a diagnostic message to stderr for all other failed attempts to duplicate file characteristics. The exit code is not affected.

In order to preserve the source file characteristics, users must have the appropriate file access permissions. This includes being super-user or having the same owner id as the destination file.

**Options** The following options are supported:

- f `mv` moves the file(s) without prompting even if it is writing over an existing *target*. Note that this is the default if the standard input is not a terminal.
- i `mv` prompts for confirmation whenever the move would overwrite an existing target. This is done regardless of whether the input is coming from a terminal. If the prompt for confirmation fails, this is equivalent to the user answering in the negative. An affirmative answer means that the move should proceed. Any other answer prevents `mv` from overwriting *target*.

`/usr/bin/mv` Specifying both the -f and the -i options is not considered an error. The -f option overrides the -i option.

`/usr/xpg4/bin/mv` Specifying both the -f and the -i options is not considered an error. The last option specified determines the behavior of `mv`.

**Operands** The following operands are supported:

- source* A path name of a file or directory to be moved.
- target\_file* A new path name for the file or directory being moved.
- target\_dir* A path name of an existing directory into which to move the input files.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `mv` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `mv`: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

Affirmative responses are processed using the extended regular expression defined for the `yesexpr` keyword in the LC\_MESSAGES category of the user's locale. The locale specified in the LC\_COLLATE category defines the behavior of ranges, equivalence classes, and multi-character collating elements used in the expression defined for `yesexpr`. The locale specified in LC\_CTYPE determines the locale for interpretation of sequences of bytes of text data a characters, the behavior of character classes used in the expression defined for the `yesexpr`. See [locale\(5\)](#).

**Exit Status** The following exit values are returned:

- 0 All input files were moved successfully.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

|             | ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|-------------|---------------------|-----------------|
| /usr/bin/mv | Availability        | system/core-os  |
|             | CSI                 | Enabled         |
|             | Interface Stability | Committed       |

|                  | ATTRIBUTE TYPE      | ATTRIBUTE VALUE   |
|------------------|---------------------|-------------------|
| /usr/xpg4/bin/mv | Availability        | system/xopen/xcu4 |
|                  | CSI                 | Enabled           |
|                  | Interface Stability | Standard          |

**See Also** [cp\(1\)](#), [cpio\(1\)](#), [ln\(1\)](#), [rm\(1\)](#), [setfacl\(1\)](#), [chmod\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** A - - permits the user to mark explicitly the end of any command line options, allowing mv to recognize filename arguments that begin with a - . As an aid to BSD migration, mv accepts - as a synonym for - -. This migration aid might disappear in a future release.

**Name** nawk – pattern scanning and processing language

**Synopsis** /usr/bin/nawk [-F *ERE*] [-v *assignment*] '*program*' | -f *progfile*...  
[*argument*]...

/usr/xpg4/bin/awk [-F *ERE*] [-v *assignment*]... '*program*' | -f *progfile*...  
[*argument*]...

**Description** The /usr/bin/nawk and /usr/xpg4/bin/awk utilities execute *programs* written in the nawk programming language, which is specialized for textual data manipulation. A nawk *program* is a sequence of patterns and corresponding actions. The string specifying *program* must be enclosed in single quotes (') to protect it from interpretation by the shell. The sequence of pattern - action statements can be specified in the command line as *program* or in one, or more, file(s) specified by the -f *progfile* option. When input is read that matches a pattern, the action associated with the pattern is performed.

Input is interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the RS built-in variable. Each record of input is matched to each pattern in the *program*. For each pattern matched, the associated action is executed.

The nawk utility interprets each input record as a sequence of fields where, by default, a field is a string of non-blank characters. This default white-space field delimiter (blanks and/or tabs) can be changed by using the FS built-in variable or the -F*ERE* option. The nawk utility denotes the first field in a record \$1, the second \$2, and so forth. The symbol \$0 refers to the entire record; setting any other field causes the reevaluation of \$0. Assigning to \$0 resets the values of all fields and the NF built-in variable.

**Options** The following options are supported:

- F *ERE* Define the input field separator to be the extended regular expression *ERE*, before any input is read (can be a character).
- f *progfile* Specifies the pathname of the file *progfile* containing a nawk program. If multiple instances of this option are specified, the concatenation of the files specified as *progfile* in the order specified is the nawk program. The nawk program can alternatively be specified in the command line as a single argument.
- v *assignment* The *assignment* argument must be in the same form as an *assignment* operand. The assignment is of the form *var=value*, where *var* is the name of one of the variables described below. The specified assignment occurs before executing the nawk program, including the actions associated with BEGIN patterns (if any). Multiple occurrences of this option can be specified.

**Operands** The following operands are supported:

- program* If no `-f` option is specified, the first operand to `nawk` is the text of the `nawk` program. The application supplies the *program* operand as a single argument to `nawk`. If the text does not end in a newline character, `nawk` interprets the text as if it did.
- argument* Either of the following two types of *argument* can be intermixed:
- file* A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no *file* operands are specified, or if a *file* operand is `-`, the standard input is used.
- assignment* An operand that begins with an underscore or alphabetic character from the portable character set, followed by a sequence of underscores, digits and alphabetic characters from the portable character set, followed by the `=` character specifies a variable assignment rather than a pathname. The characters before the `=` represent the name of a `nawk` variable. If that name is a `nawk` reserved word, the behavior is undefined. The characters following the equal sign is interpreted as if they appeared in the `nawk` program preceded and followed by a double-quote (`"`) character, as a `STRING` token, except that if the last character is an unescaped backslash, it is interpreted as a literal backslash rather than as the first character of the sequence `\.` The variable is assigned the value of that `STRING` token. If the value is considered a *numericstring*, the variable is assigned its numeric value. Each such variable assignment is performed just before the processing of the following *file*, if any. Thus, an assignment before the first *file* argument is executed after the `BEGIN` actions (if any), while an assignment after the last *file* argument is executed before the `END` actions (if any). If there are no *file* arguments, assignments are executed before processing the standard input.

**Input Files** Input files to the `nawk` program from any of the following sources:

- any *file* operands or their equivalents, achieved by modifying the `nawk` variables `ARGV` and `ARGC`
- standard input in the absence of any *file* operands
- arguments to the `getline` function

must be text files. Whether the variable `RS` is set to a value other than a newline character or not, for these files, implementations support records terminated with the specified separator up to `{LINE_MAX}` bytes and can support longer records.

If `-f progfile` is specified, the files named by each of the *progfile* option-arguments must be text files containing an *nawk* program.

The standard input are used only if no *file* operands are specified, or if a *file* operand is `-`.

**Extended Description** A *nawk* program is composed of pairs of the form:

```
pattern { action }
```

Either the pattern or the action (including the enclosing brace characters) can be omitted. Pattern-action statements are separated by a semicolon or by a newline.

A missing pattern matches any record of input, and a missing action is equivalent to an action that writes the matched record of input to standard output.

Execution of the *nawk* program starts by first executing the actions associated with all `BEGIN` patterns in the order they occur in the program. Then each *file* operand (or standard input if no files were specified) is processed by reading data from the file until a record separator is seen (a newline character by default), splitting the current record into fields using the current value of `FS`, evaluating each pattern in the program in the order of occurrence, and executing the action associated with each pattern that matches the current record. The action for a matching pattern is executed before evaluating subsequent patterns. Last, the actions associated with all `END` patterns is executed in the order they occur in the program.

Expressions in *nawk* Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators are evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while *lvalue* represents any entity that can be assigned to (that is, on the left side of an assignment operator).

| Syntax                   | Name            | Type of Result      | Associativity |
|--------------------------|-----------------|---------------------|---------------|
| <code>( expr )</code>    | Grouping        | type of <i>expr</i> | n/a           |
| <code>\$expr</code>      | Field reference | string              | n/a           |
| <code>++ lvalue</code>   | Pre-increment   | numeric             | n/a           |
| <code>-- lvalue</code>   | Pre-decrement   | numeric             | n/a           |
| <code>lvalue ++</code>   | Post-increment  | numeric             | n/a           |
| <code>lvalue --</code>   | Post-decrement  | numeric             | n/a           |
| <code>expr ^ expr</code> | Exponentiation  | numeric             | right         |
| <code>! expr</code>      | Logical not     | numeric             | n/a           |

| Syntax                                       | Name                             | Type of Result                                       | Associativity |
|----------------------------------------------|----------------------------------|------------------------------------------------------|---------------|
| $+ \text{expr}$                              | Unary plus                       | numeric                                              | n/a           |
| $- \text{expr}$                              | Unary minus                      | numeric                                              | n/a           |

| <i>lvalue</i> = <i>expr</i>  | Assignment             | type of <i>expr</i> | right         |

Each expression has either a string value, a numeric value or both. Except as stated for specific contexts, the value of an expression is implicitly converted to the type needed for the context in which it is used. A string value is converted to a numeric value by the equivalent of the following calls:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer is converted to a string by the equivalent of a call to the `sprintf` function with the string `%d` as the `fmt` argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value is converted to a string by the equivalent of a call to the `sprintf` function with the value of the variable `CONVFMT` as the `fmt` argument and the numeric value being converted as the first and only *expr* argument.

A string value is considered to be a *numeric string* in the following case:

1. Any leading and trailing blank characters is ignored.
2. If the first unignored character is a + or -, it is ignored.
3. If the remaining unignored characters would be lexically recognized as a NUMBER token, the string is considered a *numeric string*.

If a - character is ignored in the above steps, the numeric value of the *numeric string* is the negation of the numeric value of the recognized NUMBER token. Otherwise the numeric value of the *numeric string* is the numeric value of the recognized NUMBER token. Whether or not a string is a *numeric string* is relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero is treated as false and any other value is treated as true. Otherwise, a string value of the null string is treated as false and any other value is treated as true. A Boolean context is one of the following:

- the first subexpression of a conditional expression.
- an expression operated on by logical NOT, logical AND, or logical OR.
- the second expression of a for statement.
- the expression of an if statement.
- the expression of the while clause in either a while or do . . . while statement.

- an expression used as a pattern (as in Overall Program Structure).

The `nawk` language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They are initially empty, and their sizes changes dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an *lvalue* and as an expression, as described in the grammar. Unsubscripted array names are used in only the following contexts:

- a parameter in a function definition or function call.
- the `NAME` token following any use of the keyword `in`.

A valid array *index* consists of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because `nawk` arrays are really one-dimensional, such a comma-separated list is converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the `SUBSEP` variable.

Thus, the following two index operations are equivalent:

```
var[expr1, expr2, ... exprn]
var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]
```

A multi-dimensioned *index* used with the `in` operator must be put in parentheses. The `in` operator, which tests for the existence of a particular array element, does not create the element if it does not exist. Any other reference to a non-existent array element automatically creates it.

Variables and Special Variables

Variables can be used in an `nawk` program by referencing them. With the exception of function parameters, they are not explicitly declared. Uninitialized scalar variables and array elements have both a numeric value of zero and a string value of the empty string.

Field variables are designated by a `$` followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified. Uninitialized variables or string values need not be converted to numeric values in this context. New field variables are created by assigning a value to them. References to non-existent fields (that is, fields after `$NF`) produce the null string. However, assigning to a non-existent field (for example, `$(NF+2) = 5`) increases the value of `NF`, create any intervening fields with the null string as their values and cause the value of `$0` to be recomputed, with the fields being separated by the value of `OFS`. Each field variable has a string value when created. If the string, with any occurrence of the decimal-point character from the current locale changed to a period character, is considered a *numeric string* (see Expressions in `nawk` above), the field variable also has the numeric value of the *numeric string*.

`/usr/bin/nawk,`  
`/usr/xpg4/bin/awk`

`nawk` sets the following special variables that are supported by both `/usr/bin/nawk` and `/usr/xpg4/bin/awk`:

`ARGC`            The number of elements in the `ARGV` array.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARGV     | <p>An array of command line arguments, excluding options and the <i>program</i> argument, numbered from zero to ARGV-1.</p> <p>The arguments in ARGV can be modified or added to; ARGV can be altered. As each input file ends, nawk treats the next non-null element of ARGV, up to the current value of ARGV-1, inclusive, as the name of the next input file. Setting an element of ARGV to null means that it is not treated as an input file. The name - indicates the standard input. If an argument matches the format of an <i>assignment</i> operand, this argument is treated as an assignment rather than a <i>file</i> argument.</p>                                                                                                                                                             |
| ENVIRON  | <p>The variable ENVIRON is an array representing the value of the environment. The indices of the array are strings consisting of the names of the environment variables, and the value of each array element is a string consisting of the value of that variable. If the value of an environment variable is considered a <i>numeric string</i>, the array element also has its numeric value.</p> <p>In all cases where nawk behavior is affected by environment variables (including the environment of any commands that nawk executes via the <code>system</code> function or via pipeline redirections with the <code>print</code> statement, the <code>printf</code> statement, or the <code>getline</code> function), the environment used is the environment at the time nawk began executing.</p> |
| FILENAME | <p>A pathname of the current input file. Inside a BEGIN action the value is undefined. Inside an END action the value is the name of the last input file processed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| FNR      | <p>The ordinal number of the current record in the current file. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed in the last file processed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FS       | <p>Input field separator regular expression; a space character by default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| NF       | <p>The number of fields in the current record. Inside a BEGIN action, the use of NF is undefined unless a <code>getline</code> function without a <i>var</i> argument is executed previously. Inside an END action, NF retains the value it had for the last record read, unless a subsequent, redirected, <code>getline</code> function without a <i>var</i> argument is performed prior to entering the END action.</p>                                                                                                                                                                                                                                                                                                                                                                                    |
| NR       | <p>The ordinal number of the current record from the start of input. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| OFMT     | <p>The <code>printf</code> format for converting numbers to strings in output statements "% . 6g" by default. The result of the conversion is unspecified if the value of OFMT is not a floating-point format specification.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| OFS      | <p>The <code>print</code> statement output field separator; a space character by default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORS    | The print output record separator; a newline character by default.                                                                                                                                                                                                                                                                                                                                                                             |
| LENGTH | The length of the string matched by the <code>match</code> function.                                                                                                                                                                                                                                                                                                                                                                           |
| RS     | The first character of the string value of RS is the input record separator; a newline character by default. If RS contains more than one character, the results are unspecified. If RS is null, then records are separated by sequences of one or more blank lines. Leading or trailing blank lines do not produce empty records at the beginning or end of input, and the field separator is always newline, no matter what the value of FS. |
| RSTART | The starting position of the string matched by the <code>match</code> function, numbering from 1. This is always equivalent to the return value of the <code>match</code> function.                                                                                                                                                                                                                                                            |
| SUBSEP | The subscript separator string for multi-dimensional arrays. The default value is <code>\034</code> .                                                                                                                                                                                                                                                                                                                                          |

`/usr/xpg4/bin/awk` The following variable is supported for `/usr/xpg4/bin/awk` only:

|         |                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| CONVFMT | The <code>printf</code> format for converting numbers to strings (except for output statements, where OFMT is used). The default is <code>%.6g</code> . |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------|

Regular Expressions The `/usr/xpg4/bin/nawk` utility makes use of the extended regular expression notation (see [regex\(5\)](#)) except that it allows the use of C-language conventions to escape special characters within the EREs, namely `\\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, and those specified in the following table. These escape sequences are recognized both inside and outside bracket expressions. Records need not be separated by newline characters and string constants can contain newline characters, so even the `\n` sequence is valid in `nawk` EREs. Using a slash character within the regular expression requires escaping as shown in the table below:

| Escape Sequence   | Description                                                                                                                                                                                                                                          | Meaning                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\"</code>   | Backslash quotation-mark                                                                                                                                                                                                                             | Quotation-mark character                                                                                                                                                                         |

| <code>\ddd</code> | A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NULL character), the behavior is undefined.                              | The character encoded by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences, including the leading <code>\</code> for each byte. |
| <code>\c</code>   | A backslash character followed by any character not described in this table or special characters ( <code>\\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> ). | Undefined                                                                                                                                                                                        |

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, `~` and `! ~`. These operators interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the `~` expression evaluates to the value 1, and the `! ~` expression evaluates to the value 0. If the regular expression does not match the string, the `~` expression evaluates to the value 0, and the `! ~` expression evaluates to the value 1. If the right-hand operand is any expression other than the lexical token `ERE`, the string value of the expression is interpreted as an extended regular expression, including the escape conventions described above. Notice that these same escape conventions also are applied in the determining the value of a string literal (the lexical token `STRING`), and is applied a second time when a string literal is used in this context.

When an `ERE` token appears as an expression in any context other than as the right-hand of the `~` or `! ~` operator or as one of the built-in function arguments described below, the value of the resulting expression is the equivalent of:

```
$0 ~ /ere/
```

The `ere` argument to the `gsub`, `match`, `sub` functions, and the `fs` argument to the `split` function (see `String Functions`) is interpreted as extended regular expressions. These can be either `ERE` tokens or arbitrary expressions, and are interpreted in the same manner as the right-hand side of the `~` or `! ~` operator.

An extended regular expression can be used to separate fields by using the `-F ERE` option or by assigning a string containing the expression to the built-in variable `FS`. The default value of the `FS` variable is a single space character. The following describes `FS` behavior:

1. If `FS` is a single character:
  - If `FS` is the space character, skip leading and trailing blank characters; fields are delimited by sets of one or more blank characters.
  - Otherwise, if `FS` is any other character `c`, fields are delimited by each single occurrence of `c`.
2. Otherwise, the string value of `FS` is considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression delimits fields.

Except in the `gsub`, `match`, `split`, and `sub` built-in functions, regular expression matching is based on input records. That is, record separator characters (the first character of the value of the variable `RS`, a newline character by default) cannot be embedded in the expression, and no expression matches the record separator character. If the record separator is not a newline character, newline characters embedded in the expression can be matched. In those four built-in functions, regular expression matching are based on text strings. So, any character (including the newline character and the record separator) can be embedded in the pattern and an appropriate pattern matches any character. However, in all `nawk` regular expression matching, the use of one or more `NULL` characters in the pattern, input record or text string produces undefined results.

- 
- Patterns** A *pattern* is any valid *expression*, a range specified by two expressions separated by comma, or one of the two special patterns BEGIN or END.
- Special Patterns** The nawk utility recognizes two special patterns, BEGIN and END. Each BEGIN pattern is matched once and its associated action executed before the first record of input is read (except possibly by use of the `getline` function in a prior BEGIN action) and before command line assignment is done. Each END pattern is matched once and its associated action executed after the last record of input has been read. These two patterns have associated actions.
- BEGIN and END do not combine with other patterns. Multiple BEGIN and END patterns are allowed. The actions associated with the BEGIN patterns are executed in the order specified in the program, as are the END actions. An END pattern can precede a BEGIN pattern in a program.
- If an nawk program consists of only actions with the pattern BEGIN, and the BEGIN action contains no `getline` function, nawk exits without reading its input when the last statement in the last BEGIN action is executed. If an nawk program consists of only actions with the pattern END or only actions with the patterns BEGIN and END, the input is read before the statements in the END actions are executed.
- Expression Patterns** An expression pattern is evaluated as if it were an expression in a Boolean context. If the result is true, the pattern is considered to match, and the associated action (if any) is executed. If the result is false, the action is not executed.
- Pattern Ranges** A pattern range consists of two expressions separated by a comma. In this case, the action is performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.
- Actions** An action is a sequence of statements. A statement can be one of the following:
- ```

if ( expression ) statement [ else statement ]
while ( expression ) statement
do statement while ( expression )
for ( expression ; expression ; expression ) statement
for ( var in array ) statement
delete array[subscript] #delete an array element
break
continue
{ [ statement ] . . . }
expression          # commonly variable = expression
print [ expression-list ] [ >expression ]
printf format [ ,expression-list ] [ >expression ]
next                # skip remaining patterns on this input line
exit [expr] # skip the rest of the input; exit status is expr
return [expr]
```

Any single statement can be replaced by a statement list enclosed in braces. The statements are terminated by newline characters or semicolons, and are executed sequentially in the order that they appear.

The `next` statement causes all further processing of the current input record to be abandoned. The behavior is undefined if a `next` statement appears or is invoked in a `BEGIN` or `END` action.

The `exit` statement invokes all `END` actions in the order in which they occur in the program source and then terminate the program without reading further input. An `exit` statement inside an `END` action terminates the program without further execution of `END` actions. If an expression is specified in an `exit` statement, its numeric value is the exit status of `nawk`, unless subsequent errors are encountered or a subsequent `exit` statement with an expression is executed.

Output Statements Both `print` and `printf` statements write to standard output by default. The output is written to the location specified by `output_redirection` if one is supplied, as follows:

```
> expression>> expression | expression
```

In all cases, the *expression* is evaluated to produce a string that is used as a full pathname to write into (for `>` or `>>`) or as a command to be executed (for `|`). Using the first two forms, if the file of that name is not currently open, it is opened, creating it if necessary and using the first form, truncating the file. The output then is appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value simply appends output to the file. The file remains open until the `close` function, which is called with an expression that evaluates to the same string value.

The third form writes output onto a stream piped to the input of a command. The stream is created if no stream is currently open with the value of *expression* as its command name. The stream created is equivalent to one created by a call to the `popen(3C)` function with the value of *expression* as the *command* argument and a value of `w` as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value writes output to the existing stream. The stream remains open until the `close` function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the `pclose` function.

These output statements take a comma-separated list of *expression s* referred in the grammar by the non-terminal symbols `expr_list`, `print_expr_list` or `print_expr_list_opt`. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The `print` statement writes the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable `OFS` above), and terminated by the output record separator (see variable `ORS` above). All expression arguments is taken as strings, being converted if necessary; with the exception that the `printf` format in `OFMT` is used instead of the value in `CONVFMT`. An empty expression list stands for the whole input record (`$0`).

The `printf` statement produces output based on a notation similar to the File Format Notation used to describe file formats in this document Output is produced as specified with the first expression argument as the string `format` and subsequent expression arguments as the strings `arg1` to `argn`, inclusive, with the following exceptions:

1. The *format* is an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The space character in the *format* string, in any context other than a *flag* of a conversion specification, is treated as an ordinary character that is copied to the output.
2. If the character set contains a Delta character and that character appears in the *format* string, it is treated as an ordinary character that is copied to the output.
3. The *escape sequences* beginning with a backslash character is treated as sequences of ordinary characters that are copied to the output. Note that these same sequences is interpreted lexically by `nawk` when they appear in literal strings, but they is not treated specially by the `printf` statement.
4. A *field width* or *precision* can be specified as the `*` character instead of a digit string. In this case the next argument from the expression list is fetched and its numeric value taken as the field width or precision.
5. The implementation does not precede or follow output from the `d` or `u` conversion specifications with blank characters not specified by the *format* string.
6. The implementation does not precede output from the `o` conversion specification with leading zeros not specified by the *format* string.
7. For the `c` conversion specification: if the argument has a numeric value, the character whose encoding is that value is output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value is output; if the string does not contain any characters the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument is evaluated. With the exception of the `c` conversion, the value is converted to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.
10. If any character sequence in the *format* string begins with a `%` character, but does not form a valid conversion specification, the behavior is unspecified.

Both `print` and `printf` can output at least `{LINE_MAX}` bytes.

Functions The `nawk` language has a variety of built-in functions: arithmetic, string, input/output and general.

Arithmetic Functions The arithmetic functions, except for `int`, are based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `[]` brackets), such use is undefined.

`atan2(y,x)` Return arctangent of y/x .

<code>cos(x)</code>	Return cosine of x , where x is in radians.
<code>sin(x)</code>	Return sine of x , where x is in radians.
<code>exp(x)</code>	Return the exponential function of x .
<code>log(x)</code>	Return the natural logarithm of x .
<code>sqrt(x)</code>	Return the square root of x .
<code>int(x)</code>	Truncate its argument to an integer. It is truncated toward 0 when $x > 0$.
<code>rand()</code>	Return a random number n , such that $0 \leq n < 1$.
<code>srand([expr])</code>	Set the seed value for <code>rand</code> to <i>expr</i> or use the time of day if <i>expr</i> is omitted. The previous seed value is returned.

String Functions The string functions in the following list shall be supported. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the [] brackets), such use is undefined.

<code>gsub(ere,repl[, in])</code>	Behave like <code>sub</code> (see below), except that it replaces all occurrences of the regular expression (like the <code>ed</code> utility global substitute) in <code>\$0</code> or in the <i>in</i> argument, when specified.
<code>index(s,t)</code>	Return the position, in characters, numbering from 1, in string <i>s</i> where string <i>t</i> first occurs, or zero if it does not occur at all.
<code>length([s])</code>	Return the length, in characters, of its argument taken as a string, or of the whole record, <code>\$0</code> , if there is no argument.
<code>match(s,ere)</code>	Return the position, in characters, numbering from 1, in string <i>s</i> where the extended regular expression <i>ere</i> occurs, or zero if it does not occur at all. <code>RSTART</code> is set to the starting position (which is the same as the returned value), zero if no match is found; <code>RLENGTH</code> is set to the length of the matched string, <code>-1</code> if no match is found.
<code>split(s,a[,fs])</code>	Split the string <i>s</i> into array elements $a[1], a[2], \dots, a[n]$, and return n . The separation is done with the extended regular expression <i>fs</i> or with the field separator <code>FS</code> if <i>fs</i> is not given. Each array element has a string value when created. If the string assigned to any array element, with any occurrence of the decimal-point character from the current locale changed to a period character, would be considered a <i>numeric string</i> ; the array element also has the numeric value of the <i>numeric string</i> . The effect of a null string as the value of <i>fs</i> is unspecified.

<code>sprintf(fmt,expr,expr,...)</code>	Format the expressions according to the <code>printf</code> format given by <i>fmt</i> and return the resulting string.
<code>sub(ere,repl[, in])</code>	Substitute the string <i>repl</i> in place of the first instance of the extended regular expression <i>ERE</i> in string <i>in</i> and return the number of substitutions. An ampersand (&) appearing in the string <i>repl</i> is replaced by the string from <i>in</i> that matches the regular expression. An ampersand preceded with a backslash (\) is interpreted as the literal ampersand character. An occurrence of two consecutive backslashes is interpreted as just a single literal backslash character. Any other occurrence of a backslash (for example, preceding any other character) is treated as a literal backslash character. If <i>repl</i> is a string literal, the handling of the ampersand character occurs after any lexical processing, including any lexical backslash escape sequence processing. If <i>in</i> is specified and it is not an <code>lva</code> lue the behavior is undefined. If <i>in</i> is omitted, <code>nawk</code> uses the current record (<code>\$0</code>) in its place.
<code>substr(s,m[, n])</code>	Return the at most <i>n</i> -character substring of <i>s</i> that begins at position <i>m</i> , numbering from 1. If <i>n</i> is missing, the length of the substring is limited by the length of the string <i>s</i> .
<code>tolower(s)</code>	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is an upper-case letter specified to have a <code>tolower</code> mapping by the <code>LC_CTYPE</code> category of the current locale is replaced in the returned string by the lower-case letter specified by the mapping. Other characters in <i>s</i> are unchanged in the returned string.
<code>toupper(s)</code>	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is a lower-case letter specified to have a <code>toupper</code> mapping by the <code>LC_CTYPE</code> category of the current locale is replaced in the returned string by the upper-case letter specified by the mapping. Other characters in <i>s</i> are unchanged in the returned string.

All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued expression that is a regular expression as defined below.

Input/Output and General Functions

The input/output and general functions are:

<code>close(expression)</code>	Close the file or pipe opened by a <code>print</code> or <code>printf</code> statement or a call to <code>getline</code> with the same string-valued <i>expression</i> . If the <code>close</code> was successful, the function returns <code>0</code> ; otherwise, it returns non-zero.
--------------------------------	--

expression|getLine[*var*] Read a record of input from a stream piped from the output of a command. The stream is created if no stream is currently open with the value of *expression* as its command name. The stream created is equivalent to one created by a call to the `popen` function with the value of *expression* as the *command* argument and a value of `r` as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value reads subsequent records from the file. The stream remains open until the `close` function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the `pclose` function. If *var* is missing, `$0` and `NF` is set. Otherwise, *var* is set.

The `getLine` operator can form ambiguous constructs when there are operators that are not in parentheses (including concatenate) to the left of the `|` (to the beginning of the expression containing `getLine`). In the context of the `$` operator, `|` behaves as if it had a lower precedence than `$`. The result of evaluating other operators is unspecified, and all such uses of portable applications must be put in parentheses properly.

`getLine` Set `$0` to the next input record from the current input file. This form of `getLine` sets the `NF`, `NR`, and `FNR` variables.

`getLine var` Set variable *var* to the next input record from the current input file. This form of `getLine` sets the `FNR` and `NR` variables.

`getLine [var] < expression` Read the next record of input from a named file. The *expression* is evaluated to produce a string that is used as a full pathname. If the file of that name is not currently open, it is opened. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value reads subsequent records from the file. The file remains open until the `close` function is called with an expression that evaluates to the same string value. If *var* is missing, `$0` and `NF` is set. Otherwise, *var* is set.

The `getLine` operator can form ambiguous constructs when there are binary operators that are not in parentheses (including concatenate) to the right of the `<` (up to the end of the expression containing the `getLine`). The result of evaluating such a construct is unspecified, and all such uses of portable applications must be put in parentheses properly.

`system(expression)` Execute the command given by *expression* in a manner equivalent to the `system(3C)` function and return the exit

status of the command.

All forms of `getline` return 1 for successful input, 0 for end of file, and -1 for an error.

Where strings are used as the name of a file or pipeline, the strings must be textually identical. The terminology “same string value” implies that “equivalent strings”, even those that differ only by space characters, represent different files.

User-defined Functions The nawk language also provides user-defined functions. Such functions can be defined as:

```
function name(args, . . .) { statements }
```

A function can be referred to anywhere in an nawk program; in particular, its use can precede its definition. The scope of a function is global.

Function arguments can be either scalars or arrays; the behavior is undefined if an array name is passed as an argument that the function uses as a scalar, or if a scalar expression is passed as an argument that the function uses as an array. Function arguments are passed by value if scalar and by reference if array name. Argument names are local to the function; all other variable names are global. The same name is not used as both an argument name and as the name of a function or a special nawk variable. The same name must not be used both as a variable name with global scope and as the name of a function. The same name must not be used within the same scope both as a scalar variable and as an array.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars are initialized with a string value of the null string and a numeric value of zero, and the extra parameters that are used in the function body as arrays are initialized as empty arrays. If more arguments are supplied in a function call than are in the function definition, the behavior is undefined.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function's parameters are unchanged, except for array parameters passed by reference. The `return` statement can be used to return a value. If a `return` statement appears outside of a function definition, the behavior is undefined.

In the function definition, newline characters are optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a *pattern-action* pair is allowed.

Usage The `index`, `length`, `match`, and `substr` functions should not be confused with similar functions in the ISO C standard; the nawk versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

See [largefile\(5\)](#) for the description of the behavior of `nawk` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples The `nawk` program specified in the command line is most easily specified within single-quotes (for example, `'program'`) for applications using `sh`, because `nawk` programs commonly contain characters that are special to the shell, including double-quotes. In the cases where a `nawk` program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
nawk '/'\''/ { print "quote:", $0 }'
```

prints all lines from the standard input containing a single-quote character, prefixed with `quote:.`

The following are examples of simple `nawk` programs:

EXAMPLE 1 Write to the standard output all input lines for which field 3 is greater than 5:

```
$3 > 5
```

EXAMPLE 2 Write every tenth line:

```
(NR % 10) == 0
```

EXAMPLE 3 Write any line with a substring matching the regular expression:

```
/(G|D)(2[0-9][[:alpha:]]*)/
```

EXAMPLE 4 Print any line with a substring containing a G or D, followed by a sequence of digits and characters:

This example uses character classes `digit` and `alpha` to match language-independent digit and alphabetic characters, respectively.

```
/(G|D)([[:digit:][:alpha:]]*)/
```

EXAMPLE 5 Write any line in which the second field matches the regular expression and the fourth field does not:

```
$2 ~ /xyz/ && $4 !~ /xyz/
```

EXAMPLE 6 Write any line in which the second field contains a backslash:

```
$2 ~ /\
```

EXAMPLE 7 Write any line in which the second field contains a backslash (alternate method):

Notice that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression.

```
$2 ~ "\\\""
```

EXAMPLE 8 Write the second to the last and the last field in each line, separating the fields by a colon:

```
{OFS=":";print $(NF-1), $NF}
```

EXAMPLE 9 Write the line number and number of fields in each line:

The three strings representing the line number, the colon and the number of fields are concatenated and that string is written to standard output.

```
{print NR ":" NF}
```

EXAMPLE 10 Write lines longer than 72 characters:

```
{length($0) > 72}
```

EXAMPLE 11 Write first two fields in opposite order separated by the OFS:

```
{ print $2, $1 }
```

EXAMPLE 12 Same, with input fields separated by comma or space and tab characters, or both:

```
BEGIN { FS = ", [\t]*|[\t]+" }
      { print $2, $1 }
```

EXAMPLE 13 Add up first column, print sum and average:

```
{s += $1 }
END {print "sum is ", s, " average is", s/NR}
```

EXAMPLE 14 Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

EXAMPLE 15 Write all lines between occurrences of the strings “start” and “stop”:

```
/start/, /stop/
```

EXAMPLE 16 Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

EXAMPLE 17 Simulate the echo command:

```
BEGIN {
  for (i = 1; i < ARGV; ++i)
    printf "%s%s", ARGV[i], i==ARGV-1?"\n":""
```

EXAMPLE 17 Simulate the echo command: (Continued)

```
}
```

EXAMPLE 18 Write the path prefixes contained in the PATH environment variable, one per line:

```
BEGIN {  
    n = split (ENVIRON["PATH"], path, ":")  
    for (i = 1; i <= n; ++i)  
        print path[i]  
}
```

EXAMPLE 19 Print the file "input", filling in page numbers starting at 5:

If there is a file named `input` containing page headers of the form

Page#

and a file named `program` that contains

```
/Page/{ $2 = n++; }  
{ print }
```

then the command line

```
nawk -f program n=5 input
```

prints the file `input`, filling in page numbers starting at 5.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect execution: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

LC_NUMERIC Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing awk programs (including assignments in command-line arguments).

Exit Status The following exit values are returned:

0 All input files were processed successfully.

>0 An error occurred.

The exit status can be altered within the program by using an `exit` expression.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/nawk	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/core-os

/usr/xpg4/bin/awk	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/xopen/xcu4

See Also [awk\(1\)](#), [ed\(1\)](#), [egrep\(1\)](#), [grep\(1\)](#), [lex\(1\)](#), [sed\(1\)](#), [popen\(3C\)](#), [printf\(3C\)](#), [system\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#), [XPG4\(5\)](#)

Aho, A. V., B. W. Kernighan, and P. J. Weinberger, *The AWK Programming Language*, Addison-Wesley, 1988.

Diagnostics If any *file* operand is specified and the named file cannot be accessed, nawk writes a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *progfile* operand is not a valid nawk program (as specified in EXTENDED DESCRIPTION), the behavior is undefined.

Notes Input white space is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string ("") to it.

Name nc, netcat – arbitrary TCP and UDP connections and listens

Synopsis nc -h

```
nc [-46dnrtuvz] [-i interval] [-P proxy_username] [-p port]
  [-s source_ip_address] [-T dspc] [-w timeout]
  [-X proxy_protocol] [-x proxy_address[:port]][-L timeout]
  [-e program] [-b bufsize] [-q timeout] [-m bytes]
  [-I bufsize][-O bufsize] hostname port_list

nc -l [-46DdEFnrtuvzZ] [-i interval] [-T dspc] [-e program]
  [-b bufsize] [-q timeout] [-R address/port[/proto]] [-m bytes]
  [-L timeout] [-I bufsize] [-O bufsize] [hostname] port

nc -l [-46DEFdnrtuvzZ] [-i interval] [-T dspc] [-e program]
  [-b bufsize] [-q timeout] [-R address/port[/proto]] [-m bytes]
  [-L timeout] [-I bufsize] [-O bufsize]
  -p port [hostname]

nc -U [-Ddtvz] [-i interval] [-w timeout] [-e program]
  [-b bufsize] [-q timeout] [-m bytes] path

nc -Ul [-46DdktvZ] [-i interval] [-e program] [-b bufsize]
  [-q timeout] [-R address/port[/proto]] [-m bytes] path
```

Description The nc (or net cat) utility is used for a variety of tasks associated with TCP or UDP. nc can open TCP connections, send UDP packets, listen on arbitrary TCP and UDP ports, perform port scanning, and deal with both IPv4 and IPv6. Unlike [telnet\(1\)](#), nc scripts nicely, and separates error messages onto standard error instead of sending them to standard output.

The nc command is often used for the following tasks:

- simple TCP proxies
- shell-script based HTTP clients and servers
- network daemon testing
- a SOCKS or HTTP ProxyCommand for [ssh\(1\)](#)

The nc command can also be run as net cat, using the identical options.

Options The following options are supported:

```
-4
  Force nc to use IPv4 addresses only.

-6
  Force nc to use IPv6 addresses only.

-b bufsize
  Specify buffer size for read operations.
```

The default value is 1024 bytes.

-
- D
Enable debugging on the socket.
 - d
Do not attempt to read from `stdin`.
 - E
Use exclusive bind for listening TCP or UDP socket.

It is an error to use this option without the `-l` option.

This option does not have any effect when used in conjunction with the `-U` option.
 - e *program*
Execute external program after accepting a connection or making connection. Before the execution `stdin`, `stdout`, `stderr` is redirected to the network descriptor. Only one port can be used with this option.

It is an error to use this option in conjunction with the `-R`, `-k`, or `-i` options.
 - F
Do not close network socket for writing after seeing EOF on `stdin`.
 - h
Print `nc` help.
 - I *bufsize*
Set receive (input) socket buffer size.

This option does not have any effect when used in conjunction with the `-U` option.
 - i *interval*
Specify a delay time of *interval* between lines of text sent and received.

The interval is specified in seconds, with possible fractions.

This option also causes a delay time between connections to multiple ports, and therefore also affects port scan mode.
 - k
Force `nc` to listen for another connection after its current connection is closed.

It is an error to use this option without the `-l` option.

It is an error to use this option in conjunction with the `-e` option.
 - L *timeout*
Linger on close - wait for messages to be sent after network descriptor is closed up to specified timeout in seconds.

-l

Listen for an incoming connection rather than initiate a connection to a remote host.

It is an error to use this option in conjunction with the -s or -z options.

If the -l option is used with a wildcard socket (no IP address or hostname specified) and without the -4/-6 options, it accepts both IPv4 and IPv6 connections.

-m *byte_count*

Quit after receiving at least *byte_count* bytes. When used with -l option *byte_count* is compared to number of bytes received from the client.

byte_count must be greater than 0 and less than INT_MAX.

-N *file*

Specifies file with pattern for UDP port scanning. The contents of this file are used as payload for each emitted UDP packet.

It is an error to use this option without the -u and -z options.

-n

Do not do any naming or service lookups on any addresses, hostnames, or ports.

Use of this option means that *hostname* and *port* arguments are restricted to numeric values.

If used with -v option all addresses and ports are printed in numeric form, in addition to the restriction imposed on the arguments. This option does not have any effect when used in conjunction with the -U option.

-O *bufsize*

Set send (output) socket buffer size.

This option does not have any effect when used in conjunction with the -U option.

-P *proxy_username*

Specify a username (*proxy_username*) to present to a proxy server that requires authentication. If *proxy_username* is not specified, authentication is not attempted. Proxy authentication is only supported for HTTP CONNECT proxies at present.

It is an error to use this option in conjunction with the -l option.

-p *port*

When used without -l option, specify the source port nc should use, subject to privilege restrictions and availability. When used with the -l option, set the listen port.

This option can be used with -l option only provided global port argument is not specified.

-q *timeout*

After receiving EOF on stdin, wait for specified number of seconds and quit.

-R *addr/port[/proto]*

Perform port redirection to given *host* and *port*.

After the connection has been accepted, nc connects to the remote *host/port* and passes all data between the client and the remote host. The *proto* (protocol) part of the redirect specification can be either *tcp* or *udp*. If the *proto* is not specified, *redirector* uses the same protocol as the server.

It is an error to use this option in conjunction with the *-z* option.

-r

Choose destination ports randomly instead of sequentially within all ports specified by the *port_list* argument.

It is an error to use this option in conjunction with the *-l* option.

-s *source_ip_address*

Specify the IP of the interface which is used to send the packets.

It is an error to use this option in conjunction with the *-l* option.

-T *dscp*

Specify Differentiated Services Code Point for the connection.

For IPv4 this specifies the IP Type of Service (ToS) IP header field and the valid values for the argument are the string tokens: *lowdelay*, *throughput*, *reliability*, or an 8-bit hexadecimal value preceded by *0x*.

For IPv6 (Traffic Class) only hexadecimal value can be used.

-t

Cause nc to send *RFC 854 DON'T* and *WON'T* responses to *RFC 854 DO* and *WILL* requests. This makes it possible to use nc to script *telnet* sessions.

-U

Specify the use of Unix Domain Sockets. If you specify this option without *-l*, nc, it becomes *AF_UNIX* client. If you specify this option with the *-l* option, a *AF_UNIX* server is created.

Use of this option requires that a single argument of a valid Unix domain path has to be provided to nc, not a host name or port.

-u

Use UDP instead of the default option of TCP.

-v

Specify verbose output.

-w *timeout*

Silently close the connection if a connection and *stdin* are idle for more than *timeout* seconds.

The default is no timeout.

This option has no effect on the connection establishment phase in client mode or waiting for a connection in server mode.

-X *proxy_protocol*

Use the specified protocol when talking to the proxy server. Supported protocols are 4 (SOCKS v. 4), 5 (SOCKS v. 5) and connect (HTTP proxy). If the protocol is not specified, SOCKS v. 5 is used.

It is an error to use this option in conjunction with the `-l` option.

-x *proxy_address[:port]*

Request connection to *hostname* using a proxy at *proxy_address* and *port*. If *port* is not specified, the well-known port for the proxy protocol is used (1080 for SOCKS, 3128 for HTTP).

It is an error to use this option in conjunction with the `-l` option.

This option does not work with numeric representation of IPv6 addresses.

-Z

In listening mode bind to address/port in all zones using the `SO_ALLZONES` socket option.

This option requires `SYS_NET_CONFIG` privilege.

-z

Perform port scan. For TCP ports (default), connect scan (full 3-way handshake) is tried with no data sent. For UDP (`-u`) empty UDP packets are sent by default. To specify UDP payload the `-N` option can be used.

The UDP scan mode is estimative, it considers a port to be open if it does not receive negative response (ICMP Destination Port Unreachable message). For this mode the timeout set with the `-w` option is used to wait for the ICMP messages or data from remote node. With `-v` any received data is dumped as hexadecimal bytes to `stderr`.

As most of the operating systems employ rate limiting for sending ICMP messages in reaction to input packets, it is necessary to use `-i` when performing UDP scan otherwise the results is not reliable.

It is an error to use this option in conjunction with the `-l` option.

Operands The following operands are supported:

hostname Specify host name.

hostname can be a numerical IP address or a symbolic hostname (unless the `-n` option is specified).

In general, *hostname* must be specified, unless the `-l` option is given or `-U` is used (in which case the argument is a path). If *hostname* argument is specified with `-l` option then *port* argument must be given as well and nc tries to bind to that address and port. If *hostname* argument is not specified with `-l` option then nc tries to listen on a wildcard socket for given *port*.

path Specify pathname.

port

port_list Specify port.

port_list can be specified as single integers, ranges or combinations of both. Specify ranges in the form of *nn-mm*. The *port_list* must have at least one member, but can have multiple ports/ranges separated by commas.

In general, a destination port must be specified, unless the `-U` option is given, in which case a Unix Domain Socket path must be specified instead of *hostname*.

It is an error to use list of ports containing more than one port in conjunction with the `-e` option.

Usage

Client/Server Model It is quite simple to build a very basic client/server model using nc. On one console, start nc listening on a specific port for a connection. For example, the command:

```
$ nc -l 1234
```

listens on port 1234 for a connection. On a second console (or a second machine), connect to the machine and port to which nc is listening:

```
$ nc 127.0.0.1 1234
```

There should now be a connection between the ports. Anything typed at the second console is concatenated to the first, and vice-versa. After the connection has been set up, nc does not really care which side is being used as a *server* and which side is being used as a *client*. The connection can be terminated using an EOF (Ctrl/d).

Data Transfer The example in the previous section can be expanded to build a basic data transfer model. Any information input into one end of the connection is output to the other end, and input and output can be easily captured in order to emulate file transfer.

Start by using nc to listen on a specific port, with output captured into a file:

```
$ nc -l 1234 > filename.out
```

Using a second machine, connect to the listening nc process, feeding it the file which is to be transferred:

```
$ nc host.example.com 1234 < filename.in
```

After the file has been transferred, the connection closes automatically.

Talking to Servers It is sometimes useful to talk to servers *by hand* rather than through a user interface. It can aid in troubleshooting, when it might be necessary to verify what data a server is sending in response to commands issued by the client.

For example, to retrieve the home page of a web site:

```
$ echo -n "GET / HTTP/1.0\r\n\r\n" | nc host.example.com 80
```

This also displays the headers sent by the web server. They can be filtered, if necessary, by using a tool such as [sed\(1\)](#).

More complicated examples can be built up when the user knows the format of requests required by the server. As another example, an email can be submitted to an SMTP server using:

```
$ nc localhost 25 << EOF
HELO host.example.com
MAIL FROM: <user@host.example.com>
RCTP TO: <user2@host.example.com>
DATA
Body of email.
.
QUIT
EOF
```

Port Scanning It can be useful to know which ports are open and running services on a target machine. The `-z` flag can be used to tell `nc` to report open ports, rather than to initiate a connection.

In this example:

```
$ nc -z host.example.com 20-30
Connection to host.example.com 22 port [tcp/ssh] succeeded!
Connection to host.example.com 25 port [tcp/smtp] succeeded!
```

The port range was specified to limit the search to ports 20 - 30.

Alternatively, it might be useful to know which server software is running, and which versions. This information is often contained within the greeting banners. In order to retrieve these, it is necessary to first make a connection, and then break the connection when the banner has been retrieved. This can be accomplished by specifying a small timeout with the `-w` flag, or perhaps by issuing a `QUIT` command to the server:

```
$ echo "QUIT" | nc host.example.com 20-30
SSH-2.0-Sun_SSH_1.1
Protocol mismatch.
```

220 host.example.com IMS SMTP Receiver Version 0.84 Ready

inetd Capabilities One of the possible uses is to create simple services by using [inetd\(1M\)](#).

The following example creates a redirect from TCP port 8080 to port 80 on host realwww:

```
# cat << EOF >> /etc/services
wwwredir  8080/tcp  # WWW redirect
EOF
# cat << EOF > /tmp/wwwredir.conf
wwwredir stream tcp nowait nobody /usr/bin/nc /usr/bin/nc -w 3 realwww 80
EOF
# inetconv -i /tmp/wwwredir.conf
wwwredir -> /var/svc/manifest/network/wwwredir-tcp.xml
Importing wwwredir-tcp.xml ...Done
# inetadm -l wwwredir/tcp
SCOPE    NAME=VALUE
name="wwwredir"
endpoint_type="stream"
proto="tcp"
isrpc=FALSE
wait=FALSE
exec="/usr/bin/nc -w 3 realwww 80"
arg0="/usr/bin/nc"
user="nobody"
default  bind_addr=""
default  bind_fail_max=-1
default  bind_fail_interval=-1
default  max_con_rate=-1
default  max_copies=-1
default  con_rate_offline=-1
default  failrate_cnt=40
default  failrate_interval=60
default  inherit_env=TRUE
default  tcp_trace=TRUE
default  tcp_wrappers=FALSE
```

Privileges To bind to a privileged port number nc needs to be granted the `net_privaddr` privilege. If Solaris Trusted Extensions are configured and the port nc should listen on is configured as a multi-level port nc also needs the `net_bindmlp` privilege.

Privileges can be assigned to the user or role directly, by specifying them in the account's default privilege set in [user_attr\(4\)](#). However, this means that any application that this user or role starts have these additional privileges. To only grant the [privileges\(5\)](#) when nc is invoked, the recommended approach is to create and assign an [rbac\(5\)](#) rights profile. See [EXAMPLES](#) for additional information.

Examples EXAMPLE 1 Using nc

Open a TCP connection to port 42 of host . example . com, using port 3141 as the source port, with a timeout of 5 seconds:

```
$ nc -p 3141 -w 5 host.example.com 42
```

Open a UDP connection to port 53 of host . example . com:

```
$ nc -u host.example.com 53
```

Open a TCP connection to port 42 of host . example . com using 10 . 1 . 2 . 3 as the IP for the local end of the connection:

```
$ nc -s 10.1.2.3 host.example.com 42
```

Use a list of ports and port ranges for a port scan on various ports:

```
$ nc -z host.example.com 21-25,53,80,110-120,443
```

Create and listen on a Unix Domain Socket:

```
$ nc -lU /var/tmp/dsocket
```

Create and listen on a UDP socket with associated port 8888:

```
$ nc -u -l -p 8888
```

which is the same as:

```
$ nc -u -l 8888
```

Create and listen on a TCP socket with associated port 2222 and bind to address 127 . 0 . 0 . 1 only:

```
$ nc -l 127.0.0.1 2222
```

Connect to TCP port, send some data and terminate the connection with TCP RST segment (instead of classic TCP closing handshake) by setting the linger option and timeout to 0:

```
$ echo "foo" | nc -L 0 host.example.com 22
```

Perform port redirection to port 22 on host host . example . com from local port 4545:

```
$ nc -R host.example.com/22 -l 4545
```

After that, it should be possible to run [ssh\(1\)](#) client and connect to host . example . com using host redir . example . com running the above command:

```
$ ssh -oStrictHostKeyChecking=no -p 4545 redir.example.com
```

It is also possible to let nc listen on TCP port and convert the TCP data stream to UDP (or vice versa):

EXAMPLE 1 Using nc (Continued)

```
$ nc -R host.example.com/53/udp -l 4666
```

Connect to port 42 of `host.example.com` using an HTTP proxy at `10.2.3.4`, port `8080`. This example could also be used by [ssh\(1\)](#). See the `ProxyCommand` directive in [ssh_config\(4\)](#) for more information.

```
$ nc -x10.2.3.4:8080 -Xconnect host.example.com 42
```

The same example again, this time enabling proxy authentication with username `ruser` if the proxy requires it:

```
$ nc -x10.2.3.4:8080 -Xconnect -Pruser host.example.com 42
```

Basic UDP port scan can be efficiently done like this:

```
$ nc -z -w 3 -u -i 0.5 host.example.com 11-100
```

Between each 2 ports it pauses for 0.5 second (thus evading ICMP message rate limiting) and waits up to 3 seconds for reply. If no reply comes then the port might be open.

To run `nc` with the smallest possible set of privileges as a user or role that has additional privileges (such as the default root account) it can be invoked using [ppriv\(1\)](#) as well. For example, limiting it to only run with the privilege to bind to a privileged port:

```
$ ppriv -e -sA=basic,!file_link_any,!proc_exec,!proc_fork,\
!proc_info,!proc_session,net_privaddr nc -l 42
```

To allow a user or role to use only `nc` with the `net_privaddr` privilege, a rights profile needs to be created:

```
/etc/security/exec_attr
Netcat privileged:solaris:cmd:::/usr/bin/nc:privs=net_privaddr
```

```
/etc/security/prof_attr
Netcat privileged:::Allow nc to bind to privileged ports:help=None.html
```

Assigning this rights profile using [user_attr\(4\)](#) permits the user or role to run `nc` allowing it to listen on any port. To permit a user or role to use `nc` only to listen on specific ports a wrapper script should be specified in the rights profiles:

```
/etc/security/exec_attr
Netcat restricted:solaris:cmd:::/usr/bin/nc-restricted:privs=net_privaddr
```

```
/etc/security/prof_attr
Netcat restricted:::Allow nc to bind to privileged ports:help=None.html
```

and write a shell script that restricts the permissible options, for example, one that permits one to bind only on ports between 42 and 64 (non-inclusive):

EXAMPLE 1 Using nc (Continued)

```
/usr/bin/nc-restricted:
```

```
#!/bin/sh
[ $# -eq 1 ] && [ $1 -gt 42 -a $1 -lt 64 ] && /usr/bin/nc -l -p "$1"
```

This grants the extra privileges when the user or role invokes nc using the wrapper script from a profile shell. See [pfsh\(1\)](#), [pfksh\(1\)](#), [pfcsh\(1\)](#), and [pfexec\(1\)](#).

Invoking nc directly does not run it with the additional privileges, and neither does invoking the script without using pfexec or a profile shell.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/netcat
Interface Stability	See below.

The package name is Committed. The command line syntax is Committed for the `-4`, `-6`, `-l`, `-n`, `-p`, `-u`, and `-w` options and their arguments (if any). The *name* and *port* list arguments are Committed. The port range syntax is Uncommitted. The interface stability level for all other command line options and their arguments is Uncommitted.

See Also [cat\(1\)](#), [pfcsh\(1\)](#), [pfexec\(1\)](#), [pfksh\(1\)](#), [pfsh\(1\)](#), [ppriv\(1\)](#), [sed\(1\)](#), [ssh\(1\)](#), [telnet\(1\)](#), [inetadm\(1M\)](#), [inetconv\(1M\)](#), [inetd\(1M\)](#), [ssh_config\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#), [rbac\(5\)](#)

Authors The original implementation of nc was written by Hobbit, hobbit@avian.org.

nc was rewritten with IPv6 support by Eric Jackson, ericj@monkey.org.

Notes If an instance of nc is listening on a wildcard socket (regardless of address family specification) it is still possible to bind another nc process to concrete IP address and accept connections to this address. For example, with the following process running:

```
$ nc -4 -l 5656
```

it is possible to run another nc process listening on specific IP address and the same port:

```
$ nc -4 -l 10.20.30.40 5656
```

TCP connection to address `10.20.30.40` and port `5656` is accepted by the latter process, all TCP connections to port `5656` and different addresses is accepted by the former process.

Also, it is possible to steal IPv4 connections from a process which listens on a wildcard socket (without address family specification) by binding to IPv4 wildcard socket. To suppress this and the behavior described above the `-E` option could be used.

Name ncab2clf – convert binary log file to Common Log File format

Synopsis /usr/bin/ncab2clf [-Dhv] [-i *input-file*] [-o *output-file*]
[-b *size*] [-n *number*] [-s *datetime*]

Description The `ncab2clf` command is used to convert the log file generated by the Solaris Network Cache and Accelerator (NCA) from binary format, to Common Log File (CLF) format. If no *input-file* is specified, `b2clf` uses `stdin`. If no *output-file* is specified, the output goes to `stdout`.

Options

- b Specifies the binary-log-file blocking in kilobytes; the default is 64 Kbyte.
- D Specifies that direct I/O be disabled.
- h Prints usage message.
- i *input-file* Specifies the input file.
- n *number* Output *number* CLF records.
- o *output-file* Specifies the output file.
- s *datetime* Skip any records before the date and time specified in *datetime*. You can specify the date and time in CLF format or in the format specified by the [touch\(1\)](#) utility. CLF format is the dominant format, so `b2clf` first analyzes *datetime* assuming CLF.
- v Provides verbose output.

Examples EXAMPLE 1 Converting a Binary File to a Common Log File Format

The following example converts the binary file `/var//logs/.blf` to a file `/var//logs/.clf`, which is in Common Log File format.

```
example% ncab2clf -D -i /var/nca/logs/nca.blf -o /var/nca/logs/nca.clf
```

EXAMPLE 2 Converting Multiple Log Files

The following script may be used to convert multiple log files. The directory designated by “*” must only contain log files.

```
#!/bin/ksh
for filename in *
do
    ncab2clf -D < $filename > $filename.clf
done
```

EXAMPLE 3 Using -s and -n on a Raw Device

The following example shows how `ncab2clf` can be used on a raw device. If not using the `-n` option, the default is to convert all records from the starting location to the end of the file. The date and time specified with `-s`, below, is in CLF format.

EXAMPLE 3 Using -s and -n on a Raw Device *(Continued)*

```
example% ncab2clf -s '10/Apr/2001:09:23:13' -n 100 < /dev/dsk/c2t1d0s6
```

Exit Status The following exit values are returned:

- 0 The file converted successfully
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/http-cache-accelerator
Interface Stability	Committed

See Also [ncakmod\(1\)](#), [nca.if\(4\)](#), [ncakmod.conf\(4\)](#), [ncalogd.conf\(4\)](#), [attributes\(5\)](#), [nca\(7d\)](#)

System Administration Guide: IP Services

Notes The binary log files generated by NCA can become very large. When converting these large binary files, use the -b option to the ncab2clf command to help performance.

Direct I/O is a benefit to the user if the data being written does not come in as large chunks. However, if the user wishes to convert the log file in large chunks using the -b option, then direct I/O should be disabled by using the -D option.

Name ncakmod – start or stop the NCA kernel module

Synopsis /etc/init.d/ncakmod start | stop

Description ncakmod is used to start or stop the Solaris Network Cache and Accelerator (NCA) kernel module.

When the `start` option is specified at the command-line, the NCA kernel module will be activated for all physical interfaces listed in the `nca.if` file. When the `ncakmod` command is invoked with the `stop` option, the NCA kernel module will print the following message:

```
To stop NCA, please set the status configuration parameter
to disable in ncakmod.conf and then reboot your system. See
the ncakmod.conf(4) manual page for more information.
```

To properly stop NCA on your system, you must first edit the `ncakmod.conf(4)` file and set the status field to “disable,” then reboot your system.

Options `start` Starts the NCA kernel module.

`stop` Describes the current method for stopping the NCA feature.

Examples **EXAMPLE 1** Starting and Stopping the NCA Feature

The following command is used to start the NCA feature:

```
example% /etc/init.d/ncakmod start
```

Files /etc/init.d/ncakmod The NCA kernel module startup script.

/etc/nca/ncakmod.conf Specifies configuration options for the NCA kernel module.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/http-cache-accelerator
Interface Stability	Committed

See Also [ncab2clf\(1\)](#), [ncad_addr\(4\)](#), [nca.if\(4\)](#), [ncakmod.conf\(4\)](#), [ncalogd.conf\(4\)](#), [attributes\(5\)](#), [nca\(7d\)](#)

Name newform – change the format of a text file

Synopsis newform [-s] [-i*tabspec*] [-o*tabspec*] [-bn] [-en] [-pn]
[-an] [-f] [-cchar] [-ln] [*filename*]. . .

Description newform reads lines from the named *filenames*, or the standard input if no input file is named, and reproduces the lines on the standard output. Lines are reformatted in accordance with command line options in effect.

Except for -s, command line options may appear in any order, may be repeated, and may be intermingled with the optional *filenames*. Command line options are processed in the order specified. This means that option sequences like “-e15 -l60” will yield results different from “-l60 -e15”. Options are applied to all *filenames* on the command line.

Options The following options are supported:

-s Shears off leading characters on each line up to the first tab and places up to 8 of the sheared characters at the end of the line. If more than 8 characters (not counting the first tab) are sheared, the eighth character is replaced by a * and any characters to the right of it are discarded. The first tab is always discarded.

An error message and program exit will occur if this option is used on a file without a tab on each line. The characters sheared off are saved internally until all other options specified are applied to that line. The characters are then added at the end of the processed line.

For example, to convert a file with leading digits, one or more tabs, and text on each line, to a file beginning with the text, all tabs after the first expanded to spaces, padded with spaces out to column 72 (or truncated to column 72), and the leading digits placed starting at column 73, the command would be:

```
newform -s -i -l -a -e filename
```

-i*tabspec* Input tab specification: expands tabs to spaces, according to the tab specifications given. *Tabspec* recognizes all tab specification forms described in [tabs\(1\)](#). In addition, *tabspec* may be -, in which newform assumes that the tab specification is to be found in the first line read from the standard input (see [fspec\(4\)](#)). If no *tabspec* is given, *tabspec* defaults to -8. A *tabspec* of -0 expects no tabs; if any are found, they are treated as -1.

-o*tabspec* Output tab specification: replaces spaces by tabs, according to the tab specifications given. The tab specifications are the same as for -i*tabspec*. If no *tabspec* is given, *tabspec* defaults to -8. A *tabspec* of -0 means that no spaces will be converted to tabs on output.

-bn Truncate *n* characters from the beginning of the line when the line length is greater than the effective line length (see -ln). Default is to truncate the number of characters necessary to obtain the effective line length. The default

value is used when `-b` with no `n` is used. This option can be used to delete the sequence numbers from a COBOL program as follows:

```
newform -l1 -b7 filename
```

- `-en` Same as `-bn` except that characters are truncated from the end of the line.
- `-pn` Prefix `n` characters (see `-cchar`) to the beginning of a line when the line length is less than the effective line length. Default is to prefix the number of characters necessary to obtain the effective line length.
- `-an` Same as `-pn` except characters are appended to the end of a line.
- `-f` Write the tab specification format line on the standard output before any other lines are output. The tab specification format line which is printed will correspond to the format specified in the `last -o` option. If no `-o` option is specified, the line which is printed will contain the default specification of `-8`.
- `-cchar` Change the prefix/append character to `char`. Default character for `char` is a space.
- `-ln` Set the effective line length to `n` characters. If `n` is not entered, `-l` defaults to 72. The default line length without the `-l` option is 80 characters. Note: Tabs and backspaces are considered to be one character (use `-i` to expand tabs to spaces).

The `-l1` must be used to set the effective line length shorter than any existing line in the file so that the `-b` option is activated.

Operands The following operand is supported:

filename Input file

Exit Status The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [csplit\(1\)](#), [tabs\(1\)](#), [fspec\(4\)](#), [attributes\(5\)](#)

Diagnostics All diagnostics are fatal.

- usage: . . . newform was called with a bad option.
- "not -s format" There was no tab on one line.

"can't open file"	Self-explanatory.
"internal line too long"	A line exceeds 512 characters after being expanded in the internal work buffer.
"tabspec in error"	A tab specification is incorrectly formatted, or specified tab stops are not ascending.
"tabspec indirection illegal"	A <i>tabspec</i> read from a file (or standard input) may not contain a <i>tabspec</i> referencing another file (or standard input).

Notes *newform* normally only keeps track of physical characters; however, for the `-i` and `-o` options, *newform* will keep track of backspaces in order to line up tabs in the appropriate logical columns.

newform will not prompt the user if a *tabspec* is to be read from the standard input (by use of `-i-` or `-o-`).

If the `-f` option is used, and the last `-o` option specified was `-o-`, and was preceded by either a `-o-` or a `-i-`, the tab specification format line will be incorrect.

Name newgrp – log in to a new group

Synopsis

Command /usr/bin/newgrp [-| -l] [*group*]

sh Built-in newgrp [*argument*]

ksh88 Built-in *newgrp [*argument*]

ksh Built-in +newgrp [*argument*]

Description

Command The `newgrp` command logs a user into a new group by changing a user's real and effective group ID. The user remains logged in and the current directory is unchanged. The execution of `newgrp` always replaces the current shell with a new shell, even if the command terminates with an error (unknown group).

Any variable that is not exported is reset to null or its default value. Exported variables retain their values. System variables (such as `PS1`, `PS2`, `PATH`, `MAIL`, and `HOME`), are reset to default values unless they have been exported by the system or the user. For example, when a user has a primary prompt string (`PS1`) other than `$` (default) and has not exported `PS1`, the user's `PS1` is set to the default prompt string `$`, even if `newgrp` terminates with an error. Note that the shell command `export` (see [sh\(1\)](#) and [set\(1\)](#)) is the method to export variables so that they retain their assigned value when invoking new shells.

With no operands and options, `newgrp` changes the user's group IDs (real and effective) back to the group specified in the user's password file entry. This is a way to exit the effect of an earlier `newgrp` command.

A password is demanded if the group has a password and the user is not listed in `/etc/group` as being a member of that group. The only way to create a password for a group is to use [passwd\(1\)](#), then cut and paste the password from `/etc/shadow` to `/etc/group`. Group passwords are antiquated and not often used.

sh Built-in Equivalent to `exec newgrp argument` where *argument* represents the options and/or operand of the `newgrp` command.

ksh88 Built-in Equivalent to `exec to/bin/newgrp argument` where *argument* represents the options and/or operand of the `newgrp` command.

On this man page, [ksh88\(1\)](#) commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.

3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ****** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ksh Built-in Equivalent to `exec to/bin/newgrp argument` where *argument* represents the options and/or operand of the `newgrp` command.

On this man page, [ksh\(1\)](#) commands that are preceded by one or two + (plus signs) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. They are not valid function names.
5. Words, following a command preceded by **++** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and field splitting and file name generation are not performed.

Options The following option is supported:

- l | - Change the environment to what would be expected if the user actually logged in again as a member of the new group.

Operands The following operands are supported:

group A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs is set. If *group* is a non-negative numeric string and exists in the group database as a group name (see [getgrnam\(3C\)](#)), the numeric group ID associated with that group name is used as the group ID.

argument sh and ksh88 only. Options and/or operand of the `newgrp` command.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `newgrp`: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status If `newgrp` succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status is the exit status of the shell. Otherwise, the following exit value is returned:

- >0 An error occurred.

Files /etc/group System group file
 /etc/passwd System password file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name newtask – create new task and optionally change project

Synopsis newtask [-p *project*] [-v] [-c *pid* | [-F \l] [*command...*]]

Description The `newtask` command executes the user's default shell or a specified command, placing the executed command in a new task owned by the specified project. The user's default shell is the one specified in the `passwd` database, and is determined using `getpwnam()`.

Alternatively, `newtask` can be used to cause an already running process to enter a newly created task. A project for the new task can also be specified in this form of the command. This might be desirable for processes that are mission critical and cannot be restarted in order to put them into a new project.

In the case that extended accounting is active, the `newtask` command can additionally cause the creation of a task accounting record marking the completion of the preceding system task.

Options The following options are supported:

-c *pid* Cause a running process to enter a newly created task. A project for the new task can also be specified using the `-p` option. The invoking user must either own the process or have super-user privileges.

If the project is being changed, the process owner must be a member of the specified project, or the invoking user must have super-user privileges. When the project is changed for a running process, its pool binding as well as resource controls are modified to match the configuration of the new project. Controls not explicitly specified in the project entry is preserved.

This option is incompatible with the `-F` and `-l` options.

-F Creates a finalized task, within which further `newtask` or `settaskid(2)` invocations would fail. Finalized tasks can be useful at some sites for simplifying the attribution of resource consumption.

-l Changes the environment to what would be expected if the user actually logged in again as a member of the new project.

-p Changes the project ID of the new task to that associated with the given project name. The invoking user must be a valid member of the requested project, or must have super-user privileges, for the command to succeed. If no project name is specified, the new task is started in the invoking user's current project.

-v Verbose: displays the system task id as the new system task is begun.

Operands The following operands are supported:

project The project to which resource usage by the created task should be charged. The requested project must be defined in the project databases defined in `nsswitch.conf(4)`.

command The command to be executed as the new task. If no command is given, the user's login shell is invoked. (If the login shell is not available, `/bin/sh` is invoked.)

Examples EXAMPLE 1 Creating a New Shell

The following example creates a new shell in the `canada` project, displaying the task id:

```
example$ id -p
uid=565(gh) gid=10(staff) projid=10(default)
example$ newtask -v -p canada
38
example$ id -p
uid=565(gh) gid=10(staff) projid=82(canada)
```

EXAMPLE 2 Running the date Command

The following example runs the `date` command in the `russia` project:

```
example$ newtask -p russia date
Tue Aug 31 11:12:10 PDT 1999
```

EXAMPLE 3 Changing the Project of an Existing Process

The following example changes the project of the existing process with a pid of 9999 to `russia`:

```
example$ newtask -c 9999 -p russia
```

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 A fatal error occurred during execution.
- 2 Invalid command line options were specified.

Files `/etc/project` Local database containing valid project definitions for this machine.
`/proc/pid/*` Process information and control files.

Attributes See [attributes\(5\)](#) for a description of the following attributes:

Name	nice – invoke a command with an altered scheduling priority
Synopsis	<pre>/usr/bin/nice [-increment -n increment] command [argument]...</pre> <pre>/usr/xpg4/bin/nice [-increment -n increment] command [argument]...</pre>
csht Builtin	nice [-increment +increment] [command]
Description	<p>The nice utility invokes <i>command</i>, requesting that it be run with a different system scheduling priority. The <code>prctl(1)</code> command is a more general interface to scheduler functions.</p> <p>The invoking process (generally the user's shell) must be in a scheduling class that supports nice.</p> <p>If the C shell (see <code>csht(1)</code>) is used, the full path of the command must be specified. Otherwise, the <code>csht</code> built-in version of nice will be invoked. See <code>csht Builtin</code> below.</p> <p><code>/usr/bin/nice</code> If nice executes commands with arguments, it uses the default shell <code>/usr/bin/sh</code> (see <code>sh(1)</code>).</p> <p><code>/usr/xpg4/bin/nice</code> If nice executes commands with arguments, it uses <code>/usr/xpg4/bin/sh</code> (see <code>ksh88(1)</code>).</p> <p><code>csht Builtin</code> nice is also a <code>csht</code> built-in command with behavior different from the utility versions. See <code>csht(1)</code> for description.</p>
Options	<p>The following options are supported:</p> <p><code>-increment -n increment</code> <i>increment</i> is a positive or negative decimal integer that has the same effect on the execution of the utility as if the utility had called the <code>nice()</code> function with the numeric value of the <i>increment</i> option-argument. See <code>nice(2)</code>. <code>nice()</code> errors, other than <code>EINVAL</code>, are ignored. If not specified, an increment of 10 is assumed.</p> <p>The super-user may run commands with priority higher than normal by using a negative increment such as -10. A negative <i>increment</i> assigned by an unprivileged user is ignored.</p>
Operands	<p>The following operands are supported:</p> <p><i>command</i> The name of a command that is to be invoked. If <i>command</i> names any of the special built-in utilities (see <code>shell_builtins(1)</code>), the results are undefined.</p> <p><i>argument</i> Any string to be supplied as an argument when invoking <i>command</i>.</p>
Environment Variables	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of nice: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, PATH, and NLS_PATH.

Exit Status If *command* is invoked, the exit status of *nice* will be the exit status of *command*. Otherwise, *nice* will exit with one of the following values:

- 1 - 125 An error occurred.
- 126 *command* was found but could not be invoked.
- 127 *command* could not be found.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/nice	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/core-os
	CSI	Enabled

/usr/xpg4/bin/nice	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/xopen/xcu4
	CSI	Enabled
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [csh\(1\)](#), [ksh88\(1\)](#), [nohup\(1\)](#), [priocntl\(1\)](#), [sh\(1\)](#), [shell_builtins\(1\)](#), [nice\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name nl – line numbering filter

Synopsis /usr/bin/nl [-p] [-b *type*] [-d *delim*] [-f *type*]
 [-h *type*] [-i *incr*] [-l *num*] [-n *format*]
 [-s *sep*] [-w *width*] [-v *startnum*] [*file*]
 /usr/xpg4/bin/nl [-p] [-b *type*] [-d *delim*] [-f *type*]
 [-h *type*] [-i *incr*] [-l *num*] [-n *format*] [-s *sep*]
 [-w *width*] [-v *startnum*] [*file*]

Description The nl utility reads lines from the named *file*, or the standard input if no *file* is named, and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.

nl views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer. For example, -bt (the default) numbers non-blank lines in the body section and does not number any lines in the header and footer sections.

The start of logical page sections are signaled by input lines containing nothing but the following delimiter character(s):

Line contents	Start Of
\: \: \:	header
\: \:	body
\:	footer

Unless optioned otherwise, nl assumes the text being read is in a single logical page body.

Options Command options may appear in any order and may be intermingled with an optional file name. Only one file may be named. The specified default is used when the option is not entered on the command line. /usr/xpg4/bin/nl options require option arguments. A SPACE character *may* separate options from option arguments. /usr/bin/nl options *may* have option arguments. If option-arguments of /usr/bin/nl options are not specified, these options result in the default. The supported options are:

-b*type* Specifies which logical page body lines are to be numbered. Recognized *types* and their meanings are:

- a number all lines
- t number all non-empty lines.
- n no line numbering

- pexp* number only lines that contain the regular expression specified in *exp*. See NOTES below.
- Default *type* for logical page body is *t* (text lines numbered).
- f**type* Same as -*b**type* except for footer. Default *type* for logical page footer is *n* (no lines numbered).
- ddelim* The two delimiter characters specifying the start of a logical page section may be changed from the default characters (\ :) to two user-specified characters. If only one character is entered, the second character remains the default character (:). No space should appear between the -*d* and the delimiter characters. To enter a backslash, use two backslashes.
- h**type* Same as -*b**type* except for header. Default *type* for logical page header is *n* (no lines numbered).
- i**incr* *incr* is the increment value used to number logical page lines. Default *incr* is 1.
- l**num* *num* is the number of blank lines to be considered as one. For example, -*l*2 results in only the second adjacent blank being numbered (if the appropriate -*ha*, -*ba*, and/or -*fa* option is set). Default *num* is 1.
- n**format* *format* is the line numbering format. Recognized values are:
- ln* left justified, leading zeroes suppressed
 - rn* right justified, leading zeroes suppressed
 - rz* right justified, leading zeroes kept
- Default *format* is *rn* (right justified).
- p* Do not restart numbering at logical page delimiters.
- s**sep* *sep* is the character(s) used in separating the line number and the corresponding text line. Default *sep* is a TAB.
- v**startnum* *startnum* is the initial value used to number logical page lines. Default *startnum* is 1.
- w**width* *width* is the number of characters to be used for the line number. Default *width* is 6.

Operands The following operand is supported:

file A path name of a text file to be line-numbered.

Examples **EXAMPLE 1** An example of the nl command

The command:

```
example% nl -v10 -i10 -d!+ filename1
```

will cause the first line of the page body to be numbered 10, the second line of the page body to be numbered 20, the third 30, and so forth. The logical page delimiters are !+.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of nl: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files

<code>/usr/lib/locale/locale/LC_COLLATE/CollTable</code>	Collation table generated by localedef
<code>/usr/lib/locale/locale/LC_COLLATE/coll.so</code>	Shared object containing string transformation library routines

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

<code>/usr/bin/nl</code>	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/core-os

<code>/usr/xpg4/bin/nl</code>	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/xopen/xcu4
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [pr\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [regex\(5\)](#), [regexp\(5\)](#), [standards\(5\)](#)

Notes Internationalized Regular Expressions are used in the POSIX and "C" locales. In other locales, Internationalized Regular Expressions are used if the following two conditions are met:

- `/usr/lib/locale/locale/LC_COLLATE/CollTable` is present.
- `/usr/lib/locale/locale/LC_COLLATE/coll.so` is not present.

Otherwise, Simple Regular Expressions are used.

Internationalized Regular Expressions are explained on [regex\(5\)](#). Simple Regular Expressions are explained on [regexp\(5\)](#).

Name nm – print name list of an object file

Synopsis /usr/bin/nm [-ACDhLlnPpRrsTVv] [-efox] [-g | -u]
 [-t *format*] *file*...

/usr/xpg4/bin/nm [-ACDhLlnPpRrsTVv] [-efox] [-g | -u]
 [-t *format*] *file*...

Description The nm utility displays the symbol table of each ELF object file that is specified by *file*.

If no symbolic information is available for a valid input file, the nm utility reports that fact, but does not consider it an error condition.

Options The output of nm can be controlled using the following options:

- A Writes the full path name or library name of an object on each line.
- C Demangles C++ symbol names before printing them out.
- D Displays the SHT_DYNSYM symbol information. This is the symbol table used by ld.so.1 and is present even in stripped dynamic executables. If -D is not specified, the default behavior is to display the SHT_SYMTAB symbol information.
- e See NOTES below.
- f See NOTES below.
- g Writes only external (global) symbol information.
- h Does not display the output heading data.
- L Displays the SHT_SUNW_LDYNSYM symbol information. This symbol table contains local function symbols. SHT_SUNW_LDYNSM symbol tables are present even in stripped dynamic executables. These symbols augment the global symbols that are found in SHT_DYNSYM symbol table. If -L is not specified, the default behavior is to display the SHT_SYMTAB symbol information.
- l Distinguishes between WEAK and GLOBAL symbols by appending a * to the key letter for WEAK symbols.
- n Sorts external symbols by name before they are printed.
- o Prints the value and size of a symbol in octal instead of decimal (equivalent to -t o).
- p Produces easy to parse, terse output. Each symbol name is preceded by its value (blanks if undefined) and one of the letters:
 - A Absolute symbol.
 - B bss (uninitialized data space) symbol.
 - C COMMON symbol.

- D Data object symbol.
- F File symbol.
- N Symbol has no type.
- L Thread-Local storage symbol.
- R Register symbol.
- S Section symbol.
- T Text symbol.
- U Undefined.

If the symbol's binding attribute is:

LOCAL The key letter is lower case.

WEAK The key letter is upper case. If the `-l` modifier is specified, the upper case key letter is followed by a `*`

GLOBAL The key letter is upper case.

- P Writes information in a portable output format, as specified in Standard Output.
- r Prepends the name of the object file or archive to each output line.
- R Prints the archive name (if present), followed by the object file and symbol name. If the `-r` option is also specified, this option is ignored.
- s Prints section name instead of section index.
- t *format* Writes each numeric value in the specified format. The format is dependent on the single character used as the *format* option-argument:
 - d The offset is written in decimal (default).
 - o The offset is written in octal.
 - x The offset is written in hexadecimal.
- T See NOTES.
- `/usr/bin/nm` -u Prints undefined symbols only.
- `/usr/xpg4/bin/nm` -u Prints long listing for each undefined symbol. See OUTPUT below.
- v Sorts external symbols by value before they are printed.
- V Prints the version of the `nm` command executing on the standard error output.
- x Prints the value and size of a symbol in hexadecimal instead of decimal (equivalent to `-t x`).

Options can be used in any order, either singly or in combination, and can appear anywhere in the command line. When conflicting options are specified (such as `-v` and `-n`, or `-o` and `-x`) the first is taken and the second ignored with a warning message to the user. (See `-R` for exception.)

Operands The following operand is supported:

file A path name of an object file, executable file or object-file library.

Output This section describes the `nm` utility's output options.

Standard Output For each symbol, the following information is printed:

Index	The index of the symbol. (The index appears in brackets.)																
Value	The value of the symbol is one of the following: <ul style="list-style-type: none"> ▪ A section offset for defined symbols in a relocatable file. ▪ Alignment constraints for symbols whose section index is <code>SHN_COMMON</code>. ▪ A virtual address in executable and dynamic library files. 																
Size	The size in bytes of the associated object.																
Type	A symbol is of one of the following types: <table style="margin-left: 2em;"> <tr> <td>NOTYPE</td> <td>No type was specified.</td> </tr> <tr> <td>OBJECT</td> <td>A data object such as an array or variable.</td> </tr> <tr> <td>FUNC</td> <td>A function or other executable code.</td> </tr> <tr> <td>REGI</td> <td>A register symbol (SPARC only).</td> </tr> <tr> <td>SECTION</td> <td>A section symbol.</td> </tr> <tr> <td>FILE</td> <td>Name of the source file.</td> </tr> <tr> <td>COMMON</td> <td>An uninitialized common block.</td> </tr> <tr> <td>TLS</td> <td>A variable associated with Thread-Local storage.</td> </tr> </table>	NOTYPE	No type was specified.	OBJECT	A data object such as an array or variable.	FUNC	A function or other executable code.	REGI	A register symbol (SPARC only).	SECTION	A section symbol.	FILE	Name of the source file.	COMMON	An uninitialized common block.	TLS	A variable associated with Thread-Local storage.
NOTYPE	No type was specified.																
OBJECT	A data object such as an array or variable.																
FUNC	A function or other executable code.																
REGI	A register symbol (SPARC only).																
SECTION	A section symbol.																
FILE	Name of the source file.																
COMMON	An uninitialized common block.																
TLS	A variable associated with Thread-Local storage.																
Bind	The symbol's binding attributes. <table style="margin-left: 2em;"> <tr> <td>LOCAL symbols</td> <td>Have a scope limited to the object file containing their definition.</td> </tr> <tr> <td>GLOBAL symbols</td> <td>Are visible to all object files being combined.</td> </tr> <tr> <td>WEAK symbols</td> <td>Are essentially global symbols with a lower precedence than GLOBAL.</td> </tr> </table>	LOCAL symbols	Have a scope limited to the object file containing their definition.	GLOBAL symbols	Are visible to all object files being combined.	WEAK symbols	Are essentially global symbols with a lower precedence than GLOBAL.										
LOCAL symbols	Have a scope limited to the object file containing their definition.																
GLOBAL symbols	Are visible to all object files being combined.																
WEAK symbols	Are essentially global symbols with a lower precedence than GLOBAL.																
Other	An integer corresponding to one of the <code>STV_</code> symbol visibility values defined in <code><sys/elf.h></code> .																

Shndx	Except for three special values, this is the section header table index in relation to which the symbol is defined. The following special values exist:
ABS	Indicates the symbol's value does not change through relocation.
COMMON	Indicates an unallocated block and the value provides alignment constraints.
UNDEF	Indicates an undefined symbol.
Name	The name of the symbol.
Object Name	The name of the object or library if -A is specified.

If the -P option is specified, the previous information is displayed using the following portable format. The three versions differ depending on whether -t d, -t o, or -t x was specified, respectively:

```
"%s%s %s %d %d\n", library/object name, name, type, value, size
```

```
"%s%s %s %o %o\n", library/object name, name, type, value, size
```

```
"%s%s %s %x %x\n", library/object name, name, type, value, size
```

where *type* is formatted as described for the -p option, and *library/object name* is formatted as follows:

- If -A is not specified, *library/object name* is an empty string.
- If -A is specified and the corresponding *file* operand does not name a library:

```
"%s: ", file
```
- If -A is specified and the corresponding *file* operand names a library. In this case, *object file* names the object file in the library containing the symbol being described:

```
"%s[%s]: ", file, object file
```

If -A is not specified, then if more than one *file* operand is specified or if only one *file* operand is specified and it names a library, nm writes a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding *file* operand does not name a library:

```
"%s:\n", file
```
- If the corresponding *file* operand names a library; in this case, *object file* is the name of the file in the library containing the following symbols:

```
"%s[%s]:\n", file, object file
```

If -P is specified, but -t is not, the format is as if -t x had been specified.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of nm: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/nm	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	developer/base-developer-utilities

/usr/xpg4/bin/nm	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/xopen/xcu4
	Interface Stability	Committed

See Also [ar\(1\)](#), [as\(1\)](#), [dump\(1\)](#), [ld\(1\)](#), [ld.so.1\(1\)](#), [ar.h\(3HEAD\)](#), [a.out\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes The following options are obsolete because of changes to the object file format and might be deleted in a future release.

- e Prints only external and static symbols. The symbol table now contains only static and external symbols. Automatic symbols no longer appear in the symbol table. They do appear in the debugging information produced by `cc -g`, which can be examined using [dump\(1\)](#).
- f Produces full output. Redundant symbols (such as `.text`, `.data`, and so forth), which existed previously, do not exist and producing full output is identical to the default output.
- T By default, nm prints the entire name of the symbols listed. Since symbol names have been moved to the last column, the problem of overflow is removed and it is no longer necessary to truncate the symbol name.

Name nohup – run a command immune to hangups

Synopsis `/usr/bin/nohup command [argument]...`
`/usr/bin/nohup -p [-Fa] pid [pid]...`
`/usr/bin/nohup -g [-Fa] gpid [gpid]...`
`/usr/xpg4/bin/nohup command [argument]...`

Description The nohup utility invokes the named *command* with the arguments supplied. When the *command* is invoked, nohup arranges for the SIGHUP signal to be ignored by the process.

When invoked with the `-p` or `-g` flags, nohup arranges for processes already running as identified by a list of process IDs or a list of process group IDs to become immune to hangups.

The nohup utility can be used when it is known that *command* takes a long time to run and the user wants to log out of the terminal. When a shell exits, the system sends its children SIGHUP signals, which by default cause them to be killed. All stopped, running, and background jobs ignores SIGHUP and continue running, if their invocation is preceded by the nohup command or if the process programmatically has chosen to ignore SIGHUP.

The nohup utility causes processes to ignore SIGHUP but does not in any way protect those processes from other signals. Since modern shells sometimes send signals other than SIGHUP upon logout, it is possible for jobs running under `/usr/bin/nohup` to be killed when the controlling shell exits.

<code>/usr/bin/nohup</code>	Processes run by <code>/usr/bin/nohup</code> are immune to SIGHUP (hangup) and SIGQUIT (quit) signals.
<code>/usr/bin/nohup -p [-Fa]</code>	Processes specified by ID are made immune to SIGHUP and SIGQUIT, and all output to the controlling terminal is redirected to <code>nohup.out</code> . If <code>-F</code> is specified, nohup forces control of each process. If <code>-a</code> is specified, nohup changes the signal disposition of SIGHUP and SIGQUIT even if the process has installed a handler for either signal.
<code>/usr/bin/nohup -g [-Fa]</code>	Every process in the same process group as the processes specified by ID are made immune to SIGHUP and SIGQUIT, and all output to the controlling terminal is redirected to <code>nohup.out</code> . If <code>-F</code> is specified, nohup forces control of each process. If <code>-a</code> is specified, nohup changes the signal disposition of SIGHUP and SIGQUIT even if the process has installed a handler for either signal.
<code>/usr/xpg4/bin/nohup</code>	Processes run by <code>/usr/xpg4/bin/nohup</code> are immune to SIGHUP.

The nohup utility does not arrange to make processes immune to a SIGTERM (terminate) signal, so unless they arrange to be immune to SIGTERM or the shell makes them immune to SIGTERM, they receive it.

If nohup.out is not writable in the current directory, output is redirected to \$HOME/nohup.out. If a file is created, the file has read and write permission (600). See [chmod\(1\)](#). If the standard error is a terminal, it is redirected to the standard output, otherwise it is not redirected. The priority of the process run by nohup is not altered.

Options The following options are supported:

- a Always changes the signal disposition of target processes. This option is valid only when specified with -p or -g.
- F Force. Grabs the target processes even if another process has control. This option is valid only when specified with -p or -g.
- g Operates on a list of process groups. This option is not valid with -p.
- p Operates on a list of processes. This option is not valid with -g.

Operands The following operands are supported:

- pid* A decimal process ID to be manipulated by nohup -p.
- pgid* A decimal process group ID to be manipulated by nohup -g.
- command* The name of a command that is to be invoked. If the *command* operand names any of the special [shell_builtins\(1\)](#) utilities, the results are undefined.
- argument* Any string to be supplied as an argument when invoking the *command* operand.

Usage Caution should be exercised when using the -F flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the proc tool in question.

Examples **EXAMPLE 1** Applying nohup to Pipelines or Command Lists

It is frequently desirable to apply nohup to pipelines or lists of commands. This can be done only by placing pipelines and command lists in a single file, called a shell script. One can then issue:

```
example$ nohup sh file
```

EXAMPLE 1 Applying nohup to Pipelines or Command Lists (Continued)

and the nohup applies to everything in *file*. If the shell script *file* is to be executed often, then the need to type `sh` can be eliminated by giving *file* execute permission.

Add an ampersand and the contents of *file* are run in the background with interrupts also ignored (see [sh\(1\)](#)):

```
example$ nohup file &
```

EXAMPLE 2 Applying nohup -p to a Process

```
example$ long_running_command &
example$ nohup -p 'pgrep long_running_command'
```

EXAMPLE 3 Applying nohup -g to a Process Group

```
example$ make &
example$ ps -o sid -p $$
      SID
  81079
example$ nohup -g 'pgrep -s 81079 make'
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of nohup: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, PATH, NLS_PATH, and PATH.

HOME Determine the path name of the user's home directory: if the output file `nohup.out` cannot be created in the current directory, the nohup command uses the directory named by HOME to create the file.

Exit Status The following exit values are returned:

126 *command* was found but could not be invoked.

127 An error occurred in nohup, or *command* could not be found

Otherwise, the exit values of nohup are those of the *command* operand.

Files `nohup.out` The output file of the nohup execution if standard output is a terminal and if the current directory is writable.

`$HOME/nohup.out` The output file of the nohup execution if standard output is a terminal and if the current directory is not writable.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/nohup	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/core-os

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled

/usr/xpg4/bin/nohup

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/xopen/xcu4
CSI	Enabled
Interface Stability	Committed
Standard	See standards(5) .

See Also [bash\(1\)](#), [batch\(1\)](#), [chmod\(1\)](#), [csh\(1\)](#), [disown\(1\)](#), [ksh88\(1\)](#), [nice\(1\)](#), [pgrep\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [sh\(1\)](#), [shell_builtins\(1\)](#), [setpgrp\(1\)](#), [signal\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Warnings If you are running the Korn shell ([ksh88\(1\)](#)) as your login shell, and have nohup'ed jobs running when you attempt to log out, you are warned with the message:

```
You have jobs running.
```

You need to log out a second time to actually log out. However, your background jobs continues to run.

Notes The C-shell ([csh\(1\)](#)) has a built-in command nohup that provides immunity from SIGHUP, but does not redirect output to nohup.out. Commands executed with '&' are automatically immune to HUP signals while in the background.

nohup does not recognize command sequences. In the case of the following command,

```
example$ nohup command1; command2
```

the nohup utility applies only to command1. The command,

```
example$ nohup (command1; command2)
```

is syntactically incorrect.

Name nroff – format documents for display or line-printer

Synopsis nroff [-ehiq] [-mname] [-nN] [-opagelist] [-raN] [-sN]
[-Tname] [-uN] [filename...]

Description The nroff utility formats text in the named *filename* for typewriter-like devices. See also [troff\(1\)](#).

If no *filename* argument is present, nroff reads the standard input. An argument consisting of a '-' is taken to be a file name corresponding to the standard input.

Options The following options are supported. Options can appear in any order so long as they appear *before* the files.

- e Produces equally-spaced words in adjusted lines, using full terminal resolution.
- h Uses output TAB characters during horizontal spacing to speed output and reduces output character count. TAB settings are assumed to be every 8 nominal character widths.
- i Reads the standard input after the input files are exhausted.
- q Does not print output that was read from an .rd request.
- mname Prepends the macro file /usr/share/lib/tmac/*name* to the input files.
- nN Numbers first generated page *N*.
- opagelist Prints only pages whose page numbers appear in the comma-separated *list* of numbers and ranges. A range *N-M* means pages *N* through *M*; an initial -*N* means from the beginning to page *N*; and a final *N-* means from *N* to the end.
- raN Sets register *a* (one-character) to *N*.
- sN Stops every *N* pages. nroff halts prior to every *N* pages (default *N*=1) to allow paper loading or changing, and resumes upon receipt of a NEWLINE.
- Tname Prepares output for a device of the specified *name*. Known *names* are:
 - 37 Teletype Corporation Model 37 terminal — this is the default.
 - lp | tn300 GE — any line printer or terminal without half-line capability.
 - 300 DASI-300.
 - 300-12 DASI-300 — 12-pitch.
 - 300S DASI-300S.
 - 300S-12 DASI-300S.
 - 382 DASI-382 (fancy DTC 382).
 - 450 DASI-450 (Diablo Hyterm).

450-12 DASI-450 (Diablo Hyterm) — 12-pitch.

832 AJ 832.

`-uN` Set the boldening factor for the font mounted in position 3 to *N*. If *N* is missing, then set the boldening factor to 0.

Operands The following operand is supported:

filename The file containing text to be processed by `nroff`.

Examples EXAMPLE 1 Formatting with a macro package

The following command formats `users.guide` using the `-me` macro package, and stopping every 4 pages:

```
example% nroff -s4 -me users.guide
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `nroff`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Files	<code>/usr/tmp/trtmp*</code>	temporary file (see NOTES)
	<code>/usr/share/lib/tmac/tmac.*</code>	standard macro files
	<code>/usr/share/lib/nterm/*</code>	terminal driving tables for <code>nroff</code>
	<code>/usr/share/lib/nterm/README</code>	index to terminal description files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools
CSI	Enabled

See Also [checknr\(1\)](#), [col\(1\)](#), [eqn\(1\)](#), [man\(1\)](#), [tbl\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [me\(5\)](#), [ms\(5\)](#), [term\(5\)](#)

Notes `/usr/tmp` is currently a symbolic link to `/var/tmp`.

Previous documentation incorrectly described the numeric register `yr` as being the *Last two digits of current year*. `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` can be included in a document and subsequently used to display a two-digit year. Notice that any other available one- or two-character register name can be substituted for `yy`.

```
.\ " definition of new string register yy--last two digits of year
.\ " use yr (# of years since 1900) if it is < 100
.\ie \n(yr<100 .ds yy \n(yr
.\el \{          .\ " else, subtract 100 from yr, store in yy
```

```
.nr ny \n(yr-100
.ie \n(ny>9 \{      .\" use ny if it is two digits
.ds yy \n(ny
.\" remove temporary number register ny
.rr ny \}
.el \{.ds yy 0
.\" if ny is one digit, append it to 0
.as yy \n(ny
.rr ny \} \}
```

Name od – octal dump

Synopsis /usr/bin/od [-bcCdDfF0oSsvXx] [-] [*file*] [*offset_string*]
 /usr/bin/od [-bcCdDfF0oSsvXx] [-A *address_base*] [-j *skip*]
 [-N *count*] [-t *type_string*]... [-] [*file*]...
 /usr/xpg4/bin/od [-bcCdDfF0oSsvXx] [*file*] [*offset_string*]
 /usr/xpg4/bin/od [-bcCdDfF0oSsvXx] [-A *address_base*]
 [-j *skip*] [-N *count*] [-t *type_string*]... [*file*]...

Description The od command copies sequentially each input file to standard output and transforms the input data according to the output types specified by the -t or -bcCdDfF0oSsvXx options. If no output type is specified, the default output is as if -t o2 had been specified. Multiple types can be specified by using multiple -bcCdDfF0oSstvXx options. Output lines are written for each type specified in the order in which the types are specified. If no *file* is specified, the standard input is used. The [*offset_string*] operand is mutually exclusive from the -A, -j, -N, and -t options. For the purposes of this description, the following terms are used:

word	Refers to a 16-bit unit, independent of the word size of the machine.
long word	Refers to a 32-bit unit.
double long word	Refers to a 64-bit unit.

Options The following options are supported:

-A <i>address_base</i>	Specifies the input offset base. The <i>address_base</i> option-argument must be a character. The characters d, o and x specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character n specifies that the offset will not be written. Unless -A n is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the -A <i>address_base</i> option and the [<i>offset_string</i>] operand, the input offset base is displayed in octal.
-b	Interprets bytes in octal. This is equivalent to -t o1.
/usr/bin/od -c	Displays single-byte characters. Certain non-graphic characters appear as C-language escapes:
null	\0
backspace	\b
form-feed	\f
new-line	\n
return	\r
tab	\t

Others appear as 3-digit octal numbers. For example:

```
echo "hello world" | od -c
0000000 h e l l o       w o r l d \n
0000014
```

/usr/xpg4/bin/od -c

Interprets bytes as single-byte or multibyte characters according to the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Non-graphic characters appear the same as they would using the -C option.

-C

Interprets bytes as single-byte or multibyte characters according to the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes:

```
null          \0
backspace     \b
form-feed     \f
new-line      \n
return        \r
tab           \t
```

Other non-printable characters appear as one three-digit octal number for each byte in the character.

-d

Interprets words in unsigned decimal. This is equivalent to -t u2.

-D

Interprets long words in unsigned decimal. This is equivalent to -t u4.

-f

Interprets long words in floating point. This is equivalent to -t f4.

-F

Interprets double long words in extended precision. This is equivalent to -t f8.

-j *skip*

Jumps over *skip* bytes from the beginning of the input. The od command will read or seek past the first *skip* bytes in the concatenated input files. If the combined input is not at least *skip* bytes long, the od command will write a diagnostic message to standard error and exit with a non-zero exit status.

By default, the *skip* option-argument is interpreted as a decimal number. With a leading 0x or 0X, the offset is interpreted as a hexadecimal number; otherwise, with a leading 0, the offset will be interpreted as an octal number. Appending the character b, k, or m to offset will cause it to be interpreted as a

multiple of 512, 1024 or 1 048 576 bytes, respectively. If the *skip* number is hexadecimal, any appended *b* is considered to be the final hexadecimal digit. The address is displayed starting at `00000000`, and its base is not implied by the base of the *skip* option-argument.

- N *count* Formats no more than *count* bytes of input. By default, *count* is interpreted as a decimal number. With a leading `0x` or `0X`, *count* is interpreted as a hexadecimal number; otherwise, with a leading `0`, it is interpreted as an octal number. If *count* bytes of input (after successfully skipping, if *-j skip* is specified) are not available, it will not be considered an error. The `od` command will format the input that is available. The base of the address displayed is not implied by the base of the *count* option-argument.
- o Interprets words in octal. This is equivalent to `-t o2`.
- O Interprets long words in unsigned octal. This is equivalent to `-t o4`.
- s Interprets words in signed decimal. This is equivalent to `-t d2`.
- S Interprets long words in signed decimal. This is equivalent to `-t d4`.
- t *type_string* Specifies one or more output types. The *type_string* option-argument must be a string specifying the types to be used when writing the input data. The string must consist of the type specification characters:

- a *Named character*. Interprets bytes as named characters. Only the least significant seven bits of each byte will be used for this type specification. Bytes with the values listed in the following table will be written using the corresponding names for those characters.

The following are named characters in `od`:

Value	Name
<code>\000</code>	<code>nul</code>
<code>\001</code>	<code>soh</code>
<code>\002</code>	<code>stx</code>
<code>\003</code>	<code>etx</code>
<code>\004</code>	<code>eot</code>
<code>\005</code>	<code>enq</code>
<code>\006</code>	<code>ack</code>
<code>\007</code>	<code>bel</code>
<code>\010</code>	<code>bs</code>
<code>\011</code>	<code>ht</code>
<code>\012</code>	<code>lf</code>
<code>\013</code>	<code>vt</code>
<code>\014</code>	<code>ff</code>
<code>\015</code>	<code>cr</code>
<code>\016</code>	<code>so</code>

```

\017  si
\020  dle
\021  dc1
\022  dc2
\023  dc3
\024  dc4
\025  nak
\026  syn
\027  etb
\030  can
\031  em
\032  sub
\033  esc
\034  fs
\035  gs
\036  rs
\037  us
\040  sp
\177  del

```

- c *Character*. Interprets bytes as single-byte or multibyte characters specified by the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes: \0, \a, \b, \f, \n, \r, \t, \v. Other non-printable characters appear as one three-digit octal number for each byte in the character.

The type specification characters d, f, o, u, and x can be followed by an optional unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type.

- f *Floating point*. Can be followed by an optional F, D, or L indicating that the conversion should be applied to an item of type float, double, or long double, respectively.
- d, o, u, and x *Signed decimal, octal, unsigned decimal, and hexadecimal, respectively*. Can be followed by an optional C, S, I, or L indicating that the conversion should be applied to an item of type char, short, int, or long, respectively.

Multiple types can be concatenated within the same *type_string* and multiple -t options can be specified. Output lines are written for each type specified in the order in which the type specification characters are specified.

- v Shows all input data (verbose). Without the -v option, all groups of output lines that would be identical to the immediately preceding output line (except for byte offsets), will be replaced with a line containing only an asterisk (*).
- x Interprets words in hex. This is equivalent to -t x2.
- X Interprets long words in hex. This is equivalent to -t x4.

Operands

`/usr/bin/od` The following operands are supported for `/usr/bin/od` only:

- Uses the standard input in addition to any files specified. When this operand is not given, the standard input is used only if no *file* operands are specified.
- file* A path name of a file to be read. If no *file* operands are specified, the standard input will be used. If there are no more than two operands, none of the -A, -j, -N, or -t options is specified, and *any* of the following are true:
 1. the first character of the last operand is a plus sign (+)
 2. the first character of the second operand is numeric
 3. the first character of the second operand is x and the second character of the second operand is a lower-case hexadecimal character or digit
 4. the second operand is named "x"
 5. the second operand is named "."

then the corresponding operand is assumed to be an offset operand rather than a file operand.

Without the -N count option, the display continues until an end-of-file is reached.

```
[+] [0] offset [.] [b|B]
[+] [0] [offset] [.]
[+] [0x|x] [offset]
[+] [0x|x] [offset][B]
```

The *offset_string* operand specifies the byte offset in the file where dumping is to commence. The offset is interpreted in octal bytes by default. If *offset* begins with "0", it is interpreted in octal. If *offset* begins with "x" or "0x", it is interpreted in hexadecimal and any appended "b" is considered to be the final hexadecimal digit. If "." is appended, the offset is interpreted in decimal. If "b" or "B" is appended, the offset is interpreted in units of 512 bytes. If the file

argument is omitted, the *offset* argument must be preceded by a plus sign (+). The address is displayed starting at the given offset. The radix of the address will be the same as the radix of the offset, if specified, otherwise it will be octal. Decimal overrides octal, and it is an error to specify both hexadecimal and decimal conversions in the same offset operand.

`/usr/xpg4/bin/od` The following operands are supported for `/usr/xpg4/bin/od` only:

file Same as `/usr/bin/od`, except only one of the first two conditions must be true.

[+] [0] *offset* [.] [b|B]

+ [*offset*] [.]

[+] [0x] [*offset*]

[+] [0x] *offset* [B]

+x [*offset*]

+x*offset* [B]

Description of *offset_string* is the same as for `/usr/bin/od`.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `od`: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, LC_NUMERIC, and NLSPATH.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name on – execute a command on a remote system with the local environment

Synopsis on [-i] [-d] [-n] *host command [argument] ...*

Description The on program is used to execute commands on another system, in an environment similar to that invoking the program. All environment variables are passed and the current working directory is preserved. To preserve the working directory, the working file system must be either already mounted on the host or be exported to it. Relative path names will only work if they are within the current file system. Absolute path names may cause problems.

The standard input is connected to the standard input of the remote command. The standard output and the standard error from the remote command are sent to the corresponding files for the on command.

Note that the on program requires that the `rpc.rexd(1M)` service be running on the remote machine. By default, `rpc.rexd` is present but not running on an Oracle Solaris system. Because of its better security, `ssh(1)` is the preferred method of invoking commands on remote machines.

Options The following options are supported:

- d Debug mode. Prints out some messages as work is being done.
- i Interactive mode. Uses remote echoing and special character processing. This option is needed for programs that expect to be talking to a terminal. All terminal modes and window size changes are propagated.
- n No Input. This option causes the remote program to get EOF when it reads from the standard input, instead of passing the standard input from the standard input of the on program. For example, -n is necessary when running commands in the background with job control.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

Diagnostics

unknown host	Host name not found.
cannot connect to server	Host down or not running the server.
can't find	Problem finding the working directory.
can't locate mount point	Problem finding current file system.
RPC: Authentication error	The server requires DES authentication and you do not have a secret key registered with

keyserv. Perhaps you logged in without a password. Try to keylogin. If that fails, try to set your publickey with chkey.

on *server*: RPC: can't encode arguments

The 10240 byte limit for arguments to be encoded and passed from the sending to the receiving system has been exceeded.

Other diagnostic messages may be passed back from the server.

Bugs When the working directory is remote mounted over NFS, a Control-Z hangs the window.

Root cannot use on.

Name optisa – determine which variant instruction set is optimal to use

Synopsis optisa *instruction_set*...

Description optisa prints which *instruction_set* out of the ones specified in the command will perform best on this machine. In this case, “best” is defined by the order in which instruction set names are returned by [isalist\(1\)](#). Possible values for *instruction_set* are given in [isalist\(5\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Exit Status The following exit values are returned:

- 0 One of the *instruction_set* values you specified is printed by this command.
- 1 There is no output; that is, this machine cannot use any *instruction_set* that you specified with the optisa command.

See Also [isalist\(1\)](#), [uname\(1\)](#), [attributes\(5\)](#), [isalist\(5\)](#)

Notes optisa is preferable to `uname -p` or `uname -m` (see [uname\(1\)](#)) in determining which of several binary versions of a given program should be used on the given machine.

Name pack, pcat, unpack – compress and expand files

Synopsis pack [-f/] [-] file...

pcat file...

unpack [-/] file...

Description

pack The pack command attempts to store the specified files in a compressed form. Wherever possible (and useful), each input file `file` is replaced by a packed file `file.z` with the same access modes, access and modified dates, and owner as those of `file`. If pack is successful, `file` is removed.

The amount of compression obtained depends on the size of the input file and the character frequency distribution. Because a decoding tree forms the first part of each `.z` file, it is usually not worthwhile to pack files smaller than three blocks, unless the character frequency distribution is very skewed, which can occur with printer plots or pictures.

Typically, text files are reduced to 60-75% of their original size. Load modules, which use a larger character set and have a more uniform distribution of characters, show little compression, the packed versions being about 90% of the original size.

The pack utility returns a value that is the number of files that it failed to compress. If that number exceeds 255, 255 is returned.

No packing occurs if:

- the file appears to be already packed
- the file name is too long to add the `.z` suffix
- the file has links
- the file is a directory
- the file cannot be opened
- the file is empty
- no disk storage blocks are saved by packing
- a file called `file.z` already exists
- the `.z` file cannot be created
- an I/O error occurred during processing.

The last segment of the file name must be short enough to allow space for the appended `.z` extension. Directories cannot be compressed.

pcat The pcat command does for packed files what [cat\(1\)](#) does for ordinary files, except that pcat cannot be used as a filter. The specified files are unpacked and written to the standard output.

pcat returns the number of files it was unable to unpack. Failure can occur if:

- the file cannot be opened;
- the file does not appear to be the output of pack.

unpack The `unpack` command expands files created by `pack`. For each `file` specified in the command, a search is made for a file called `file.z` (or just `file`, if `file` ends in `.z`). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the `.z` suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file.

`unpack` returns a value that is the number of files it was unable to unpack. Failure can occur for the same reasons that it can in `pcat`, as well as for the following:

- a file with the unpacked name already exists;
- the unpacked file cannot be created.

Options The following options are supported by `pack`:

- f Forces packing of `file`. This is useful for causing an entire directory to be packed even if some of the files do not benefit. Packed files can be restored to their original form using `unpack` or `pcat`.

The following options are supported by `pack` and `unpack`:

- / When packing or unpacking, copies any ACL and extended system attributes associated with the source file to the target file. If an ACL or extended system attributes cannot be copied, the original file is retained, a diagnostic message is written to `stderr`, and the final exit status is non-zero.

Operands The following operands are supported:

- `file` A path name of a file to be packed, unpacked, or `pcated`; `file` can include or omit the `.z` suffix.
- `pack` uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the – argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of – in place of `file` causes the internal flag to be set and reset.

Usage See [largefile\(5\)](#) for the description of the behavior of `pack`, `pcat`, and `unpack` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Viewing a Packed File

To view a packed file named `file.z` use:

```
example% pcat file.z
```

or just:

EXAMPLE 1 Viewing a Packed File *(Continued)*

```
example% pcat file
```

EXAMPLE 2 Making and Unpacked Copy:

To make an unpacked copy, say `nnn`, of a packed file named `file.z` (without destroying `file.z`) use the command:

```
example% pcat file >nnn
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `pack`, `pcat`, and `unpack`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred. The number of files the command failed to pack/unpack is returned. If the number of failures exceeds 255, then 255 is returned.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled

See Also [cat\(1\)](#), [compress\(1\)](#), [zcat\(1\)](#), [fgetattr\(3C\)](#), [fsetattr\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#)

Name packagemanager – GUI for the Image Packaging System

Synopsis /usr/bin/packagemanager [*options*]

```
/usr/bin/packagemanager [-h | --help]
                        [-i | --info-install file] [-U | --update-all]
                        [-R | --image-dir dir]
```

```
/usr/bin/packagemanager [file]
```

Description packagemanager is the graphical user interface for pkg(5), the Image Packaging System software.

The Package Manager enables you to perform the following tasks:

- Search, install, and remove packages.
- Add, remove, and modify publishers.
- Create, remove, and manage boot environments.

If the *file* operand is specified and its suffix is .p5i, packagemanager launches in Web Install mode, which adds one or more publishers and a number of packages for each publisher.

Options The following options are supported:

-h

--help

Display a usage message.

-i *file*

--info-install *file*

Specify a .p5i file to run packagemanager in Web Install mode. The *file* must have the suffix .p5i.

-R *dir*

--image-dir *dir*

Operate on the image rooted at *dir*, rather than the image discovered automatically.

-U

--update-all

Update all installed packages that have updates available.

Note – If the package/pkg, package/pkg/package-manager, or package/pkg/update-manager packages need to be updated, packagemanager first updates these packages and then restarts to carry out any remaining updates.

Operands *file* A Web Install file. This file must have the suffix .p5i. See the Package Manager online help for more information about Web Install.

Examples EXAMPLE 1 Operate on the Current Image

Invoke packagemanager on the current image.

```
$ packagemanager
```

EXAMPLE 2 Operate on a Specified Image

Invoke packagemanager in the image stored at /aux0/example_root.

```
$ packagemanager -R /aux0/example_root
```

EXAMPLE 3 Invoke in Web Install Mode

Invoke packagemanager in Web Install mode.

```
$ packagemanager ~/test.p5i
```

Exit Status The following exit values are returned:

- 0 Everything worked.
- 1 An error occurred.
- 2 Invalid command line options were specified.

Files Since pkg(5) images can be located arbitrarily within a larger file system, the token \$IMAGE_ROOT is used to distinguish relative paths. For a typical system installation, \$IMAGE_ROOT is equivalent to /.

```
$IMAGE_ROOT/var/pkg
```

Metadata directory for a full or partial image.

```
$IMAGE_ROOT/.org.opensolaris, pkg
```

Metadata directory for a user image.

Within the metadata of a particular image, certain files and directories contain information useful during repair and recovery. The token \$IMAGE_META is used to refer to the top-level directory that contains the metadata. \$IMAGE_META is typically one of the two paths given above.

```
$IMAGE_META/gui-cache
```

Location for cached metadata maintained by packagemanager to speed up program startup and switching between publishers.

Other paths within the \$IMAGE_META directory hierarchy are Private, and are subject to change.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	package/pkg/package-manager
Interface Stability	Uncommitted

See Also [pm-updatemanager\(1\)](#), [pkg\(1\)](#), [pkg\(5\)](#)

Package Manager online help

<http://hub.opensolaris.org/bin/view/Project+pkg/>

Notes packagemanager needs to be invoked with sufficient privilege to operate on an image's files and directories.

Name pagesize – display the size or sizes of a page of memory

Synopsis /usr/bin/pagesize [-a]

Description The pagesize utility prints the default size of a page of memory in bytes, as returned by [getpagesize\(3C\)](#). This program is useful in constructing portable shell scripts.

Options The following option is supported:

-a Prints out all possible hardware address translation sizes supported by the system.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [ppgsz\(1\)](#), [getpagesize\(3C\)](#), [getpagesizes\(3C\)](#), [attributes\(5\)](#)

Name pargs – print process arguments, environment variables, or auxiliary vector

Synopsis pargs [-aceFlx] [*pid* | *core*]...

Description The pargs utility examines a target process or process core file and prints arguments, environment variables and values, or the process auxiliary vector.

pargs outputs unprintable characters as escaped octal in the format `\xxx`, unless the character is one of the characters specified in the “Escape Sequences” section of [formats\(5\)](#), in which case the character is printed as specified in that section.

pargs attempts to be sensitive to the locale of the target process. If the target process and the pargs process do not share a common character encoding, pargs attempts to employ the [iconv\(3C\)](#) facility to generate a printable version of the extracted strings. In the event that such a conversion is impossible, strings are displayed as 7-bit ASCII.

Options The following options are supported:

- a Prints process arguments as contained in `argv[]` (default).
- c Treats strings in the target process as though they were encoded in 7-bit ASCII, regardless of the locale of the target. The use of [iconv\(3C\)](#) is suppressed.
- e Prints process environment variables and values as pointed at by the `_environ` symbol or by `pr_envp` in `/proc/pid/psinfo`.
- F Force. Grabs the target process even if another process has control.
- l Displays the arguments as a single command line. The command line is printed in a manner suitable for interpretation by `/bin/sh`. If the arguments contain unprintable characters, or if the target process is in a different locale, a warning message is displayed. The resulting command line might not be interpreted correctly by `/bin/sh`.
- x Prints process auxiliary vector.

Operands The following operands are supported:

pid Process ID list.
core Process core file.

Usage Caution should be exercised when using the `-F` flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the `proc` tool in question.

Exit Status The following exit values are returned:

- 0 Successful operation.
- non-zero An error has occurred (such as no such process, permission denied, or invalid option).

Files /proc/pid/* Process information and control files.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also [proc\(1\)](#), [iconv\(3C\)](#), [proc\(4\)](#), [ascii\(5\)](#), [attributes\(5\)](#), [environ\(5\)](#), [formats\(5\)](#)

Name passwd – change login password and password attributes

Synopsis passwd [-r files | -r ldap | -r nis] [*name*]
passwd [-r files] [-egh] [*name*]
passwd [-r files] -s [-a]
passwd [-r files] -s [*name*]
passwd [-r files] [-d | -l | -u | -N] [-f] [-n *min*]
 [-w *warn*] [-x *max*] *name*
passwd -r ldap [-egh] [*name*]
passwd [-r ldap] -s [-a]
passwd [-r ldap] -s [*name*]
passwd -r ldap [-d | -l | -u | -N] [-f] [-n *min*]
 [-w *warn*] [-x *max*] *name*
passwd -r nis [-egh] [*name*]

Description The passwd command changes the password or lists password attributes associated with the user's login *name*. Additionally, authorized users can use passwd to install or change passwords and attributes associated with any login *name*.

When used to change a password, passwd prompts everyone for their old password, if any. It then prompts for the new password twice. When the old password is entered, passwd checks to see if it has aged sufficiently. If aging is insufficient, passwd terminates; see [pwconv\(1M\)](#) and [shadow\(4\)](#) for additional information.

The pwconv command creates and updates /etc/shadow with information from /etc/passwd. pwconv relies on a special value of x in the password field of /etc/passwd. This value of x indicates that the password for the user is already in /etc/shadow and should not be modified.

If aging is sufficient, a check is made to ensure that the new password meets construction requirements. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated for, at most, two more times.

Passwords must be constructed to meet the following requirements:

- Each password must have PASSLENGTH characters, where PASSLENGTH is defined in /etc/default/passwd and is set to 6. Setting PASSLENGTH to more than eight characters requires configuring [policy.conf\(4\)](#) with an algorithm that supports greater than eight characters.
- Each password must meet the configured complexity constraints specified in /etc/default/passwd.

- Each password must not be a member of the configured dictionary as specified in `/etc/default/passwd`.
- For accounts in name services which support password history checking, if prior password history is defined, new passwords must not be contained in the prior password history.

If all requirements are met, by default, the `passwd` command consults `/etc/nsswitch.conf` to determine in which repositories to perform password update. It searches the `passwd` and `passwd_compat` entries. The sources (repositories) associated with these entries are updated. However, the password update configurations supported are limited to the following cases. Failure to comply with the configurations prevents users from logging onto the system. The password update configurations are:

- `passwd: files`
 - `passwd: files ldap`
 - `passwd: files nis`
 - `passwd: compat (==> files nis)`
 - `passwd: compat (==> files ldap)`
- `passwd_compat: ldap`

You can append the `ad` keyword to any of the `passwd` configurations in the above list. However, you cannot use the `passwd` command to change the password of an Active Directory (AD) user. If the `ad` keyword is found in the `passwd` entry during a password update operation, it is ignored.

Network administrators, who own the password table, can change any password attributes. The administrator configured for updating LDAP shadow information can also change any password attributes. See [ldapclient\(1M\)](#).

When a user has a password stored in one of the name services as well as a local `files` entry, the `passwd` command updates both. It is possible to have different passwords in the name service and local `files` entry. Use `passwd -r` to change a specific password repository.

The `passwd` command does not prompt authorized users for the old password.

If LDAP is in effect, an authorized user on any Native LDAP client system can change any password without being prompted for the old LDAP password.

By default, even users authorized to change the password of other users must comply with the configured password policy. See [pam_authok_check\(5\)](#).

Normally, `passwd` entered with no arguments changes the password of the current user. When a user logs in and then invokes [su\(1M\)](#) to become role or another user, `passwd` changes the original user's password, not the password of the role or the new user.

The `-s` argument is restricted to an authorized user.

The format of the display is:

name status mm/dd/yy min max warn

or, if password aging information is not present,

name status

where

name

The login ID of the user.

status

The password status of *name*.

The *status* field can take the following values:

LK

The account is locked. `passwd -l` was run or the account was automatically locked due to the number of authentication failures reaching the configured maximum allowed. See [policy.conf\(4\)](#) and [user_attr\(4\)](#) and the “Security” section.

NL

The account is a non UNIX authentication account. `passwd -N` has been run. See “Security”. Accounts in this state are not automatically locked when the system or per user policy is `LOCK_AFTER_RETRIES=YES`.

NP

This account has no password and is therefore open without authentication.

PS

This account has a password.

UN

The data in the password field is unknown. It is not a recognizable hashed password or any of the above entries. See [crypt\(3C\)](#) for valid password hashes.

UP

This account has not yet been activated by the administrator and cannot be used. See [Security](#).

mm/dd/yy

The date password was last changed for *name*. All password aging dates are determined using Greenwich Mean Time (Universal Time) and therefore can differ by as much as a day in other time zones.

min

The minimum number of days required between password changes for *name*. `MINWEEKS` is found in `/etc/default/passwd` and is set to `NULL`.

max

The maximum number of days the password is valid for *name*. MAXWEEKS is found in `/etc/default/passwd` and is set to NULL.

warn

The number of days relative to *max* before the password expires and the *name* are warned.

Security `passwd` uses [pam\(3PAM\)](#) for password change. It calls PAM with a service name `passwd` and uses service module type `auth` for authentication and `password` for password change.

Locking an account (`-l` option) does not allow its use for any logins or delayed execution (such as [at\(1\)](#), [batch\(1\)](#), or [cron\(1M\)](#)). The `-N` option can be used to disallow password based login, while continuing to allow delayed execution or login with non UNIX authentication methods.

Locked accounts that have never had a password cannot have their status changed directly to an active password. See `-d`. Changing a password on a locked account that had a password prior to being locked, changes the password without unlocking the account. See `-u` to unlock the account. An authorized administrator can activate an account in the not yet activated state by giving it a password or running `passwd -N` to activate it for non UNIX authentication or delayed execution only.

An account can become locked following inactivity. To unlock such an account use the `-u` or `-f` options. With `-u`, the password is not changed; the use of `-f` forces a password change.

Options The following options are supported:

`-a`

Shows password attributes for all entries. Use only with the `-s` option. *name* must not be provided. For the `files` and `ldap` repositories, this is restricted to the authorized user.

`-e`

Changes the login shell. A normal user can change his/her own shell information, an authorized user can change it for any user. The choice of shell is limited by the requirements of [getusershell\(3C\)](#). If the user currently has a shell that is not allowed by `getusershell`, an authorized user can change it.

`-g`

Changes the `gecos` (finger) information. A normal user can change their own `gecos` information, an authorized user can change it for any user.

`-h`

Changes the home directory.

`-r`

Specifies the repository to which an operation is applied. The supported repositories are `files`, `ldap`, or `nis`.

-s *name*

Shows password attributes for the login *name*. For the `files` and `ldap` repositories, this only works for the authorized user. It does not work at all for the `nis` repository, which does not support password aging.

The output of this option, and only this option, is Committed and parsable. The format is *username* followed by white space followed by one of the following codes.

New codes might be added in the future so code that parses this must be flexible in the face of unknown codes. While all existing codes are two characters in length that might not always be the case.

The following are the current status codes:

LK

The account is locked. `passwd -l` was run or the account was automatically locked due to the number of authentication failures reaching the configured maximum allowed. See [policy.conf\(4\)](#) and [user_attr\(4\)](#) and the “Security” section.

NL

The account is a non UNIX authentication account. `passwd -N` has been run. See “Security”. Accounts in this state are not automatically locked when the system or per user policy is `LOCK_AFTER_RETRIES=YES`.

NP

Account has no password. `passwd -d` was run.

PS

The account probably has a valid password.

UN

The data in the password field is unknown. It is not a recognizable hashed password or any of the above entries. See [crypt\(3C\)](#) for valid password hashes.

UP

This account has not yet been activated by the administrator and cannot be used. See [Security](#).

Authorized User Options

An administrator needs to be granted the User Security profile to be able to lock and unlock an existing account. That profile also provides the ability to activate a newly created account, set password aging options and view password attributes. The following lists shows the authorizations required to perform the various operations.

Only an authorized user can use the following options:

-d

Deletes password for *name* and unlocks the account. The login *name* is not prompted for password. It is only applicable to the `files` and `ldap` repositories.

If the [login\(1\)](#) option `PASSREQ=YES` is configured, the account is not able to login. `PASSREQ=YES` is the delivered default.

- f
Forces the user to change password at the next login by expiring the password for *name*. This option is useful for unlocking accounts that have become locked due to inactivity.
- l
Locks account for *name* unless it is already locked. See the -u option for unlocking the account. Accounts that are marked for non UNIX authentication or delayed execution only can be locked and will return to the same state when unlocked.
- N
Makes the password entry for *name* a value that cannot be used for login with UNIX authentication, but does not lock the account. See the -d option for removing the value, or -l to lock the account.
- n *min*
Sets minimum field for *name*. The *min* field contains the minimum number of days between password changes for *name*. If *min* is greater than *max*, the user can not change the password. Always use this option with the -x option, unless *max* is set to -1 (aging turned off). In that case, *min* need not be set.
- u
Unlocks a locked password for entry *name*. The -u option is useful for unlocking accounts that have become locked due to failed attempts or were administratively locked with the -l option. An account that is marked as a non UNIX authentication account (`passwd -N`) returns to that state when it is unlocked.
- w *warn*
Sets warn field for *name*. The *warn* field contains the number of days before the password expires and the user is warned. This option is not valid if password aging is disabled.
- x *max*
Sets maximum field for *name*. The *max* field contains the number of days that the password is valid for *name*. The aging for *name* is turned off immediately if *max* is set to -1.

Operands The following operand is supported:

name
User login name.

Environment Variables If any of the `LC_*` variables, that is, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY` (see [environ\(5\)](#)), are not set in the environment, the operational behavior of `passwd` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the C (U.S. style) locale determines how `passwd` behaves.

LC_CTYPE

Determines how `passwd` handles characters. When `LC_CTYPE` is set to a valid value, `passwd` can display and handle text and filenames containing valid characters for that locale. `passwd` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `passwd` can also handle EUC characters of 1, 2, or more column widths. In the C locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the C locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

Exit Status The `passwd` command exits with one of the following values:

- 0
Success.
- 1
Permission denied.
- 2
Invalid combination of options.
- 3
Unexpected failure. Password file unchanged.
- 4
Unexpected failure. Password file(s) missing.
- 5
Password file(s) busy. Try again later.
- 6
Invalid argument to option.
- 7
Aging option is disabled.
- 8
No memory.
- 9
System error.
- 10
Account expired.
- 11
Password information unchanged.

Files /etc/default/passwd

Default values can be set for the following flags in /etc/default/passwd. For example:
MAXWEEKS=26

DICTIONBDDIR

The directory where the generated dictionary databases reside. Defaults to
/var/passwd.

If neither DICTIONLIST nor DICTIONBDDIR is specified, the system does not perform a dictionary check.

DICTIONLIST

DICTIONLIST can contain list of comma separated dictionary files such as
DICTIONLIST=*file1, file2, file3*. Each dictionary file contains multiple lines and each line consists of a word and a NEWLINE character (similar to
/usr/share/lib/dict/words.) You must specify full path names. The words from these files are merged into a database that is used to determine whether a password is based on a dictionary word.

If neither DICTIONLIST nor DICTIONBDDIR is specified, the system does not perform a dictionary check.

To pre-build the dictionary database, see [mkpwdict\(1M\)](#).

HISTORY

Maximum number of prior password history to keep for a user. Setting the HISTORY value to zero (0), or removing the flag, causes the prior password history of all users to be discarded at the next password change by any user. The default is not to define the HISTORY flag. The maximum value is 26. Currently, this functionality is enforced only for user accounts defined in the files name service (local [passwd\(4\)/shadow\(4\)](#)).

MAXREPEATS

Maximum number of allowable consecutive repeating characters. If MAXREPEATS is not set or is zero (0), the default is no checks

MAXWEEKS

Maximum time period that password is valid.

MINALPHA

Minimum number of alpha character required. If MINALPHA is not set, the default is 2.

MINDIFF

Minimum differences required between an old and a new password. If MINDIFF is not set, the default is 3.

MINDIGIT

Minimum number of digits required. If MINDIGIT is not set or is set to zero (0), the default is no checks. You cannot specify MINDIGIT if MINNONALPHA is also specified.

MINLOWER

Minimum number of lower case letters required. If not set or zero (0), the default is no checks.

MINNONALPHA

Minimum number of non-alpha (including numeric and special) required. If MINNONALPHA is not set, the default is 1. You cannot specify MINNONALPHA if MINDIGIT or MINSPECIAL is also specified.

MINWEEKS

Minimum time period before the password can be changed.

MINSPECIAL

Minimum number of special (non-alpha and non-digit) characters required. If MINSPECIAL is not set or is zero (0), the default is no checks. You cannot specify MINSPECIAL if you also specify MINNONALPHA.

MINUPPER

Minimum number of upper case letters required. If MINUPPER is not set or is zero (0), the default is no checks.

NAMECHECK

Enable/disable checking of the login name. The default is to do login name checking. A case insensitive value of no disables this feature.

PASSLENGTH

Minimum length of password, in characters.

WARNWEEKS

Time period until warning of date of password's ensuing expiration.

WHITESPACE

Determine if white space characters are allowed in passwords. Valid values are YES and NO. If WHITESPACE is not set or is set to YES, white space characters are allowed.

/etc/oshadow

Temporary file used by passwd and pwconv to update the real shadow file.

/etc/passwd

Password file.

/etc/shadow

Shadow password file.

/etc/shells

Shell database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	See below.

The human readable output is Uncommitted. The options are Committed.

See Also [at\(1\)](#), [batch\(1\)](#), [finger\(1\)](#), [login\(1\)](#), [cron\(1M\)](#), [domainname\(1M\)](#), [eeprom\(1M\)](#), [id\(1M\)](#), [ldapclient\(1M\)](#), [mkpwdict\(1M\)](#), [pwconv\(1M\)](#), [su\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [crypt\(3C\)](#), [getpwnam\(3C\)](#), [getspnam\(3C\)](#), [getusershell\(3C\)](#), [pam\(3PAM\)](#), [loginlog\(4\)](#), [nsswitch.conf\(4\)](#), [pam.conf\(4\)](#), [passwd\(4\)](#), [policy.conf\(4\)](#), [shadow\(4\)](#), [shells\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_ldap\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), [pam_unix_session\(5\)](#), [crypt_unix\(5\)](#)

Notes The `yppasswd` command is a wrapper around `passwd`. Use of `yppasswd` is discouraged. Use `passwd -r repository_name` instead.

Changing a password in the files and ldap repositories clears the failed login count.

Changing a password reactivates an account deactivated for inactivity for the length of the inactivity period.

Input terminal processing might interpret some key sequences and not pass them to the `passwd` command.

An account with no password, status code NP, might not be able to login. See the [login\(1\)](#) PASSREQ option.

Authorizations required to perform various options:

-d	delete password	solaris.passwd.assign
-N	set nologin	solaris.passwd.assign
	change any passwd	solaris.passwd.assign
-l	lock account	solaris.account.setpolicy
-u	unlock account	solaris.account.setpolicy
-n	set min field for name	solaris.account.setpolicy
-w	set warn field for name	solaris.account.setpolicy
-x	set max field for name	solaris.account.setpolicy
-f	forces password expiration	solaris.account.setpolicy
-s	display password attributes	solaris.account.setpolicy
-a	display password attributes for all entries	solaris.account.setpolicy
-e	change login shell	solaris.user.manage

```
-g    change gecos information      solaris.user.manage
-h    change home directory        solaris.user.manage
      set a newly created account's
      passwd for the first time    solaris.account.activate
```

All password hash algorithms except `crypt_unix(5)` have a maximum password length of 255.

Name paste – merge corresponding or subsequent lines of files

Synopsis /usr/bin/paste [*options*] [*file...*]

Description The paste utility concatenates the corresponding lines of the given input files, and write the resulting lines to standard output.

The default operation of paste concatenates the corresponding lines of the input files. The NEWLINE character of every line except the line from the last input file is replaced with a TAB character.

If an EOF (end-of-file) condition is detected on one or more input files, but not all input files, paste behaves as though empty lines were read from the files on which EOF was detected, unless the -s option is specified.

Options The following options are supported:

-d *list* Unless a backslash character (\) appears in list, each character in list is an element specifying a delimiter character. If a backslash character appears in list, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default TAB character, to replace the NEWLINE character of the input lines. The elements in list are used circularly. That is, when the list is exhausted, the first element from the list is reused.

When the -s option is specified:

- The last NEWLINE character in a file is not modified.
- The delimiter is reset to the first element of list after each file operand is processed.

When the option is not specified:

- The NEWLINE characters in the file specified by the last file is not modified.
- The delimiter is reset to the first element of list each time a line is processed from each file.

If a backslash character appears in list, it and the character following it is used to represent the following delimiter characters:

\n NEWLINE character.

\t TAB character.

\\ Backslash character.

\0 Empty string (not a null character). If 0 is immediately followed by the character x, the character X, or any character defined by the LC_CTYPE digit keyword, the results are unspecified.

If any other characters follow the backslash, the results are unspecified.

- s Concatenate all of the lines of each separate input file in command line order. The NEWLINE character of every line except the last line in each input file is replaced with the TAB character, unless otherwise specified by the -d option.

Operands The following operand is supported:

file A path name of an input file. If is specified for one or more of the files, the standard input is used. The standard input is read one line at a time, circularly, for each instance of dot .. Implementations support pasting of at least 12 file operands.

Usage See [largefile\(5\)](#) for the description of the behavior of `paste` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Listing a Directory in One Column

The following example lists a directory in one column:

```
example% ls | paste -d" " -
```

EXAMPLE 2 Listing a Directory in Four Columns

The following example lists a directory in four columns:

```
example% ls | paste - - - -
```

EXAMPLE 3 Combining Pairs of Lines from a File into Single Lines

The following example combines pairs of lines from a file into single lines:

```
example% paste -s -d"\ t\ n" file
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `paste`: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name patch – apply changes to files

Synopsis patch [-bLNR] [-c | -e | -n | -u] [-d *dir*] [-D *define*]
[-i *patchfile*] [-o *outfile*] [-p *num*] [-r *rejectfile*]
[*file*]

Description The patch command reads a source (patch) file containing any of the three forms of difference (diff) listings produced by the `diff(1)` command (normal, context or in the style of `ed(1)`) and apply those differences to a file. By default, patch reads from the standard input.

patch attempts to determine the type of the diff listing, unless overruled by a -c, -e, or -n option.

If the patch file contains more than one patch, patch attempts to apply each of them as if they came from separate patch files. (In this case the name of the patch file must be determinable for each diff listing.)

Options The following options are supported:

- b Saves a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix `.orig` appended to it. If the file already exists, it is overwritten. If multiple patches are applied to the same file, the `.orig` file is written only for the first patch. When the `-o outfile` option is also specified, `file.orig` is not created but, if `outfile` already exists, `outfile.orig` is created.
- c Interprets the patch file as a context difference (the output of the command `diff` when the `-c` or `-C` options are specified).
- d *dir* Changes the current directory to *dir* before processing as described in EXTENDED DESCRIPTION.
- D *define* Marks changes with the C preprocessor construct:

```
#ifdef define
. . .
#endif
```

The option-argument *define* is used as the differentiating symbol.

- e Interprets the patch file as an ed script, rather than a diff script.
- i *patchfile* Reads the patch information from the file named by the path name *patchfile*, rather than the standard input.
- l (The letter ell.) Causes any sequence of blank characters in the difference script to match any sequence of blank characters in the input file. Other characters is matched exactly.
- n Interprets the script as a normal difference.

-
- N Ignores patches where the differences have already been applied to the file; by default, already-applied patches are rejected.
 - o *outfile* Instead of modifying the files (specified by the *file* operand or the difference listings) directly, writes a copy of the file referenced by each patch, with the appropriate differences applied, to *outfile*. Multiple patches for a single file is applied to the intermediate versions of the file created by any previous patches, and results in multiple, concatenated versions of the file being written to *outfile*.
 - p *num* For all path names in the patch file that indicate the names of files to be patched, deletes *num* path name components from the beginning of each path name. If the path name in the patch file is absolute, any leading slashes are considered the first component (that is, -p 1 removes the leading slashes). Specifying -p 0 causes the full path name to be used. If -p is not specified, only the basename (the final path name component) is used.
 - R Reverses the sense of the patch script. That is, assumes that the difference script was created from the new version to the old version. The -R option cannot be used with ed scripts. patch attempts to reverse each portion of the script before applying it. Rejected differences is saved in swapped format. If this option is not specified, and until a portion of the patch file is successfully applied, patch attempts to apply each portion in its reversed sense as well as in its normal sense. If the attempt is successful, the user is prompted to determine if the -R option should be set.
 - r *rejectfile* Overrides the default reject file name. In the default case, the reject file has the same name as the output file, with the suffix .rej appended to it. See Patch Application.
 - u Interprets the patch file as a unified context difference, that is, the output of the command diff when the -u or -U options are specified.

Operands The following operand is supported:

file A path name of a file to patch.

Usage The -R option does not work with ed scripts because there is too little information to reconstruct the reverse operation.

The -p option makes it possible to customize a patch file to local user directory structures without manually editing the patch file. For example, if the file name in the patch file was `/curds/whey/src/blurfl/blurfl.c`:

- Setting -p 0 gives the entire path name unmodified.
- Setting -p 1 gives:

`curds/whey/src/blurfl/blurfl.c`

- Without the leading slash, `-p 4` gives:

```
blurfl/blurfl.c
```

- Not specifying `-p` at all gives:

```
blurfl.c
```

When using `-b` in some file system implementations, the saving of a `.orig` file might produce unwanted results. In the case of 12-, 13-, or 14-character file names, on file systems supporting 14-character maximum file names, the `.orig` file overwrites the new file.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `patch`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

Affirmative responses are processed using the extended regular expression defined for the `yesexpr` keyword in the `LC_MESSAGES` category of the user's locale. The locale specified in the `LC_COLLATE` category defines the behavior of ranges, equivalence classes, and multi-character collating elements used in the expression defined for `yesexpr`. The locale specified in `LC_CTYPE` determines the locale for interpretation of sequences of bytes of text data a characters, the behavior of character classes used in the expression defined for the `yesexpr`. See [locale\(5\)](#).

Output Files The output of `patch` the save files (`.orig` suffixes) and the reject files (`.rej` suffixes) are text files.

Extended Description A patch file can contain patching instructions for more than one file. File names are determined as specified in [Patch Determination](#). When the `-b` option is specified, for each patched file, the original is saved in a file of the same name with the suffix `.orig` appended to it.

For each patched file, a reject file can also be created as noted in [Patch Application](#). In the absence of an `-r` option, the name of this file is formed by appending the suffix `.rej` to the original file name.

Patch File Format The patch file must contain zero or more lines of header information followed by one or more patches. Each patch must contain zero or more lines of file name identification in the format produced by `diff -c`, and one or more sets of `diff` output, which are customarily called hunks.

`patch` recognizes the following expression in the header information:

Index: *pathname* The file to be patched is named *pathname*.

If all lines (including headers) within a patch begin with the same leading sequence of blank characters, `patch` removes this sequence before proceeding. Within each patch, if the type of difference is context, `patch` recognizes the following expressions:

- * * * *filename timestamp* The patches arose from *filename*.
- - - *filename timestamp* The patches should be applied to *filename*.

Each hunk within a patch must be the `diff` output to change a line range within the original file. The line numbers for successive hunks within a patch must occur in ascending order.

File Name Determination

If no *file* operand is specified, `patch` performs the following steps to obtain a path name:

1. If the patch contains the strings `***` and `- - -`, `patch` strips components from the beginning of each path name (depending on the presence or value of the `-p` option), then tests for the existence of both files in the current directory (or directory specified with the `-d` option).
2. If both files exist, `patch` assumes that no path name can be obtained from this step. If the header information contains a line with the string `Index:`, `patch` strips components from the beginning of the path name (depending on `-p`), then tests for the existence of this file in the current directory (or directory specified with the `-d` option).
3. If an SCCS directory exists in the current directory, `patch` attempts to perform a `get -e SCCS/s .filename` command to retrieve an editable version of the file.
4. If no path name can be obtained by applying the previous steps, or if the path names obtained do not exist, `patch` writes a prompt to standard output and request a file name interactively from standard input.

Patch Application

If the `-c`, `-e`, `-n`, or `-u` option is present, `patch` interprets information within each hunk as a context difference, an `ed` difference, a normal difference, or a unified context difference, respectively. In the absence of any of these options, `patch` determines the type of difference based on the format of information within the hunk.

For each hunk, `patch` begins to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, `patch` scans both forwards and backwards at least 1000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan takes place, ignoring the first and last line of context. If that fails, the first two and last two lines of context is ignored and another scan is made. Implementations can search more extensively for installation locations.

If no location can be found, `patch` appends the hunk to the reject file. The rejected hunk is written in context-difference format regardless of the format of the patch file. If the input was a normal or `ed -style` difference, the reject file can contain differences with zero lines of context. The line numbers on the hunks in the reject file can be different from the line numbers in the patch file since they reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an ed diff, the implementation can accomplish the patching by invoking the ed command.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 One or more lines were written to a reject file.
- >1 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Standard	See standards(5) .

See Also [ed\(1\)](#), [diff\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

- Name** pathchk – check path names
- Synopsis** pathchk [-p] *path*...
- Description** The pathchk command will check that one or more path names are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation will result). More extensive portability checks are provided by the -p option.
- By default, pathchk will check each component of each *path* operand based on the underlying file system. A diagnostic will be written for each *path* operand that:
- is longer than PATH_MAX bytes.
 - contains any component longer than NAME_MAX bytes in its containing directory
 - contains any component in a directory that is not searchable
 - contains any character in any component that is not valid in its containing directory.
- The format of the diagnostic message is not specified, but will indicate the error detected and the corresponding *path* operand.
- It will not be considered an error if one or more components of a *path* operand do not exist as long as a file matching the path name specified by the missing components could be created that does not violate any of the checks specified above.
- Options** The following option is supported:
- p Instead of performing checks based on the underlying file system, write a diagnostic for each *path* operand that:
- is longer than _POSIX_PATH_MAX bytes
 - contains any component longer than _POSIX_NAME_MAX bytes
 - contains any character in any component that is not in the portable filename character set.
- Operands** The following operand is supported:
- path* A path to be checked.
- Usage** See [largefile\(5\)](#) for the description of the behavior of pathchk when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).
- Examples** **EXAMPLE 1** Using the pathchk command
- To verify that all paths in an imported data interchange archive are legitimate and unambiguous on the current system:
- ```
example% pax -f archive | sed -e '/ == ./s///' | xargs pathchk
if [$? -eq 0]
then
```

EXAMPLE 1 Using the pathchk command (Continued)

```

 pax -r -f archive
else
 echo Investigate problems before importing files.
 exit 1
fi

```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the X/Open specification that also supports the `pax(1)` command:

```

example% find . -print | xargs pathchk -p
if [$? -eq 0]
then
 pax -w -f archive .
else
 echo Portable archive cannot be created.
 exit 1
fi

```

To verify that a user-supplied path names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```

example% case $- in
 C) reset="";;
 *) reset="set +C"
 set -C;;
esac
test -r "$path" && pathchk "$path.out" &&
rm "$path.out" > "$path.out"
if [$? -ne 0]; then
 printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
 $reset # reset the noclobber option in case a trap
 # on EXIT depends on it
 exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"

```

The following assumptions are made in this example:

1. PROCESSING represents the code that will be used by the application to use `$path` once it is verified that `$path.out` will work as intended.
2. The state of the `noclobber` option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The `reset` variable is used in this example to restore the initial state.)

EXAMPLE 1 Using the pathchk command (Continued)

3. Note the usage of:

```
rm "$path.out" > "$path.out"
```

- a. The pathchk command has already verified, at this point, that `$path.out` will not be truncated.
- b. With the `noclobber` option set, the shell will verify that `$path.out` does not already exist before invoking `rm`.
- c. If the shell succeeded in creating `$path.out`, `rm` will remove it so that the application can create the file again in the `PROCESSING` step.
- d. If the `PROCESSING` step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

should be replaced with:

```
> "$path.out"
```

which will verify that the file did not already exist, but leave `$path.out` in place for use by `PROCESSING`.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `pathchk`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 All *path* operands passed all of the checks.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [pax\(1\)](#), [test\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Name** pax – portable archive interchange

**Synopsis** pax [-cdnv] [-H | -L] [-f *archive*] [-o *options*]...  
 [-s *replstr*]... [*pattern*]...  
 pax -r [-cdiknuv@/] [-H | -L] [-f *archive*] [-o *options*]...  
 [-p *string*]... [-s *replstr*]... [*pattern*]...  
 pax -w [-dituvX@/] [-H | -L] [-b *blocksize*] [-a]  
 [-f *archive*] [-o *options*]... [-s *replstr*]...  
 [-x *format*] [*file*]...  
 pax -r -w [-diklntuvX@/] [-H | -L] [-o *options*]...  
 [-p *string*]... [-s *replstr*]... [*file*]... *directory*

**Description** pax reads, writes, and writes lists of the members of archive files and copies directory hierarchies. A variety of archive formats are supported. See the *-x format* option.

**Modes of Operations** The action to be taken depends on the presence of the *-r* and *-w* options. The four combinations of *-r* and *-w* are referred to as the four modes of operation: *list*, *read*, *write*, and *copy* modes, corresponding respectively to the four forms shown in the SYNOPSIS.

**list** In *list* mode, that is, when neither *-r* nor *-w* are specified, pax writes the names of the members of the archive file read from the standard input, with path names matching the specified patterns, to standard output. If a named file has extended attributes, the extended attributes are also listed. If a named file is of type directory, the file hierarchy rooted at that file is listed as well.

**read** In *read* mode, that is, when *-r* is specified, but *-w* is not, pax extracts the members of the archive file read from the standard input, with path names matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file is extracted as well. The extracted files are created performing path name resolution with the directory in which pax was invoked as the current working directory.

If an attempt is made to extract a directory when the directory already exists, this is not considered an error. If an attempt is made to extract a FIFO when the FIFO already exists, this is not considered an error.

The ownership, access and modification times, and file mode of the restored files are discussed under the *-p* option.

**write** In *write* mode, that is, when *-w* is specified, but *-r* is not, pax writes the contents of the *file* operands to the standard output in an archive format. If no *file* operands are specified, a list of files to copy, one per line, are read from the standard input. A file of type directory includes all of the files in the file hierarchy rooted at the file.

**copy** In *copy* mode, that is, when both *-r* and *-w* are specified, pax copies the *file* operands to the destination directory.

If no *file* operands are specified, a list of files to copy, one per line, are read from the standard input. A file of type directory includes all of the files in the file hierarchy rooted at the file.

The effect of the copy is as if the copied files were written to an archive file and then subsequently extracted, except that there can be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. It is an error if *directory* does not exist, is not writable by the user, or is not a directory.

In read or copy modes, if intermediate directories are necessary to extract an archive member, pax performs actions equivalent to the `mkdir(2)` function, called with the following arguments:

- The intermediate directory used as the *path* argument.
- The octal value of 777 or *rxw* (read, write, and execute permissions) as the *mode* argument (see `chmod(1)`).

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, pax writes a diagnostic message to standard error for each one that did not match and exits with a non-zero exit status.

The supported archive formats are automatically detected on input. The default output archive format is `tar(1)`.

A single archive can span multiple files. pax determines what file to read or write as the next file.

If the selected archive format supports the specification of linked files, it is an error if these files cannot be linked when the archive is extracted, except if the files to be linked are symbolic links and the system is not capable of making hard links to symbolic links. In that case, separate copies of the symbolic link are created instead. Any of the various names in the archive that represent a file can be used to select the file for extraction. For archive formats that do not store file contents with each name that causes a hard link, if the file that contains the data is not extracted during this pax session, either the data is restored from the original file, or a diagnostic message is displayed with the name of a file that can be used to extract the data. In traversing directories, pax detects infinite loops, that is, entering a previously visited directory that is an ancestor of the last file visited. When it detects an infinite loop, pax writes a diagnostic message to standard error and terminates.

**Options** The following options are supported:

- a Appends files to the end of the archive. This option does not work for some archive devices, such as 1/4-inch streaming tapes and 8mm tapes.

- b *blocksize* Blocks the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats can impose restrictions on blocking. Blocking is automatically determined on input. Portable applications must not specify a *blocksize* value larger than 32256. Default blocking when creating archives depends on the archive format. See the -x option below.
- c Matches all file or archive members except those specified by the *pattern* or *file* operands.
- d Causes files of type directory being copied or archived or archive members of type directory being extracted or listed to match only the file or archive member itself and not the file hierarchy rooted at the file.
- f *archive* Specifies the path name of the input or output archive, overriding the default standard input (in `list` or `read` modes) or standard output (`write` mode).
- H If a symbolic link referencing a file of type directory is specified on the command line, `pax` archives the file hierarchy rooted in the file referenced by the link, using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any other file type which `pax` can normally archive is specified on the command line, then `pax` archives the file referenced by the link, using the name of the link. The default behavior is to archive the symbolic link itself.
- i Interactively renames files or archive members. For each archive member matching a *pattern* operand or file matching a *file* operand, a prompt is written to the file `/dev/tty`. The prompt contains the name of the file or archive member. A line is then read from `/dev/tty`. If this line is blank, the file or archive member is skipped. If this line consists of a single period, the file or archive member is processed with no modification to its name. Otherwise, its name is replaced with the contents of the line. `pax` immediately exits with a non-zero exit status if end-of-file is encountered when reading a response or if `/dev/tty` cannot be opened for reading and writing.  
  
The results of extracting a hard link to a file that has been renamed during extraction are unspecified.
- k Prevents the overwriting of existing files.
- l Links files. In copy mode, hard links are made between the source and destination file hierarchies whenever possible. If specified in conjunction with -H or -L, when a symbolic link is encountered, the hard link created in the destination file hierarchy is to the file referenced by the symbolic link. If specified when neither -H nor -L is specified, when a symbolic link is encountered, the implementation creates a hard link to the symbolic link in the source file hierarchy or copies the symbolic link to the destination.

- L If a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, pax archives the file hierarchy rooted in the file referenced by the link, using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any other file type which pax can normally archive is specified on the command line or encountered during the traversal of a file hierarchy, pax archives the file referenced by the link, using the name of the link. The default behavior is to archive the symbolic link itself.
- n Selects the first archive member that matches each *pattern* operand. No more than one archive member is matched for each pattern, although members of type directory still match the file hierarchy rooted at that file.
- o *options* Provides information to the implementation to modify the algorithm for extracting or writing files. The value of options consists of one or more comma-separated keywords of the form:
- ```
keyword[[:]=value][,keyword[[:]=value], ...]
```
- Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being processed produces undefined results.
- Keywords in the *options* argument must be a string that would be a valid portable filename.
- Keywords are not expected to be filenames, merely to follow the same character composition rules as portable filenames.
- Keywords can be preceded with white space. The *value* field consists of zero or more characters. Within *value*, the application precedes any literal comma with a backslash, which is ignored, but preserves the comma as part of *value*. A comma as the final character, or a comma followed solely by white space as the final characters, in *options* is ignored. Multiple -o options can be specified. If keywords given to these multiple -o options conflict, the keywords and values appearing later in command line sequence take precedence and the earlier ones are silently ignored. The following keyword values of *options* are supported for the file formats as indicated:
- delete=pattern*
- This keyword is applicable only to the -x pax format. When used in write or copy mode, pax omits from extended header records that it produces any keywords matching the string pattern. When used in read or list mode, pax ignores any keywords matching the string pattern in the extended header records. In both cases, matching is performed using the pattern matching notation. For example:
- ```
-o delete=security.*
```

would suppress security-related information.

When multiple `-o delete=pattern` options are specified, the patterns are additive. All keywords matching the specified string patterns are omitted from extended header records that `pax` produces.

#### `exthdr.name=string`

This keyword is applicable only to the `-x pax` format. This keyword allows user control over the name that is written into the `ustar` header blocks for the extended header. The name is the contents of *string*, after the following character substitutions have been made:

- `%d` The directory name of the file, equivalent to the result of the *dirname* utility on the translated path name.
- `%f` The filename of the file, equivalent to the result of the *basename* utility on the translated path name.
- `%p` The process ID of the `pax` process.
- `%%` A `'%'` character.

Any other `'%'` characters in *string* produce undefined results.

If no `-o exthdr.name=string` is specified, `pax` uses the following default value:

```
%d/PaxHeaders.%p/%f
```

#### `globexthdr.name=string`

This keyword is applicable only to the `-x pax` format. When used in `wri te` or `copy` mode with the appropriate options, `pax` creates global extended header records with `ustar` header blocks that are treated as regular files by previous versions of `pax`. This keyword allows user control over the name that is written into the `ustar` header blocks for global extended header records. The name is the contents of *string*, after the following character substitutions have been made:

- `%n` An integer that represents the sequence number of the global extended header record in the archive, starting at 1.
- `%p` The process ID of the `pax` process.
- `%%` A `'%'` character.

Any other `'%'` characters in *string* produce undefined results.

If no `-o globexthdr.name=string` is specified, `pax` uses the following default value:

```
$TMPDIR/GlobalHead.%p.%n
```

where `$TMPDIR` represents the value of the `TMPDIR` environment variable. If `TMPDIR` is not set, `pax` uses `/tmp`.

#### `invalid=action`

This keyword is applicable only to the `-x pax` format. This keyword allows user control over the action `pax` takes upon encountering values in an extended header record that, in `read` or `copy` mode, are invalid in the destination hierarchy or, in `list` mode, cannot be written in the codeset and current locale of the implementation. The following are invalid values that are recognized by `pax`:

- In `read` or `copy` mode, a filename or link name that contains character encodings invalid in the destination hierarchy. For example, the name can contain embedded NULs.
- In `read` or `copy` mode, a filename or link name that is longer than the maximum allowed in the destination hierarchy, for either a path name component or the entire path name.
- In `list` mode, any character string value (filename, link name, user name, and so on) that cannot be written in the codeset and current locale of the implementation.

The following mutually-exclusive values of the `action` argument are supported:

- |                     |                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bypass</code> | In <code>read</code> or <code>copy</code> mode, <code>pax</code> bypasses the file, causing no change to the destination hierarchy. In <code>list</code> mode, <code>pax</code> writes all requested valid values for the file, but its method for writing invalid values is unspecified.                                                                             |
| <code>rename</code> | In <code>read</code> or <code>copy</code> mode, <code>pax</code> acts as if the <code>-i</code> option were in effect for each file with invalid filename or link name values, allowing the user to provide a replacement name interactively. In <code>list</code> mode, <code>pax</code> behaves identically to the <code>bypass</code> action.                      |
| <code>UTF-8</code>  | <code>pax</code> uses the actual UTF-8 encoding for the name when it is used in <code>read</code> , <code>copy</code> , or <code>list</code> mode and a filename, link name, owner name, or any other field in an extended header record cannot be translated from the <code>pax UTF-8</code> codeset format to the codeset and current locale of the implementation. |
| <code>write</code>  | In <code>read</code> or <code>copy</code> mode, <code>pax</code> writes the file, translating the name, regardless of whether this can overwrite an existing file with a valid name. In <code>list</code> mode, <code>pax</code> behaves identically to the <code>bypass</code> action.                                                                               |

If no `-o invalid=` option is specified, `pax` acts as if `-o invalid=bypass` were specified. Any overwriting of existing files that can be allowed by the

`-o invalid=actions` are subject to permission (`-p`) and modification time (`-u`) restrictions, and are suppressed if the `-k` option is also specified.

#### linkdata

This keyword is applicable only to the `-x pax` format. In `write` mode, `pax` writes the contents of a file to the archive even when that file is merely a hard link to a file whose contents have already been written to the archive.

#### listopt=format

This keyword specifies the output format of the table of contents produced when the `-v` option is specified in `list` mode. (See `List Mode Format Specifications` below.) To avoid ambiguity, the `listopt=format` is the only or final `keyword=value` pair in an `-o` option-argument. All characters in the remainder of the option-argument are considered to be part of the format string. When multiple `-o listopt=format` options are specified, the format strings are considered to be a single, concatenated string, evaluated in command line order.

#### times

This keyword is applicable only to the `-x pax` and `-x xustar` formats. When used in `write` or `copy` mode, `pax` includes `atime` and `mtime` extended header records for each file.

In addition to these keywords, if the `-x pax` format is specified, any of the keywords and values, including implementation extensions, can be used in `-o` option-arguments, in either of two modes:

`keyword=value` When used in `write` or `copy` mode, these keyword/value pairs are included at the beginning of the archive as `typeflag g` global extended header records. When used in `read` or `list` mode, these keyword/value pairs act as if they had been at the beginning of the archive as `typeflag g` global extended header records.

`keyword:=value` When used in `write` or `copy` mode, these keyword/value pairs are included as records at the beginning of a `typeflag x` extended header for each file. This is equivalent to the equal-sign form except that it creates no `typeflag g` global extended header records. When used in `read` or `list` mode, these keyword/value pairs act as if they were included as records at the end of each extended header. Thus, they override any global or file-specific extended header record keywords of the same names. For example, in the command:

```
pax -r -o "
gname:=mygroup,
" <archive
```

the group name is forced to a new value for all files read from the archive.

**-p *string*** Specifies one or more file characteristic options (privileges). The *string* option-argument must be a string specifying file characteristics to be retained or discarded on extraction. The string consists of the specification characters a, e, m, o, and p. Multiple characteristics can be concatenated within the same string and multiple -p options can be specified. The meaning of the specification characters is as follows:

- a Does not preserve file access times.
- e Preserves the user ID, group ID, file mode bits, access time, and modification time.
- m Does not preserve file modification times.
- o Preserves the user ID and group ID.
- p Preserves the file mode bits.

In the preceding list, preserve indicates that an attribute stored in the archive is given to the extracted file, subject to the permissions of the invoking process. Otherwise, the attribute is determined as part of the normal file creation action. The access and modification times of the file is preserved unless otherwise specified with the -p option or not stored in the archive. All attributes that are not preserved are determined as part of the normal file creation action.

If neither the e nor the o specification character is specified, or the user ID and group ID are not preserved for any reason, pax does not set the `setuid` and `setgid` bits of the file mode.

If the preservation of any of these items fails for any reason, pax writes a diagnostic message to standard error. Failure to preserve these items affects the final exit status, but does not cause the extracted file to be deleted.

If file-characteristic letters in any of the *string* option-arguments are duplicated or conflict with each other, the ones given last take precedence. For example, if -p eme is specified, file modification times are preserved.

**-r** Reads an archive file from standard input.

**-s *replstr*** Modifies file or archive member names named by *pattern* or *file* operands according to the substitution expression *replstr*, which is based on the `ed(1)` s (substitution) utility, using the regular expression syntax of `regex(5)`. The concepts of “address” and “line” are meaningless in the context of the pax command, and must not be supplied. The format is:

`-s /old/new/ [gp]`

where, as in `ed`, *old* is a basic regular expression and *new* can contain an ampersand (&), a `\n` backreference, where *n* is a digit, or subexpression matching. The *old* string is also permitted to contain newlines.

Any non-null character can be used as a delimiter (/ shown here). Multiple `-s` expressions can be specified. The expressions are applied in the order specified, terminating with the first successful substitution. The optional trailing `g` is as defined in the `ed` command. The optional trailing `p` causes successful substitutions to be written to standard error. File or archive member names that substitute to the empty string are ignored when reading and writing archives.

`-t` When reading files from the file system, and if the user has the permissions required by `utime()` to do so, sets the access time of each file read to the access time that it had before being read by `pax`.

`-u` Ignores files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name.

`read mode` An archive member with the same name as a file in the file system is extracted if the archive member is newer than the file.

`write mode` An archive file member with the same name as a file in the file system is superseded if the file is newer than the archive member. If option `-a` is also specified, this is accomplished by appending to the archive. Otherwise, it is unspecified whether this is accomplished by actual replacement in the archive or by appending to the archive.

`copy mode` The file in the destination hierarchy is replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.

`-v` In `list` mode, produces a verbose table of contents (see Standard Output). Otherwise, writes archive member path names and extended attributes to standard error (see Standard Error).

`-w` Writes files to the standard output in the specified archive format.

`-x format` Specifies the output archive format. The `pax` utility recognizes the following formats:

`cpio` The extended `cpio(1)` interchange format. See IEEE Std 1003.1–2001. The default *blocksize* for this format for character special archive files is 5120. Implementations support all *blocksize* values less than or equal to 32256 that are multiples of 512.

This archive format allows files with UIDs and GIDs up to 262143 to be stored in the archive. Files with UIDs and GIDs greater than this value are archived with the UID and GID of 60001.

**pax** The pax interchange format. See IEEE Std 1003.1–2001. The default *blocksize* for this format for character special archive files is 5120. Implementations support all *blocksize* values less than or equal to 32256 that are multiples of 512.

Similar to *ustar*. Also allows archiving and extracting files whose size is greater than 8GB; whose UID, GID, *devmajor*, or *devminor* values are greater than 2097151; whose path (including filename) is greater than 255 characters; or whose *linkname* is greater than 100 characters.

**ustar** The extended *tar(1)* interchange format. See the IEEE 1003.1(1990) specifications. The default *blocksize* for this format for character special archive files is 10240. Implementations support all *blocksize* values less than or equal to 32256 that are multiples of 512.

This archive format allows files with UIDs and GIDs up to 2097151 to be stored in the archive. Files with UIDs and GIDs greater than this value are archived with the UID and GID of 60001.

**xustar** Similar to *ustar*. Also allows archiving and extracting files whose size is greater than 8GB; whose UID, GID, *devmajor*, or *devminor* values are greater than 2097151; whose path (including filename) is greater than 255 characters; or whose *linkname* is greater than 100 characters. This option should not be used if the archive is to be extracted by an archiver that cannot handle the larger values.

Any attempt to append to an archive file in a format different from the existing archive format causes *pax* to exit immediately with a non-zero exit status.

In copy mode, if no *-x* format is specified, *pax* behaves as if *-x pax* were specified.

- X** When traversing the file hierarchy specified by a path name, *pax* does not descend into directories that have a different device ID (*st\_dev*, see *stat(2)*).
- @** Includes extended attributes in the archive. *pax* does not place extended attributes in the archive by default.

When traversing the file hierarchy specified by a path name, `pax` descends into the attribute directory for any file with extended attributes. Extended attributes go into the archive as special files.

When this flag is used during file extraction, any extended attributes associated with a file being extracted are also extracted. Extended attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.

-/ Includes extended system attributes in the archive. `pax` does not place extended system attributes in the archive by default.

When traversing the file hierarchy specified by a path name, `pax` descends into the attribute directory for any file with extended attributes. Extended attributes go into the archive as special files. When this flag is used during file extraction, any extended attributes associated with a file being extracted are also extracted. Extended attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.

Specifying more than one of the mutually-exclusive options `-H` and `-L` is not considered an error. The last option specified determines the behavior of the utility.

The options that operate on the names of files or archive members (`-c`, `-i`, `-n`, `-s`, `-u` and `-v`) interact as follows.

In `read` mode, the archive members are selected based on the user-specified *pattern* operands as modified by the `-c`, `-n` and `-u` options. Then, any `-s` and `-i` options modify, in that order, the names of the selected files. The `-v` option writes names resulting from these modifications.

In `write` mode, the files are selected based on the user-specified path names as modified by the `-n` and `-u` options. Then, any `-s` and `-i` options modify, in that order, the names of these selected files. The `-v` option writes names resulting from these modifications.

If both the `-u` and `-n` options are specified, `pax` does not consider a file selected unless it is newer than the file to which it is compared.

#### List Mode Format Specifications

In `list` mode with the `-o listopt=format` option, the *format* argument is applied for each selected file. `pax` appends a NEWLINE to the `listopt` output for each selected file. The *format* argument is used as the format string with the following exceptions. (See [printf\(1\)](#) for the first five exceptions.)

1. A SPACE character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.
2. A ' ' character in the format string is treated as a ' ' character, not as a SPACE.

3. In addition to the escape sequences described in the [formats\(5\)](#) manual page, (`\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`), `\ddd`, where *ddd* is a one-, two-, or three-digit octal number, is written as a byte with the numeric value specified by the octal number.
4. Output from the `d` or `u` conversion specifiers is not preceded or followed with BLANKs not specified by the format operand.
5. Output from the `o` conversion specifier is not preceded with zeros that are not specified by the format operand.
6. The sequence (*keyword*) can occur before a format conversion specifier. The conversion argument is defined by the value of *keyword*. The following keywords are supported (see IEEE Std 1003.1–2001):
  - Any of the Field Name entries in `ustar Header Block` and `Octet-Oriented cpio Archive Entry`. The implementation supports the `cpio` keywords without the leading `c_` in addition to the form required by `Values for cpio c_ mode Field`.
  - Any keyword defined for the extended header in `pax Extended Header`.
  - Any keyword provided as an implementation-defined extension within the extended header defined in `pax Extended Header`.

For example, the sequence “%(charset)s” is the string value of the name of the character set in the extended header.

The result of the keyword conversion argument is the value from the applicable header field or extended header, without any trailing NULs.

All keyword values used as conversion arguments are translated from the UTF-8 encoding to the character set appropriate for the local file system, user database, and so on, as applicable.

7. An additional conversion specifier character, `T`, is used to specify time formats. The `T` conversion specifier character can be preceded by the sequence (*keyword=subformat*), where *subformat* is a date format as defined by *date* operands. The default *keyword* is *mtime* and the default *subformat* is:
 

```
%b %e %H:%M %Y
```
8. An additional conversion specifier character, `M`, is used to specify the file mode string as defined in `ls Standard Output`. If (*keyword*) is omitted, the mode keyword is used. For example, `%.1M` writes the single character corresponding to the *entry type* field of the `ls -l` command.
9. An additional conversion specifier character, `D`, is used to specify the device for block or special files, if applicable, in an implementation-defined format. If not applicable, and (*keyword*) is specified, then this conversion is equivalent to `%(keyword)u`. If not applicable, and (*keyword*) is omitted, then this conversion is equivalent to `SPACE`.

10. An additional conversion specifier character, F, is used to specify a path name. The F conversion character can be preceded by a sequence of comma-separated keywords:

*(keyword[ ,keyword] ... )*

The values for all the keywords that are non-null are concatenated, each separated by a '/'. The default is (path) if the keyword path is defined. Otherwise, the default is (*prefix,name*).

11. An additional conversion specifier character, L, is used to specify a symbolic link expansion. If the current file is a symbolic link, then %L expands to:

*"%s -> %s", value of keyword, contents of link*

Otherwise, the %L conversion specification is the equivalent of %F.

**Operands** The following operands are supported:

|                  |                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>directory</i> | The destination directory path name for copy mode.                                                                                                                                                                                                                  |
| <i>file</i>      | A path name of a file to be copied or archived.                                                                                                                                                                                                                     |
| <i>pattern</i>   | A pattern matching one or more path names of archive members. A pattern must conform to the pattern matching notation found on the <a href="#">fnmatch(5)</a> manual page. The default, if no <i>pattern</i> is specified, is to select all members in the archive. |

**Output** Output formats are discussed below:

**Standard Output** In write mode, if -f is not specified, the standard output is the archive formatted according to one of the formats described below. See -x format for a list of supported formats.

In list mode, when the -o listopt=*format* option has been specified, the selected archive members are written to standard output using the format described above under List Mode Format Specifications. In list mode without the -o listopt=*format* option, the table of contents of the selected archive members are written to standard output using the following format:

*"%s\n", pathname*

If the -v option is specified in list mode, the table of contents of the selected archive members are written to standard output using the following formats:

- For path names representing hard links to previous members of the archive:

*"%s == %s\n", <ls -l listing, linkname*

- For all other path names:

*"%s\n", <ls -l listing>*

where *<ls -l listing>* is the format specified by the ls command with the -l option. When writing path names in this format, it is unspecified what is written for fields for which the

underlying archive format does not have the correct information, although the correct number of blank-character-separated fields is written.

In `list` mode, standard output is not buffered more than a line at a time.

**Standard Error** If `-v` is specified in `read`, `write` or `copy` modes, `pax` writes the path names it processes to the standard error output using the following format:

```
"%s\n", pathname
```

These path names are written as soon as processing is begun on the file or archive member, and are flushed to standard error. The trailing NEWLINE character, which is not buffered, is written when the file has been read or written.

If the `-s` option is specified, and the replacement string has a trailing `p`, substitutions are written to standard error in the following format:

```
"%s >> %s\n", <original pathname>, <new pathname>
```

In all operating modes of `pax`, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes, and media parts as well as other diagnostic messages can be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in path names or link names are written.

When `pax` is in `read` mode or `list` mode, using the `-x pax` archive format, and a file name, link name, owner name, or any other field in an extended header record cannot be translated from the `pax` UTF-8 codeset format to the codeset and current locale of the implementation, `pax` writes a diagnostic message to standard error, processes the file as described for the `-o invalid=` option, and then processes the next file in the archive.

**Output Files** In `read` mode, the extracted output files are of the archived file type. In `copy` mode, the copied output files are the type of the file being copied. In either mode, existing files in the destination hierarchy are overwritten only when all permission (`-p`), modification time (`-u`), and invalid-value (`-o invalid=`) tests allow it. In `write` mode, the output file named by the `-f` option-argument is a file formatted according to one of the specifications in IEEE Std 1003.1-2001.

**Errors** If `pax` cannot create a file or a link when reading an archive, or cannot find a file when writing an archive, or cannot preserve the user ID, group ID, or file mode when the `-p` option is specified, a diagnostic message is written to standard error and a non-zero exit status is returned, but processing continues. In the case where `pax` cannot create a link to a file, `pax` does not, by default, create a second copy of the file.

If the extraction of a file from an archive is prematurely terminated by a signal or error, `pax` can have only partially extracted the file or, if the `-n` option was not specified, can have

extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories can have additional bits from the read, write, execute mask set as well as incorrect modification and access times.

**Usage** The `-p` (privileges) option was invented to reconcile differences between historical [tar\(1\)](#) and [cpio\(1\)](#) implementations. In particular, the two utilities use `-m` in diametrically opposed ways. The `-p` option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it can seem complex, there are really two modes that are most commonly used:

- p e Preserve everything. This would be used by the historical superuser, someone with all the appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The `e` flag is the sum of `o` and `p`, and other implementation-dependent attributes.
- p p Preserve the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.

The one path name per line format of standard input precludes path names containing newlines. Although such path names violate the portable filename guidelines, they can exist and their presence can inhibit usage of `pax` within shell scripts. This problem is inherited from historical archive programs. The problem can be avoided by listing file name arguments on the command line instead of on standard input.

It is almost certain that appropriate privileges are required for `pax` to accomplish parts of this. Specifically, creating files of type block special or character special, restoring file access times unless the files are owned by the user (the `-t` option), or preserving file owner, group, and mode (the `-p` option) all probably require appropriate privileges.

In read mode, implementations are permitted to overwrite files when the archive has multiple members with the same name. This can fail if permissions on the first version of the file do not permit it to be overwritten.

When using the `-x xustar` and `-x -pax` archive formats, if the underlying file system reports that the file being archived contains holes, the Solaris `pax` utility records the presence of holes in an extended header record when the file is archived. If this extended header record is associated with a file in the archive, those holes are recreated whenever that file is extracted from the archive. See the `SEEK_DATA` and `SEEK_HOLE` whence values in [lseek\(2\)](#). In all other cases, any NUL (`\0`) characters found in the archive is written to the file when it is extracted.

See [largefile\(5\)](#) for the description of the behavior of `pax` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Standard Input** In *w*rite mode, the standard input is used only if no *f*ile operands are specified. It is a text file containing a list of path names, one per line, without leading or trailing blanks. In *l*ist and *r*ead modes, if *-f* is not specified, the standard input is an archive file. Otherwise, the standard input is not used.

**Input Files** The input file named by the *archive* option-argument, or standard input when the archive is read from there, is a file formatted according to one of the formats described below. See **Extended Description**. The file `/dev/tty` is used to write prompts and read responses.

**Examples** **EXAMPLE 1** Copying the Contents of the Current Directory

The following command:

```
example% pax -w -f /dev/rmt/1m .
```

copies the contents of the current directory to tape drive 1, medium density. This assumes historical System V device naming procedures. The historical BSD device name would be `/dev/rmt9`.

**EXAMPLE 2** Copying the Directory Hierarchy

The following commands:

```
example% mkdir newdir
example% pax -rw olddir newdir
```

copy the `olddir` directory hierarchy to `newdir`.

**EXAMPLE 3** Reading an Archive Extracted Relative to the Current Directory

The following command:

```
example% pax -r -s '^/*usr/*,' -f a.pax
```

reads the archive `a.pax`, with all files rooted in `/usr` in the archive extracted relative to the current directory.

**EXAMPLE 4** Overriding the Default Output Description

Using the option:

```
-o listopt="%M %(atime)T %(size)D %(name)s"
```

overrides the default output description in Standard Output and instead writes:

```
-rw-rw- - - Jan 12 15:53 2003 1492 /usr/foo/bar
```

Using the options:

```
-o listopt='%L\t%(size)D\n%.7' \
-o listopt='(name)s\n%(atime)T\n%T'
```

**EXAMPLE 4** Overriding the Default Output Description (Continued)

overrides the default output description in standard output and instead writes:

```
usr/foo/bar -> /tmp 1492
/usr/foo
Jan 12 15:53 1991
Jan 31 15:53 2003
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of pax: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, LC\_TIME, and NLS\_PATH.

**LC\_COLLATE** Determine the locale for the behaviour of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the *pattern* operand, the basic regular expression for the -s option, and the extended regular expression defined for the *yesexpr* locale keyword in the LC\_MESSAGES category.

**TMPDIR** Determine the path name that provides part of the default global extended header record file, as described for the -o *globexthdr=* keyword as described in the OPTIONS section.

**TZ** Determine the timezone used to calculate date and time strings when the -v option is specified. If TZ is unset or null, an unspecified default timezone is used.

**Exit Status** The following exit values are returned:

- 0 All files were processed successfully.
- >0 An error occurred.

### Extended Description

**pax Interchange Format** A pax archive tape or file produced in the -xpax format contains a series of blocks. The physical layout of the archive is identical to the *ustar* format described in *ustar Interchange Format*. Each file archived is represented by the following sequence:

- An optional header block with extended header records. This header block is of the form 27403 with a *typeflag* value of x or g. The extended header records is included as the data for this header block.
- A header block that describes the file. Any fields in the preceding optional extended header overrides the associated fields in this header block for this file.
- Zero or more blocks that contain the contents of the file.

At the end of the archive file there are two 512-byte blocks filled with binary zeroes, interpreted as an end-of-archive indicator.

The following is a schematic of an example archive with global extended header records and two actual files in pax format archive. In the example, the second file in the archive has no extended header preceding it, presumably because it has no need for extended attributes.

| Description                            | Block                                                                                                               |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Global Extended Header                 | ustar Header [ <i>typeflag</i> =g]<br>Global Extended Header Data                                                   |
| File 1: Extended Header is included    | ustar Header [ <i>typeflag</i> =x]<br>Extended Header Data<br>[ <i>typeflag</i> =0]<br>ustar Header Data for File 1 |
| File 2: No Extended Header is included | ustar Header [ <i>typeflag</i> =0]<br>Data for File2                                                                |
| End of Archive Indicator               | Block of binary zeros<br>Block of binary zeros                                                                      |

- pax Header Block The pax header block is identical to the ustar header block described in ustar Interchange Format except that two additional *typeflag* values are defined:
- g Represents global extended header records for the following files in the archive. The format of these extended header records are as described in pax Extended Header. Each value affects all subsequent files that do not override that value in their own extended header record and until another global extended header record is reached that provides another value for the same field. The *typeflag* g global headers should not be used with interchange media that could suffer partial data loss in transporting the archive.
  - x Represents extended header records for the following file in the archive (which has its own ustar header block). The format of these extended header records is as described in pax Extended Header.

For both of these types, the *size* field is the size of the extended header records in octets. The other fields in the header block are not meaningful to this version of pax. However, if this archive is read by pax conforming to a previous version of *ISO POSIX-2:1993 Standard*, the header block fields are used to create a regular file that contains the extended header records as data. Therefore, header block field values should be selected to provide reasonable file access to this regular file.

A further difference from the ustar header block is that data blocks for files of *typeflag* 1 (the digit one) (hard link) might be included, which means that the *size* field can be greater than zero. Archives created by pax -o linkdata includes these data blocks with the hard links.

**pax Extended Header** A pax extended header contains values that are inappropriate for the `ustar` header block because of limitations in that format: fields requiring a character encoding other than that described in the *ISO/IEC 646: 1991 standard*, fields representing file attributes not described in the `ustar` header, and fields whose format or length do not fit the requirements of the `ustar` header. The values in an extended header add attributes to the specified file or files or override values in the specified header blocks, as indicated in the following list of keywords. See the description of the `typeflag g` header block.

An extended header consists of one or more records, each constructed as follows:

```
"%d %s=%s\n", length, keyword, value
```

The extended header records are encoded according to the *ISO/IEC 10646-1: 2000 standard* (UTF-8). `length`, BLANK, equals sign (=), and NEWLINE are limited to the portable character set, as encoded in UTF-8. `keyword` and `value` can be any UTF-8 characters. `length` is the decimal length of the extended header record in octets, including the trailing NEWLINE.

`keyword` is one of the entries from the following list or a keyword provided as an implementation extension. Keywords consisting entirely of lowercase letters, digits, and periods are reserved for future standardization. A keyword does not include an equals sign.

In the following list, the notation of `file(s)` or `block(s)` are used to acknowledge that a keyword affects the specified single file after a `typeflag x` extended header, but possibly multiple files after `typeflag g`. Any requirements in the list for pax to include a record when in write or copy mode applies only when such a record has not already been provided through the use of the `-o` option. When used in copy mode, pax behaves as if an archive had been created with applicable extended header records and then extracted.

**atime** The file access time for the specified files, equivalent to the value of the `st_atime` member of the `stat` structure for a file, as described by the [stat\(2\)](#) function. The access time (`atime`) is restored if the process has the appropriate privilege required to do so. The format of the `value` is as described in `pax Extended Header File Times`.

**charset** The name of the character set used to encode the data in the specified files. The entries in the following table are defined to refer to known standards; additional names can be agreed on between the originator and recipient.

| <i>value</i>       | Formal Standard     |
|--------------------|---------------------|
| ISO-IR 646 1990    | ISO/IEC646:1990     |
| ISO-IR 8859 1 1998 | ISO/IEC8859-1:1998  |
| ISO-IR 8859 2 1999 | ISO/IEC 8859-2:1999 |
| ISO-IR 8859 3 1999 | ISO/IEC 8859-3:1999 |

|                         |                              |
|-------------------------|------------------------------|
| ISO-IR 8859 4 1999      | ISO/IEC8859-4:1998           |
| ISO-IR 8859 5 1999      | ISO/IEC8859-5-1999           |
| ISO-IR 8859 6 1999      | ISO/IEC8859-6-1999           |
| ISO-IR 8859 7 1987      | ISO/IEC8859-7:1987           |
| ISO-IR 8859 8 1999      | ISO/IEC8859-8:1999           |
| ISO-IR 8859 9 1999      | ISO/IEC8859-9:1999           |
| ISO-IR 8859 10 1998     | ISO/IEC8859-10:1999          |
| ISO-IR 8859 13 1998     | ISO/IEC8859-13:1998          |
| ISO-IR 8859 14 1998     | ISO/IEC8859-14:1998          |
| ISO-IR 8859 15 1999     | ISO/IEC8859-15:1999          |
| ISO-IR 10646 2000       | ISO/IEC 10646:2000           |
| ISO-IR 10646 2000 UTF-8 | ISO/IEC 10646,UTF-8 encoding |
| BINARY                  | None                         |

The encoding is included in an extended header for information only; when *pax* is used as described in *IEEE Std 1003.1-200x*, it does not translate the file data into any other encoding. The BINARY entry indicates unencoded binary data. When used in write or copy mode, it is implementation-defined whether *pax* includes a charset extended header record for a file.

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>comment</i> | A series of characters used as a comment. All characters in the <i>value</i> field are ignored by <i>pax</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>gid</i>     | The group ID of the group that owns the file, expressed as a decimal number using digits from the <i>ISO/IEC 646: 1991 standard</i> . This record overrides the <i>gid</i> field in the specified header blocks. When used in write or copy mode, <i>pax</i> includes a <i>gid</i> extended header record for each file whose group ID is greater than 2097151 (octal 7777777).                                                                                                                                                                                                                                                            |
| <i>gname</i>   | The group of the files, formatted as a group name in the group database. This record overrides the <i>gid</i> and <i>gname</i> fields in the specified header blocks, and any <i>gid</i> extended header record. When used in read, copy, or list mode, <i>pax</i> translates the name from the UTF-8 encoding in the header record to the character set appropriate for the group database on the receiving system. If any of the UTF-8 characters cannot be translated, and if the <code>-o invalid=UTF-8</code> option is not specified, the results are implementation-defined. When used in write or copy mode, <i>pax</i> includes a |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | <p><i>gname</i> extended header record for each file whose group name cannot be represented entirely with the letters and digits of the portable character set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>linkpath</code>     | <p>The pathname of a link being created to another file, of any type, previously archived. This record overrides the <i>linkname</i> field in the specified <i>ustar</i> header blocks. The specified <i>ustar</i> header block determines the type of link created. If <i>typeflag</i> of the specified header block is 1, it is a hard link. If <i>typeflag</i> is 2, it is a symbolic link and the <code>linkpath</code> value is the contents of the symbolic link. <i>pax</i> translates the name of the link (contents of the symbolic link) from the UTF-8 encoding to the character set appropriate for the local file system. When used in write or copy mode, <i>pax</i> includes a <code>linkpath</code> extended header record for each link whose pathname cannot be represented entirely with the members of the portable character set other than NULL.</p> |
| <code>mtime</code>        | <p>The pathname of a link being created to another file, of any type, previously archived. This record overrides the <i>linkname</i> field in the specified <i>ustar</i> header blocks. The specified <i>ustar</i> header block determines the type of link created. If <i>typeflag</i> of the specified header block is 1, it is a hard link. If <i>typeflag</i> is 2, it is a symbolic link and the <code>linkpath</code> value is the contents of the symbolic link. <i>pax</i> translates the name of the link (contents of the symbolic link) from the UTF-8 encoding to the character set appropriate for the local file system. When used in write or copy mode, <i>pax</i> includes a <code>linkpath</code> extended header record for each link whose pathname cannot be represented entirely with the members of the portable character set other than NULL.</p> |
| <code>path</code>         | <p>The pathname of the specified files. This record overrides the name and <i>prefix</i> fields in the specified header blocks. <i>pax</i> translates the pathname of the file from the UTF-8 encoding to the character set appropriate for the local file system. When used in write or copy mode, <i>pax</i> includes a <code>path</code> extended header record for each file whose pathname cannot be represented entirely with the members of the portable character set other than NULL.</p>                                                                                                                                                                                                                                                                                                                                                                         |
| <code>realtime.any</code> | <p>The keywords prefixed by <code>realtime</code> are reserved for future standardization.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>security.any</code> | <p>The keywords prefixed by <code>security</code> are reserved for future standardization.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>size</code>         | <p>The size of the file in octets, expressed as a decimal number using digits from the <i>ISO/IEC 646: 1991 standard</i>. This record overrides the <i>size</i> field in the specified header blocks. When used in write or copy mode, <i>pax</i> includes a <code>size</code> extended header record for each file with a <i>size</i> value greater than 8589934591 (octal 7777777777).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uid</i>   | The user ID of the file owner, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record overrides the <i>uid</i> field in the following header block(s). When used in write or copy mode, pax includes a <i>uid</i> extended header record for each file whose owner ID is greater than 2097151 (octal 777777).                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>uname</i> | The owner of the specified files, formatted as a user name in the user database. This record overrides the <i>uid</i> and <i>uname</i> fields in the specified header blocks, and any <i>uid</i> extended header record. When used in read, copy, or list mode, pax translates the name from the UTF-8 encoding in the header record to the character set appropriate for the user database on the receiving system. If any of the UTF-8 characters cannot be translated, and if the <code>-o invalid=UTF-8</code> option is not specified, the results are implementation-defined. When used in write or copy mode, pax includes a <i>uname</i> extended header record for each file whose user name cannot be represented entirely with the letters and digits of the portable character set. |

If the *value* field is zero length, it deletes any header block field, previously entered extended header value, or global extended header value of the same name.

If a keyword in an extended header record (or in an `-o` option-argument) overrides or deletes a corresponding field in the *ustar* header block, pax ignores the contents of that header block field.

Unlike the *ustar* header block fields, *NULLs* does not delimit values; all characters within the *value* field are considered data for the field.

#### pax Extended Header Keyword Precedence

This section describes the precedence in which the various header records and fields and command line options are selected to apply to a file in the archive. When pax is used in read or list modes, it determines a file attribute in the following sequence:

1. If `-o delete=keyword-prefix` is used, the affected attributes is determined from step 7, if applicable, or ignored otherwise.
2. If `-o keyword:=` is used, the affected attributes is ignored.
3. If `-o keyword=value` is used, the affected attribute is assigned the value.
4. If there is a *typeflag* *x* extended header record, the affected attribute is assigned the value. When extended header records conflict, the last one given in the header takes precedence.
5. If `-o keyword=value` is used, the affected attribute is assigned the value.
6. If there is a *typeflag* *g* global extended header record, the affected attribute is assigned the value. When global extended header records conflict, the last one given in the global header takes precedence.
7. Otherwise, the attribute is determined from the *ustar* header block.

**pax Extended Header File Times** pax writes an *mtime* record for each file in write or copy modes if the file's modification time cannot be represented exactly in the *ustar* header logical record described in *ustar* Interchange Format. This can occur if the time is out of *ustar* range, or if the file system of the underlying implementation supports non-integer time granularities and the time is not an integer. All of these time records are formatted as a decimal representation of the time in seconds since the Epoch. If a period (.) decimal point character is present, the digits to the right of the point represents the units of a sub-second timing granularity, where the first digit is tenths of a second and each subsequent digit is a tenth of the previous digit. In read or copy mode, pax truncates the time of a file to the greatest value that is not greater than the input header file time. In write or copy mode, pax outputs a time exactly if it can be represented exactly as a decimal number, and otherwise generates only enough digits so that the same time is recovered if the file is extracted on a system whose underlying implementation supports the same time granularity.

**ustar Interchange Format** A *ustar* archive tape or file contains a series of logical records. Each logical record is a fixed-size logical record of 512 octets. Although this format can be thought of as being stored on 9-track industry-standard 12.7mm (0.5 in) magnetic tape, other types of transportable media are not excluded. Each file archived is represented by a header logical record that describes the file, followed by zero or more logical records that give the contents of the file. At the end of the archive file there are two 512-octet logical records filled with binary zeros, interpreted as an end-of-archive indicator.

The logical records can be grouped for physical I/O operations, as described under the *-bblocksize* and *-x* *ustar* options. Each group of logical records can be written with a single operation equivalent to the `write(2)` function. On magnetic tape, the result of this write is a single tape physical block. The last physical block always is the full size, so logical records after the two zero logical records can contain undefined data.

The header logical record is structured as shown in the following table. All lengths and offsets are in decimal.

TABLE 1 *ustar* Header Block

| Field Name    | Octet Offset | Length (in Octets) |
|---------------|--------------|--------------------|
| <i>name</i>   | 0            | 100                |
| <i>mode</i>   | 100          | 8                  |
| <i>uid</i>    | 108          | 8                  |
| <i>gid</i>    | 116          | 8                  |
| <i>size</i>   | 124          | 12                 |
| <i>mtime</i>  | 136          | 12                 |
| <i>chksum</i> | 148          | 8                  |

| Field Name      | Octet Offset | Length (in Octets) |
|-----------------|--------------|--------------------|
| <i>typeflag</i> | 156          | 1                  |
| <i>linkname</i> | 157          | 100                |
| <i>magic</i>    | 257          | 6                  |
| <i>version</i>  | 263          | 2                  |
| <i>uname</i>    | 265          | 32                 |
| <i>gname</i>    | 297          | 32                 |
| <i>devmajor</i> | 329          | 8                  |
| <i>devminor</i> | 337          | 8                  |
| <i>prefix</i>   | 345          | 155                |

All characters in the header logical record is represented in the coded character set of the *ISO/IEC 646: 1991* standard. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside of slash and the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters are provided for interchange purposes.

*pax* never creates filenames on the local system that cannot be accessed using the procedures described in *IEEE Std 1003.1-200x*. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored. *pax* can choose to ignore these files as long as it produces an error indicating that the file is being ignored. Each field within the header logical record is contiguous; that is, there is no padding used.

Each field within the header logical record is contiguous. There is no padding used. Each character on the archive medium is stored contiguously.

The fields *magic*, *uname* and *gname* are character strings, each of which is terminated by a NULL character. The fields *name*, *linkname*, and *prefix* are NULL-terminated character strings except when all characters in the array contain non-NULL characters including the last character. The *version* field is two octets containing the characters *00* (zero-zero) The *typeflag* contains a single character. All other fields are leading zero-filled octal numbers using digits from the *ISO/IEC 646:1991* standard IRV. Each numeric field is terminated by one or more SPACE or NULL characters.

Each character on the archive medium is stored contiguously. The fields *magic*, *uname*, and *gname* are character strings each terminated by a NULL character.

*name*, *linkname*, and *prefix* are NULL-terminated character strings except when all characters in the array contain non-NULL characters including the last character. The *version* field is two octets containing the characters 00 (zero-zero). The *typeflag* contains a single character. All other fields are leading zero-filled octal numbers using digits from the *ISO/IEC 646: 1991* standard IRV. Each numeric field is terminated by one or more spaces or NULL characters.

The *name* and the *prefix* fields produce the pathname of the file. A new pathname is formed, if *prefix* is not an empty string (its first character is not NULL), by concatenating *prefix* (up to the first NULL character), a slash character, and *name*; otherwise, *name* is used alone. In either case, *name* is terminated at the first NULL character. If *prefix* begins with a NULL character, it is ignored. In this manner, pathnames of at most 256 characters can be supported. If a pathname does not fit in the space provided, *pax* notifies the user of the error, and does not store any part of the file-header or data-on the medium.

The *linkname* field does not use the *prefix* to produce a pathname. As such, a *linkname* is limited to 100 characters. If the name does not fit in the space provided, *pax* notifies the user of the error, and does not attempt to store the link on the medium. The *mode* field provides 12 bits encoded in the *ISO/IEC 646: 1991* standard octal digit representation. The encoded bits represent the following values in the *ustar mode* field:

| Bit Value | IEE Std 1003.1–2001 Bit | Description                                    |
|-----------|-------------------------|------------------------------------------------|
| 04000     | S_ISUID                 | Set UID on execution                           |
| 02000     | S_ISGID                 | Set GID on execution                           |
| 01000     | <i>reserved</i>         | Reserved for future standardization            |
| 00400     | S_IRUSR                 | Read permission for file owner class           |
| 00200     | S_IWUSR                 | Write permission for file owner class          |
| 00100     | S_IXUSR                 | Execute/search permission for file owner class |
| 00040     | S_IRGRP                 | Read permission for file group class           |
| 00020     | S_IWGRP                 | Write permission for file group class          |
| 00010     | S_IXGRP                 | Execute/search permission for file group class |
| 00004     | S_IROTH                 | Read permission for file other class           |
| 00002     | S_IWOTH                 | Write permission for file other class          |
| 00001     | S_IXOTH                 | Execute/search permission for file other class |

When appropriate privilege is required to set one of these mode bits, and the user restoring the files from the archive does not have the appropriate privilege, the mode bits for which the user

does not have appropriate privilege are ignored. Some of the mode bits in the archive format are not mentioned elsewhere in volume *IEEE Std 1003.1-200x*. If the implementation does not support those bits, they can be ignored.

The *uid* and *gid* fields are the user and group ID of the owner and group of the file, respectively.

The *size* field is the size of the file in octets. If the *typeflag* field is set to specify a file to be of type 1 (a link) or 2 (a symbolic link), the *size* field is specified as zero. If the *typeflag* field is set to specify a file of type 5 (directory), the *size* field is interpreted as described under the definition of that record type. No data logical records are stored for types 1, 2, or 5. If the *typeflag* field is set to 3 (character special file), 4 (block special file), or 6 (FIFO), the meaning of the *size* field is unspecified by volume *IEEE Std 1003.1-200x*, and no data logical records is stored on the medium. Additionally, for type 6, the *size* field is ignored when reading. If the *typeflag* field is set to any other value, the number of logical records written following the header is  $(size+511)/512$ , ignoring any fraction in the result of the division.

The *mtime* field is the modification time of the file at the time it was archived. It is the *ISO/IEC 646: 1991* standard representation of the octal value of the modification time obtained from the `stat()` function.

The *chksum* field is the *ISO/IEC 646: 1991* standard IRV representation of the octal value of the simple sum of all octets in the header logical record. Each octet in the header is treated as an unsigned value. These values are added to an unsigned integer, initialized to zero, the precision of which is not less than 17 bits. When calculating the checksum, the *chksum* field is treated as if it were all spaces.

The *typeflag* field specifies the type of file archived. If a particular implementation does not recognize the type, or the user does not have appropriate privilege to create that type, the file is extracted as if it were a regular file if the file type is defined to have a meaning for the *size* field that could cause data logical records to be written on the medium. If conversion to a regular file occurs, `pax` produces an error indicating that the conversion took place. All of the *typeflag* fields are coded in the *ISO/IEC 646: 1991* standard IRV:

- |   |                                                                                                                                                                                                                                                                                                                                                              |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Represents a regular file. For backward compatibility, a <i>typeflag</i> value of binary zero ('0') should be recognized as meaning a regular file when extracting files from the archive. Archives written with this version of the archive file format create regular files with a <i>typeflag</i> value of the <i>ISO/IEC 646: 1991</i> standard IRV '0'. |
| 1 | Represents a file linked to another file, of any type, previously archived. Such files are identified by each file having the same device and file serial number. The linked-to name is specified in the <i>linkname</i> field with a NULL-character terminator if it is less than 100 octets in length.                                                     |
| 2 | Represents a symbolic link. The contents of the symbolic link are stored in the <i>linkname</i> field.                                                                                                                                                                                                                                                       |

---

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3, 4          | Represents character special files and block special files respectively. In this case the <i>devmajor</i> and <i>devminor</i> fields contain information defining the device, the format of which is unspecified by volume <i>IEEE Std 1003.1-200x</i> . Implementations can map the device specifications to their own local specification or can ignore the entry.                                                                                                                                                                                               |
| 5             | Specifies a directory or subdirectory. On systems where disk allocation is performed on a directory basis, the <i>size</i> field contain the maximum number of octets (which can be rounded to the nearest disk block allocation unit) that the directory can hold. A <i>size</i> field of zero indicates no such limiting. Systems that do not support limiting in this manner should ignore the <i>size</i> field.                                                                                                                                               |
| 6             | Specifies a FIFO special file. The archiving of a FIFO file archives the existence of this file and not its contents.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 7             | Reserved to represent a file to which an implementation has associated some high- performance attribute. Implementations without such extensions should treat this file as a regular file (type 0).                                                                                                                                                                                                                                                                                                                                                                |
| A - Z         | The letters A through Z inclusive are reserved for custom implementations. All other values are reserved for future versions of <i>IEEE Std 1003.1-200x</i> .                                                                                                                                                                                                                                                                                                                                                                                                      |
| SUN.devmajor  | <p>A Solaris extension to pax extended header keywords. Specifies the major device number of the file.</p> <p>When used in write or copy mode and the <i>xustar</i> or <i>pax</i> format (see <i>-x format</i>) was specified, pax includes a <i>SUN.devmajor</i> extended header record for each file whose major device number is too large to fit in 8 octets.</p>                                                                                                                                                                                              |
| SUN.devminor  | <p>A Solaris extension to pax extended header keywords. Specifies the minor device number of the file.</p> <p>When used in write or copy mode and the <i>xustar</i> or <i>pax</i> format (see <i>-x format</i>) is specified, pax includes a <i>SUN.devminor</i> extended header record for each file whose minor device number is too large to fit in 8 octets.</p>                                                                                                                                                                                               |
| SUN.holesdata | <p>A Solaris extension to pax extended header keywords. Specifies the data and hole pairs for a sparse file.</p> <p>In write or copy modes and when the <i>xustar</i> or <i>pax</i> format (see <i>-x format</i>) is specified, pax includes a <i>SUN.holesdata</i> extended header record if the underlying file system supports the detection of files with holes (see <a href="#">fpathconf(2)</a>) and reports that there is at least one hole in the file being archived. <i>value</i> consists of two or more consecutive entries of the following form:</p> |

*SPACEdata\_offsetSPACEhole\_offset*

where the data and hole offsets are the long values returned by passing `SEEK_DATA` and `SEEK_HOLE` to `lseek(2)`, respectively. For example, the following entry is an example of the `SUN.holesdata` entry in the extended header for a file with data offsets at bytes 0, 24576, and 49152, and hole offsets at bytes 8192, 32768, and 49159: 49 SUN.holesdata= 0 8192 24576 32768 49152 49159:

```
49 SUN.holesdata= 0 8192 24576 32768 49152 49159
```

When extracting a file from an archive in read or copy modes, if a `SUN.holesdata = pair` is found in the extended header for the file, then the file is restored with the holes identified using this data. For example, for the `SUN.holesdata` provided in the example above, bytes from 0 to 8192 are restored as data, a hole is created up to the next data position (24576), bytes 24576 to 32768 is restored as data, and so forth.

- X A Solaris custom `typeflag` implementation which specifies an `xstar` format (see `-x` format) extended header. The `typeflag 'x'` extended header is treated as a `ustar typeflag 'x'` extended header.
- E A Solaris custom `typeflag` implementation which specifies an extended attributes header. See `fsattr(5)`.

Attempts to archive a socket using `ustar` interchange format produce a diagnostic message. Handling of other file types is implementation-defined.

The *magic* field is the specification that this archive was output in this archive format. If this field contains `ustar` (the five characters from the *ISO/IEC 646: 1991* standard IRV shown followed by `NULL`), the *uname* and *gname* fields contain the *ISO/IEC 646: 1991* standard IRV representation of the owner and group of the file, respectively (truncated to fit, if necessary). When the file is restored by a privileged, protection-preserving version of the utility, the user and group databases are scanned for these names. If found, the user and group IDs contained within these files are used rather than the values contained within the *uid* and *gid* fields.

**cpio Interchange Format** The octet-oriented `cpio` archive format are a series of entries, each comprising a header that describes the file, name of the file, and contents of the file.

An archive can be recorded as a series of fixed-size blocks of octets. This blocking is used only to make physical I/O more efficient. The last group of blocks are always at the full size.

For the octet-oriented `cpio` archive format, the individual entry information are in the order indicated and described by the following table: Octet-Oriented `cpio` Archive Entry. See the `cpio.h` header for additional details.

| Header Field Name | Length (in Octets) | Interpreted as |
|-------------------|--------------------|----------------|
| <i>c_magic</i>    | 6                  | Octal number   |
| <i>c_dev</i>      | 6                  | Octal number   |
| <i>c_ino</i>      | 6                  | Octal number   |
| <i>c_mode</i>     | 6                  | Octal number   |
| <i>c_uid</i>      | 6                  | Octal number   |
| <i>c_gid</i>      | 6                  | Octal number   |
| <i>c_nlink</i>    | 6                  | Octal number   |
| <i>c_rdev</i>     | 6                  | Octal number   |
| <i>c_mtime</i>    | 11                 | Octal number   |
| <i>c_namesize</i> | 6                  | Octal number   |
| <i>c_filesize</i> | 11                 | Octal number   |

| Filename Field Name | Length            | Interpreted as  |
|---------------------|-------------------|-----------------|
| <i>c_name</i>       | <i>c_namesize</i> | Pathname string |

| Filename Field Name | Length            | Interpreted as |
|---------------------|-------------------|----------------|
| <i>c_filedata</i>   | <i>c_filesize</i> | Data           |

**cpio Header** For each file in the archive, a header as defined previously written. The information in the header fields is written as streams of the *ISO/IEC 646: 1991* standard characters interpreted as octal numbers. The octal numbers are extended to the necessary length by appending the *ISO/IEC 646: 1991* standard IRV zeros at the most-significant-digit end of the number. The result is written to the most-significant digit of the stream of octets first. The fields are interpreted as follows:

|                     |                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>c_magic</i>      | Identifies the archive as being a transportable archive by containing the identifying value "070707".                                                                                                                                                |
| <i>c_dev, c_ino</i> | Contains values that uniquely identify the file within the archive (that is, no files contain the same pair of <i>c_dev</i> and <i>c_ino</i> values unless they are links to the same file). The values are determined in an unspecified manner.     |
| <i>c_mode</i>       | Contains the file type and access permissions as defined in the following table.<br><br>Directories, FIFOs, symbolic links, and regular files are supported on a system conforming to volume <i>IEEE Std 1003.1-200x</i> ; additional values defined |

previously are reserved for compatibility with existing systems. Additional file types can be supported. Such files should not be written to archives intended to be transported to other systems.

| File Permissions Name | Value  | Indicates |
|-----------------------|--------|-----------|
| C_IRUSR               | 000400 | by owner  |
| C_IWUSR               | 000200 | by owner  |
| C_IXUSR               | 000100 | by owner  |
| C_IRGRP               | 000040 | by group  |
| CW_IWFGP              | 000020 | by group  |
| CW_IXGRP              | 000010 | by group  |
| CW_IROTH              | 000004 | by others |
| CW_IWOTH              | 000002 | by others |
| CW_IXOTH              | 000001 | by others |
| CW_ISUID              | 004000 | Set uid   |
| W_ISGID               | 002000 | Set gid   |
| W_ISVTX               | 001000 | Reserved  |

| File Type Name | Value   | Indicates              |
|----------------|---------|------------------------|
| C_ISDIR        | 040000  | Directory              |
| C_ISFIFO       | 010000  | FIFO                   |
| C_ISREG        | 0100000 | Regular file           |
| C_ISLNK        | 0120000 | Symbolic link          |
| C_ISBLK        | 060000  | Block special file     |
| C_ISCHR        | 020000  | Character special file |
| C_ISSOCK       | 0140000 | Socket                 |
| C_ISCTG        | 0110000 | Reserved               |

*c\_uid* Contains the user ID of the owner.  
*c\_gid* Contains the group ID of the group

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>c_nlink</i>    | Contains a number greater than or equal to the number of links in the archive referencing the file. If the <i>-a</i> option is used to append to a <i>cpio</i> archive, <i>pax</i> does need not to account for the files in the existing part of the archive when calculating the <i>c_nlink</i> values for the appended part of the archive. It does also need not alter the <i>c_nlink</i> values in the existing part of the archive if additional files with the same <i>c_dev</i> and <i>c_ino</i> values are appended to the archive. |
| <i>c_rdev</i>     | Contains implementation-defined information for character or block special files.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>c_mtime</i>    | Contains the latest time of modification of the file at the time the archive was created.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>c_namesize</i> | Contains the length of the pathname, including the terminating NULL character.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>c_filesize</i> | Contains the length of the file in octets. This is the length of the data section following the header structure.                                                                                                                                                                                                                                                                                                                                                                                                                            |

**cpio Filename** The *c\_name* field contains the pathname of the file. The length of this field in octets is the value of *c\_namesize*. If a filename is found on the medium that would create an invalid pathname, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored. All characters are represented in the *ISO/IEC 646: 1991* standard IRV. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters are provided for interchange purposes. *pax* does not create filenames on the local system that cannot be accessed by way of the procedures described in volume *IEEE Std 1003.1-200x*. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the local file system and under what name it is stored. *pax* can choose to ignore these files as long as it produces an error indicating that the file is being ignored.

**cpio File Data** Following *c\_name*, there is *c\_filesize* octets of data. Interpretation of such data occurs in a manner dependent on the file. If *c\_filesize* is zero, no data is contained in *c\_filedata*. When restoring from an archive:

- If the user does not have the appropriate privilege to create a file of the specified type, *pax* ignores the entry and writes an error message to standard error.
- Only regular files have data to be restored. Presuming a regular file meets any selection criteria that might be imposed on the format-reading utility by the user, such data is restored.
- If a user does not have appropriate privilege to set a particular *mode* flag, the flag is ignored. Some of the *mode* flags in the archive format are not mentioned in volume *IEEE Std 1003.1-200x*. If the implementation does not support those flags, they can be ignored.

`cpio` Special Entries FIFO special files, directories, and the trailer are recorded with `c_filesize` equal to zero. For other special files, `c_filesize` is unspecified in volume *IEEE Std 1003.1-200x*. The header for the next file entry in the archive are written directly after the last octet of the file entry preceding it. A header denoting the filename trailer indicates the end of the archive; the contents of octets in the last block of the archive following such a header are undefined.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

## LANGUAGE-SPECIFIC

|        |                                         |
|--------|-----------------------------------------|
| perlcn | Perl for Simplified Chinese (in EUC-CN) |
| perljp | Perl for Japanese (in EUC-JP)           |
| perlko | Perl for Korean (in EUC-KR)             |
| perltw | Perl for Traditional Chinese (in Big5)  |

## PLATFORM-SPECIFIC

|             |                        |
|-------------|------------------------|
| perlsolaris | Perl notes for Solaris |
|-------------|------------------------|

**Platform-Specific** If you're new to Perl, you should start with `perlintro`, which is a general intro for beginners and provides some background to help you navigate the rest of Perl's extensive documentation. For ease of access, the Perl manual has been split up into several sections.

The manpages listed above are installed in the `/usr/perl5/man/` directory.

---

Extensive additional documentation for Perl modules is available. This additional documentation is in the `/usr/perl5/man` directory. Some of this additional documentation is distributed standard with Perl, but you'll also find documentation for any customer-installed third-party modules there.

You can view Perl's documentation with `man(1)` by including `/usr/perl5/man` in the `MANPATH` environment variable. Notice that running `catman(1M)` on the Perl manual pages is not supported. For other Solaris-specific details, see the `NOTES` section below.

You can also use the supplied `/usr/perl5/bin/perl5doc` script to view Perl information.

If something strange has gone wrong with your program and you're not sure where you should look for help, try the `-w` switch first. It will often point out exactly where the trouble is.

Perl is a language optimized for scanning arbitrary text files, extracting information from those text files, and printing reports based on that information. It's also a good language for many system management tasks. The language is intended to be practical (easy to use, efficient, complete) rather than beautiful (tiny, elegant, minimal).

Perl combines (in the author's opinion, anyway) some of the best features of C, `sed`, `awk`, and `sh`, so people familiar with those languages should have little difficulty with it. (Language historians will also note some vestiges of `csh`, Pascal, and even BASIC-PLUS.) Expression syntax corresponds closely to C expression syntax. Unlike most Unix utilities, Perl does not arbitrarily limit the size of your data -if you've got the memory, Perl can slurp in your whole file as a single string. Recursion is of unlimited depth. And the tables used by hashes (sometimes called "associative arrays") grow as necessary to prevent degraded performance. Perl can use sophisticated pattern matching techniques to scan large amounts of data quickly. Although optimized for scanning text, Perl can also deal with binary data, and can make `dbm` files look like hashes. Setuid Perl scripts are safer than C programs through a dataflow tracing mechanism that prevents many stupid security holes.

If you have a problem that would ordinarily use `sed` or `awk` or `sh`, but it exceeds their capabilities or must run a little faster, and you don't want to write the silly thing in C, then Perl may be for you. There are also translators to turn your `sed` and `awk` scripts into Perl scripts.

But wait, there's more...

Begun in 1993 (see `perlhist`), Perl version 5 is nearly a complete rewrite that provides the following additional benefits:

- Modularity and reusability using innumerable modules Described in `perlmod`, `perlmodlib`, and `perlmodinstall`.
- Embeddable and extensible Described in `perlembed`, `perlxsut`, `perlxs`, `perlcall`, `perlguts`, and `xsubpp`.
- Roll-your-own magic variables (including multiple simultaneous DBM implementations). Described in `perltie` and `AnyDBM_File`.

- Subroutines can now be overridden, autoloaded, and prototyped. Described in `perlsub`.
- Arbitrarily nested data structures and anonymous functions. Described in `perlreftut`, `perlref`, `perldsc`, and `perllo1`.
- Object-oriented programming. Described in `perlobj`, `perlboot`, `perltoot`, `perltoc`, and `perlbot`.
- Support for light-weight processes (threads). Described in `perltut` and `threads`.
- Support for Unicode, internationalization, and localization Described in `perluniintro`, `perllocale` and `Locale::Maketext`.
- Lexical scoping. Described in `perlsub`.
- Regular expression enhancements. Described in `perlre`, with additional examples in `perlop`.
- Enhanced debugger and interactive Perl environment, with integrated editor support. Described in `perldebtut`, `perldebug` and `perldebguts`.
- POSIX 1003.1 compliant library Described in `POSIX`.

Okay, that's *definitely* enough hype.

**Environment Variables** The Perl shipped with Solaris is installed under `/usr/perl5` rather than the default `/usr/local` location. This is so that it can coexist with a customer-installed Perl in the default `/usr/local` location.

Any additional modules that you choose to install will be placed in the `/usr/perl5/site_perl/5.8.4` directory. The `/usr/perl5/vendor_perl` directory is reserved for SMI-provided modules.

Notice that the Perl utility scripts such as `perldoc` and `perlbug` are in the `/usr/perl5/bin` directory, so if you wish to use them you need to include `/usr/perl5/bin` in your `PATH` environment variable.

See also the `perlrun` mapage.

**Author** Larry Wall, with the help of oodles of other folks.

If your Perl success stories and testimonials may be of help to others who wish to advocate the use of Perl in their applications, or if you wish to simply express your gratitude to Larry and the Perl developers, please write to `perl-thanks@perl.org`.

**Files** "@INC" Locations of Perl libraries

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Availability        | runtime/perl-584, runtime/perl-584/extra,<br>runtime/perl-584/manual, SUNWpl5u, SUNWpl5v<br>SUNWpl5p, SUNWpl5m<br><br>See below. |
| Interface Stability | See below.                                                                                                                       |

Perl is available for most operating systems, including virtually all Unix-like platforms. See "Supported Platforms" in `perlport` for a listing.

The Script interface, the XSUB interface, and the Directory layout are Committed. The Binary interface is Uncommitted.

**Diagnostics** The 'use warnings' pragma (and the `-w` switch) produce some lovely diagnostics.

See `perldiag` for explanations of all Perl's diagnostics. The 'use diagnostics' pragma automatically turns Perl's normally terse warnings and errors into these longer forms.

Compilation errors will tell you the line number of the error, with an indication of the next token or token type that was to be examined. (In a script passed to Perl via `-e` switches, each `-e` is counted as one line.)

Setuid scripts have additional constraints that can produce error messages such as "Insecure dependency". See `perlsec`.

Did we mention that you should definitely consider using the `-w` switch?

**Notes** Perl 5.8.4 has been built to be largefile-aware and to use 64-bit integers, although the interpreter itself is a 32-bit application (LP32). To view detailed configuration information, use `perl -V` and `perlbug -dv`.

If you wish to build and install add-on modules from CPAN using `gcc`, you can do so using the `/usr/perl5/5.8.4/bin/perlgcc` script – see `perlgcc(1)` for details.

If you wish to build and install your own version of Perl, you should NOT remove the 5.8.4 version of perl under `/usr/perl5`, as it is required by several system utilities. The Perl package names are as follows:

|                 |                             |
|-----------------|-----------------------------|
| SUNWperl584core | Perl 5.8.4 (Core files)     |
| SUNWperl584usr  | Perl 5.8.4 (Non-core files) |
| SUNWperl584man  | Perl 5.8.4 (Manual pages)   |

Solaris 10 also ships with the 5.6.1 version of Perl that was included in Solaris 9. If you are upgrading your system and wish to continue to use Perl 5.6.1 as the default Perl version you should refer to the `perlsolaris` manpage for details of how to do this. Note that you should upgrade your installation to use Perl 5.8.4 as soon as is practicable, as Perl 5.6.1 may be removed in a future release.

The Perl motto is "There's more than one way to do it." Divining how many more is left as an exercise to the reader.

The three principal virtues of a programmer are Laziness, Impatience, and Hubris. See the Camel Book for why.

**Bugs** The `-w` switch is not mandatory.

Perl is at the mercy of your machine's definitions of various operations such as type casting, `atoi()`, and floating-point output with `sprintf()`.

If your `stdio` requires a seek or eof between reads and writes on a particular stream, so does Perl. (This doesn't apply to `sysread()` and `syswrite()`.)

While none of the built-in data types have any arbitrary size limits (apart from memory size), there are still a few arbitrary limits: a given variable name may not be longer than 251 characters. Line numbers displayed by diagnostics are internally stored as short integers, so they are limited to a maximum of 65535 (higher numbers usually being affected by wraparound).

You may mail your bug reports (be sure to include full configuration information as output by the `myconfig` program in the perl source tree, or by `'perl -V'`) to `perlbug@perl.org`. If you've succeeded in compiling perl, the `perlbug` script in the `utils/` subdirectory can be used to help mail in a bug report.

Perl actually stands for Pathologically Eclectic Rubbish Lister, but don't tell anyone I said that.

- Name** pfexec, pfbash, pfcsh, pfksh, pfsh, pftcsh, pfzsh – execute a command in a profile
- Synopsis** `/usr/bin/pfexec command`  
`/usr/bin/pfexec -P privspec command [ arg ]...`  
`/usr/bin/pfsh [ options ] [ argument ]...`  
`/usr/bin/pfcsh [ options ] [ argument ]...`  
`/usr/bin/pfksh [ options ] [ argument ]...`
- Description** The pfexec program sets the PRIV\_PFEEXEC process flag and marks the current process as a profile shell. It then executes the specified command. The kernel queries the [exec\\_attr\(4\)](#) database and executes with the appropriate attributes.
- Profiles are searched in the order specified in the user's entry in the [user\\_attr\(4\)](#) database. If the same command appears in more than one profile, the profile shell uses the first matching entry.
- The second form, `pfexec -P privspec`, allows a user to obtain the additional privileges awarded to the user's profiles in [prof\\_attr\(4\)](#). The privileges specification on the commands line is parsed using [priv\\_str\\_to\\_set\(3C\)](#). The resulting privileges are intersected with the union of the privileges specified using the `privs` keyword in [prof\\_attr\(4\)](#) for all the user's profiles and added to the inheritable set before executing the command.
- Usage** pfexec is used to execute commands with predefined process attributes, such as specific user or group IDs.
- Refer to the [sh\(1\)](#), [csh\(1\)](#), and [ksh\(1\)](#) man pages for complete usage descriptions of the profile shells.
- Examples** **EXAMPLE 1** Obtaining additional user privileges  

```
example% pfexec -P all chown user file
```

This command runs `chown user file` with all privileges assigned to the current user, not necessarily all privileges.
- Exit Status** The following exit values are returned:
- 0 Successful completion.
  - 1 An error occurred.
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

| <b>Name</b>        | pg – files perusal filter for CRTs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Synopsis</b>    | pg [-number] [-p string] [-cefnrs] [+ linenumber]<br>[+/ pattern /] [filename]...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>The pg command is a filter that allows the examination of <i>filenames</i> one screenful at a time on a CRT. If the user types a RETURN, another page is displayed; other possibilities are listed below.</p> <p>This command is different from previous paginators in that it allows you to back up and review something that has already passed. The method for doing this is explained below.</p> <p>To determine terminal attributes, pg scans the <a href="#">terminfo(4)</a> data base for the terminal type specified by the environment variable TERM. If TERM is not defined, the terminal type dumb is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Options</b>     | <p><b>-number</b> An integer specifying the size (in lines) of the window that pg is to use instead of the default. (On a terminal containing 24 lines, the default window size is 23).</p> <p><b>-pstring</b> pg uses <i>string</i> as the prompt. If the prompt string contains a %d, the first occurrence of %d in the prompt will be replaced by the current page number when the prompt is issued. The default prompt string is “:”.</p> <p><b>-c</b> Home the cursor and clear the screen before displaying each page. This option is ignored if <code>clear_screen</code> is not defined for this terminal type in the <a href="#">terminfo(4)</a> data base.</p> <p><b>-e</b> pg does <i>not</i> pause at the end of each file.</p> <p><b>-f</b> Normally, pg splits lines longer than the screen width, but some sequences of characters in the text being displayed (for instance, escape sequences for underlining) generate undesirable results. The -f option inhibits pg from splitting lines.</p> <p><b>-n</b> Normally, commands must be terminated by a &lt;newline&gt; character. This option causes an automatic end of command as soon as a command letter is entered.</p> <p><b>-r</b> Restricted mode. The shell escape is disallowed. pg prints an error message but does not exit.</p> <p><b>-s</b> pg prints all messages and prompts in the standard output mode (usually inverse video).</p> <p><b>+linenumber</b> Start up at <i>linenumber</i>.</p> <p><b>+/pattern/</b> Start up at the first line containing the regular expression pattern.</p> |

**Operands** The following operands are supported:

*filename* A path name of a text file to be displayed. If no *filename* is given, or if it is `-`, the standard input is read.

### Usage

**Commands** The responses that may be typed when `pg` pauses can be divided into three categories: those causing further perusal, those that search, and those that modify the perusal environment.

Commands that cause further perusal normally take a preceding *address*, an optionally signed number indicating the point from which further text should be displayed. This *address* is interpreted in either pages or lines depending on the command. A signed *address* specifies a point relative to the current page or line, and an unsigned *address* specifies an address relative to the beginning of the file. Each command has a default address that is used if none is provided.

The perusal commands and their defaults are as follows:

|                                            |                                                                                                                                                                                                                                     |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (+1)< <i>newline</i> > or < <i>blank</i> > | This causes one page to be displayed. The address is specified in pages.                                                                                                                                                            |
| (+1) <i>l</i>                              | With a relative address this causes <code>pg</code> to simulate scrolling the screen, forward or backward, the number of lines specified. With an absolute address this command prints a screenful beginning at the specified line. |
| (+1) <i>d</i> or <i>^D</i>                 | Simulates scrolling half a screen forward or backward.                                                                                                                                                                              |
| <i>if</i>                                  | Skip <i>i</i> screens of text.                                                                                                                                                                                                      |
| <i>iz</i>                                  | Same as < <i>newline</i> > except that <i>i</i> , if present, becomes the new default number of lines per screenful.                                                                                                                |

The following perusal commands take no *address*.

|                             |                                                                                       |
|-----------------------------|---------------------------------------------------------------------------------------|
| <code>.</code> or <i>^L</i> | Typing a single period causes the current page of text to be redisplayed.             |
| <code>\$</code>             | Displays the last full window in the file. Use with caution when the input is a pipe. |

The following commands are available for searching for text patterns in the text. The regular expressions are described on the [regex\(5\)](#) manual page. They must always be terminated by a <*newline*>, even if the `-n` option is specified.

|                   |                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>i/pattern/</i> | Search forward for the <i>i</i> th (default <i>i</i> =1) occurrence of <i>pattern</i> . Searching begins immediately after the current page and continues to the end of the current file, without wrap-around. |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*i*<sup>^</sup>*pattern*<sup>^</sup>

*i*?*pattern*? Search backwards for the *i*th (default *i*=1) occurrence of *pattern*. Searching begins immediately before the current page and continues to the beginning of the current file, without wrap-around. The ^ notation is useful for Adds 100 terminals which will not properly handle the ?.

After searching, pg will normally display the line found at the top of the screen. This can be modified by appending m or b to the search command to leave the line found in the middle or at the bottom of the window from now on. The suffix t can be used to restore the original situation.

The user of pg can modify the environment of perusal with the following commands:

|                      |                                                                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>in</i>            | Begin perusing the <i>i</i> th next file in the command line. The <i>i</i> is an unsigned number, default value is 1.                                                                                                                            |
| <i>ip</i>            | Begin perusing the <i>i</i> th previous file in the command line. <i>i</i> is an unsigned number, default is 1.                                                                                                                                  |
| <i>iw</i>            | Display another window of text. If <i>i</i> is present, set the window size to <i>i</i> .                                                                                                                                                        |
| <i>s filename</i>    | Save the input in the named file. Only the current file being perused is saved. The white space between the <i>s</i> and <i>filename</i> is optional. This command must always be terminated by a <newline>, even if the -n option is specified. |
| <i>h</i>             | Help by displaying an abbreviated summary of available commands.                                                                                                                                                                                 |
| <i>q</i> or <i>Q</i> | Quit pg.                                                                                                                                                                                                                                         |
| <i>!command</i>      | <i>Command</i> is passed to the shell, whose name is taken from the SHELL environment variable. If this is not available, the default shell is used. This command must always be terminated by a <newline>, even if the -n option is specified.  |

At any time when output is being sent to the terminal, the user can hit the quit key (normally CTRL-\) or the interrupt (break) key. This causes pg to stop sending output, and display the prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, because any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

If the standard output is not a terminal, then pg acts just like [cat\(1\)](#), except that a header is printed before each file (if there is more than one).

Large File Behavior See [largefile\(5\)](#) for the description of the behavior of pg when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** An example of the pg command.

The following command line uses pg to read the system news:

```
example% news | pg -p "(Page %d) :"
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of pg: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

The following environment variables affect the execution of pg:

**COLUMNS** Determine the horizontal screen size. If unset or NULL, use the value of TERM, the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.

**LINES** Determine the number of lines to be displayed on the screen. If unset or NULL, use the value of TERM, the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.

**SHELL** Determine the name of the command interpreter executed for a !command.

**TERM** Determine terminal attributes. Optionally attempt to search a system-dependent database, keyed on the value of the TERM environment variable. If no information is available, a terminal incapable of cursor-addressable movement is assumed.

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Files** /tmp/pg\* temporary file when input is from a pipe

/usr/share/lib/terminfo/??/\* terminal information database

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |
| CSI            | Enabled         |

**See Also** [cat\(1\)](#), [grep\(1\)](#), [more\(1\)](#), [terminfo\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#)

**Notes** While waiting for terminal input, pg responds to BREAK, CTRL-C, and CTRL-\ by terminating execution. Between prompts, however, these signals interrupt pg's current task and place the user in prompt mode. These should be used with caution when input is being read from a pipe, since an interrupt is likely to terminate the other commands in the pipeline.

The terminal /, ^, or ? may be omitted from the searching commands.

If terminal tabs are not set every eight positions, undesirable results may occur.

When using `pg` as a filter with another command that changes the terminal I/O options, terminal settings may not be restored correctly.

**Name** pgrep, pkill – find or signal processes by name and other attributes

**Synopsis** `pgrep [-flvx] [-n | -o] [-d delim] [-P ppidlist]`  
`[-g pgrplist] [-s sidlist] [-u euidlist] [-U uidlist]`  
`[-G gidlist] [-J projidlist] [-t termlist]`  
`[-T taskidlist] [-c ctidlist] [-z zoneidlist]`  
`[pattern]`

`pkill [-signal] [-fvx] [-n | -o] [-P ppidlist]`  
`[-g pgrplist] [-s sidlist] [-u euidlist] [-U uidlist]`  
`[-G gidlist] [-J projidlist] [-t termlist]`  
`[-T taskidlist] [-c ctidlist] [-z zoneidlist]`  
`[pattern]`

**Description** The `pgrep` utility examines the active processes on the system and reports the process IDs of the processes whose attributes match the criteria specified on the command line. Each process ID is printed as a decimal value and is separated from the next ID by a delimiter string, which defaults to a newline. For each attribute option, the user can specify a set of possible values separated by commas on the command line. For example,

**pgrep -G other,daemon**

matches processes whose real group ID is `other` OR `daemon`. If multiple criteria options are specified, `pgrep` matches processes whose attributes match the logical AND of the criteria options. For example,

**pgrep -G other,daemon -U root,daemon**

matches processes whose attributes are:

(real group ID is `other` OR `daemon`) AND  
(real user ID is `root` OR `daemon`)

`pkill` functions identically to `pgrep`, except that each matching process is signaled as if by `kill(1)` instead of having its process ID printed. A signal name or number may be specified as the first command line option to `pkill`.

**Options** The following options are supported:

- c *ctidlist* Matches only processes whose process contract ID is in the given list.
- d *delim* Specifies the output delimiter string to be printed between each matching process ID. If no `-d` option is specified, the default is a newline character. The `-d` option is only valid when specified as an option to `pgrep`.
- f The regular expression *pattern* should be matched against the full process argument string (obtained from the `pr_psargs` field of the `/proc/nnnnn/psinfo` file). If no `-f` option is specified, the expression is matched only against the name of the executable file (obtained from the `pr_fname` field of the `/proc/nnnnn/psinfo` file).

- 
- g pgrplist** Matches only processes whose process group ID is in the given list. If group 0 is included in the list, this is interpreted as the process group ID of the `pgrep` or `kill` process.
- G gidlist** Matches only processes whose real group ID is in the given list. Each group ID may be specified as either a group name or a numerical group ID.
- J projidlist** Matches only processes whose project ID is in the given list. Each project ID may be specified as either a project name or a numerical project ID.
- l** Long output format. Prints the process name along with the process ID of each matching process. The process name is obtained from the `pr_psargs` or `pr_fname` field, depending on whether the `-f` option was specified (see above). The `-l` option is only valid when specified as an option to `pgrep`.
- n** Matches only the newest (most recently created) process that meets all other specified matching criteria. Cannot be used with option `-o`.
- o** Matches only the oldest (earliest created) process that meets all other specified matching criteria. Cannot be used with option `-n`.
- P ppidlist** Matches only processes whose parent process ID is in the given list.
- s sidlist** Matches only processes whose process session ID is in the given list. If ID 0 is included in the list, this is interpreted as the session ID of the `pgrep` or `kill` process.
- t termlist** Matches only processes which are associated with a terminal in the given list. Each terminal is specified as the suffix following “/dev/” of the terminal's device path name in `/dev`. For example, `term/a` or `pts/0`.
- T taskidlist** Matches only processes whose task ID is in the given list. If ID 0 is included in the list, this is interpreted as the task ID of the `pgrep` or `kill` process.
- u euidlist** Matches only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
- U uidlist** Matches only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
- v** Reverses the sense of the matching. Matches all processes *except* those which meet the specified matching criteria.
- x** Considers only processes whose argument string or executable file name *exactly* matches the specified *pattern* to be matching processes. The pattern match is considered to be exact when all characters in the process argument string or executable file name match the pattern.
- z zoneidlist** Matches only processes whose zone ID is in the given list. Each zone ID may be specified as either a zone name or a numerical zone ID. This option is only

useful when executed in the global zone. If the `kill` utility is used to send signals to processes in other zones, the process must have asserted the `{PRIV_PROC_ZONE}` privilege (see [privileges\(5\)](#)).

**-signal** Specifies the signal to send to each matched process. If no signal is specified, `SIGTERM` is sent by default. The value of *signal* can be one of the symbolic names defined in [signal.h\(3HEAD\)](#) without the `SIG` prefix, or the corresponding signal number as a decimal value. The *-signal* option is only valid when specified as the first option to `kill`.

**Operands** The following operand is supported:

*pattern* Specifies an Extended Regular Expression (ERE) pattern to match against either the executable file name or full process argument string. See [regex\(5\)](#) for a complete description of the ERE syntax.

**Examples** **EXAMPLE 1** Obtaining a Process ID

Obtain the process ID of `sendmail`:

```
example% pgrep -x -u root sendmail
283
```

**EXAMPLE 2** Terminating a Process

Terminate the most recently created `xterm`:

```
example% pkill -n xterm
```

**Exit Status** The following exit values are returned:

- 0 One or more processes were matched.
- 1 No processes were matched.
- 2 Invalid command line options were specified.
- 3 A fatal error occurred.

**Files** `/proc/nnnnn/psinfo` Process information files

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [kill\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [truss\(1\)](#), [kill\(2\)](#), [signal.h\(3HEAD\)](#), [proc\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#), [regex\(5\)](#), [zones\(5\)](#)

**Notes** Both utilities match the ERE *pattern* argument against either the `pr_fname` or `pr_psargs` fields of the `/proc/nnnnn/psinfo` files. The lengths of these strings are limited according to definitions in `<sys/procfs.h>`. Patterns which can match strings longer than the current limits may fail to match the intended set of processes.

If the *pattern* argument contains ERE meta-characters which are also shell meta-characters, it may be necessary to enclose the pattern with appropriate shell quotes.

Defunct processes are never matched by either `pgrep` or `kill`.

The current `pgrep` or `kill` process will never consider itself a potential match.

**Name** pkcs11\_inspect – print certificate contents

**Synopsis** /usr/lib/pam\_pkcs11/pkcs11\_inspect [debug] [config\_file=*filename*]

**Description** pkcs11\_inspect uses the pam\_pkcs11 library infrastructure to obtain the content of a certificate and display it.

pkcs11\_inspect uses the same configuration file and arguments as the [pam\\_pkcs11\(5\)](#) PAM module. It loads defined mapper modules, and uses them to look into the certificate for required entries, that is, ms\_mapper looks for ms UPN entries, and so forth.

When a mapper module finds a proper entry in the certificate, it converts to UTF-8 and prints it to stdout.

**Options** The following options are supported:

`config_file=filename` Set the configuration file. The default value is  
/etc/security/pam\_pkcs11/pam\_pkcs11.conf.

`debug` Enable debugging output.

As it uses the same configuration file as [pam\\_pkcs11\(5\)](#), all of the pam\_pkcs11 options are available. Some of these options make no sense in a non-PAM environment, and are therefore ignored. Some mapper options (`mapfile`, `ignorecase`) have no effect on certificate contents, and they are ignored as well.

**Exit Status** The following exit values are returned:

0 Successful completion.

pkcs11\_inspect prints on stdout all certificate contents that are found for mappers.

1 An error occurred.

**Examples** EXAMPLE 1 Using pkcs\_inspect

The following example runs the pkcs\_inspect command without any options:

```
% pkcs11_inspect
```

EXAMPLE 2 Using pkcs\_inspect with Options

The following example runs the pkcs\_inspect command with options:

```
% pkcs11_inspect debug config_file=${HOME}/.pam_pkcs11.conf
```

**Files** /etc/security/pam\_pkcs11/pam\_pkcs11.conf

**Authors** Juan Antonio Martinez, jonsito@teleline.es

---

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                        |
|---------------------|----------------------------------------|
| Availability        | library/security/pam/module/pam-pkcs11 |
| Interface Stability | Uncommitted                            |

```

**Description** pkg is the retrieval client for the Image Packaging System. With a valid configuration, pkg can be invoked to create locations for packages to be installed, called images, and install packages into those images. Packages are published by publishers, who can make their packages available at one or more repositories, or in package archives. pkg retrieves packages from a publisher's repository or package archives and installs the packages into an image.

A publisher name identifies a person, group of persons, or an organization as the source of one or more packages. To avoid publisher name collisions and help identify the publisher, a best practice is to use a domain name that represents the entity publishing the packages as a publisher name.

A repository is a location where clients can publish and retrieve package content (files contained within the package such as programs and documents) and metadata (information about the package such as its name and description). As an example, a publisher named `example.org` might have their repository located at the URI `http://example.org/repository`.

`pkg` can also uninstall packages, refresh publisher metadata (such as the list of available packages), validate package installation in an image, and query the image for various tokens. These queries can also be made of `pkg(5)` repositories.

Images can be of three types: full images, capable of providing a complete system; partial images, which are linked to a full image (parent image), but do not provide a complete system on their own; and user images.

**Options** The following options are supported:

`-?`

`--help`

Display a usage message.

`-R dir`

`--image-dir dir`

Operate on the image rooted at *dir*. If no directory was specified or determined based on environment, the default is `/`. See the “Environment Variables” section for more information.

**Sub-commands** The following subcommands are supported:

`pkg refresh [-q] [--full] [publisher ...]`

Update the client's list of available packages and publisher metadata for all publishers.

*publisher*

Update the client's list of available packages and publisher metadata only for the specified publishers.

`-q`

Hide progress messages during the requested operation.

`--full`

Force a full retrieval of all publisher metadata, instead of attempting an incremental update, and request that any proxies used during the operation ignore cached data. This option exists for troubleshooting purposes and should not be used on a regular basis.

```
pkg install [-nvq] [-C n] [-g path_or_uri ...] [--accept] [--licenses] [--no-be-activate]
[--no-index] [--no-refresh] [--no-backup-be | --require-backup-be]
[--backup-be-name name] [--deny-new-be | --require-new-be] [--be-name name]
[--reject pkg_fmri_pattern ...] pkg_fmri_pattern ...
```

Install and update the specified packages to the newest version that match *pkg\_fmri\_pattern* allowed by the packages installed in the image. To explicitly request the latest version of a package, use `latest` for the version portion of *pkg\_fmri\_pattern*. For example, specify `vim@latest`.

Packages are selected based on publisher search order and stickiness. See the `pkg publisher` and `pkg set-publisher` commands for information about search order and stickiness. If the *pkg\_fmri\_pattern* does not specify the publisher, the first publisher that provides a matching package is used as the installation source. If that publisher does not provide a version of the package that can be installed in this image, then the installation operation fails. Use the `pkg list -a` command to see which publishers provide a version of the package that can be installed in this image.

If more than one *pkg\_fmri\_pattern* is specified, and if any of the specified packages cannot be installed in this image, then none of the specified packages will be installed.

Some configuration files might be renamed or replaced during the installation process. For more information on how the package system determines which files to preserve, and how they are preserved during package operations, see “File Actions” in the `pkg(5)` man page.

If a package is on the avoid list, installing it removes it from that list.

**-g *path\_or\_uri***

Temporarily add the specified package repository or archive to the list of sources in the image from which to retrieve package data. Repositories that require a client SSL certificate cannot be used with this option. This option can be specified multiple times.

When deciding which version of a package to use, publishers configured in the image, but not found in the specified *path\_or\_uri* sources, take precedence. If the version of the package to be installed is provided by a publisher configured in the image and by a *path\_or\_uri* source, the client retrieves the content for that package from the *path\_or\_uri* sources. After installation or update, any packages provided by publishers not configured in the image are added to the image configuration without an origin. Use the `pkg publisher` command to see which publishers are configured in the image.

**-n**

Perform a trial run of the operation with no package changes made.

**-v**

Issue verbose progress messages during the requested operation, and display detailed planning information (such as changing facets, mediators, and variants). This option can be specified multiple times to increase the amount of planning information displayed.

- 
- q  
Hide progress messages during the requested operation.
  - C *n*  
Specify the number of child images to update in parallel. When recursing into child images (usually zones), update at most *n* child images in parallel. The default number of child images to update in parallel is 1. If *n* is 0 or a negative number, all child images are updated in parallel. See also `PKG_CONCURRENCY` in the “Environment Variables” section.
  - accept  
Indicate that you agree to and accept the terms of the licenses of the packages that are updated or installed. If you do not provide this option, and any package licenses require acceptance, the installation operation fails.
  - licenses  
Display all of the licenses for the packages that are installed or updated as part of this operation.
  - no-backup-be  
Do not create a backup boot environment.
  - no-be-activate  
If a boot environment is created, do not set it as the active boot environment on the next boot. See the `beadm(1M)` man page for more information.
  - no-index  
Do not update the search indexes after the operation has completed successfully.
  - no-refresh  
Do not attempt to contact the repositories for the image's publishers to retrieve the newest list of available packages and other metadata.
  - backup-be-name *name*  
Name the created backup boot environment using the given argument. Use of `--backup-be-name` implies `--require-backup-be`. See also the `beadm(1M)` man page.
  - be-name *name*  
Rename the newly created boot environment to be the argument given. Use of `--be-name` implies `--require-new-be`. See also the `beadm(1M)` man page.
  - require-backup-be  
Always create a backup boot environment if a new boot environment will not be created. Without this option, a backup boot environment is created based on image policy. See `be-policy` in “Image Properties” below for an explanation of when backup boot environments are created automatically.

--require-new-be

Always create a new boot environment. Without this option, a boot environment is created based on image policy. See `be-policy` in “Image Properties” below for an explanation of when boot environments are created automatically. This option cannot be combined with `--require-backup-be`.

--deny-new-be

Do not create a new boot environment. This operation is not performed if a new boot environment is required.

--reject *pkg\_fmri\_pattern*

Prevent packages with names matching the given pattern from being installed. If matching packages are already installed, they are removed as part of this operation. Rejected packages that are the target of group dependencies are placed on the avoid list.

```
pkg uninstall [-nvq] [-C n] [--no-be-activate] [--no-index] [--no-backup-be |
--require-backup-be] [--backup-be-name name] [--deny-new-be | --require-new-be]
[--be-name name] pkg_fmri_pattern ...
```

Remove installed packages that match *pkg\_fmri\_pattern*.

If a package is the subject of a group dependency, uninstalling it places it on the avoid list. See the `avoid` subcommand below.

For descriptions of options, see the `install` command above.

In the command output, note any messages that say a new boot environment has been created. If a new boot environment has been created and activated, that is the environment that is booted by default on next reboot. See the `beadm(1M)` man page for information about managing boot environments.

```
pkg update [-fnvq] [-C n] [-g path_or_uri ...] [--accept] [--licenses] [--no-be-activate]
[--no-index] [--no-refresh] [--no-backup-be | --require-backup-be]
[--backup-be-name name] [--deny-new-be | --require-new-be] [--be-name name]
[--reject pkg_fmri_pattern ...] [pkg_fmri_pattern ...]
```

Update all packages installed in the current image to the newest version allowed by the constraints imposed on the system by installed packages and publisher configuration.

*pkg\_fmri\_pattern*

Update only the specified packages installed in the current image. If asterisk (\*) is one of the *pkg\_fmri\_pattern* patterns provided, update all packages installed in the current image as described above.

To explicitly request the latest version of a package, use `latest` for the version portion of *pkg\_fmri\_pattern*. For example, specify `vim@latest`.

Versions older or newer than what is already installed can be specified to perform in-place downgrades or upgrades of specific packages. Updating specific packages across package rename or obsolete boundaries is not supported.

Any preserved configuration files that are part of packages to be downgraded and that have been changed since the original version was installed are renamed using the extension `.update`. For more information about how the package system determines which files to preserve, and how these files are preserved during package upgrades, see “File Actions” in the `pkg(5)` man page.

If more than one `pkg_fmri_pattern` is specified, and if any of the specified packages cannot be updated in this image, then none of the specified packages will be updated.

`-f`

Do not execute the client up-to-date check when updating all installed packages.

For all other options, see the `install` command above.

In the command output, note any messages that say a new boot environment has been created. If a new boot environment has been created and activated, that is the environment that is booted by default on next reboot if you do not specify the `--no-be-activate` option. See the `beadm(1M)` man page for information about managing boot environments.

```
pkg list [-Hafnsuv] [-g path_or_uri ...] [--no-refresh] [pkg_fmri_pattern ...]
```

Display a list of all packages installed in the current image, including information such as version and installed state. By default, package variants for a different architecture or zone type are excluded. The usual output is in three columns:

| NAME (PUBLISHER)       | VERSION                | IFO |
|------------------------|------------------------|-----|
| system/core-os         | 0.5.11-0.175.0.0.0.2.1 | i-- |
| x11/wm/fvwm (fvwm.org) | 2.6.5                  | i-- |

The first column contains the name of the package. If the publisher from which the package is installed (or available, if not installed) is not the first in the publisher search order, then the publisher name is listed in parentheses after the package name. The second column contains the release and branch versions of the package. See the `pkg(5)` man page for information about release and branch versions and about variants.

The last column contains a set of flags that show the status of the package:

- An `i` in the `I` column shows that the package is installed.
- An `f` in the `F` column shows that the package is frozen.
- An `o` in the `O` column shows that the package is obsolete. An `r` in the `O` column shows that the package has been renamed (a form of obsolescence).

`pkg_fmri_pattern`

List only the specified packages.

`-H`

Omit the headers from the listing.

- a  
List installed packages and the newest version of packages that are available for installation. Packages are considered to be available for installation if they are allowed by the installed incorporations and by the image's variants. If one or more patterns are specified, then the newest version matching the specified pattern and allowed by any installed incorporations and the image's variants is listed. Without -a, list only installed packages.
- af  
List all versions of all packages for all variants regardless of incorporation constraints or installed state. To explicitly list the latest version of a package when using these options, use `latest` for the version portion of *pkg\_fmri\_pattern*. For example, specify `vim@latest`.
- g *path\_or\_uri*  
Use the specified package repository or archive as the source of package data for the operation. Repositories that require a client SSL certificate cannot be used with this option. This option can be specified multiple times. Use of -g implies -a if -n is not specified.
- n  
Display the newest versions of all known packages, regardless of installed state.
- s  
Display a one-line short-form giving the package name and summary. This option can be used with -a, -n, -u or -v.
- u  
List only packages with newer versions available. This option cannot be used with -g.
- v  
Show full package FMRIs, including publisher and complete version, all in the first column (the VERSION column disappears). This option can be used with -a, -n, or -u.
- no-refresh  
Do not attempt to contact the repositories for the image's publishers to retrieve the newest list of available packages.

`pkg info [-lr] [-g path_or_uri ...] [--license] [pkg_fmri_pattern ...]`

Display information about all packages installed in the current image in a human-readable form.

*pkg\_fmri\_pattern*

Display information for only the specified packages.

-g *path\_or\_uri*

Use the specified package repository or archive as the source of package data for the operation. Repositories that require a client SSL certificate cannot be used with this option. This option can be specified multiple times. Use of -g implies -r.

-l

Only display information for installed packages. This is the default.

-r

Match packages based on the newest available versions, retrieving information for packages not currently installed (if necessary) from the repositories of the image's configured publishers. At least one package must be specified when using this option. Without -r, only installed packages are displayed by default.

--license

Display the license texts for the packages. This option can be combined with -l or -r.

pkg contents [-Hmr] [-a *attribute=pattern* ...] [-g *path\_or\_uri* ...] [-o *attribute*,...] [-s *sort\_key*] [-t *action\_name* ...] [*pkg\_fmri\_pattern* ...]

Display the contents (action attributes) of all packages installed in the image. With no options, display the value of the path attribute for actions installed in the current image, sorted alphabetically by attribute value. For information about actions and their attributes, see “Actions” in the pkg(5) man page. See also the list of pseudo attribute names below.

*pkg\_fmri\_pattern*

Display contents of only the specified packages.

-H

Omit the headers from the output.

-a *attribute=pattern*

Limit the output to those actions that have an attribute named in the option argument with a value that matches the (glob) pattern in the option argument (following the attribute name with an equals sign). If multiple -a options are given, then actions matching any of them are displayed.

-g *path\_or\_uri*

Display information for packages that could be installed in this image from the specified package repository or archive. Repositories that require a client SSL certificate cannot be used with this option. Packages that could be installed include packages that are currently installed and other packages that satisfy criteria for installation in this image, such as variant and facet restrictions. This option can be specified multiple times. Use of -g implies -r.

-m

Display all attributes of all actions in the specified packages, including actions that could not be installed in this image.

-o *attribute*

Display the specified attributes, sorted according to the values of the first attribute listed. The -o option can be specified multiple times, or multiple attributes can be specified as the argument to one -o option by separating the attribute names with commas. Only actions that have the requested attributes are displayed.

-r

Display information for the newest available versions of packages that could be installed in this image from the repositories of the publishers configured in this image. Packages that could be installed include packages that are currently installed and other packages that satisfy criteria for installation in this image, such as variant and facet restrictions. At least one package must be specified when using this option.

-s *sort\_key*

Sort actions by the specified action attribute. If not provided, the default is to sort by path or by the first attribute specified by the -o option. The -s option can be specified multiple times.

-t *action\_name*

Only list the specified actions. Multiple actions can be specified in a comma-separated list. The value of *action\_name* is one of the actions listed in “Actions” in the pkg(5) man page, such as file, directory, driver, depend, set. This option can be specified multiple times.

Several special pseudo attribute names are available for convenience:

`action.hash`

The value of the action's hash, if the action carries a payload.

`action.key`

The value of the action's key attribute. For example, for a file action, the key attribute is the path to the file. Some actions do not have a key attribute.

`action.name`

The name of the action. For example, for a file action, this is file.

`action.raw`

All attributes of matching actions.

`pkg.fmri`

The full FMRI of the package containing the action, such as

`pkg://solaris/group/feature/amp@0.5.11,5.11-0.175.0.0.0.2.1:20120705T153434Z.`

`pkg.name`

The name of the package containing the action, such as web/amp.

`pkg.publisher`

The publisher of the package containing the action, such as solaris.

`pkg.shortfmri`

The short form FMRI of the package containing the action, such as

`pkg://solaris/group/feature/amp@0.5.11,5.11-0.175`

The contents and search subcommands are related: Both query the system for the contents of packages. The contents subcommand displays actions in one or more installed

or installable packages, filtering the output based on the specified options. The `search` subcommand approaches the query from the other direction, displaying the names of all packages that contain a user-supplied token.

Each subcommand is capable of formulating some queries of which the other is capable. Care should be taken in choosing the subcommand, as a given query can be more naturally formulated in one than in the other.

`pkg search [-HIaf\lr] [-o attribute,...] [-s repo_uri] query`

Search for matches to the *query*, and display the results. See the description of *query* below.

`-H`

Omit the headers from the output.

`-I`

Use a case-sensitive search.

`-a`

Perform the search and display information about the matching actions. This is the default.

`-f`

Show all results, regardless of package version. By default, `search` prunes results from packages older than the currently installed version and from package versions excluded by current incorporations.

`-l`

Search the image's installed packages.

Both `-l` and `-r` (or `-s`) can be specified together, in which case both local and remote searches are performed.

`-p`

Display packages that have some actions that match each query term. Using this option is equivalent to putting angle brackets (`<>`) around each term in the query. See *query* below for more description of the `<>` operator.

`-r`

Search the repositories corresponding to the image's publishers. This is the default.

Both `-l` and `-r` (or `-s`) can be specified together, in which case both local and remote searches are performed.

`-o attribute`

Control the columns of the results. The `-o` option can be specified multiple times, or multiple attributes can be specified as the argument to one `-o` option by separating the attribute names with commas. In addition to the pseudo attributes outlined above, the following attributes are defined for search results:

`search.match`

The string that matched the search query.

`search.match_type`

The attribute that contained the string that matched the search query.

`-s repo_uri`

Search the `pkg(5)` repository located at the given URI. This can be specified multiple times. Package archives are not supported.

*query*

By default, *query* is interpreted as a series of terms to be matched exactly. The `?` and `*` characters can be used as `glob(3C)`-style wildcards, allowing more flexible query matches.

In addition to simple token matching and wildcard search, a more complicated query language is supported. Phrases can be searched for by using single or double quotation marks (`'` or `"`). Be sure to take your shell into account so that `pkg` actually sees the `'` or `"`.

Boolean search using AND and OR is supported.

Which tokens are indexed is action-dependent, but can include content hashes and path names. For information about actions and their attributes, see “Actions” in the `pkg(5)` man page. See also the list of pseudo attribute names in `pkg contents` and `-o` above.

Structured queries are supported with the following syntax:

*pkg\_name:action\_name:index:token*

The value of *action\_name* is one of the actions listed in “Actions” in the `pkg(5)` man page. The *index* is an attribute of the action. The value of *index* must match *token*.

Not all action attributes are searchable. For example, `mode` is an attribute of the `file` action, but `mode` is not a valid value for *index*.

Some values for *index* are not action attributes but are values derived from other attributes. For example, *index* can be `basename`, which is not an attribute of any action but is derived from the `path` attribute of the `file` or `dir` action by taking the last component of the path.

Different action types have different valid values for *index*. This documentation does not list all possible values. Some of the more useful *index* values are `basename` and `path` for file system actions, the dependency type (for example, `require`, `optional`, `group`) for depend actions, and `driver_name` and `alias` for driver actions.

One special value for *index* is the value of a name attribute for a set action. In this case, *token* is matched against the value of the `value` attribute that corresponds to the specified name attribute. For example, the following search finds packages that are classified as either `Development/Databases` or `System/Databases`. In the “Examples” section, see the example of finding SMF services.

**\$ pkg search info.classification:databases**

Missing fields in a structured query are implicitly wildcarded. A search for `basename:pkg` matches all actions in all packages that have an *index* of `basename` and that match the *token* `pkg`, as shown in the following partial output:

**\$ pkg search basename:pkg**

| INDEX    | ACTION | VALUE         | PACKAGE                                  |
|----------|--------|---------------|------------------------------------------|
| basename | dir    | usr/share/pkg | pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1  |
| basename | dir    | var/sadm/pkg  | pkg:/package/svr4@0.5.11-0.175.0.0.0.2.1 |
| basename | dir    | var/spool/pkg | pkg:/package/svr4@0.5.11-0.175.0.0.0.2.1 |
| basename | file   | usr/bin/pkg   | pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1  |

Adding another field narrows the search, as shown in the following complete output:

**\$ pkg search file:basename:pkg**

| INDEX    | ACTION | VALUE       | PACKAGE                                 |
|----------|--------|-------------|-----------------------------------------|
| basename | file   | usr/bin/pkg | pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 |

Explicit wildcards are supported in the *pkg\_name* and *token* fields. The *action\_name* and *index* must match exactly.

See the “Examples” section for examples of searching for files and dependencies.

To convert actions to the packages that contain those actions, use `<>`, as shown in the following partial output:

**\$ pkg search \<pkg\>**

| PACKAGE                                  | PUBLISHER |
|------------------------------------------|-----------|
| pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1  | solaris   |
| pkg:/package/svr4@0.5.11-0.175.0.0.0.2.1 | solaris   |

With the `-a` option (and by default), searching for `token` results in information about the actions that match `token`, while searching for `<token>` results in a list of packages that contain actions that match `token`.

**pkg verify [-Hqv] [*pkg\_fmri\_pattern* ...]**

Validate the installation of all packages installed in the current image. If current signature policy for related publishers is not `ignore`, the signatures of each package are validated based on policy. See `signature-policy` in “Image Properties” below for an explanation of how signature policies are applied.

***pkg\_fmri\_pattern***

Validate the installation of only the specified packages installed in the current image.

**-H**

Omit the headers from the verification output.

**-q**

Print nothing, but return failure if there are any fatal errors.

**-v**

Include informational messages regarding packages.

`pkg fix` [`--accept`] [`--licenses`] [*pkg\_fmri\_pattern* ...]

Fix any errors reported by `pkg verify`. Verification of installed package content is based on a custom content analysis that might return different results than those of other programs.

*pkg\_fmri\_pattern*

Fix errors reported by `pkg verify` for only the specified packages installed in the current image.

`--accept`

Indicate that you agree to and accept the terms of the licenses of the packages that are updated or installed. If you do not provide this option, and any package licenses require acceptance, the operation fails.

`--licenses`

Display all of the licenses for the packages to be installed or updated as part of this operation.

`pkg revert` [`-nv`] [`--no-be-activate`] [`--no-backup-be` | `--require-backup-be`]  
[`--backup-be-name` *name*] [`--deny-new-be` | `--require-new-be`] [`--be-name` *name*]  
(`--tagged` *tag-name* ... | *path-to-file* ...)

Revert files delivered by `pkg(5)` packages to their as-delivered condition. File ownership and protections are also restored.

**Caution** – Reverting some editable files to their default values can make the system unbootable, or cause other malfunctions.

`--tagged` *tag-name*

Revert all files tagged with *tag-name*.

*path-to-file*

Revert the specified files.

For all other options, see the `install` command above.

`pkg mediator` [`-aH`] [`-F` *format*] [*mediator* ...]

Display the current selected version and/or implementation of all mediators.

*mediator*

Display the current selected version and/or implementation of only the specified mediators.

`-a`

List the mediations that can be set for currently installed packages.

`-F`

Specify an alternative output format. Currently, only `tsv` (Tab Separated Values) is valid.

`-H`

Omit the headers from the listing.

```
pkg set-mediator [-nv] [-I implementation] [-V version] [--no-be-activate]
[--no-backup-be | --require-backup-be] [--backup-be-name name] [--deny-new-be |
--require-new-be] [--be-name name] mediator ...
```

Set the version and/or implementation for the specified mediators in the current image.

*-I implementation*

Set the implementation of the mediated interface to use. By default, if no version is specified, all implementation versions are allowed. To specify an implementation with no version, append an at sign (@).

*-V version*

Set the version of the mediated interface to use.

If the specified mediator version and/or implementation is not currently available, any links using the specified mediators are removed.

For all other options, see the `install` command above.

```
pkg unset-mediator [-nvIV] [--no-be-activate] [--no-backup-be |
--require-backup-be] [--backup-be-name name] [--deny-new-be | --require-new-be]
[--be-name name] mediator ...
```

Revert the version and/or implementation of the specified mediators to the system default.

*-I*

Revert only the implementation of the mediated interface.

*-V*

Revert only the version of the mediated interface.

For all other options, see the `install` command above.

```
pkg variant [-H] [variant.variant_name ...]
```

Display the current values of all variants set in this image. See “Facets and Variants” in the `pkg(5)` man page for more information about variants.

*variant.variant\_name*

Display the current values of only the specified variants set in this image.

*-H*

Omit the headers from the listing.

```
pkg change-variant [-nvq] [-C n] [-g path_or_uri ...] [--accept] [--licenses]
[--no-be-activate] [--no-backup-be | --require-backup-be] [--backup-be-name name]
[--deny-new-be | --require-new-be] [--be-name name] variant_name=value ...
```

Change the values of the specified variants set in the current image.

Changing the value of a variant can cause package content to be removed, updated, or installed. Changing a variant value can also cause entire packages to be installed, updated, or removed to satisfy the new image configuration. See “Facets and Variants” in the `pkg(5)` man page for more information about variants.

For descriptions of options, see the `install` command above.

`pkg facet [-H] [facet_name ...]`

Display the current values of all facets that have been explicitly set in this image by using the `pkg change-facet` command. See “Facets and Variants” in the `pkg(5)` man page for more information about facets.

*facet\_name*

Display the current values of only the specified facets set in this image.

-H

Omit the headers from the listing.

`pkg change-facet [-nvq] [-C n] [-g path_or_uri ...] [--accept] [--licenses] [--no-be-activate] [--no-backup-be | --require-backup-be] [--backup-be-name name] [--deny-new-be | --require-new-be] [--be-name name] facet_name=[True|False|None] ...`

Change the values of the specified facets set in the current image.

Facets can be set to `True` or `False`. Setting a facet to `None` applies the default value of `True` to that facet; thus, any actions subject to the facet will be installed. See “Actions” in the `pkg(5)` man page for information about actions.

Changing the value of a facet can cause package content to be removed, updated, or installed. Changing a facet value can also cause entire packages to be installed, updated, or removed to satisfy the new image configuration. See “Facets and Variants” in the `pkg(5)` man page for more information about facets.

For descriptions of options, see the `install` command above.

`pkg avoid [pkg_fmri_pattern ...]`

Display each avoided package along with any packages that have a group dependency on that package.

Packages that are on the avoid list are installed if needed to satisfy a required dependency. If that dependency is removed, the package is uninstalled.

*pkg\_fmri\_pattern*

Avoid the specified packages if they are the target of a group dependency by placing the package names that currently match the specified patterns on the avoid list. Only packages that are not currently installed can be avoided. If a package is currently the target of a group dependency, uninstalling the package places it on the avoid list.

`pkg unavoid [pkg_fmri_pattern ...]`

Display the list of avoided packages.

*pkg\_fmri\_pattern*

Remove the specified packages from the avoid list. Packages on the avoid list that match an installed package's group dependency cannot be removed using this subcommand. To remove a package from the avoid list that matches a group dependency, install the

package.

`pkg freeze [-n] [-c reason] [pkg_fmri_pattern] ...`

Display information about currently frozen packages: package names, versions, when the package was frozen, and any associated reasons for freezing the packages.

Freezing a package does not prevent removal of the package. No warning is displayed if the package is removed.

*pkg\_fmri\_pattern*

Freeze the specified packages to the specified versions. If no version is given, the package must be installed and is frozen at that installed version. Freezing a package that is already frozen replaces the freeze version with the newly specified version.

When a package that is frozen is installed or updated, it must end up at a version that matches the version at which it was frozen. For example, if a package was frozen at 1.2, then it could be updated to 1.2.1, 1.2.9, 1.2.0.0.1, and so on. That package could not end up at 1.3, or 1.1. A publisher presented in the *pkg\_fmri\_pattern* is used to find matching packages. However, publisher information is not recorded as part of the freeze. A package is frozen with respect to its version only, not its publisher.

`-c reason`

Record the *reason* with the packages that are frozen. The reason is shown if a freeze prevents an installation or update from succeeding.

`-n`

Perform a trial run of the freeze operation, displaying the list of packages that would be frozen without freezing any packages.

`pkg unfreeze [-n] [pkg_name_pattern] ...`

Display information about currently frozen packages: package names, versions, when the package was frozen, and any associated reasons for freezing the packages.

*pkg\_fmri\_pattern*

Remove the constraints that freezing imposes from the specified packages. Any versions provided are ignored.

`-n`

Perform a trial run of the unfreeze operation, displaying the list of packages that would be unfrozen without unfreezing any packages.

`pkg property [-H] [propname ...]`

Display the names and values of all image properties. See “Image Properties” below for descriptions of image properties.

*propname*

Display the names and values for only the specified properties.

`-H`

Omit the headers from the listing.

`pkg set-property propname propvalue`

Update an existing image property or add a new image property.

`pkg add-property-value propname propvalue`

Add a value to an existing image property or add a new image property.

`pkg remove-property-value propname propvalue`

Remove a value from an existing image property.

`pkg unset-property propname ...`

Remove an existing image property or properties.

`pkg publisher [-HPn] [-F format] [publisher ...]`

Display the list of all publishers, their origin URIs, and mirrors in order of search preference.

*publisher*

Display detailed configuration for only the specified publishers.

-H

Omit the headers from the listing.

-P

Display only the first publisher in the publisher search order.

-n

Display only enabled publishers.

-F

Specify an alternative output format. Currently, only `tsv` (Tab Separated Values) is valid.

`pkg set-publisher [-Ped] [-k ssl_key] [-c ssl_cert] [-g origin_to_add | --add-origin origin_to_add ...] [-G origin_to_remove | --remove-origin origin_to_remove ...] [-m mirror_to_add | --add-mirror mirror_to_add ...] [-M mirror_to_remove | --remove-mirror mirror_to_remove ...] [--enable] [--disable] [--no-refresh] [--reset-uuid] [--non-sticky] [--sticky] [--search-after publisher] [--search-before publisher] [--search-first] [--approve-ca-cert path_to_CA] [--revoke-ca-cert hash_of_CA_to_remove] [--unset-ca-cert hash_of_CA_to_remove] [--set-property name_of_property=value] [--add-property-value name_of_property=value_to_add] [--remove-property-value name_of_property=value_to_remove] [--unset-property name_of_property_to_delete] [--proxy proxy_to_use] publisher`

Update an existing publisher or add a publisher. If no options affecting search order are specified, new publishers are appended to the search order and are thus searched last.

-P

--search-first

Set the specified publisher first in the search order. When installing new packages, this publisher is searched first. Updates to already installed packages come from the same publisher that originally provided the package as long as that publisher remains sticky.

- 
- non-sticky  
Higher ranked publishers than this one can provide updates to packages originally installed from this publisher.
  - sticky  
Updates to packages that were installed from this publisher must also come from this publisher. This is the default behavior.
  - search-before *publisher*  
Alter the publisher search order so that the publisher being added or modified is searched before the publisher specified in this option.
  - search-after *publisher*  
Alter the publisher search order so that the publisher being added or modified is searched after the publisher specified in this option.
  - approve-ca-cert *path\_to\_CA*  
Add the specified certificate as a CA certificate that is trusted. The hashes of the PEM representation of the user-approved CA certificates are listed in the detailed output of the `pkg publisher` command.
  - revoke-ca-cert *hash\_of\_CA\_to\_remove*  
Treat the certificate with the given hash of its PEM representation as revoked. The hashes of the user-revoked CA certificates are listed in the detailed output of the `pkg publisher` command.
  - unset-ca-cert *hash\_of\_CA\_to\_remove*  
Remove the certificate with the given hash from the list of approved certificates and the list of revoked certificates.
  - set-property *name\_of\_property=value*  
Update an existing publisher property or add a new publisher property.
  - add-property-value *name\_of\_property=value\_to\_add*  
Add a value to an existing publisher property or add a new publisher property.
  - remove-property-value *name\_of\_property=value\_to\_remove*  
Remove a value from an existing publisher property.
  - unset-property *name\_of\_property\_to\_delete*  
Remove an existing publisher property.
  - k *ssl\_key*  
Specify the client SSL key.
  - c *ssl\_cert*  
Specify the client SSL certificate.
  - g *origin\_to\_add*  
--add-origin *origin\_to\_add*

Add the specified URI or path as an origin for the given publisher. This should be the location of a package repository or archive.

*-G origin\_to\_remove*

*--remove-origin origin\_to\_remove*

Remove the URI or path from the list of origins for the given publisher. The special value *\** can be used to remove all origins.

*--no-refresh*

Do not attempt to contact the repositories for the image's publishers to retrieve the newest list of available packages and other metadata.

*--reset-uuid*

Choose a new unique identifier that identifies this image to its publisher.

*-m mirror\_to\_add*

*--add-mirror mirror\_to\_add*

Add the URI as a mirror for the given publisher.

*-M mirror\_to\_remove*

*--remove-mirror mirror\_to\_remove*

Remove the URI from the list of mirrors for the given publisher. The special value *\** can be used to remove all mirrors.

*-e*

*--enable*

Enable the publisher.

*-d*

*--disable*

Disable the publisher. A disabled publisher is not used when populating the package list or in certain package operations (install, uninstall, and update). However, the properties for a disabled publisher can still be set and viewed. If only one publisher exists, it cannot be disabled.

*--proxy proxy\_to\_use*

Use the specified web proxy URI to retrieve content for the specified origin (*-g*) or mirror (*-m*). The proxy value is stored as part of the publisher configuration. At run time, `$http_proxy` or related environment variables override this proxy setting. See the `curl(1)` man page for the list of accepted environment variable names.

```
pkg set-publisher -p repo_uri [-Ped] [-k ssl_key] [-c ssl_cert] [--non-sticky] [--sticky]
[--search-after publisher] [--search-before publisher] [--search-first]
[--approve-ca-cert path_to_CA] [--revoke-ca-cert hash_of_CA_to_remove]
[--unset-ca-cert hash_of_CA_to_remove] [--set-property name_of_property=value]
[--add-property-value name_of_property=value_to_add] [--remove-property-value
name_of_property=value_to_remove] [--unset-property name_of_property_to_delete]
[--proxy proxy_to_use] [publisher]
```

Retrieve publisher configuration information from the *repo\_uri* repository URI.

If a publisher operand is specified to this `set-publisher` subcommand, then only that publisher is added or updated. If no publisher is specified, all publishers in `repo_uri` are added or updated as appropriate.

For descriptions of options, see the `set-publisher` command above. When used with `-p`, the `-P`, `--search-first`, `--search-before`, and `--search-after` options only apply to added publishers, not to updated publishers.

The `-p` option cannot be combined with the `-g`, `--add-origin`, `-G`, `--remove-origin`, `-m`, `--add-mirror`, `-M`, `--remove-mirror`, `--disable`, `--enable`, `--no-refresh`, or `--reset-uuid` options.

`pkg unset-publisher publisher ...`

Remove the configuration associated with the specified publisher or publishers.

`pkg history [-HNL] [-t [time | time-time],...] [-o column,...] [-n number]`

Display the command history of the applicable image.

`-H`

Omit the headers from the listing.

`-t time`

`-t time-time`

Display log records for a comma-separated list of timestamps, formatted with `%Y-%m-%dT%H:%M:%S` (see `strftime(3C)`). To specify a range of times, use a hyphen (`-`) between a start and finish timestamp. The keyword `now` can be used as an alias for the current time. If the timestamps specified contain duplicate timestamps or overlapping date ranges, only a single instance of each duplicate history event is printed.

`-l`

Display log records in long format, which, in addition to the standard format, includes the outcome of the command, the time the command completed, the version and name of the client used, the name of the user who performed the operation, and any errors that were encountered while executing the command.

`-N`

Display the release note text.

`-n number`

Display only the specified number of most recent entries.

`-o column`

Display output using the specified comma-separated list of column names. Valid column names are:

`be`

The name of the boot environment this operation was started on.

`be_uuid`

The uuid of the boot environment this operation was started on.

`client`

The name of the client.

`client_ver`

The version of the client.

`command`

The command line used for this operation.

`finish`

The time that this operation finished.

`id`

The user id that started this operation.

`new_be`

The new boot environment created by this operation.

`new_be_uuid`

The uuid of the new boot environment created by this operation.

`operation`

The name of the operation.

`outcome`

A summary of the outcome of this operation.

`reason`

Additional information on the outcome of this operation.

`release_note`

Indicates whether this operation generated release notes.

`snapshot`

The snapshot taken during this operation. This is only recorded if the snapshot was not automatically removed after successful operation completion.

`start`

The time that this operation started.

`time`

The total time taken to perform this operation. For operations that take less than one second, 0:00:00 is shown.

`user`

The username that started this operation.

If the `command` or `reason` columns are specified, they must be the last item in the `-o` list, in order to preserve output field separation. These two columns cannot be shown in the same `history` command.

An asterisk (\*) is shown after the values for `be` or `new_be` if the boot environment is no longer present on the system.

The values for `be` and `new_be` are obtained by looking up the current boot environment name, using the `be_uuid` or `new_be_uuid` fields. If a boot environment was subsequently renamed, and later deleted, the values displayed for `be` and `new_be` are the values recorded at the time of the `pkg` operation.

`pkg purge-history`

Delete all existing history information.

`pkg rebuild-index`

Rebuild the index used by `pkg search`. This is a recovery operation not intended for general use.

`pkg update-format`

Update the format of the image to the current version. Once this operation has completed, the image can no longer be used with older versions of the `pkg(5)` system.

`pkg version`

Display a unique string identifying the version of `pkg`. This string is not guaranteed to be comparable in any fashion between versions.

`pkg help`

Display a usage message.

`pkg image-create [-FPUz] [-f|--force] [--full|--partial|--user] [--zone] [-k ssl_key] [-c ssl_cert] [--no-refresh] [--variant variant_name=value ...] [-g path_or_uri] [--origin path_or_uri ...] [-m uri] [--mirror uri ...] [--set-property name_of_property=value] [--facet facet_name=(True|False) ...] [(-p|--publisher) [name=]repo_uri] dir`

At the location given by *dir*, create an image suitable for package operations. The default image type is `user`, as given by the `-U` (`--user`) option. The image type can be set to a full image (`--F` or `--full`) or to a partial image (`-P` or `--partial`) linked to the full image enclosing the given *dir* path. Additional origins can be specified using `-g` or `--origin`. Additional mirrors can be specified using `-m` or `--mirror`.

A package repository URI must be provided using the `-p` or `--publisher` option. If a publisher name is also provided, then only that publisher is added when the image is created. If a publisher name is not provided, then all publishers known by the specified repository are added to the image. An attempt to retrieve the catalog associated with this publisher is made following the initial creation operations.

For publishers using client SSL authentication, a client key and client certificate can be registered via the `-c` and `-k` options. This key and certificate are used for all publishers added during image creation.

If the image is to be run within non-global zone context, then the `-z` (`--zone`) option can be used to set an appropriate variant.

- f
- force  
Force the creation of an image over an existing image. This option should be used with care.
- no-refresh  
Do not attempt to contact the repositories for the image's publishers to retrieve the newest list of available packages and other metadata.
- variant *variant\_name=value*  
Set the specified variant to the indicated value. See “Facets and Variants” in the pkg(5) man page for more information about variants.
- facet *facet\_name=(True|False)*  
Set the specified facet to the indicated value. See “Facets and Variants” in the pkg(5) man page for more information about facets.
- set-property *name\_of\_property=value*  
Set the specified image property to the indicated value. See “Image Properties” below for descriptions of image properties.

**Image Properties** The following properties define characteristics of the image. These properties store information about the purpose, content, and behavior of the image. To view the current values of these properties in the image, use the `pkg property` command. To modify the values of these properties, use the `pkg set-property` and `pkg unset-property` commands.

**be-policy**

(string) Specify when a boot environment is created during packaging operations. The following values are allowed:

**default**

Apply the default boot environment creation policy, `create-backup`.

**always-new**

Requires a reboot for all package operations by performing them in a new boot environment set as active on the next boot. A backup boot environment is not created unless explicitly requested.

This policy is the safest, but is more strict than most sites need since no packages can be added without a reboot.

**create-backup**

For package operations that require a reboot, a new boot environment is created and set as active on the next boot. If packages are modified or content that could affect the kernel is installed and the operation affects the live boot environment, a backup boot environment is created but not set as active. A backup boot environment can also be explicitly requested.

This policy is potentially risky only if newly installed software causes system instability, which is possible but relatively rare.

#### when-required

For package operations that require a reboot, a new boot environment is created and set as active on the next boot. A backup boot environment is not created unless explicitly requested.

This policy carries the greatest risk since if a packaging change to the live boot environment makes further changes impossible, there might be no recent boot environment to which one can fallback.

#### ca-path

(string) A path name that points to a directory where CA certificates are kept for SSL operations. The format of this directory is specific to the underlying SSL implementation. To use an alternate location for trusted CA certificates, change this value to point to a different directory. See the `CPath` portions of `SSL_CTX_load_verify_locations(3openssl)` for requirements for the CA directory.

Default value: `/etc/openssl/certs`

#### check-certificate-revocation

(boolean) If this is set to `True`, the package client attempts to contact any CRL distribution points in the certificates used for signature verification to determine whether the certificate has been revoked since being issued.

Default value: `False`

#### flush-content-cache-on-success

(boolean) If this is set to `True`, the package client removes the files in its content-cache when install or update operations complete. For update operations, the content is removed only from the source boot environment. When a packaging operation next occurs in the destination boot environment, the package client flushes its content cache if this option has not been changed.

This property can be used to keep the content-cache small on systems with limited disk space. This property can cause operations to take longer to complete.

Default value: `True`

#### mirror-discovery

(boolean) This property tells the client to discover link-local content mirrors using mDNS and DNS-SD. If this property is set to `True`, the client attempts to download package content from mirrors it dynamically discovers. To run a mirror that advertises its content via mDNS, see the `pkg.depotd(1M)` man page.

Default value: `False`

#### send-uuid

(boolean) Send the image's Universally Unique Identifier (UUID) when performing network operations. Although users can disable this option, some network repositories might refuse to talk to clients that do not supply a UUID.

Default value: True

#### signature-policy

(string) Determine what checks will be performed on manifests when installing, updating, modifying, or verifying packages in the image. The final policy applied to a package depends on the combination of image policy and publisher policy. The combination will be at least as strict as the stricter of the two policies taken individually. By default, the package client does not check whether certificates have been revoked. To enable those checks, which might require the client to contact external web sites, set the `check-certificate-revocation-image` property to True. The following values are allowed:

##### ignore

Ignore signatures for all manifests.

##### verify

Verify that all manifests with signatures are validly signed, but do not require all installed packages to be signed. This is the default value.

##### require-signatures

Require that all newly installed packages have at least one valid signature. The `pkg fix` and `pkg verify` commands also warn if an installed package does not have a valid signature.

##### require-names

Follow the same requirements as `require-signatures` but also require that the strings listed in the `signature-required-names` property appear as a common name of the certificates used to verify the chains of trust of the signatures.

#### signature-required-names

(list of strings) A list of names that must be seen as common names of certificates while validating the signatures of a package.

#### trust-anchor-directory

(string) The path name of the directory that contains the trust anchors for the image. This path is relative to the image. The default value is `ignore`.

#### use-system-repo

(boolean) This property indicates whether the image should use the system repository as a source for image and publisher configuration and as a proxy for communicating with the publishers provided. The default value is `False`. See the `pkg.sysrepo(1M)` man page for information about system repositories.

**Publisher Properties** The following properties define signature policy for a particular publisher. The image properties of the same name define signature policy for the image. To view the current values of these properties for a particular publisher, use the `pkg publisher publisher_name` command. To modify the values of these publisher signature policy properties, use the `--set-property` and `--unset-property` options of the `pkg set-publisher` command.

`signature-policy`

(string) This property functions identically to the `image` property of the same name except that it only applies to packages from the particular publisher.

`signature-required-names`

(list of strings) This property functions identically to the `image` property of the same name except that it only applies to packages from the particular publisher.

### Examples EXAMPLE 1 Create an Image With Publisher Configured

Create a new, full image, with publisher `example.com`, stored at `/aux0/example_root`.

```
$ pkg image-create -F -p example.com=http://pkg.example.com:10000 \
/aux0/example_root
```

### EXAMPLE 2 Create an Image, Specifying Additional Origins and Mirror

Create a new, full image, with publisher `example.com`, that also has an additional mirror, two additional origins, and is stored at `/aux0/example_root`.

```
$ pkg image-create -F -p example.com=http://pkg.example.com:10000 \
-g http://alternate1.example.com:10000/ \
-g http://alternate2.example.com:10000/ \
-m http://mirror.example.com:10000/ \
/aux0/example_root
```

### EXAMPLE 3 Create an Image With No Publisher Configured

Create a new, full image with no publishers configured at `/aux0/example_root`.

```
$ pkg image-create -F /aux0/example_root
```

### EXAMPLE 4 Install a Package

Install the latest version of the `widget` package in the current image.

```
$ pkg install application/widget
```

### EXAMPLE 5 List Specified Contents of a Package

List the contents of the `system/file-system/zfs` package. Display the action name, the mode of the file (if defined), the size (if defined), the path, and the target (if a link). Limit the action to types `dir`, `file`, `link`, and `hardlink`, since specifying the `action.name` attribute, which is available for all actions, displays a line for all actions, which is not desired here.

```
$ pkg contents -t dir,file,link,hardlink \
-o action.name,mode,pkg.size,path,target system/file-system/zfs
ACTION.NAME MODE PKG.SIZE PATH TARGET
dir 0755 etc
dir 0755 etc/fs
dir 0755 etc/fs/zfs
link etc/fs/zfs/mount ../../../../usr/sbin/zfs
```

**EXAMPLE 5** List Specified Contents of a Package *(Continued)*

```

link etc/fs/zfs/umount ../../../../usr/sbin/zfs
dir 0755 etc/zfs
dir 0755 kernel
dir 0755 kernel/drv
dir 0755 kernel/drv/amd64
file 0755 1706744 kernel/drv/amd64/zfs
file 0644 980 kernel/drv/zfs.conf
dir 0755 kernel/fs
dir 0755 kernel/fs/amd64
hardlink kernel/fs/amd64/zfs ../../../../kernel/drv/amd64/zfs
...

```

**EXAMPLE 6** List Specified Contents of Two Packages

List the contents of `web/browser/firefox` and `mail/thunderbird`, limiting the display to just the package name and path attributes of actions whose path attribute ends in `.desktop` or `.png`.

```

$ pkg contents -o pkg.name,path -a path=*.desktop \
-a path=*.png web/browser/firefox mail/thunderbird
PKG.NAME PATH
web/browser/firefox usr/share/applications/firefox.desktop
mail/thunderbird usr/share/applications/thunderbird.desktop
web/browser/firefox usr/share/pixmaps/firefox-icon.png
mail/thunderbird usr/share/pixmaps/thunderbird-icon.png
...

```

**EXAMPLE 7** Search for a Package

Search the package database for the token `bge`.

```

$ pkg search bge
INDEX ACTION VALUE PACKAGE
driver_name driver bge pkg:/driver/network/ethernet/bge@0.5.11-0.
basename file kernel/drv/sparcv9/bge pkg:/driver/network/ethernet/bge@0.5.11-0.
basename file kernel/drv/amd64/bge pkg:/driver/network/ethernet/bge@0.5.11-0.
basename file platform/sun4v/kernel/drv/sparcv9/bge pkg:/system/kernel/platform@0.5.11-0.175.0
pkg_fmri set solaris/driver/network/bge pkg:/driver/network/bge@0.5.11-0.173.0.0.0
pkg_fmri set solaris/driver/network/ethernet/bge pkg:/driver/network/ethernet/bge@0.5.11-0.

```

The token is in the package `driver/network/bge` both as the basename for the file action representing `/kernel/drv/arch/bge` and as a driver name.

**EXAMPLE 8** Search for a File

Search for the package that delivers a file by specifying the full path name of the file, including the leading slash character.

**EXAMPLE 8** Search for a File (Continued)

```
$ pkg search -o path,pkg.name -l /usr/bin/vim
PATH PKG.NAME
usr/bin/vim editor/vim/vim-core
```

Search for a file and the package that delivers that file by specifying *file* for the *action\_name*, *path* or *basename* for the *index*, and the full or partial file name for the *token*.

```
$ pkg search -o path,pkg.name -l file:basename:vim
PATH PKG.NAME
usr/bin/vim editor/vim/vim-core
```

**EXAMPLE 9** Search for Files and Directories

Search for files and directories and the packages that deliver them by specifying *path* or *basename* for the *index* and the full or partial file name for the *token*. Depending on your shell, you might need to escape wildcards.

```
$ pkg search -o path,pkg.name -l path:*/vim
PATH PKG.NAME
usr/bin/vim editor/vim/vim-core
usr/share/vim editor/vim
usr/share/vim editor/vim/vim-core
$ pkg search -o path,pkg.name -l basename:vim
PATH PKG.NAME
usr/share/vim editor/vim
usr/share/vim editor/vim/vim-core
usr/bin/vim editor/vim/vim-core
```

**EXAMPLE 10** Show Which Packages Provide Which SMF Services

Show which packages provide a particular SMF service by specifying the value `org.opensolaris.smf.fmri` for the *index* in a structured search and the name of the service you want to find for the *token*. The value `org.opensolaris.smf.fmri` is the name of an attribute of a set action. Remember to escape the `:` in the name of the service.

For example, show which HTTP servers are available by specifying the value `svc:/network/http` for the *token*.

```
$ pkg search 'org.opensolaris.smf.fmri:svc\:/network/http*'
INDEX ACTION VALUE PACKAGE
org.opensolaris.smf.fmri set svc:/network/http pkg:/web/server/lighttpd-14@1.4.
org.opensolaris.smf.fmri set svc:/network/http pkg:/web/proxy/privoxy@3.0.17-0.
org.opensolaris.smf.fmri set svc:/network/http pkg:/web/proxy/squid@3.1.18-0.17
org.opensolaris.smf.fmri set svc:/network/http pkg:/web/java-servlet/tomcat@6.0
org.opensolaris.smf.fmri set svc:/network/http pkg:/web/server/apache-22@2.2.22
org.opensolaris.smf.fmri set svc:/network/http:apache22 pkg:/web/server/apache-22@2.2.22
org.opensolaris.smf.fmri set svc:/network/http:lighttpd14 pkg:/web/server/lighttpd-14@1.4.
org.opensolaris.smf.fmri set svc:/network/http:privoxy pkg:/web/proxy/privoxy@3.0.17-0.
```

**EXAMPLE 10** Show Which Packages Provide Which SMF Services *(Continued)*

```
org.opensolaris.smf.fmri set svc:/network/http:squid pkg:/web/proxy/squid@3.1.18-0.175.0.0
org.opensolaris.smf.fmri set svc:/network/http:tomcat6 pkg:/web/java-servlet/tomcat@6.0.35-0.
```

**EXAMPLE 11** Search for Packages that Depend on the Specified Package

Search for installed packages that depend on package/pkg.

```
$ pkg search -l depend:package/pkg
INDEX ACTION VALUE PACKAGE
incorporate depend package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/consolidation/ips/ips-incorporation
require depend pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/package/pkg/package-manager@0.5.11-
require depend pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/system/library/install@0.5.11-0.175
require depend pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/package/pkg/update-manager@0.5.11-0
require depend pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/system/library/boot-management@0.5
require depend package/pkg pkg:/system/zones/brand/brand-solaris@0.
require depend pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/install/distribution-constructor@0.
require depend pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/system/boot-environment-utilities@0
require depend pkg:/package/pkg@0.5.11-0.175.0.0.0.2.1 pkg:/package/pkg/system-repository@0.5.1
```

**EXAMPLE 12** Search for Dependencies

Search for all incorporate dependencies in installed packages.

```
$ pkg search -l depend:incorporate:
INDEX ACTION VALUE PACKAGE
incorporate depend pkg:/BRcMbnx@0.5.11-0.175.0.0.0.2.1 pkg:/consolidation/osnet/osnet-incorporati
incorporate depend pkg:/BRcMbnxe@0.5.11-0.175.0.0.0.2.1 pkg:/consolidation/osnet/osnet-incorporati
...
```

**EXAMPLE 13** Add a Publisher

Add a new publisher `example.com`, with a repository located at `http://www.example.com/repo`.

```
$ pkg set-publisher -g http://www.example.com/repo example.com
```

**EXAMPLE 14** Add a Publisher With Key and Certificate

Add a new publisher `example.com`, with a secure repository located at `https://secure.example.com/repo`, and a key and certificate stored in the directory `/root/creds`.

```
$ pkg set-publisher -k /root/creds/example.key \
-c /root/creds/example.cert -g https://secure.example.com/repo \
example.com
```

**EXAMPLE 15** Add and Automatically Configure a Publisher

Add a new publisher with a repository located at `/export/repo` using automatic configuration.

---

EXAMPLE 15 Add and Automatically Configure a Publisher (Continued)

```
$ pkg set-publisher -p /export/repo
```

EXAMPLE 16 Add and Manually Configure a Publisher

Add a new publisher `example.com` with a repository located at `/export/repo/example.com` using manual configuration.

```
$ pkg set-publisher -g /export/repo example.com
```

EXAMPLE 17 Add a Publisher and Configure a Proxy

Add a new publisher `mypub` with origin `http://server/repo` and proxy `http://webcache:8080`.

```
$ pkg set-publisher -g http://server/repo \
--proxy http://webcache:8080 mypub
```

EXAMPLE 18 Verify All Signed Packages

Configure an image to verify all signed packages.

```
$ pkg set-property signature-policy verify
```

EXAMPLE 19 Require All Packages To Be Signed

Configure an image to require all packages to be signed, and require the string `example.com` to be seen as a common name for one of the certificates in the chain of trust.

```
$ pkg set-property signature-policy require-names example.com
```

EXAMPLE 20 Require All Packages From a Specified Publisher To Be Signed

Configure an image so that all packages installed from publisher `example.com` must be signed.

```
$ pkg set-publisher --set-property signature-policy=require-signatures \
example.com
```

EXAMPLE 21 Require a Specified String in the Chain of Trust

Add the string `foo` to the image's list of common names that must be seen in a signature's chain of trust to be considered valid.

```
$ pkg add-property-value signature-require-names foo
```

EXAMPLE 22 Remove a String From the Chain of Trust for a Specified Publisher

Remove the string `foo` from the list of common names that must be seen to validate a signature for the publisher `example.com`.

```
$ pkg set-publisher --remove-property-value signature-require-names=foo \
example.com
```

**EXAMPLE 23** Add a Trusted CA Certificate

Add the certificate stored in `/tmp/example_file.pem` as a trusted CA certificate for the publisher `example.com`.

```
$ pkg set-publisher --approve-ca-cert /tmp/example_file.pem \
example.com
```

**EXAMPLE 24** Revoke a Certificate

Revoke the certificate with the hash `a12345` for publisher `example.com`, preventing the certificate from validating any signatures for packages from `example.com`.

```
$ pkg set-publisher --revoke-ca-cert a12345 example.com
```

**EXAMPLE 25** Forget About a Certificate

Make `pkg` forget that the certificate `a12345` was ever added or revoked by the user.

```
$ pkg set-publisher --unset-ca-cert a12345 example.com
```

**EXAMPLE 26** Downgrade a Package

Downgrade the installed package `foo@1.1` to an older version.

```
$ pkg update foo@1.0
```

**EXAMPLE 27** Switch Conflicting Package Installation

In the case of two conflicting packages, change which package is installed. Suppose package `A` depends on either package `B` or package `C`, and `B` and `C` are mutually exclusive. If `A` and `B` are installed, use the following command to switch to using `C` instead of `B` without uninstalling `A`:

```
$ pkg install --reject B C
```

**EXAMPLE 28** List Packages in a Package Archive

List all versions of all packages in a package archive.

```
$ pkg list -f -g /my/archive.p5p
```

**EXAMPLE 29** List Packages in a Package Repository

List all versions of all packages in a repository.

```
$ pkg list -f -g http://example.com:10000
```

**EXAMPLE 30** Display Information About a Package in a Package Archive

Display the package information for the latest version of a package in a package archive. The package might or might not be currently installed.

```
$ pkg info -g /my/archive.p5p pkg_name
```

**EXAMPLE 31** Display Contents of a Package in a Package Archive

Display the contents of a package in a package archive. The package is not currently installed.

```
$ pkg contents -g /my/archive.p5p pkg_name
```

**EXAMPLE 32** Remove All Publisher Origins and Mirrors

Remove all of the origins and mirrors for a publisher and add a new origin.

```
$ pkg set-publisher -G '*' -M '*' -g http://example.com:10000 \
example.com
```

**Environment  
Variables****PKG\_IMAGE**

The directory containing the image to use for package operations. Ignored if -R is specified.

**PKG\_CLIENT\_CONNECT\_TIMEOUT**

Seconds to wait trying to connect during transport operations (for each attempt) before the client aborts the operation. A value of 0 means wait indefinitely.

Default value: 60

**PKG\_CLIENT\_LOWSPEED\_TIMEOUT**

Seconds below the lowspeed limit (1024 bytes/sec) during transport operations before the client aborts the operation. A value of 0 means do not abort the operation.

Default value: 30

**PKG\_CLIENT\_MAX\_CONSECUTIVE\_ERROR**

Maximum number of transient transport errors before the client aborts the operation. A value of 0 means do not abort the operation.

Default value: 4

**PKG\_CLIENT\_MAX\_REDIRECT**

Maximum number of HTTP or HTTPS redirects allowed during transport operations before a connection is aborted. A value of 0 means do not abort the operation.

Default value: 5

**PKG\_CONCURRENCY**

The number of child images to update in parallel. Ignored if the -C option is specified.

When recursing into child images (usually zones), update at most \$PKG\_CONCURRENCY child images in parallel. If \$PKG\_CONCURRENCY is 0 or a negative number, all child images are updated in parallel.

Default value: 1

**PKG\_CLIENT\_MAX\_TIMEOUT**

Maximum number of transport attempts per host before the client aborts the operation. A value of 0 means do not abort the operation.

Default value: 4

http\_proxy, https\_proxy

HTTP or HTTPS proxy server.

**Exit Status** The following exit values are returned:

- 0 Command succeeded.
- 1 An error occurred.
- 2 Invalid command line options were specified.
- 3 Multiple operations were requested, but only some of them succeeded.
- 4 No changes were made - nothing to do.
- 5 The requested operation cannot be performed on a live image.
- 6 The requested operation cannot be completed because the licenses for the packages being installed or updated have not been accepted.
- 7 The image is currently in use by another process and cannot be modified.
- 99 An unanticipated exception occurred.

**Files** A pkg(5) image can be located arbitrarily within a larger file system. In the following file descriptions, the token `$IMAGE_ROOT` is used to distinguish relative paths. For a typical system installation, `$IMAGE_ROOT` is equivalent to `/`

`$IMAGE_ROOT/var/pkg`

Metadata directory for a full or partial image.

`$IMAGE_ROOT/.org.opensolaris/pkg`

Metadata directory for a user image.

Within a particular image's metadata, certain files and directories can contain information useful during repair and recovery. The token `$IMAGE_META` refers to the top-level directory containing the metadata. `$IMAGE_META` is typically one of the two paths given above.

`$IMAGE_META/lost+found`

Location of conflicting directories and files moved during a package operation. Location of unpackaged contents of a removed directory.

`$IMAGE_META/publisher`

Contains a directory for each publisher. Each directory stores publisher-specific metadata.

Other paths within the `$IMAGE_META` directory hierarchy are private and are subject to change.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

---

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | package/pkg     |
| Interface Stability | Uncommitted     |

**See Also** [pkgsend\(1\)](#), [pkg.depotd\(1M\)](#), [glob\(3C\)](#), [pkg\(5\)](#), [beadm\(1M\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

**Name** pkgdepend – Image Packaging System dependency analyzer

**Synopsis** /usr/bin/pkgdepend [*options*] *command* [*cmd\_options*] [*operands*]

```
/usr/bin/pkgdepend generate [-IMm] -d dir [-d dir]
 [-D name=value] [-k path] manifest_file
```

```
/usr/bin/pkgdepend resolve [-moSv] [-d output_dir]
 [-s suffix] manifest_file ...
```

**Description** The pkgdepend command generates and resolves dependencies for packages. A package might depend on files from other packages. The pkgdepend command is typically used in two passes: file dependency generation and file-to-package resolution.

The generate subcommand examines the content of a package and determines what external files the package needs.

The resolve subcommand takes the list of files from the generate step, and searches a reference set of packages to determine the names of the packages that contain those dependent files. The reference set of packages that are searched for the dependent files are the packages that are currently installed on the publisher's system.

Several components of delivered files are used as sources of dependency information:

**ELF** ELF headers in delivered files are analyzed for dependency information, with the -k and -D options modifying the information obtained. For more details on ELF dependencies, see ldd and the [Linker and Libraries Guide](#).

**Scripts** Shell scripts that contain #! lines referencing an interpreter result in a dependency on the package that delivers that interpreter.

**Python** Python scripts are first analyzed as scripts. In addition, any imports the script declares might also serve as sources of dependency information.

**Hard links** Hard links in manifests result in a dependency on the package that delivers the link target.

**SMF** Delivered SMF service manifests that include require\_all dependencies result in dependencies on the packages that deliver the SMF manifests that provide those FMRIs.

**Options** The following options are supported:

-?

--help

Display a usage message.

-R *dir*

--image-dir *dir*

Operate on the image rooted at *dir*. If no directory was specified or determined based on environment, the default is /. See the “Environment Variables” section for more

information.

**Sub-commands** The following subcommands are supported:

`pkgdepend generate [-IMm] -d dir [-d dir] [-D name=value] [-k path] manifest_file`  
 Produce the dependencies on files of the manifest specified by *manifest\_file*.

`-I`

Show the dependencies that are satisfied within *manifest\_file*. Do not use the result of `-I` with `pkgdepend resolve`.

`-M`

Display a list of file types that could not be analyzed.

`-m`

Repeat the original manifest with any discovered dependencies added after.

`-d dir`

Add *dir* to a list of directories to search for the manifest's files.

`-D name=value`

Add the *value* as a way to expand the token *name* in run paths for ELF file dependencies.

`-k path`

Add the *path* to the list of run paths to search for kernel modules. Using the `-k` option removes the default paths, which are `/kernel` and `/usr/kernel`.

Run paths such as those specified by the `-k` option can also be specified per action or per manifest by using the action or manifest attribute `pkg.depend.runpath`. The value of the `pkg.depend.runpath` attribute is a colon-separated string of the paths to use. Setting any `pkg.depend.runpath` attributes in the manifest or action overrides paths specified with the `-k` option.

The special token `$PKGDEPEND_RUNPATH` can be used as one component of the `pkg.depend.runpath` attribute value in order to include the standard system run path for the file being analyzed.

In some cases, you might want to prevent automatic generation of dependencies. For example, if a package delivers a sample Python script that imports a set of modules, those modules imported by the sample script are not dependencies for the package that delivers the sample script. Use the action or manifest attribute `pkg.depend.bypass-generate` to prevent generating dependencies against the specified files.

The `pkg.depend.bypass-generate` values are Python regular expressions that match file names. The regular expressions are implicitly anchored at the start and end of the file path. The value given in the following example matches `this/that` but does not match `something/this/that/the/other`.

```
pkg.depend.bypass-generate=this/that
```

For more information about Python regular expression syntax, use the command `pydoc re` or see more complete documentation at <http://docs.python.org/dev/howto/regex.html>.

When `pkgdepend` generate input manifests contain SMF manifest files, any SMF services or instances declared by those SMF manifest files are included in the `pkgdepend` output. These SMF services or instances are included in the form of a set action with the name `org.opensolaris.smf.fmri`.

`pkgdepend resolve [-moSv] [-d output_dir] [-s suffix] manifest_file ...`

Transform dependencies on files into dependencies on the packages that deliver those files. Dependencies are first resolved against the manifests given on the command line and then against the packages installed on the system. By default, the dependencies for each manifest are placed in a file named *manifest\_file.res*.

-m

Repeat the manifest, with any dependencies produced by the generate step removed, before adding the resolved dependencies.

-o

Write the results to standard output. This option is intended for human consumption. Appending this output to a file might result in an invalid manifest. The `-d` or `-s` options are strongly recommended instead of `-o` for use in a pipeline for manifest processing.

-d *output\_dir*

Write the resolved dependencies for each manifest provided in a separate file in *output\_dir*. By default, each file has the same base name as the manifest that was the source of the dependencies written to that file.

-s *suffix*

For each output file, append *suffix* to the base name of the file that was the source of the resolved dependencies. If *suffix* is not *.suffix*, a period (.) is prepended to *suffix*.

-S

Only resolve against the manifests given on the command line and not against the manifests installed on the system.

-v

Include additional package dependency debugging metadata.

### Examples EXAMPLE 1 Generate Dependencies

Generate the dependencies for the manifest written in `foo`, whose content directory is in `./bar/baz`, and store the results in `foo.fdeps`.

```
$ pkgdepend generate -d ./bar/baz foo > foo.fdeps
```

**EXAMPLE 2** Resolve Dependencies

Resolve the file dependencies in `foo.fdeps` and `bar.fdeps` against each other and against the packages currently installed on the system.

```
$ pkgdepend resolve foo.fdeps bar.fdeps
$ ls *.res
foo.fdeps.res bar.fdeps.res
```

**EXAMPLE 3** Generate and Resolve Dependencies For Two Manifests

Generate the file dependencies for two manifests (`foo` and `bar`) and retain all the information in the original manifests. Then resolve the file dependencies and place the resulting manifests in `./res`. These resulting manifests can be used with `pkgsend publish`.

```
$ pkgdepend generate -d /proto/foo -m foo > ./deps/foo
$ pkgdepend generate -d /proto/bar -m bar > ./deps/bar
$ pkgdepend resolve -m -d ./res ./deps/foo ./deps/bar
$ ls ./res
foo bar
```

**EXAMPLE 4** Add Values To Tokens For ELF File Dependencies

Replace all `PLATFORM` tokens in the run paths in ELF files with `sun4v` and `sun4u` while generating the dependencies for the manifest written in `foo` whose content directory is in `/`.

```
$ pkgdepend generate -d / -D 'PLATFORM=sun4v' -D 'PLATFORM=sun4u' foo
```

**EXAMPLE 5** Specify a Kernel Module Directory

Specify `/kmod` as the directory in which to find kernel modules when generating the dependencies for the manifest written in `foo` whose content directory is in `/`.

```
$ pkgdepend generate -d / -k /kmod foo
```

**EXAMPLE 6** Bypass Dependency Generation

Append `opt/python` to the standard Python run path for a given Python script, and bypass dependency generation against all Python modules called `test` for a file delivered as `opt/python/foo/file.py`.

Avoid generating dependencies against any file delivered in `usr/lib/python2.6/vendor-packages/xdg`.

```
$ cat manifest.py
set name=pkg.fmri value=pkg:/mypackage@1.0,1.0
set name=pkg.summary value="My test package"
dir path=opt mode=0755 group=sys owner=root
dir path=opt/python mode=0755 group=sys owner=root
dir path=opt/python/foo mode=0755 group=sys owner=root
file NOHASH path=opt/python/__init__.py mode=0644 group=sys owner=root
file NOHASH path=opt/python/foo/__init__.py mode=0644 group=sys owner=root
```

**EXAMPLE 6** Bypass Dependency Generation (Continued)

```
#
Add runpath and bypass-generate attributes:
#
file NOHASH path=opt/python/foo/file.py mode=0644 group=sys owner=root \
 pkg.depend.bypass-generate=.*test.py.* \
 pkg.depend.bypass-generate=.*testmodule.so \
 pkg.depend.bypass-generate=.*test.so \
 pkg.depend.bypass-generate=usr/lib/python2.6/vendor-packages/xdg/.* \
 pkg.depend.runpath=$PKGDEPEND_RUNPATH:/opt/python

$ pkgdepend generate -d proto manifest.py
```

**Environment Variables** `PKG_IMAGE` Specifies the directory that contains the image to use for package operations. This value is ignored if `-R` is specified.

**Exit Status** The following exit values are returned:

- 0 Everything worked.
- 1 An error occurred.
- 2 Invalid command line options were specified.
- 99 An unanticipated exception occurred.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | package/pkg     |
| Interface Stability | Uncommitted     |

**See Also** [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

- 
- Name** pkgdiff – compare package manifests
- Synopsis** /usr/bin/pkgdiff [-i *attribute* ...] [-o *attribute*]  
 [-v *name=value* ...] *file1 file2*
- Description** pkgdiff compares two package manifests and reports differences. pkgdiff sorts each manifest and action into a consistent order before comparison.
- Output is in the following form:
- + *complete\_action*  
 This action is in *file2* but not in *file1*.
  - *complete\_action*  
 This action is in *file1* but not in *file2*.
  - actionname keyvalue [variant values, if any]*
  - *attribute1=value1*  
 This *attribute,value* is in *file1* but not in *file2*.
  - + *attribute2=value2*  
 This *attribute,value* is in *file2* but not in *file1*.
- Actions with different variants but the same type and key attribute value are treated as separate actions for purposes of comparison. Thus, actions that change attributes are shown in their complete form rather than as attribute changes.
- Options** The following options are supported:
- help  
 Display a usage message.
  - i *attribute*  
 Ignore *attribute* if present during comparisons. File hash values can be ignored with -i *hash*. This option cannot be used with the -o option. This option can be repeated.
  - o *attribute*  
 Only report differences in *attribute*. This option cannot be used with the -i option. This option elides any action changes that do not affect *attribute* on an action.
  - v *name=value*  
 Only compute differences for this variant value. For example, only compute differences for arch=sparc. This variant tag is removed for all actions before comparison. Only one value can be specified per variant. This option can be repeated for different variants.
- Exit Status** The following exit values are returned:
- 0 No differences were found.
  - 1 Differences were found.
  - >1 An error occurred.

99 An unanticipated exception occurred.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | package/pkg     |
| Interface Stability | Uncommitted     |

**See Also** [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

**Name** pkgfmt – format a package manifest

**Synopsis** /usr/bin/pkgfmt [-c|-d|-u] [*package-manifest-file*]

**Description** pkgfmt without the -c or -d options formats a package manifest in a consistent manner, including wrapping lines at 80 characters, sorting actions by type, and sorting attributes. Lines that do not parse into actions (such as macros, comments, or transforms) do not appear in sorted order.

If no arguments are given, pkgfmt reads stdin until EOF, and then writes the formatted manifest to stdout. Any manifests specified on the command line are formatted in place.

pkgfmt with the -c option checks whether the manifests are formatted in pkgfmt style. The -d option displays the differences if the file is not properly formatted.

**Options** The following options are supported:

- ?            Display a usage message.
- help       Display a usage message.
- c            Check whether the manifest is formatted in the pkgfmt style.
- d            Display manifest differences from the formatted version in unified form.
- u            Do not wrap lines at 80 characters. This option is useful for applying traditional text processing tools to package manifests.

**Exit Status** The following exit values are returned:

- 0            Command succeeded.
- 1            The -c or -d options were specified, and one or more manifests are not in pkgfmt normal form, or an error occurred.
- 2            Invalid command line options were specified.
- 99           An unanticipated exception occurred.

**Attributes** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | package/pkg     |
| Interface Stability | Uncommitted     |

**See Also** pkg(5)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

**Name** pkginfo – display software package information

**Synopsis** pkginfo [-q | -x | -l] [-p | -i] [-r] [-a *arch*]  
[-v *version*] [-c *category*]... [*pkginst*]...

pkginfo -d *device* [-R *root\_path*] [-q | -x | -l] [-a *arch*]  
[-v *version*] [-c *category*]... [*pkginst*]...

**Description** pkginfo displays information about software packages that are installed on the system (with the first synopsis) or that reside on a particular device or directory (with the second synopsis).

Without options, pkginfo lists the primary category, package instance, and the names of all completely installed and partially installed packages. It displays one line for each package selected.

**Options** The -p and -i options are meaningless if used in conjunction with the -d option.

The options -q, -x, and -l are mutually exclusive.

-a *arch*

Specify the architecture of the package as *arch*.

-c *category*

Display packages that match *category*. Categories are defined with the CATEGORY parameter in the [pkginfo\(4\)](#) file. If more than one category is supplied, the package needs to match only one category in the list. The match is not case specific.

-d *device*

Defines a device, *device*, on which the software resides. *device* can be an absolute directory pathname or the identifiers for tape, removable disk, and so forth. The special token `spool` may be used to indicate the default installation spool directory (`/var/spool/pkg`).

-i

Display information for fully installed packages only.

-l

Specify long format, which includes all available information about the designated package(s).

-p

Display information for partially installed packages only.

-q

Do not list any information. Used from a program to check whether or not a package has been installed.

-r

List the installation base for relocatable packages.

-R *root\_path*

Defines the full path name of a directory to use as the *root\_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root\_path*.

**-v** *version*

Specify the version of the package as *version*. The version is defined with the `VERSION` parameter in the [pkginfo\(4\)](#) file. All compatible versions can be requested by preceding the version name with a tilde (`≈`). Multiple white spaces are replaced with a single white space during version comparison.

**-x**

Designate an extracted listing of package information. The listing contains the package abbreviation, package name, package architecture (if available) and package version (if available).

**Operands** *pkginst*

A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, `inst.1` or `inst.2`). All instances of a package can be requested by `inst.*`. The asterisk character (`*`) is a special character to some shells and may need to be escaped. In the C-Shell, "`*`" must be surrounded by single quotes (`'`) or preceded by a backslash (`\`).

**Exit Status** `0`

Successful completion.

`>0`

An error occurred.

**Files** `/var/spool/pkg`  
default installation spool directory

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [pkgtrans\(1\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgchk\(1M\)](#), [pkgrm\(1M\)](#), [pkginfo\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

*Application Packaging Developer's Guide*

**Notes** Package commands are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.

**Name** pkglint – Image Packaging System package lint

**Synopsis** /usr/bin/pkglint [-c *cache\_dir*] [-r *repo\_uri*] [-p *regexp*]  
[-f *config\_file*] [-b *build\_no*] [-v]  
[-l *lint\_uri*] | *manifest* ...  
  
/usr/bin/pkglint -L [-v]

**Description** pkglint runs a series of checks on one or more package manifests, optionally referencing another repository.

pkglint should be used during the package authoring process, prior to package publication. pkglint performs exhaustive testing on the manifests that might be too expensive to perform during normal operation of pkgsend or pkg.depotd. pkglint checks include tests for duplicate actions, missing attributes, and unusual file permissions.

Manifests for linting can be passed as a space-separated list of local files on the command line, or manifests can be retrieved from a repository.

When retrieving manifests from repositories, on first run pkglint creates and populates pkg(5) user images in the specified cache directory. If the -r option is supplied, a user image named *cache\_dir/ref\_image* is created for the reference repository. If the -l option is supplied, a user image named *cache\_dir/lint\_image* is created for the lint repository. No content is installed in these images. These images are only used by pkglint to retrieve manifests from the repositories.

Subsequent invocations of pkglint can reuse the cache directory and can omit any -r or -l arguments.

pkglint provides limited support for configuring publishers in the cache directory. Use pkg to perform more complex publisher configuration on these images.

pkglint allows package authors to bypass checks for a given manifest or action. A manifest or action that contains the attribute *pkg.linted* set to True does not produce any lint output for that manifest or action.

More granular *pkg.linted* settings can be made using substrings of pkglint check names. For example, *pkg.linted.check.id* set to True bypasses all checks with the name *check.id* for the given manifest or action.

The behavior of pkglint can be configured by specifying a *pkglintrc* file. By default, pkglint searches in */usr/share/lib/pkg/pkglintrc* and *\$HOME/.pkglintrc* for configuration options. Use the -f option to specify a different configuration file.

During the lint run, any errors or warnings encountered are printed to *stderr*.

**Options** The following options are supported:

- h
- help  
Display a usage message.
- b *build\_no*  
Specify a build number used to narrow the list of packages used during linting from lint and reference repositories. If no -b option is specified, the latest versions of packages are used. See also the `version.pattern` configuration property.
- c *cache\_dir*  
Specify a local directory used for caching package metadata from the lint and reference repositories.
- l *lint\_uri*  
Specify a URI representing the location of the lint repository. Both HTTP and file system based publication are supported. If you specify -l, then you must also specify -c.
- L  
List the known and excluded lint checks and then exit. Display the short name and description of each check. When combined with the -v flag, display the method that implements the check instead of the description.
- f *config\_file*  
Configure the pkglint session using the *config\_file* configuration file.
- p *regexp*  
Specify a regular expression used to narrow the list of packages to be checked from the lint repository. All manifests from the reference repository are loaded (assuming they match the value for -b, if supplied), ignoring this pattern.
- r *repo\_uri*  
Specify a URI representing the location of the reference repository. If you specify -r, then you must also specify -c.
- v  
Run pkglint in a verbose mode, overriding any `log_level` settings in the configuration file.

**Files** The `pkglintrc` configuration file takes the following key/value arguments:

- `log_level`  
The minimum level at which to emit lint messages. Lint messages lower than this level are discarded. The default value is `INFO`.  
  
Log levels in order of least to most severe are `DEBUG`, `INFO`, `WARNING`, `ERROR`, and `CRITICAL`.
- `do_pub_checks`  
If `True`, perform checks that might only make sense for published packages. The default value is `True`.

**pkglint.ext.\***

The plugin mechanism of pkglint allows for additional lint modules to be added at runtime. Any key that starts with `pkglint.ext.` takes a value that must be a fully-specified Python module. See the “Developers” section for more information.

**pkglint.exclude**

A space-separated list of fully specified Python modules, classes, or function names to omit from the set of checks performed.

**use\_progress\_tracker**

If `True`, use a progress tracker when iterating over manifests during lint runs. The default value is `True`.

**version.pattern**

A version pattern, used when specifying a build number to lint against (`-b`). If not specified in the configuration file, the `-b` option uses the pattern `*,5.11-0.`, matching all components of the 5.11 build, with a branch prefix of 0.

**Developers** To extend the set of checks performed by pkglint, subclass `pkg.lint.base.Checker` and its subclasses, `ManifestChecker`, `ActionChecker`, and `ContentChecker`. Add the Python module name that contains those classes to a new `pkglint.ext.` key in the configuration file.

Instances of those new subclasses are created by pkglint on startup. Methods inside each subclass with the special keyword argument `pkglint_id` are invoked during the course of the lint session. Those methods should have the same signature as the corresponding `check()` method in the super class. Methods should also be assigned a `pkglint_desc` attribute, which is used as the description printed by `pkglint -L`.

Parameters are available to Checker subclasses, allowing them to tune their behavior. The recommended parameter naming convention is `pkglint_id.name`. Parameter values can be stored in the configuration file, or accessed in manifests or actions retrieved using the `LintEngine.get_param()` method. When accessing parameters from the manifest, the prefix `pkg.lint` is prepended to the key name to ensure that pkglint parameters do not overlap with any existing action or manifest values.

**Examples** **EXAMPLE 1** First Run on a Particular Repository

Running a pkglint session for the first time on a given repository.

```
$ pkglint -c /space/cache -r http://localhost:10000 mymanifest.mf
```

**EXAMPLE 2** Subsequent Run on the Same Repository

A subsequent run against the same repository used in Example 1.

```
$ pkglint -c /space/cache mymanifest-fixed.mf
```

**EXAMPLE 3** Using a Lint Repository With a Narrowed Manifest Set

Running a pkglint session with a lint repository and specifying a subset of manifests to check.

**EXAMPLE 3** Using a Lint Repository With a Narrowed Manifest Set *(Continued)*

```
$ pkglint -c /space/othercache -l http://localhost:10000 \
-p '.*firefox.*'
```

**EXAMPLE 4** Specifying a Build

Running a pkglint session against a given build in verbose mode.

```
$ pkglint -c /space/cache -r http://localhost:10000 \
-l http://localhost:12000 -b 147 -v
```

**EXAMPLE 5** Modifying a Configuration File

A configuration file with a new lint module, excluding some checks.

```
$ cat ~/.pkglintrc
[pkglint]

log_level = DEBUG
log_level = INFO

pkglint.ext.mycheck = org.timf.mychecks
pkglint.ext.opensolaris = pkg.lint.opensolaris
pkglint.exclude: pkg.lint.opensolaris.OpenSolarisActionChecker
pkg.lint.pkglint.PkgActionChecker.unusual_perms pkg.lint.pkglint.PkgManifestChecker
pkg.lint.opensolaris.OpenSolarisManifestChecker
```

**Exit Status** The following exit values are returned:

- 0 Command succeeded.
- 1 One or more lint checks emitted output.
- 2 Invalid command line options were specified.
- 99 An unanticipated exception occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | package/pkg     |
| Interface Stability | Uncommitted     |

**See Also** [pkg\(1\)](#), [pkg.depotd\(1M\)](#), [pkgsend\(1\)](#), [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

**Name** pkgmerge – Image Packaging System package merging utility

**Synopsis** `/usr/bin/pkgmerge [-n] -d dest_repo  
-s variant=value[,...],src_repo ...  
[pkg_fmri_pattern ...]`

**Description** pkgmerge is a package publication tool for creating multi-variant packages. It does this by merging packages with identical names and versions (excluding time stamp), tagging actions that are unique in the versions being merged with the specified variant name and value for the given source, and then publishing the new packages to the target repository. Only the newest version of every package from each source is used.

If an action has the attribute `pkg.merge.blend` set to the name of the variant being merged, that action is copied to the other manifests prior to merging so that the action appears without any added variant tags in the final output. Note that the attribute `pkg.merge.blend` itself is removed from any actions in the output manifest. This attribute can be repeated with different values for multiple pass merges.

Non-identical actions that deliver to the same path in an input manifest result in pkgmerge exiting with an error.

**Options** The following options are supported:

-?

--help

Display a usage message.

-d *dest\_repo*

Specify the file system path or URI of the target repository to publish the merged packages to. The target repository must already exist. New repositories can be created using `pkgrepo`.

-n

Perform a trial run with no changes made to the target repository.

-s *variant=value[,...],src\_repo*

Specify the variant name and value to use for packages from this source, followed by the file system path or URI of the source repository or package archive to retrieve packages from.

Multiple variants can be specified separated by commas. The same variants must be named for all sources. This option can be specified multiple times.

**Environment Variables** The following environment variable is supported:

**TMPDIR** The absolute path of the directory where temporary data should be stored during program execution. If not set, the default is to store temporary data in `/var/tmp`.

**Examples** **EXAMPLE 1** Specify Variant Name and Value

Tag each package found in the specified source with the given variant name and value specified for the source it was retrieved from:

**EXAMPLE 1** Specify Variant Name and Value *(Continued)*

```
$ pkgmerge -s arch=sparc,http://src.example.com \
-d http://dest.example.com
```

Sample package:

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163427Z
dir group=sys mode=0755 owner=root path=usr
```

Sample package after operation:

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163427Z
set name=variant.arch value=sparc
dir group=sys mode=0755 owner=root path=usr
```

**EXAMPLE 2** Merge and Publish Packages

Merge the newest version of each package from the given sources and publish the new packages to the target repository:

```
$ pkgmerge -s arch=sparc,http://src1.example.com \
-s arch=i386,http://src2.example.com \
-d /path/to/target/repository
```

Sample package from source 1 (SPARC):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T121410Z
file id mode=0555 owner=root group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Sample package from source 2 (i386):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163427Z
file id mode=0555 owner=root group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Merged package:

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163427Z
set name=variant.arch value=sparc value=i386
file id mode=0555 owner=root group=bin path=usr/bin/foo variant.arch=sparc
file id mode=0555 owner=root group=bin path=usr/bin/foo variant.arch=i386
dir group=sys mode=0755 owner=root path=usr
```

**EXAMPLE 3** Merge Debug and Non-Debug Packages for i386 and SPARC Systems

Merge the newest version of each package in a set of debug and non-debug repositories for i386 and SPARC systems:

**EXAMPLE 3** Merge Debug and Non-Debug Packages for i386 and SPARC Systems *(Continued)*

```
$ pkgmerge -s arch=sparc,debug=false,/repo/sparc-nondebug \
-s arch=sparc,debug=true,/repo/sparc-debug \
-s arch=i386,debug=false,/repo/i386-nondebug \
-s arch=i386,debug=true,/repo/i386-debug \
-d /path/to/target/repository
```

Sample package from source 1 (SPARC non-debug):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T121410Z
file id mode=0555 owner=root group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Sample package from source 2 (SPARC debug):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T121411Z
file id mode=0555 owner=root group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Sample package from source 3 (i386 non-debug):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163427Z
file id mode=0555 owner=root group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Sample package from source 4 (i386 debug):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163428Z
file id mode=0555 owner=root group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Merged package:

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163428Z
set name=variant.arch value=sparc value=i386
set name=variant.debug value=false value=true
file id mode=0555 owner=root group=bin path=usr/bin/foo variant.arch=sparc variant.debug=false
file id mode=0555 owner=root group=bin path=usr/bin/foo variant.arch=sparc variant.debug=true
file id mode=0555 owner=root group=bin path=usr/bin/foo variant.arch=i386 variant.debug=false
file id mode=0555 owner=root group=bin path=usr/bin/foo variant.arch=i386 variant.debug=true
dir group=sys mode=0755 owner=root path=usr
```

**EXAMPLE 4** Merge Using pkg.merge.blend

Merge packages for two architectures that do not collide, using the `pkg.merge.blend` attribute.

```
$ pkgmerge -s arch=sparc,http://src1/example.com \
-s arch=i386,http://src2.example.com \
-d /path/to/target/repository
```

**EXAMPLE 4** Merge Using pkg.merge.blend (Continued)

Sample package from source 1 (SPARC):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T121410Z
file 1d5eac1aab628317f9c088d21e4afda9c754bb76 mode=0555 owner=root \
 group=bin path=usr/bin/sparc/foo pkg.merge.blend=arch
file d285ada5f3cae14ea00e97a8d99bd3e357caadc0 mode=0555 owner=root \
 group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Sample package from source 2 (i386):

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163427Z
file a285ada5f3cae14ea00e97a8d99bd3e357cb0dca mode=0555 owner=root \
 group=bin path=usr/bin/i386/foo pkg.merge.blend=arch
file d285ada5f3cae14ea00e97a8d99bd3e357caadc0 mode=0555 owner=root \
 group=bin path=usr/bin/foo
dir group=sys mode=0755 owner=root path=usr
```

Merged package:

```
set name=pkg.fmri value=pkg://example.com/foo@5.11,5.11-0.200:20381001T163427Z
set name=variant.arch value=sparc value=i386
file d285ada5f3cae14ea00e97a8d99bd3e357caadc0 mode=0555 owner=root \
 group=bin path=usr/bin/foo
file a285ada5f3cae14ea00e97a8d99bd3e357cb0dca mode=0555 owner=root \
 group=bin path=usr/bin/i386/foo
file 1d5eac1aab628317f9c088d21e4afda9c754bb76 mode=0555 owner=root \
 group=bin path=usr/bin/sparc/foo
dir group=sys mode=0755 owner=root path=usr
```

**Exit Status** The following exit values are returned:

- 0 Command succeeded.
- 1 An error occurred.
- 2 Invalid command line options were specified.
- 99 An unanticipated exception occurred.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | package/pkg     |
| Interface Stability | Uncommitted     |

**See Also** [pkgrepo\(1\)](#), [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

**Name** pkgmk – produce an installable package

**Synopsis** pkgmk [-o] [-a *arch*] [-b *base\_src\_dir*] [-d *device*]  
 [-f *prototype*] [-l *limit*] [-p *pstamp*] [-r *root\_path*]  
 [-v *version*] [*variable=value*]... [*pkginst*]

**Description** The pkgmk utility produces an installable package to be used as input to the [pkgadd\(1M\)](#) command. The package contents is in directory structure format.

The command uses the package [prototype\(4\)](#) file as input and creates a [pkgmap\(4\)](#) file. The contents for each entry in the prototype file is copied to the appropriate output location. Information concerning the contents (checksum, file size, modification date) is computed and stored in the pkgmap file, along with attribute information specified in the prototype file.

pkgmk searches for the files listed in the [prototype\(4\)](#) file as described in the following conditions. *Note:* If a prototype file contains the explicit location of the file to include in the package, then the following search explanations do not apply.

1. If neither -b nor -r options are specified, the file name component of each file path listed in the [prototype\(4\)](#) file is expected to be found in the same directory as the [prototype\(4\)](#) file
2. If -b is specified as a relative path (without a leading “/”), then *base\_src\_dir* is prepended to the relative file paths from the [prototype\(4\)](#) file. The resulting path is searched for in the *root\_path* directories. If a *root\_path* is not specified, it defaults to “/”.
3. If -b is specified as an absolute path (with a leading “/”), then *base\_src\_dir* is prepended to the relative paths from the [prototype\(4\)](#) file and the result is the location of the file. *root\_path* is *not* searched.
4. If -r is specified, then full file paths are used from the [prototype\(4\)](#) file. Relative paths have *base\_src\_dir* prepended. If *base\_src\_dir* is not specified, it defaults to “”. The resulting path is searched for in each directory of the *root\_path*.

If you created your prototype file using "pkgproto a/relative/path" or "pkgproto a/relative/path=install/path", you should use the -r *root\_path* option to specify the location of a/relative/path so that pkgmk can correctly locate your source files.

Package commands, including pkgmk, are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.

**Options** The following options are supported:

- a *arch* Overrides the architecture information provided in the [pkginfo\(4\)](#) file with *arch*.
- b *base\_src\_dir* Prepends the indicated *base\_src\_dir* to locate relocatable objects on the source machine. Use this option to search for all objects in the prototype file. pkgmk expects to find the objects in */base\_src\_dir* or to locate the objects by use of the -b and -r options, respectively.

- d *device*** Creates the package on *device*. *device* can be an absolute directory pathname or the identifiers for a removable disk. The default device is the installation spool directory (`/var/spool/pkg`).
- f *prototype*** Uses the file *prototype* as input to the command. The default *prototype* filename is `[Pp]prototype`.
- l *limit*** Specifies the maximum size in 512 byte blocks of the output device as `limit`. By default, if the output file is a directory or a mountable device, `pkgmk` employs the `df(1M)` command to dynamically calculate the amount of available space on the output device. This option is useful in conjunction with `pkgtrans(1)` to create a package with a datastream format.
- o** Overwrites the same instance; package instance is overwritten if it already exists.
- p *pstamp*** Overrides the production stamp definition in the `pkginfo(4)` file with *pstamp*.
- r *root\_path*** Uses the indicated *root\_path* with the source pathname appended to locate objects on the source machine, using a comma (,) as the separator for the path elements. If this option is specified, look for the full destination path in each of the directories specified. If neither `-b` nor `-r` is specified, look for the leaf filename in the current directory.
- v *version*** Overrides the version information provided in the `pkginfo(4)` file with *version*.
- variable=value*** Places the indicated variable in the packaging environment. (See `prototype(4)` for definitions of variable specifications.)

**Operands** The following operand is supported:

- pkginst*** A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, `inst.1` or `inst.2`). All instances of a package can be requested by `inst.*`. The asterisk character (\*) is a special character to some shells and might need to be escaped. In the C-Shell, \* must be surrounded by single quotes (') or preceded by a backslash (\).

**Exit Status** The following exit values are returned:

- 0** Successful completion.
- >0** An error occurred.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [pkgparam\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [uname\(1\)](#), [df\(1M\)](#), [pkgadd\(1M\)](#), [pkginfo\(4\)](#), [pkgmap\(4\)](#), [prototype\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

*Application Packaging Developer's Guide*

**Notes** Architecture information is provided on the command line with the `-a` option or in the [prototype\(4\)](#) file. If no architecture information is supplied, pkgmk uses the output of `uname -m` (see [uname\(1\)](#)).

Version information is provided on the command line with the `-v` option or in the [pkginfo\(4\)](#) file. If no version information is supplied, a default based on the current date is provided.

Command line definitions for both architecture and version override the [prototype\(4\)](#) definitions.

pkgmk fails if one of the following invalid combinations of zone-related parameters is used:

1. Both `SUNW_PKG_ALLZONES` and `SUNW_PKG_THISZONE` are set to `TRUE`.
2. `SUNW_PKG_HOLLOW` is set to `TRUE` and `SUNW_PKG_ALLZONES` is set to `FALSE`.
3. The package contains a request script and `SUNW_PKG_THISZONE` set to `TRUE`.

For additional information regarding these parameters, see [pkginfo\(4\)](#).

**Name** pkgmogrify – Image Packaging System manifest transmogriker

**Synopsis** /usr/bin/pkgmogrify [-vi] [-I *includedir* ...]  
[-D *macro=value* ...] [-O *outputfile*]  
[-P *printfile*] [*inputfile* ...]

**Description** `pkgmogrify` provides for programmatic editing of package manifests to simplify the typical transformations needed when automating software builds and package publication.

`pkgmogrify` provides the following:

- Macro replacement to facilitate sharing of a single manifest across various architectures and platforms.
- Inclusion of other manifests or manifest fragments such as standard components and transforms.
- Transformation of package actions, including the modification, deletion, or addition of action attributes.

**Options** The following options are supported:

-?

--help

Display a usage message.

-D *macro=value*

Define *macro* as a macro, with the value *value*. Macros appear in the input file as `$(macro)`. Substitution is repeated until no more translations are found. Common idioms include:

- Elimination of lines in a manifest on other architectures by using an architecture-specific tag at the beginning of the line:

```
$(sparc_ONLY)file ...
```

When processing the SPARC architecture, this macro would be set to the empty string.

When processing other architectures, this macro would be set to # on the command line, thus eliminating this action from the manifest on the current architecture.

- Specifying platform-specific portions of path names, such as the name of the 64-bit architecture directory for executables and libraries:

```
file NOHASH path=usr/bin/$(ARCH64)/cputrack ...
```

These macros should be set to the desired value on the command line. There are no predefined macro values.

-I *includedir*

Add the specified directory to the search path for both files specified on the command line and embedded include directives.

**-O *outputfile***

Write manifest output to the specified file. The file is not written if an error occurs or if a transform directive causes an abort operation. By default, manifest output is written to `stdout`.

**-P *printfile***

Write output resulting from transform directive print operations to the specified file. The file is not written if an error occurs or if a transform directive causes an abort operation. By default, print output is written to `stdout`.

**-i**

Ignore include directives in files. Only files specified on the command line (or `stdin`) are processed.

**-v**

Write comments into the output manifest showing the effect of transforms. This information can aid in debugging.

**Embedded Directives**

Two types of directives are supported in manifest files: include directives and transform directives.

Include directives are of the form:

```
<include file>
```

This directive causes `pkgmogrify` to search for a file named `file` first in the current directory and then in the directories specified with the `-I` option. If found, the contents of the file are inserted into the manifest at the point at which the directive is encountered. If not found, `pkgmogrify` exits with an error.

Transform directives are of the form:

```
<transform matching-criteria -> operation>
```

These directives are accumulated until all inputs have been read into memory, and then applied to the actions in the order in which they were encountered.

Matching criteria are of the form:

```
[action-name ...] [attribute=<value-regexp> ...]
```

At least one specified *action-name* must match. Every specified *attribute* must match. Action names and attributes are listed in “Actions” in the `pkg(5)` man page. The regular expression syntax used is that of Python. For more information about Python regular expression syntax, use the command `pydoc re` or see more complete documentation at <http://docs.python.org/dev/howto/regex.html>. The regular expression is anchored at the beginning but not at the end. Therefore, a regular expression matching files by their extensions must include a leading `.*` and should include a trailing `$`.

Multiple criteria can be specified, separated by spaces.

The following operations are available:

- `add`        Add a value to an attribute. This operation takes two arguments. The first argument is the name of the attribute, and the second is the value.
- `default`    Set the value of an attribute if it doesn't already exist. This operation takes the same two arguments as the `add` operation.
- `delete`     Remove attribute values. This operation takes two arguments. The first argument is the name of the attribute. The second argument is a regular expression to match the attribute values deleted. Unlike the regular expression used to match an action, this expression is unanchored.
- `drop`       Discards this action.
- `edit`       Modifies an attribute of the action. This operation takes three arguments. The first argument is the name of the attribute, and the second is a regular expression matching the attribute value. The third argument is the replacement string substituted for the portion of the value matched by the regular expression. Unlike the regular expression used to match an action, this expression is unanchored. Normal regular expression backreferences, of the form `\1`, `\2`, and so on, are available in the replacement string if groups are defined in the regular expression.
- `emit`       Emit a line to the manifest output stream. This must be a valid action string, empty (resulting in a blank line), or a comment (a `#` followed by arbitrary text).
- `exit`       Terminate manifest processing. No manifest is output and no `print` operations are applied. If one argument is given, it must be an integer, and it is used as the exit code. The default is 0. If two arguments are given, the first is the exit code, and the second is a message to be printed to `stderr`.
- `print`      Print a message to the output file specified with `-P`.
- `set`        Set the value of an attribute. This operation takes the same two arguments as the `add` operation.

All operations except for `delete` and `drop` take (possibly optional) arguments whose contents go to the output stream. These strings can contain three different kinds of special tokens which allow the output to contain information that is not based on a fixed transformation of each action.

The first kind of substitution allows the operation to refer to the values of attributes of the current action by putting the name of the attribute inside parentheses following a percent sign. For example, `%(alias)` refers to the value of the action's `alias` attribute.

Several synthetic attributes exist. Two are unique to `pkgmogrify`:

- `pkg.manifest.filename` refers to the name of the file in which the action was found.
- `pkg.manifest.lineno` refers to the line on which the action was found.

Three synthetic attributes are similar to ones used in `pkg`:

- `action.hash` refers to the hash value of the action if the action carries a payload. For actions with payloads, the `set` operation can change the hash of the action by operating on the `action.hash` attribute.
- `action.key` refers to the value of the key attribute.
- `action.name` refers to the name of the action.

If the attribute whose value is requested does not exist, `pkgmogrify` exits with an error. To prevent exiting with an error, follow the attribute name with `;notfound=` and a value to substitute in place of the attribute value. For example, `%(alias;notfound='no alias')` prints the value of the attribute `alias` if it exists, and prints `no alias` otherwise.

If the attribute whose value is requested is multi-valued, each value is printed, separated by spaces. Similarly to the `notfound` token, the tokens `prefix`, `suffix`, and `sep` can be used to change this behavior. The string denoted by `prefix` is prepended to each value, the string denoted by `suffix` is appended to each value, and `sep` is placed in between the suffix of one value and the prefix of the next.

Similarly to action attributes, `pkgmogrify` directives can reference package attributes using braces instead of parentheses: `%(pkg.fMRI)`. At the point at which the transform directive is applied, the attribute must have been defined in a `set` action, or it is treated as `notfound`, described above. When the processing reaches the end of the manifest file describing the package, the attributes are cleared for the next package.

It is useful not only to reference package attributes as if they were action attributes, but also to match on them, and even temporarily modify them. Therefore a synthetic action name, `pkg`, is available (only in the context of `pkgmogrify`) for use in these situations.

When `pkgmogrify` finishes reading a manifest specified on the command line and that manifest defined a `pkg.fMRI` package attribute, `pkgmogrify` creates this synthetic `pkg` action, whose attributes are the package's attributes. A `<transform>` directive can then match on this action, just as it can match on any other action.

Operations on a `pkg` action are special in that they take place only in memory and do not directly affect the emitted manifest. For instance, trying to set an attribute on a `pkg` action via the `add`, `default`, or `set` operations does not result in a `set` action being added to the manifest, though it will be available for other `<transform>` directives to match on. Attempting to `emit` a `pkg` action causes an error. To add a package attribute, `emit` a `set` action instead.

The third kind of substitution is a backreference. This substitution is not like the ones usable in the `edit` operation, but is a reference to groups listed in the transformation match on the left-hand side of the `->`. These are indicated by `%<1>`, `%<2>`, and so on, in the order seen in the matching criteria.

The order of processing is as follows:

1. Lines are read from input files.
2. Macros are applied.
3. `<include . . .>` and `<transform>` directives are processed, causing additional files to be found and read.
4. Once all input has been accumulated, each line in the input is converted into actions and all transforms applied.
5. Once processing is complete and successful, the output is written.

#### Examples **EXAMPLE 1** Add Tags To SMF Manifests

Add tags to Service Management Facility (SMF) manifests so they get imported when the package is installed on a live system.

```
<transform file path=(var|lib)/svc/manifest/*.xml -> \
 add restart_fmri svc:/system/manifest-import:default>
```

#### **EXAMPLE 2** Move Files

Move files from `usr/sfw/bin` to `usr/bin`.

```
<transform file -> edit path usr/sfw/bin usr/bin>
```

#### **EXAMPLE 3** Specify Reboot Needed

Add `reboot-needed` tags to files under `/kernel` that are not `.conf` files. Note that this example leverages how transforms are applied to each action in the order seen in the input files.

```
<transform file path=kernel/* -> set reboot-needed true>
<transform file path=kernel/*.conf -> delete reboot-needed .*>
```

This can also be done in a single transform rule with regular expressions.

#### **EXAMPLE 4** Convert FMRI Attribute To Depend Action

Convert the package attribute `pkg.fmri` into a `depend` action to become part of an incorporation.

```
<transform set name=pkg.fmri -> \
 emit depend type=incorporate fmri=%(value)>
<transform set name=pkg.fmri -> drop>
```

**EXAMPLE 5** Print a List of Bug Numbers

Print a comma-separated list of quoted and prefixed bug numbers.

```
set name=bugs value=12345 value=54321 value=13579 value=97531
<transform set name=bugs -> \
 print %(value;sep=",";prefix="bug='";suffix="'")>
```

**EXAMPLE 6** Allow For Missing Attributes

Safely print a message even when an attribute is missing.

```
<transform driver -> print Found aliases: %(alias;notfound=<none>)>
```

**EXAMPLE 7** Set Default Values

Set default owner, group, and permission values.

```
<transform file dir -> default owner root>
<transform file dir -> default group bin>
<transform file -> default mode 0444>
<transform dir -> default mode 0755>
```

**EXAMPLE 8** Add Dependencies To Packages That Are Not Marked Obsolete

For any package that is not marked obsolete, add a dependency on the incorporation for the consolidation that delivers the package. This set of transforms must occur after the manifest has been read in, or the dependency will always be emitted. Because modifying a pkg action has no permanent effect, there is no need to clean up attributes matching `pkg.obsolete=false`.

```
<transform pkg -> default pkg.obsolete false>
<transform pkg pkg.obsolete=false -> emit depend \
 fmri=consolidation/$(CONS)/$(CONS)-incorporation type=require>
```

**EXAMPLE 9** Exit and Print a Message When an Error Is Found

Error out with a message when an obsolete attribute is found in a manifest.

```
<transform file dir link hardlink opensolaris.zone=* -> \
 exit 1 The opensolaris.zone attribute is obsolete.>
```

**EXAMPLE 10** Set the Appropriate Locale Facet

Set the locale facet appropriate for the path name under consideration.

```
<transform dir file link hardlink path=.*/locale/([^\+]* -> \
 default facet.locale.%<1> true>
```

**Exit Status** The following exit values are returned:

0 Everything worked.

- 1 Something bad but anticipated happened.
- 2 Invalid command line options were specified.
- 99 Unexpected processing error.

**Files** /usr/share/pkg/t/transforms

This directory contains files with useful transforms to set facets, actuators, and other attributes.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	package/pkg
Interface Stability	Uncommitted

**See Also** [pkg\(1\)](#), [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

- 
- Name** pkgparam – display package parameter values
- Synopsis** pkgparam [-v] [-d *device*] [-R *root\_path*] *pkginst* [*param*]...  
 pkgparam -f *filename* [-v] [*param*]...
- Description** pkgparam displays the value associated with the parameter or parameters requested on the command line. The values are located in either the [pkginfo\(4\)](#) file for *pkginst* or from the specific file named with the -f option.
- One parameter value is shown per line. Only the value of a parameter is given unless the -v option is used. With this option, the output of the command is in this format:
- ```
parameter1='value1'
parameter2='value2'
parameter3='value3'
```
- If no parameters are specified on the command line, values for all parameters associated with the package are shown.
- Options** Options and arguments for this command are:
- d *device* Specify the *device* on which a *pkginst* is stored. It can be a directory pathname or the identifiers for a tape or removable disk (for example, /var/tmp or /dev/dsk/c1d0s0). The special token spool may be used to represent the default installation spool directory (/var/spool/pkg).
 - f *filename* Read *filename* for parameter values.
 - R *root_path* Defines the full path name of a subdirectory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*.
 - v Verbose mode. Display name of parameter and its value.
- Operands** *pkginst* Defines a specific package instance for which parameter values should be displayed.
- param* Defines a specific parameter whose value should be displayed.
- Errors** If parameter information is not available for the indicated package, the command exits with a non-zero status.
- Exit Status** 0 Successful completion.
 >0 An error occurred.
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | system/core-os |

See Also [pkgmk\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [pkgadd\(1M\)](#), [pkginfo\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Application Packaging Developer's Guide

Notes With the `-f` option, you can specify the file from which parameter values should be extracted. This file should be in the same format as a [pkginfo\(4\)](#) file. For example, such a file might be created during package development and used while testing software during this stage.

Package commands are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.

-
- Name** pkgproto – generate prototype file entries for input to pkgmk command
- Synopsis** pkgproto [-i] [-c *class*] [*path1*]
 pkgproto [-i] [-c *class*] [*path1=path2*]...
- Description** pkgproto scans the indicated paths and generates [prototype\(4\)](#) file entries that may be used as input to the [pkgmk\(1\)](#) command.
- If no paths are specified on the command line, standard input is assumed to be a list of paths. If the pathname listed on the command line is a directory, the contents of the directory is searched. However, if input is read from `stdin`, a directory specified as a pathname will not be searched.
- Package commands, such as pkgproto, are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.
- Options**
- i Ignores symbolic links and records the paths as `f`type=f (a file) versus `f`type=s (symbolic link).
 - c *class* Maps the class of all paths to *class*.
- Operands**
- path1* Pathname where objects are located.
 - path2* Pathname which should be substituted on output for *path1*.
- Examples**
- EXAMPLE 1** Basic Usage
- The following example shows a common usage of pkgproto and a partial listing of the output produced.
- ```
example% pkgproto /bin=bin /usr/bin=usrbin /etc=etc
f none bin/sed=/bin/sed 0775 bin bin
f none bin/sh=/bin/sh 0755 bin daemon
f none bin/sort=/bin/sort 0755 bin bin
f none usrbin/sdb=/usr/bin/sdb 0775 bin bin
f none usrbin/shl=/usr/bin/shl 4755 bin bin
d none etc/master.d 0755 root daemon
f none etc/master.d/kernel=/etc/master.d/kernel 0644 root daemon
f none etc/rc=/etc/rc 0744 root daemon
```
- EXAMPLE 2** Using pkgproto in a Pipeline
- The following command shows pkgproto accepting the output of the `find` command.
- ```
example% find / -type d -print | pkgproto
d none / 755 root root
d none /bin 755 bin bin
d none /usr 755 root root
d none /usr/bin 775 bin bin
d none /etc 755 root root
```

EXAMPLE 2 Using pkgproto in a Pipeline (Continued)

```
d none /tmp 777 root root
```

Exit Status 0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|----------------|
| Availability | system/core-os |

See Also [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgtrans\(1\)](#), [pkgadd\(1M\)](#), [prototype\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Application Packaging Developer's Guide

Notes By default, pkgproto creates symbolic link entries for any symbolic link encountered (ftype=s). When you use the -i option, pkgproto creates a file entry for symbolic links (ftype=f). The [prototype\(4\)](#) file would have to be edited to assign such file types as v (volatile), e (editable), or x (exclusive directory). pkgproto detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.

By default, pkgproto prints prototype entries on the standard output. However, the output should be saved in a file (named Prototype or prototype, for convenience) to be used as input to the [pkgmk\(1\)](#) command.

Name pkgrecv – Image Packaging System content retrieval utility

Synopsis /usr/bin/pkgrecv [-s *src_uri*] [-a] [-d (*path|dest_uri*)]
 [-c *cache_dir*] [-kr] [-m *match*] [-n] [--raw]
 [--key *keyfile* --cert *certfile*] (*fMRI|pattern*) ...
 /usr/bin/pkgrecv [-s *src_uri*] --newest

Description pkgrecv allows the user to retrieve packages from a pkg(5) repository or package archive. pkgrecv can also optionally republish the retrieved packages to a different package repository or archive them. By default, packages are retrieved in package repository format suitable for use with pkg, pkg.depotd, and package publication tools.

After a pkgrecv operation, run pkgrepo refresh or pkgrepo rebuild on the repository to build search indexes.

Options The following options are supported:

-h

Display a usage message.

-a

Store the retrieved package data in a pkg(5) archive at the location specified by -d. The file cannot already exist. This option can be used only with file system based destinations. Although not required, using a file extension of .p5p (for example, archive.p5p) is strongly suggested. This option cannot be combined with --raw.

-c *cache_dir*

Specify the path to a directory that will be used to cache downloaded content. If this directory is not supplied, the client automatically selects a cache directory. In the case where a download is interrupted, and a cache directory was automatically chosen, use this option to resume the download. See the “Environment Variables” section below for details about how to set the location used for temporary data storage.

-d (*path|dest_uri*)

Specify the file system path or URI of the target to republish packages to. If -a is specified, the target is a new package archive that cannot already exist. Otherwise, the target must be a package repository that already exists. New repositories can be created using pkgrepo.

-k

Keep the retrieved package content compressed. This option is ignored when republishing. Compressed package content should not be used with pkgsend.

-m *match*

Control matching behavior using the following values:

all-timestamps

Includes all matching timestamps, not just the latest (implies all-versions).

all-versions

Includes all matching versions, not just the latest.

- n
Perform a trial run with no changes made.
- r
Recursively retrieve all dependencies for the provided list of packages.
- s *src_uri*
Specify a URI representing the location of a pkg(5) repository or package archive from which to receive package data.
- cert *certfile*
Specify a client SSL certificate file to use for package retrieval from an HTTPS repository.
- key *keyfile*
Specify a client SSL key file to use for package retrieval from an HTTPS repository.
- newest
List the most recent versions of the packages available from the specified repository and exit. (All other options except -s are ignored.)
- raw
Retrieve and store the raw package data in a set of directory structures by stem and version at the location specified by -d. This option can be used only with file system based destinations. This package data can be used to conveniently modify and republish packages, perhaps by correcting file contents or providing additional package metadata. This option cannot be combined with -a.

Examples

EXAMPLE 1 List Newest Packages

List the newest packages available from the repository on the system named `test`.

```
$ pkgrecv -s http://test --newest
pkg://solaris/system/library/c++-runtime@0.5.11,5.11-0.175.0.0.0.2.1:20120921T190358Z
pkg://solaris/system/library/freetype-2@2.4.8,5.11-0.175.1.0.0.7.1234:20120109T215840Z
pkg://solaris/system/library/math@0.5.11,5.11-0.175.0.0.0.2.1:20120921T190432Z
```

EXAMPLE 2 Retrieve Raw Package Data

Receive the `c++-runtime` package from Example 1 in a format suitable for use with `pkgsend publish`.

```
$ pkgrecv -s http://test \
-d /local/repo --raw \
c++-runtime@0.5.11,5.11-0.175.0.0.0.2.1:20120921T190358Z
Processing packages for publisher solaris ...
Retrieving and evaluating 1 package(s)...
PROCESS      ITEMS      GET (MB)      SEND (MB)
Completed    1/1        3.5/3.5       0.0/0.0
$ ls /local/repo
pkg5.repository publisher system%2Flibrary%2Fc%2B%2B-runtime
```

EXAMPLE 3 Retrieve Dependencies From a System

Receive the package `editor/vim` and all of its dependencies from the system named `test`.

```
$ pkgrecv -s http://test -d /local/repo -r editor/vim
```

EXAMPLE 4 Retrieve All Versions

Receive all versions of the package `editor/vim` from the system named `test`.

```
$ pkgrecv -s http://test -d /local/repo -m all-versions \
editor/vim
```

Processing packages for publisher solaris ...

Retrieving and evaluating 2 package(s)...

| PROCESS | ITEMS | GET (MB) | SEND (MB) |
|-----------|-------|-----------|-----------|
| Completed | 2/2 | 16.7/16.7 | 44.9/44.9 |

EXAMPLE 5 Retrieve All Versions and Republish Remotely

Receive all versions of the package `library/zlib` from the system named `test` and republish it to a remote repository on the system named `remote`.

```
$ pkgrecv -s http://test -d http://remote:10000 \
-m all-versions library/zlib
```

EXAMPLE 6 Retrieve Dependencies From a Repository

Receive the package `editor/gnu-emacs` and all of its dependencies from the repository located at `/export/repo`.

```
$ pkgrecv -s /export/repo -d /local/repo -r editor/gnu-emacs
```

EXAMPLE 7 Retrieve Additional Packages and Changed Content

Receive all packages that do not already exist and all changed content from the repository located at `http://pkg.oracle.com/solaris/release/` to the repository located at `/export/repoSolaris11`.

```
$ pkgrecv -s http://pkg.oracle.com/solaris/release/ \
-d /export/repoSolaris11 -m all-timestamps '*'
```

Receive all packages that do not already exist and all changed content from the secure repository located at `http://pkg.oracle.com/solaris/support/` to the repository located at `/export/repoSolaris11`.

```
$ pkgrecv -s http://pkg.oracle.com/solaris/support/ \
-d /export/repoSolaris11 -m all-timestamps \
--key /var/pkg/ssl/Oracle_Solaris_11_Support.key.pem \
--cert /var/pkg/ssl/Oracle_Solaris_11_Support.certificate.pem '*'
```

EXAMPLE 8 Create a Package Archive

Create a package archive containing the package `editor/gnu-emacs` and all of its dependencies from the repository located at `http://example.com:10000`.

EXAMPLE 8 Create a Package Archive *(Continued)*

```
$ pkgrecv -s http://example.com:10000 -d /my/emacs.p5p -a \
-r editor/gnu-emacs
```

EXAMPLE 9 Copy Packages From an Archive to a Repository

Copy all of the packages in a package archive to an existing repository located at /export/repo.

```
$ pkgrecv -s /my/archive.p5p -d /export/repo '*'
```

Environment Variables The following environment variables are supported:

PKG_DEST The path of a directory to save the retrieved package to, or the file system path or URI of a repository or package archive where the packages will be copied.

PKG_SRC A URI or file system path representing the location of a pkg(5) repository or package archive from which to retrieve packages.

TMPDIR The absolute path of the directory where temporary data should be stored during program execution. If not set, the default is to store temporary data in /var/tmp.

Exit Status The following exit values are returned:

0 Command succeeded.

1 An error occurred.

2 Invalid command line options were specified.

3 Multiple operations were requested, but only some of them succeeded.

99 An unanticipated exception occurred.

Attributes See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | package/pkg |
| Interface Stability | Uncommitted |

Name pkgrepo – Image Packaging System repository management utility

Synopsis /usr/bin/pkgrepo create [--version *ver*] *uri_or_path*
 /usr/bin/pkgrepo add-publisher -s *repo_uri_or_path* *publisher* ...
 /usr/bin/pkgrepo get [-F *format*] [-H] [-p *publisher* ...]
 -s *repo_uri_or_path* [*section/property* ...]
 /usr/bin/pkgrepo info [-F *format*] [-H] [-p *publisher* ...]
 -s *repo_uri_or_path*
 /usr/bin/pkgrepo list [-F *format*] [-H] [-p *publisher* ...]
 -s *repo_uri_or_path* [*pkg_fmri_pattern* ...]
 /usr/bin/pkgrepo rebuild [-p *publisher* ...]
 -s *repo_uri_or_path* [--no-catalog] [--no-index]
 /usr/bin/pkgrepo refresh [-p *publisher* ...]
 -s *repo_uri_or_path* [--no-catalog] [--no-index]
 /usr/bin/pkgrepo remove [-n] [-p *publisher* ...]
 -s *repo_uri_or_path* *pkg_fmri_pattern* ...
 /usr/bin/pkgrepo set [-p *publisher*] -s *repo_uri_or_path*
 section/property=[*value*]
 /usr/bin/pkgrepo set [-p *publisher*] -s *repo_uri_or_path*
 section/property=([*value*]) ...
 /usr/bin/pkgrepo help
 /usr/bin/pkgrepo version

Description pkgrepo provides the ability to create and manage pkg(5) package repositories. Package repositories are a predefined set of directories and files that permit the storage and retrieval of package data by pkg and publication clients such as pkgsend or pkgrecv. In addition, when network-based access to a package repository is needed, pkg.depotd can provide clients access to the repository to store and/or retrieve package data.

Options The following options are supported:

-?
 --help
 Display a usage message.

Sub-commands The following subcommands are supported:

pkgrepo create [--version *ver*] *uri_or_path*
 Create a pkg(5) repository at the specified location.

 This subcommand can be used only with file system based repositories.

--version

Create a repository in a format compatible with the specified version. By default, version 4 repositories are created. Supported versions are:

- 3 Supports storage of packages for a single publisher, catalog version 1, and search version 1.
- 4 Supports storage of packages for multiple publishers, catalog version 1, and search version 1.

pkgrepo add-publisher -s *repo_uri_or_path* *publisher* ...

Add the specified publishers to the repository. The new publishers have no packages or content.

This subcommand can be used only with version 4 file system based repositories.

pkgrepo get [-F *format*] [-H] [-p *publisher* ...] -s *repo_uri_or_path* [*section/property* ...]

Display the property information for the repository or its publishers.

By default, each property and its value are printed on separate lines. Empty ASCII string values are represented by a pair of double quotation marks (""). The following Bourne shell metacharacters, and newline, space, and tab, in ASCII string values must be escaped by backslash characters (\):

; & () | ^ < > \ " ' `

See the “Examples” section for examples displaying publisher and repository properties.

For a list of properties and the purpose and value of each property, see the **set** subcommand below.

-F *format*

Specify an alternative output format. The value of *format* can be `tsv` (Tab Separated Values), `json` (JavaScript Object Notation as a single line), or `json-formatted` (JavaScript Object Notation, formatted for readability).

-H

Omit the headers from the listing.

-p *publisher*

Display the property information for the given publisher. The special value `all` displays the properties for all publishers. This option can be specified multiple times.

-s *repo_uri_or_path*

Operate on the repository located at the given URI or file system path.

section/property

Display values for only the specified properties, such as `publisher/prefix` or `repository/version`. See the **set** subcommand for a complete list of properties.

`pkgrepo info [-F format] [-H] [-p publisher ...] -s repo_uri_or_path`

Display a listing of the package publishers known by the repository. The listing includes the number of packages for each publisher, when the publisher's package data was last updated, and the status of the publisher's package data (such as whether it is currently being processed).

`-F format`

Specify an alternative output format. The value of *format* can be `tsv` (Tab Separated Values), `json` (JavaScript Object Notation as a single line), or `json-formatted` (JavaScript Object Notation, formatted for readability).

`-H`

Omit the headers from the listing.

`-p publisher`

Only display the data for the given publisher. If not provided, the data for all publishers is displayed. This option can be specified multiple times.

`-s repo_uri_or_path`

Operate on the repository located at the given URI or file system path.

`pkgrepo list [-F format] [-H] [-p publisher ...] -s repo_uri_or_path [pkg_fmri_pattern ...]`

List the packages in the *repo_uri_or_path* repository that match the specified *pkg_fmri_pattern* patterns. If no patterns are specified, all packages in the repository are listed.

In the default output, the first column contains the name of the publisher of the package. The second column contains the name of the package. The third column is a flag that shows the status of the package. A value of `o` in the status column indicates the package is obsolete. A value of `r` in the status column indicates the package has been renamed, which is a form of obsolescence. The fourth column contains the release and branch versions of the package. See `pkg(5)` for information about release and branch versions.

`-F format`

Specify an alternative output format. The value of *format* can be `tsv` (Tab Separated Values), `json` (JavaScript Object Notation as a single line), or `json-formatted` (JavaScript Object Notation, formatted for readability).

`-H`

Omit the headers from the listing.

`-p publisher`

Only display the packages for the given publisher. If not provided, the packages for all publishers are displayed. This option can be specified multiple times.

`-s repo_uri_or_path`

Operate on the repository located at the given URI or file system path.

`pkgrepo rebuild [-p publisher ...] -s repo_uri_or_path [--no-catalog] [--no-index]`

Discard all catalog, search, and other cached information found in the repository, and then recreates it based on the current contents of the repository.

`-p publisher`

Perform the operation only for the given publisher. If not provided, or if the special value `all` is specified, the operation is performed for all publishers. This option can be specified multiple times.

`-s repo_uri_or_path`

Operate on the repository located at the given URI or file system path.

`--no-catalog`

Do not rebuild package data.

`--no-index`

Do not rebuild search indexes.

`pkgrepo refresh [-p publisher ...] -s repo_uri_or_path [--no-catalog] [--no-index]`

Catalog any new packages found in the repository and updates all search indexes. This is intended for use with deferred publication (`--no-catalog` or `--no-index` options of `pkgsend`).

`-p publisher`

Perform the operation only for the given publisher. If not provided, or if the special value `all` is specified, the operation is performed for all publishers. This option can be specified multiple times.

`-s repo_uri_or_path`

Operate on the repository located at the given URI or file system path.

`--no-catalog`

Do not add any new packages.

`--no-index`

Do not update search indexes.

`pkgrepo remove [-n] [-p publisher ...] -s repo_uri_or_path pkg_fmri_pattern ...`

Remove the packages matching the specified patterns from the repository, including any files they reference that are not in use by any other package.

Note – All search index data for related publishers is removed.

This subcommand can be used only with file system based repositories.

Caution – This operation is not reversible and should not be used while other clients are accessing the repository since it might cause them to fail during retrieval operations.

`-n`

Perform a trial run of the operation with no package changes made. A list of the packages to be removed is displayed before exiting.

-p publisher

Only remove matching packages for the given publisher. If not provided, any matching packages are removed for all publishers. This option can be specified multiple times.

-s repo_uri_or_path

Operate on the repository located at the given URI or file system path.

`pkgrepo set [-p publisher] -s repo_uri_or_path section/property=[value] ...`

`set [-p publisher] -s repo_uri_or_path section/property=([value]) ...`

Set the value of the specified properties for the repository or publisher.

This subcommand can be used only with file system based repositories.

-p publisher

Only set property data for the given publisher. If the publisher does not already exist, it is added. The special value `all` can be used to set the property for all publishers.

-s repo_uri_or_path

Operate on the repository located at the given URI or file system path.

Properties and values can be specified using one of the following forms:

section/property=

Clear the property value.

section/property=*value*

Replace the property value with the given value.

section/property=(*value1 value2 valueN*)

Replace the property value with the list of values.

For repository versions 3 and 4, the following properties can be set for the repository:

`publisher/prefix` A string that represents the name of the default publisher. The first character must be a-z, A-Z, or 0-9. The remainder of the string can only contain the characters 0-9, -, ., a-z, and A-Z. This value indicates the publisher that should be used when more than one publisher's packages are present, or when packages are published to the repository and a publisher is not specified.

For repository versions 3 and 4, the following properties can be set for individual publishers in the repository:

`publisher/alias` A string that represents the default alias that clients should use when adding a publisher using the repository's configuration data. The first character must be a-z, A-Z, or 0-9. The remainder of the string can only contain the characters 0-9, -, ., a-z, and A-Z.

| | |
|--|---|
| <code>repository/collection_type</code> | <p>Can have the value <code>core</code> or <code>supplemental</code>, indicating the type of packages offered in this repository.</p> <p>The <code>core</code> type indicates that the repository contains all of the dependencies declared by packages in the repository. The <code>core</code> type is primarily used for operating system repositories.</p> <p>The <code>supplemental</code> type indicates that the repository contains packages that rely on or are intended to be used with packages located in another repository.</p> |
| <code>repository/description</code> | <p>A paragraph of plain text that describes the purpose and contents of the repository.</p> |
| <code>repository/detailed_url</code> | <p>A URI that represents the location of a document (such as a web page) that provides additional information about the repository.</p> |
| <code>repository/legal_uris</code> | <p>A list of locations (URIs) for documents that provide additional legal information about the repository.</p> |
| <code>repository/mirrors</code> | <p>A list of locations (URIs) of repositories that contain a copy of the repository's package content but not the package metadata.</p> |
| <code>repository/name</code> | <p>A plain text string that contains the name of the repository.</p> |
| <code>repository/origins</code> | <p>A list of locations (URIs) of repositories that contain a complete copy of the repository's package metadata and content.</p> |
| <code>repository/refresh_seconds</code> | <p>An integer value that represents the number of seconds clients should wait before checking the repository for updated package data after each update check.</p> |
| <code>repository/registration_uri</code> | <p>A URI that represents the location of a resource that must be used to obtain credentials for access to the repository. A registration web page is one example.</p> |
| <code>repository/related_uris</code> | <p>A list of locations (URIs) of repositories that contain packages that users might be interested in.</p> |

Properties not documented here, but listed in the output of the `get` subcommand, are reserved for internal use and should not be set.

`pkgrepo help`
 Display a usage message.

`pkgrepo version`
 Display a unique string that identifies the version of the pkg(5) system. The values produced by the version operation are not sortable and are not safe for comparison beyond equality.

Examples EXAMPLE 1 Create a Package Repository

```
$ pkgrepo create /my/repository
```

EXAMPLE 2 Display Information

Display a summary of publishers and the number of packages in a repository.

```
$ pkgrepo info -s /my/repository
PUBLISHER  PACKAGES STATUS UPDATED
example.com 5          online 2011-07-22T18:09:09.769106Z
$ pkgrepo info -s http://pkg.oracle.com/solaris/release/
PUBLISHER  PACKAGES STATUS UPDATED
solaris    3941         online 2010-11-12T19:24:25.967246Z
```

EXAMPLE 3 Rebuild Catalogs and Search Data

Rebuild the repository's catalogs and search data.

```
$ pkgrepo rebuild -s /my/repository
```

EXAMPLE 4 Refresh Catalogs and Search Data

Refresh the repository's catalogs and search data.

```
$ pkgrepo refresh -s /my/repository
$ pkgrepo refresh -s http://example.com/repository
```

EXAMPLE 5 Display All Repository Properties

```
$ pkgrepo get -s /export/repoSolaris11
SECTION  PROPERTY  VALUE
publisher prefix    solaris
repository description Local\ copy\ of\ the\ Oracle\ Solaris\ 11\ repository
repository name      Oracle\ Solaris\ 11
repository version   4
$ pkgrepo get -s http://pkg.oracle.com/solaris/release/
SECTION  PROPERTY  VALUE
deployment content  s11_11-11
deployment pubdate  20111102T222051Z
publisher prefix    solaris
repository version  4
```

EXAMPLE 6 Display All Publisher Properties

```
$ pkgrepo get -s http://pkg.oracle.com/solaris/release/ -p all
PUBLISHER SECTION   PROPERTY           VALUE
solaris  publisher  alias
solaris  publisher  prefix            solaris
solaris  repository collection-type  core
solaris  repository description  This\ repository\ serves\ the\ Oracle\
Solaris\ 11\ Package\ repository.
solaris  repository legal-uris   ()
solaris  repository mirrors     (http://pkg-cdn1.oracle.com/solaris.release/)
solaris  repository name        Oracle\ Solaris\ 11\ Package\ Repository
solaris  repository origins     ()
solaris  repository refresh-seconds
solaris  repository registration-uri ""
solaris  repository related-uris  ()
```

EXAMPLE 7 Set the Default Publisher

```
$ pkgrepo set -s /my/repository publisher/prefix=example.com
```

EXAMPLE 8 Set a Publisher Property

```
$ pkgrepo set -s /my/repository -p example.com \
repository/origins=http://example.com/repository
```

EXAMPLE 9 Add a New Publisher To the Repository

```
$ pkgrepo add-publisher -s /my/repository example.com
```

Exit Status The following exit values are returned:

- 0 Command succeeded.
- 1 An error occurred.
- 2 Invalid command line options were specified.
- 3 Multiple operations were requested, but only some of them succeeded.
- 4 No changes were made, nothing to do.
- 99 An unanticipated exception occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | package/pkg |
| Interface Stability | Uncommitted |

See Also [pkg\(1\)](#), [pkgrecv\(1\)](#), [pkgsend\(1\)](#), [pkg.depotd\(1M\)](#), [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

Name pkgsend – Image Packaging System publication client

Synopsis /usr/bin/pkgsend [*options*] *command* [*cmd_options*] [*operands*]

/usr/bin/pkgsend generate [-T *pattern*] [--target *file*]
source ...

/usr/bin/pkgsend publish [-b *bundle* ...] [-d *source* ...]
[-s *repo_uri_or_path*] [-T *pattern*] [--no-catalog]
[*manifest* ...]

Description pkgsend enables the publication of new packages and new package versions to an image packaging repository using package manifests. To create or manage repositories, see pkgrepo(1). To create package archives from packages in an existing repository, see pkgrecv(1). For more information about package manifests, see pkg(5).

After a pkgsend operation, run pkgrepo refresh or pkgrepo rebuild on the repository to build search indexes.

Options The following options are supported:

-?
--help
Display a usage message.

Sub-commands The following subcommands are supported:

pkgsend generate [-T *pattern*] [--target *file*] *source* ...

Read each *source* (such as an SVR4 package, a directory, or a tar file) and emit the manifest that describes the *source* to stdout. In the output manifest, file and dir actions have owner set to root and group set to bin.

The output manifest can then be annotated, have dependencies added or analyzed using pkgdepend, and have its correctness verified using pkglint before being passed to the publish subcommand.

The following are supported sources:

- Filesystem format SVR4 packages
- Datastream format SVR4 packages
- tar files
- Directories

If the base name of files in the source match the patterns specified with -T, the timestamp of the file is added to the action for that file. The *pattern* uses shell matching rules:

- * Matches everything.
- ? Matches any single character.
- [*seq*] Matches any character in *seq*.

!*seq*] Matches any character not in *seq*.

When the specified source is a directory, there is no clear way to distinguish a file action from a hardlink action when there are multiple path names for a single inode. Normally, the first one found in the file system walk is treated as a file and the rest as hardlinks. This can be arbitrary, depending on the implementation of the file system. To specify which path names should be treated as files, pass each path name as an argument to the `--target` option. This option has no effect on other types of sources because they are capable of expressing which path names are files and which are hardlinks.

When SVR4 packages are provided as a source, `pkgsend` checks that no files with class action scripts are present and no `preinstall`, `postinstall`, `preremove`, or `postremove` scripts are present. An exception is made for any SMF manifests installed with the `manifest` class. `BASEDIR` is removed from all relocatable paths.

The `SVR4DESC` parameter is converted to a `pkg.description` value. The `SVR4NAME` parameter is converted to a `pkg.summary` value.

```
pkgsend publish [-b bundle ...] [-d source ...] [-s repo_uri_or_path] [-T pattern]
[- --no-catalog] [manifest ...]
```

Publish a package using the specified package manifests to the target package repository, retrieving files for the package from the provided sources. If multiple manifests are specified, they are joined in the order provided. If a manifest is not specified, the manifest is read from `stdin`.

If not specified, `pkgsend publish` adds the build version to the package FMRI. The `publish` tool also adds the timestamp (the current time in UTC) to the package FMRI. See the `pkg(5)` man page for information about the version string of a package FMRI.

-b *bundle*

Add the specified bundle to the list of sources to search when looking for files in the manifest. Bundles are sources such as tar files and SVR4 packages. If this option is specified multiple times, sources are searched in the order they appear on the command line. If both `-b` and `-d` are specified, `-d` sources are searched first. For a description of supported bundles and how they are used, refer to the `generate` subcommand above.

-d *source*

Add the specified directory to the list of sources to search when looking for files in the manifest. If this option is specified multiple times, sources are searched in the order they appear on the command line. For a description of supported sources and how they are used, refer to the `generate` subcommand above.

-s *repo_uri_or_path*

Publish the package to the repository located at the given URI or file system path. See the “Notes” section below for more information about restrictions and suggestions for publication. See also the “Environment Variables” section.

`--no-catalog`

Do not add the package to the publisher's catalog. This option is recommended whenever multiple packages are being published at one time as updates to publisher catalogs must be performed serially. Once publication is complete, the `refresh` subcommand of `pkgrepo` can be used to add the new packages to the respective publisher catalogs.

For a descriptions of the `-T` option, see the `generate` subcommand above.

Environment Variables `PKG_REPO` The path or URI of the destination repository.

Examples **EXAMPLE 1** Generate and Publish a Package

Create a package using `pkgsend generate` and publish it.

```
$ pkgsend generate /path/to/proto > /path/to/manifests/foo.p5m
```

Add the package FMRI for the `example.com` publisher to the beginning of `foo.p5m`.

```
set name=pkg.fmri value=pkg://example.com/foo@1.0
```

The resulting manifest should look like this:

```
set name=pkg.fmri value=pkg://example.com/foo@1.0
dir group=sys mode=0755 owner=root path=usr
dir group=bin mode=0755 owner=root path=usr/bin
file usr/bin/foo group=bin mode=0555 owner=root path=usr/bin/foo

$ pkgsend publish -s http://example.com:10000 -d /path/to/proto \
/path/to/manifests/foo.p5m
```

EXAMPLE 2 Create and Publish a Trivial Package

Create a manifest for publisher `example.com` containing the following lines:

```
set name=pkg.fmri value=pkg://example.com/foo@1.0-1
file /exdir/foo mode=0555 owner=root group=bin path=/usr/bin/foo
```

Publish the package:

```
$ pkgsend publish -s http://example.com:10000 -d /exdir
```

EXAMPLE 3 Use a Preexisting Manifest

Publish a package using file system based publication and a preexisting manifest.

```
$ pkgsend publish -s /tmp/example_repo -d /tmp/pkg_files \
/tmp/pkg_manifest
```

Exit Status The following exit values are returned:

`0` Command succeeded.

- 1 An error occurred.
- 2 Invalid command line options were specified.
- 99 An unanticipated exception occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability | package/pkg |
| Interface Stability | Uncommitted |

See Also [pkgdepend\(1\)](#), [pkgrepo\(1\)](#), [pkg.depotd\(1M\)](#), [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

Notes Because of publication protocol limitations, file system based publication must be used when publishing individual package files that are greater than 128 MB in size. File system based publication is also recommended when access control for a repository is needed.

When using file system based publication, any `pkg.depotd` processes that are serving the target repository must be restarted after publication is completed for the changes to be reflected in its web interface or search responses. See `pkg.depotd(1M)` for more information.

Name pkgsign – Image Packaging System signing utility

Synopsis /usr/bin/pkgsign [-a *hash_algorithm*]
[-c *path_to_signing_certificate*]
[-i *path_to_intermediate_cert*] ...
[-k *path_to_private_key*] [-n] -s *path_or_uri*
[- -help] [- -no-index] [- -no-catalog]
(*fmri|pattern*) ...

Description pkgsign updates the manifest for the given FMRI in place in the repository by adding a signature action using the provided key and certificates. The modified package retains the original timestamp.

Options The following options are supported:

- -help

Display a usage message.

-a *hash_algorithm*

Use the signature algorithm *hash_algorithm* instead of the default. The default signature algorithm is *rsa-sha256*. Supported signature algorithms are *rsa-sha256*, *rsa-sha384*, *rsa-sha512*, *sha256*, *sha384*, and *sha512*. A signature algorithm that only specifies a hash algorithm causes the signature value to be the hash of the manifest of the package. A signature algorithm that specifies *rsa* and a hash algorithm causes the signature value to be the hash of the manifest signed with the private key provided (see the *-c* and *-k* options).

-c *path_to_signing_certificate*

Add the certificate *path_to_signing_certificate* as the certificate to use when verifying the value of the signature in the action. The *-c* option can only be used with the *-k* option.

-i *path_to_intermediate_cert*

Add the certificate *path_to_intermediate_cert* as a certificate to use when validating the certificate *path_to_signing_certificate* given as an argument to *-c*. Multiple certificates can be provided by specifying *-i* multiple times.

-k *path_to_private_key*

Use the private key stored in *path_to_private_key* to sign the manifest. The *-k* option can only be used with the *-c* option. If *-k* is not set, then the signature value is the hash of the manifest.

-n

Perform a trial run that does not change the repository in any way.

-s *path_or_uri*

Sign packages in the repository at *path_or_uri*.

- -no-index

Do not update the repository search indexes after the signed manifest has been republished.

--no-catalog

Do not update the repository catalog after the signed manifest has been republished.

Examples EXAMPLE 1 Sign Using the Hash Value of the Manifest

Sign a package published to `http://localhost:10000` using the hash value of the manifest. This is often useful for testing.

```
$ pkgsign -s http://localhost:10000 -a sha256 \
example_pkg@1.0,5.11-0:20100626T030108Z
```

EXAMPLE 2 Sign Using a Key and Certificate

Sign a package published into the file repository in `/foo/bar` using `rsa-sha384` to hash and sign the manifest. The signature key is in `/key/usr2.key`, its associated certificate is in `/key/usr2.cert`, and a certificate needed to validate the certificate is in `/icerts/usr1.cert`.

```
$ pkgsign -s file:///foo/bar/ -a rsa-sha384 \
-k /key/usr2.key -c /key/usr2.cert -i /icerts/usr1.cert \
example_pkg@1.0,5.11-0:20100626T031341Z
```

Exit Status The following exit values are returned:

- 0 Command succeeded.
- 1 An error occurred.
- 2 Invalid command line options were specified.
- 3 Multiple operations were requested, but only some of them succeeded.
- 99 An unanticipated exception occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | package/pkg |
| Interface Stability | Uncommitted |

See Also [pkg\(1\)](#), [pkgreceive\(1\)](#), [pkgsend\(1\)](#), [pkgrepo\(1\)](#), [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

Name pkgtrans – translate package format

Synopsis pkgtrans [-inosg] [-k *keystore*] [-a *alias*] [-P *passwd*] *device1 device2*
[*pkginst*]...

Description The pkgtrans utility translates an installable package from one format to another. It translates:

- a file system format to a datastream
- a file system format to a signed datastream
- a datastream to a file system format
- one file system format to another file system format

Options The options and arguments for this command are:

- a *alias* Use public key certificate associated with friendlyName *alias*, and the corresponding private key. See KEYSTORE LOCATIONS and KEYSTORE AND CERTIFICATE FORMATS in [pkgadd\(1M\)](#) for more information.
- g Sign resulting datastream.
- i Copies only the [pkginfo\(4\)](#) and [pkgmap\(4\)](#) files.
- k *keystore* Use keystore to retrieve private key used to generate signature. If it not specified, default locations are searched to find the specified private key specified by -a. If no alias is given, and multiple keys exist in the key store, pkgtrans will abort. See KEYSTORE LOCATIONS and KEYSTORE AND CERTIFICATE FORMATS in [pkgadd\(1M\)](#) for more information on search locations and formats.

When running as a user other than root, the default base directory for certificate searching is ~/ .pkg/security, where ~ is the home directory of the user invoking pkgtrans.
- n Creates a new instance of the package on the destination device if any instance of this package already exists, up to the number specified by the MAXINST variable in the [pkginfo\(4\)](#) file.
- o Overwrites the same instance on the destination device. Package instance will be overwritten if it already exists.
- P *passwd* Supply password used to decrypt the keystore. See PASS PHRASE ARGUMENTS in [pkgadd\(1M\)](#) for details on the syntax of the argument to this option.
- s Indicates that the package should be written to *device2* as a datastream rather than as a file system. The default behavior is to write a file system format on devices that support both formats.

- Operands**
- device1* Indicates the source device. The package or packages on this device will be translated and placed on *device2*. See DEVICE SPECIFIERS, below.
 - device2* Indicates the destination device. Translated packages will be placed on this device. See DEVICE SPECIFIERS, below.
 - pkginst* Specifies which package instance or instances on *device1* should be translated. The token `all` may be used to indicate all packages. `pkginst.*` can be used to indicate all instances of a package. If no packages are defined, a prompt shows all packages on the device and asks which to translate.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, the * must be surrounded by single quotes (') or preceded by a backslash (\).

Device Specifiers Packaging tools, including `pkgtrans`, `pkgadd(1M)`, and `pkgchk(1M)`, have options for specifying a package location by specifying the device on which it resides. Listed below are the device types that a package can be stored to and retrieved from. Note that source and destination devices cannot be the same.

- device** Packages can be stored to a character or block device by specifying the device identifier as the device. A common example of this device type is `/dev/rmt/0` for a removable magnetic tape. `pkgtrans` can also produce regular file system files in a stream format, which is suitable for storage on a character device, web server, or as input to `pkgadd(1M)`.
- directory** Packages can be stored onto a directory by specifying an absolute path to a file system directory. The package contents reside in a directory within the specified directory. The package directory name must be identical to its PKG specification in the `pkginfo(4)` file. An example device specification of this type is `/export/packages`.

Examples **EXAMPLE 1** Translating Packages on /tmp

The following example translates packages `pkg1` and `pkg2` on `/tmp` into a datastream format:

```
example% pkgtrans -s /tmp /tmp/datastream.pkg pkg1 pkg2
```

EXAMPLE 2 Creating a Signed Package

The following example creates a signed package from `pkg1` and `pkg2`, and reads the password from the `$PASS` environment variable:

```
example% pkgtrans -sg -k /tmp/keystore.p12 -a foo \
-p env:PASS /tmp /tmp/signedpkg pkg1 pkg2
```

EXAMPLE 3 Translating a Package Datastream

The following example translates a package datastream into a file system format package:

```
example% pkgtrans /tmp/pkg1.pkg ~/tmp pkg1
```

Environment Variables The MAXINST variable is set in the [pkginfo\(4\)](#) file and declares the maximum number of package instances.

Exit Status 0 Successful completion.
>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | package/svr4 |
| Interface Stability | Committed |

See Also [pkginfo\(1\)](#), [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgproto\(1\)](#), [installf\(1M\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgrm\(1M\)](#), [removef\(1M\)](#), [pkginfo\(4\)](#), [pkgmap\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Application Packaging Developer's Guide

Notes By default, `pkgtrans` does not translate any instance of a package if any instance of that package already exists on the destination device. Using the `-n` option creates a new instance if an instance of this package already exists. Using the `-o` option overwrites an instance of this package if it already exists. Neither of these options are useful if the destination device is a datastream.

Package commands are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), `pkgtrans` and other package commands can process a datastream of up to 4 GB.

Name pklogin_finder – map certificates into a user

Synopsis /usr/lib/pam_pkcs11/pklogin_finder [debug] [config_file=*filename*]

Description pklogin_finder uses the pam_pkcs11 library infrastructure to interactively map a PKCS#11 provided certificate to a user.

pklogin_finder uses the same configuration file and arguments than [pam_pkcs11\(5\)](#) PAM module. It loads defined mapper modules and tries to find a map between found certificates and a user login.

Options The following options are supported:

`config_file=fileame` Set the configuration file.

The default value is
/etc/security/pam_pkcs11/pam_pkcs11.conf.

`debug` Enable debugging output.

The default is no debug.

As it uses the same configuration file as [pam_pkcs11\(5\)](#), all of the pam_pkcs11 options are available. Some of these options make no sense in a non-PAM environment, and are therefore ignored. Some mapper options (`mapfile`, `ignorecase`) have no effect on certificate contents, and they are ignored as well.

Exit Status The following exit values are returned:

0 Successful completion.

pkcs11_inspect prints on stdout the login name and exits.

1 An error occurred.

A user mapping error was found.

2 An error occurred.

No user match was found.

Examples EXAMPLE 1 Using pklogin_finder

The following example runs the pklogin_finder command without any options:

```
% pkcs11_inspect
```

EXAMPLE 2 Using pklogin_finder with Options

The following example runs the pkcs_finder command with options:

```
% pklogin_finder debug config_file=${HOME}/.pam_pkcs11.conf
```

Files /etc/security/pam_pkcs11/pam_pkcs11.conf

Authors Juan Antonio Martinez, jonsito@teleline.es

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--|
| Availability | library/security/pam/module/pam-pkcs11 |
| Interface Stability | Uncommitted |

PAM-PKCS11 User Manual, http://www.opensc-project.org/pam_pkcs11

Name pktool – manage certificates and keys

Synopsis pktool [-f *option_file*] [-i] *subcommand subcommand_options ...*

Description The pktool command allows users to manage the certificates and keys on multiple keystores including PKCS#11 tokens (that is, Cryptographic Framework), Netscape Security Services (NSS) tokens, and standard file based keystore for OpenSSL.

pktool also provides support to list, delete and import a Certificate Revocation List (CRL). pktool does not provide support for creating CRLs, signing CRLs, or exporting CRLs. The CRL support for the PKCS#11 keystore is file-based.

Options The following command options are supported:

-f *option_file*

Allows the user to set up the options in a file instead of entering the options on the command line.

This option is provided as a convenience for users because pktool can potentially have a large list of subcommands and associated options to be specified on the command line.

The format of the *option_file* is one option or value pair per-line.

An example *option_file* might look as follows:

```
list
keystore=nss
dir=/export/foo
objtype=key
```

-i

Allows the user to specify the subject -DN interactively for the gencert and gencsr subcommands. When -i is specified, the user is prompted to input some data to form a subject-DN.

An example of using the -i option follows:

```
Country Name (2 letter code) [US]:US
State or Province Name (full name) [Some-State]:CA
Locality Name (eg, city) []:Menlo Park
Organization Name (eg, company):Sun Microsystems Inc.
Organizational Unit Name (eg, section):OPG
Common Name (eg, YOUR name):John Smith
Email Address []: john.smith@sun.com
```

The resulting subject -DN is:

```
"C=US, ST=CA, L=Menlo Park, O=Sun Microsystems Inc., \
OU=OPG, emailAddress=john.smith@sun.com, \
CN=John Smith"
```

Subcommands The following subcommands are supported:

delete

The format for the delete subcommand is as follows:

```
pktool delete [token=token[:manuf[:serial]]]  
              [objtype=private|public|both]  
              [label=object-label]  
  
pktool delete keystore=pkcs11  
              objtype=cert[:public | private | both]  
              [token=token[:manuf[:serial]]]  
              [label=cert-label]  
              [serial=hex-serial-number]  
              [issuer=issuer-DN]  
              [subject=subject-DN]  
  
pktool delete keystore=nss  
              objtype=cert  
              [subject=subject-DN]  
              [issuer=issuer-DN]  
              [serial=hex-serial-number]  
              [nickname=cert-nickname]  
              [token=token[:manuf[:serial]]]  
              [dir=directory-path]  
              [prefix=DBprefix]  
  
pktool delete keystore=nss  
              objtype=crl  
              [nickname=cert-nickname]  
              [subject=subject-DN]  
              [token=token[:manuf[:serial]]]  
              [dir=directory-path]  
              [prefix=DBprefix]  
  
pktool delete keystore=pkcs11  
              objtype=key[:public | private | both]  
              [token=token[:manuf[:serial]]]  
              [label=key-label]  
  
pktool delete keystore=pkcs11  
              objtype=crl  
              infile=input-fn  
  
pktool delete keystore=file  
              objtype=cert  
              [infile=input-fn]  
              [dir=directory-path]  
              [serial=hex-serial-number]  
              [issuer=issuer-DN]
```

```
[subject=subject-DN]
```

```
pktool delete keystore=file
               objtype=key
               [infile=input-fn]
               [dir=directory-path]
```

```
pktool delete keystore=file
               objtype=crl
               infile=input-fn
```

Deletes a certificate, key, or certificate revocation list (CRL).

To delete a private certificate or key from PKCS#11 token, the user is prompted to authenticate to the PKCS#11 by entering the correct Personal Identification Number (PIN).

download

The format for the download subcommand is as follows:

```
pktool download url=url_str
                 [objtype=crl|cert]
                 [http_proxy=proxy_str]
                 [outfile=output-fn]
                 [dir=directory-path]
```

Downloads a CRL file or a certificate file from the specified URL location. Once the file is successfully downloaded, checks the validity of the downloaded CRL or certificate file. If the CRL or the certificate is expired, download issues a warning.

export

The format for the export subcommand is as follows:

```
pktool export [token=token[:manuf[:serial]]]
              outfile=output-fn
```

```
pktool export keystore=pkcs11
               outfile=output-fn
               [objtype=cert|key]
               [label=label]
               [subject=subject-DN]
               [issuer=issuer-DN]
               [serial=hex-serial-number]
               [outformat=pem|der|pkcs12|raw]
               [token=token[:manuf[:serial]]]
```

```
pktool export keystore=nss
               outfile=output-fn
               [subject=subject-DN]
               [issuer=issuer-DN]
```

```

[serial=hex-serial-number]
[nickname=cert-nickname]
[token=token[:manuf[:serial]]]
[dir=directory-path]
[prefix=DBprefix]
[outputformat=pem|der|pkcs12]

```

```

pktool export keystore=file
certfile=cert-input-fn
keyfile=key-input-fn
outfile=output-pkcs12-fn

```

Saves the contents of PKCS#11 token or certificates in the NSS token or file-based keystore to the specified file.

gencert

The format for the gencert subcommand is as follows:

```

pktool gencert [-i] keystore=nss
label=cert-nickname
subject=subject-DN
serial=hex_serial_number
[altname=[critical:]subjectAltName,subjectAltName...]
[keyusage=[critical:]usage,usage...]
[token=token[:manuf[:serial]]]
[dir=directory-path]
[prefix=DBprefix]
[keytype=rsa | ec [curve=ECC Curve Name] \
[hash= md5 | sha1 | sha224 | sha256 | sha384 | sha512]]
[keytype=dsa [hash=sha1 | sha224 ]]
[keylen=key-size]
[trust=trust-value]
[eku=[critical:]EKU_name,...]
[listcurves ]
[lifetime=number-hour|number-day|number-year]

```

```

pktool gencert [-i] [ keystore=pkcs11]
label=key/cert-label
subject=subject-DN
serial=hex_serial_number
[altname=[critical:]subjectAltName,subjectAltName...]
[keyusage=[critical:]usage,usage...]
[token=token[:manuf[:serial]]]
[ keytype=rsa | ec [curve=ECC Curve Name] \
[hash=md5 | sha1 | sha224 | sha256 | sha384 | sha512]]
[ keytype=dsa [hash=sha1 | sha224 | sha256 ]]
[keylen=key-size]
[eku=[critical:]EKU_name,...]
[listcurves]

```

```
[lifetime=number-hour|number-day|number-year]
```

```
pktool gencert [-i] keystore=file
                outcert=cert-fn
                outkey=key-fn
                subject=subject-DN
                serial=hex_serial_number
                [altname=[critical:]subjectAltName,subjectAltName...]
                [keyusage=[critical:]usage,usage...]
                [format=der|pem]
                [ keytype=rsa [hash=md5 | sha1 | sha224 | sha256 | sha384 | sha512]]
                [ keytype=dsa [hash=sha1 | sha224 | sha256 ]]
                [keylen=key-size]
                [eku=[critical:]EKU_name,...]
                [lifetime=number-hour|number-day|number-year]
```

Generates a self-signed certificate and installs it and its associated private key to the specified keystore.

gencert prompts the user to enter a PIN for token-based keystore.

gencsr

The format for the gencsr subcommand is as follows:

```
pktool gencsr [-i] keystore=nss
                nickname=key-nickname
                outcsr=csr-fn
                subject=subject-DN
                [altname=[critical:]subjectAltName,subjectAltName...]
                [keyusage=[critical:]usage,usage...]
                [token=token[:manuf[:serial]]]
                [dir=directory-path]
                [prefix=DBprefix]
                [keytype=rsa | ec [curve=ECC Curve Name] \
                [hash= md5 | sha1 | sha224 | sha256 | sha384 | sha512]
                [keytype=dsa [hash=sha1 | sha224]
                [keylen=key-size]
                [format=pem|der]
                [eku=[critical:]EKU_name,...]
                [listcurves]
```

```
pktool gencsr [-i] keystore=pkcs11
                label=key-label
                outcsr=csr-fn
                subject=subject-DN
                [altname=[critical:]subjectAltName,subjectAltName...]
                [keyusage=[critical:]usage,usage...]
                [token=token[:manuf[:serial]]]
                [ keytype=rsa | ec [curve=ECC Curve Name] \
```

```

[hash=md5 | sha1 | sha224 | sha256 | sha384 | sha512]]
[keylen=key-size]
[format=pem|der]
[eku=[critical:]EKU_name,...]
[listcurves]

```

```

pktool gensr [-i] keystore=file
outcsr=csr-fn
outkey=key-fn
subject=subject-DN
[altname=[critical:]subjectAltName,subjectAltName...]
[keyusage=[critical:]usage,usage...]
[dir=directory-path]
[ keytype=rsa [hash=md5 | sha1 | sha224 | sha256 | sha384 | sha512]]
[ keytype=dsa [hash=sha1 | sha224 | sha256 ]]
[keylen=key-size]
[format=pem|der]
[eku=[critical:]EKU_name,...]

```

Creates a PKCS#10 certificate signing request (CSR) file. This CSR can be sent to a Certifying Authority (CA) for signing. The `gensr` subcommand prompts the user to enter a PIN for token-based keystore.

genkey

The format for the `genkey` subcommand is as follows:

```

pktool genkey [keystore=pkcs11]
label=key-label
[keytype=aes|arcfour|des|3des|generic]
[keylen=key-size (for aes, arcfour, or \
generic keytypes only)]
[token=token[:manuf[:serial]]]
[sensitive=y|n]
[extractable=y|n]
[print=y|n]

```

```

pktool genkey keystore=nss
label=key-label
[keytype=aes|arcfour|des|3des|generic]
[keylen=key-size (for aes, arcfour, or \
generic keytypes only)]
[token=token[:manuf[:serial]]]
[dir=directory-path]
[prefix=DBprefix]

```

```

pktool genkey keystore=file
outkey=key-fn
[keytype=aes|arcfour|des|3des|generic]
[keylen=key-size (for aes, arcfour, \

```

```

    or generic keytypes only)]
    [print=y|n]

```

Generates a symmetric key in the specified keystore. The `genkey` subcommand prompts the user to enter a PIN for token-based keystore.

genkeypair

The format for the `genkeypair` subcommand is as follows:

```

pktool genkeypair keystore=nss
                  label=key-nickname
                  [token=token[:manuf[:serial]]]
                  [dir=directory-path]
                  [prefix=DBprefix]
                  [keytype=rsa|dsa|ec [curve=ECC Curve Name]]
                  [keylen=key-size]
                  [listcurves]

```

```

pktool genkeypair [keystore=pkcs11]
                  label=key-label
                  [token=token[:manuf[:serial]]]
                  [keytype=rsa|dsa|ec [curve=ECC Curve Name]]
                  [keylen=key-size]
                  [listcurves]

```

```

pktool genkeypair keystore=file
                  outkey=key_filename
                  [format=der|pem]
                  [keytype=rsa|dsa]
                  [keylen=key-size]

```

import

The format for the `import` subcommand is as follows:

```

pktool import [token=token>[:manuf>[:serial>]]]
              infile=input-fn

pktool import [keystore=pkcs11]
              infile=input-fn
              label=object-label
              [keytype=aes|arcfour|des|3des|generic]
              [sensitive=y|n]
              [extractable=y|n]
              [token=token[:manuf[:serial]]]
              [objtype=cert|key]

pktool import keystore=pkcs11
              objtype=crl
              infile=input-fn
              outcrl=output-crl-fn

```

```
        outformat=pem|der

pktool import keystore=nss
              objtype=cert
              infile=input-fn
              label=cert-label
              [token=token[:manuf[:serial]]]
              [dir=directory-path]
              [prefix=DBprefix]
              [trust=trust-value]

pktool import keystore=nss
              objtype=crl
              infile=input-fn
              [verifycrl=y|n]
              [token=token[:manuf[:serial]]]
              [dir=directory-path]
              [prefix=DBprefix]

pktool import keystore=file
              infile=input-fn
              outkey=output-key-fn
              outcert=output-key-fn
              [outformat=pem|der]

pktool import keystore=file
              objtype=crl
              infile=input-fn
              outcrl=output-crl-fn
              outformat=pem|der
```

Loads certificates, keys, or CRLs from the specified input file into the specified keystore.

`inittoken`

The format for the `inittoken` subcommand is as follows:

```
pktool inittoken [ slotid=slot number ]
                 [ currlabel=token[:manuf[:serial]]]
                 [ newlabel=new token label ]
```

This command initializes a PKCS#11 token using `C_InitToken` API. The preferred method of locating a token is to specify its default label. Optionally, a new label can be assigned to the token by using the `newlabel` argument. If `newlabel` is not present, the token label is not modified. The user is prompted to enter the security officer (SO) PIN for this command to proceed.

`list`

The format for the `list` subcommand is as follows:

```
pktool list [token=token[:manuf[:serial]]]
            [objtype=private|public|both]
```

```

        [label=label]

pktool list [keystore=pkcs11]
            [objtype=cert[:public | private | both]]
            [token=token[:manuf[:serial]]]
            [label=cert-label]
            [serial=hex-serial-number]
            [issuer=issuer-DN]
            [subject=subject-DN]

pktool list [keystore=pkcs11]
            objtype=key[:public | private | both]]
            [token=token[:manuf[:serial]]]
            [label=key-label]
            [keyvalue=y[n]]

pktool list keystore=pkcs11
            objtype=crl
            infile=input-fn

pktool list keystore=nss
            objtype=cert
            [subject=subject-DN]
            [issuer=issuer-DN]
            [serial=hex-serial-number]
            [nickname=cert-nickname]
            [token=token[:manuf[:serial]]]
            [dir=directory-path]
            [prefix=DBprefix]

pktool list keystore=nss
            objtype=key
            [token=token[:manuf[:serial]]]
            [dir=directory-path]
            [prefix=DBprefix]

pktool list keystore=file
            objtype=cert
            [infile=input-fn]
            [dir=directory-path]
            [serial=hex-serial-number]
            [issuer=issuer-DN]
            [subject=subject-DN]

pktool list keystore=file
            objtype=key
            [infile=input-fn]
            [dir=directory-path]
            [keyvalue=y[n]]

```

Lists certificates, list keys, or list certificate revocation lists (CRL). When displaying a private certificate or key in PKCS#11 token, the user is prompted to authenticate to the PKCS#11 token by entering the correct PIN.

setpin

The format for the `setpin` subcommand is as follows:

```
pktool setpin keystore=nss
    [token=token]
    [dir=directory-path]
    [prefix=DBprefix]

pktool setpin [ keystore=pkcs11]
    [token=token[:manuf[:serial]]]
    [usertype=user | so]
```

Changes the passphrase used to authenticate a user to the PKCS#11 or NSS token. Passphrases can be any string of characters with lengths between 1 and 256 with no nulls.

`setpin` prompts the user for the old passphrase, if any. If the old passphrase matches, `pktool` prompts for the new passphrase twice. If the two entries of the new passphrases match, it becomes the current passphrase for the token.

For the Sun Software PKCS#11 softtoken keystore (default), the user must use the `setpin` command with the default passphrase `changeme` as the old passphrase to change the passphrase of the object store. This action is needed to initialize and set the passphrase to a newly created token object store.

If the `usertype=so` option is specified for PKCS#11 based tokens, the Security Officer (SO) user PIN is changed as opposed to the normal user PIN. By default the `usertype` is assumed to be `user`.

signcsr

The format for the `signcsr` subcommand is as follows:

```
signcsr keystore=pkcs11
    signkey=label (label of key to use for signing)
    csr=CSR_filename
    serial=serial_number_hex_string_for_final_certificate
    outcert=filename_for_final_certificate
    issuer=issuer-DN
    [store=y|n] (store the new cert in NSS DB, default=n)
    [outlabel=certificate label]
    [format=pem|der] (certificate output format)
    [subject=subject-DN] (override the CSR subject name)
    [altname=subjectAltName,subjectAltName...] (add subjectAltName )
    [keyusage=[critical:]usage,...] (add key usage bits)
    [eku=[critical:]EKU_Name,...] (add Extended Key Usage )
    [lifetime=number-hour|number-day|number-year]
```

```

        [token=token[:manuf[:serial]]]
signcsr keystore=file
        signkey=filename
        csr=CSR_filename
        serial=serial_number_hex_string_for_final_certificate
        outcert=filename_for_final_certificate
        issuer=issuer-DN
        [format=pem|der] (certificate output format)
        [subject=subject-DN] (override the CSR subject name)
        [altname=subjectAltName,subjectAltName...] (add a subjectAltName)
        [keyusage=[critical:]usage,...] (add key usage bits)
        [lifetime=number-hour|number-day|number-year]
        [eku=[critical:]EKU_Name,...] (add Extended Key Usage)
signcsr keystore=nss
        signkey=label (label of key to use for signing)
        csr=CSR_filename
        serial=serial_number_hex_string_for_final_certificate
        outcert=filename_for_final_certificate
        issuer=issuer-DN
        [store=y|n] (store the new cert in NSS DB, default=n)
        [outlabel=certificate label]
        [format=pem|der] (certificate output format)
        [subject=subject-DN] (override the CSR subject name)
        [altname=subjectAltName,subjectAltName...] (add a subjectAltName)
        [keyusage=[critical:]usage,...] (add key usage bits)
        [eku=[critical:]EKU_Name,...] (add Extended Key Usage)
        [lifetime=number-hour|number-day|number-year]
        [token=token[:manuf[:serial]]]
        [dir=directory-path]
        [prefix=DBprefix]

```

tokens

The format for the tokens subcommand is as follows:

```
pktool tokens
```

The tokens subcommand lists all visible PKCS#11 tokens.

-?

The format for the subcommand is as follows:

```
pktool -?
pktool --help
```

The -? option displays usage and help information. --help is a synonym for -?.

Usage The pktool subcommands support the following options:

`altname=[critical:]subjectAltName,subjectAltName...`

Subject Alternative Names the certificate. The argument that follows the `altname` option should be in the form of `tag=value`. Valid tags are IP, DNS, EMAIL, URI, DN, KRB, UPN, and RID. The `SubjectAltName` extension is marked as `critical` if the `altname` string is pre-pended with the word `critical`.

The `critical` flag is shared by all the `altnames`, and should be placed at the beginning of the first subject alternative name.

The delimiter between `altname` tags (for example, IP, EMAIL, DN, and so forth) is a comma (,). The delimiter between components in the DN type is a semicolon (;).

Example 1: Add an IP address to the `subjectAltName` extension. `altname="IP=1.2.3.4"`

Example 2: Add an email address to the `subjectAltName` extension, and mark it as being `critical`. `altname="critical:EMAIL=first.last@company.com"`

Example 3: Add multiple subject alternative names IP address, email address and distinguished name to the `subjectAltName` extension, and mark it as being `critical`.

```
altname="critical:IP=1.2.3.4,EMAIL=first.last@company.com,\
DN=C=US;O=Oracle;OU=Security;CN=John Smith"
```

`currlabel=token label`

This option is only used by the `inittoken` command. This is used to locate the default token that is being initialized. See the `token` option for details about the format of the token name to be used.

`curve=Elliptic_Curve_Name`

This option is for specifying the Elliptic Curve parameters to be used when generating an X.509 certificate or certificate signing request or when generating an Elliptic Curve keypair.

The following named curves are supported:

```
secp112r1, secp112r2, secp128r1, secp128r2, secp160k1
secp160r1, secp160r2, secp192k1, secp192r1, secp224k1
secp224r1, secp256k1, secp256r1, secp384r1, secp521r1
sect113r1, sect113r2, sect131r1, sect131r2, sect163k1
sect163r1, sect163r2, sect193r1, sect193r2, sect233k1
sect233r1, sect239k1, sect283k1, sect283r1, sect409k1
sect409r1, sect571k1, sect571r1, c2pnb163v1, c2pnb163v2
c2pnb163v3, c2pnb176v1, c2tnb191v1, c2tnb191v2, c2tnb191v3
c2pnb208w1, c2tnb239v1, c2tnb239v2, c2tnb239v3, c2pnb272w1
c2pnb304w1, c2tnb359v1, c2pnb368w1, c2tnb431r1, prime192v2
prime192v3
```

The list of named curves can also be seen by using the `listcurves` option with the `gencert`, `gencsr`, or `genkeypair` subcommands.

dir=directory_path

Specifies the NSS database directory, or OpenSSL keystore directory where the requested object is stored.

eku=[critical:]EKU_Name,[critical:]EKU_Name, ...]

Specifies the extended key usage X.509v3 extension values to add to the certificate or certificate request.

Specify *EKU_Name* as one of the following: `serverAuth`, `clientAuth`, `codeSigning`, `emailProtection`, `ipsecEndSystem`, `ipsecTunnel`, `ipsecUser`, `timeStamping`, `OCSPSigning`, `KPClientAuth`, `KPKdc`, or `scLogon`.

An example is:

```
eku=KPClientAuth,clientAuth
```

extractable=y | n

Specifies the resulting symmetric key in the PKCS#11 token is extractable or not extractable. The valid values are: `y` and `n`. The default value is `y`.

format=pem | der | pkcs12

For the `gencert` subcommand, this option only applies to the file based keystore such as OpenSSL. It is used to specify the output format of the key or certificate file to be created. The valid formats are: `pem` or `der`. The default format is `pem`.

For the `gencsr` subcommand, this option specifies the output encoded format of the CSR file. The valid formats are: `pem` or `der`. The default format is `pem`.

hash=md5 | sha1 | sha224 | sha256 | sha384 | sha512

For the `gencert` and `gencsr` subcommands, this option allows the caller to specify the hash algorithm to be use for generating the X.509 certificate signature. This can be used when creating EC or RSA based certificates using the NSS or PKCS#11 keystores. Elliptic Curve support is not available when using the OpenSSL file-based keystore.

infile=input-fn

Specifies the certificate filename for `list` and `delete` subcommands when `objtype=cert` and `keystore=file`. For the `import` subcommand, this option specifies the filename to be imported. Specifies the input CRL filename for `list`, `delete` and `import` subcommands when `objtype=crl`.

issuer=issuer-DN

Specifies the issuer of a certificate.

keylen=key-size

Specifies the size (bits) of the private or symmetric key to generate.

For the `gencert` and `gencsr` subcommands, the default key length is 1024 bits.

For the `genkey` subcommand, the minimum and maximum bits of the symmetric key to generate using AES algorithm are 128 and 256. Using the ARCFOUR algorithm, the

minimum and maximum bits are 8 and 2048. The minimum bits for a generic secret key is 8 and the maximum bits is arbitrary. The default key length for the AES, ARCFOUR or generic secret keys is 128. For a DES key or a 3DES key, the key length is fixed and this option is ignored if specified.

`keystore=nss | pkcs11 | file`

Specifies the type of the underlying keystore: NSS token, PKCS#11 token, or file-based plugin.

`keytype=rsa | dsa | ec | aes | arcfour | des | 3des | generic`

Specifies the type of the private or symmetric key to generate.

For the `gencert` and `genscr` subcommands, the valid private key types are: `rsa`, `ec` or `dsa`. The default key type is `rsa`.

For the `genkey` subcommand, the valid symmetric key types are: `aes`, `arcfour`, `des`, `3des`, or `generic`. The default key type is `aes`.

`keyusage=[critical:]usage,usage,usage,...`

Key Usage strings:

- * `digitalSignature`
- * `nonRepudiation`
- * `keyEncipherment`
- * `dataEncipherment`
- * `keyAgreement`
- * `keyCertSign`
- * `cRLSign`
- * `encipherOnly`
- * `decipherOnly`

Example 1: Set the `KeyUsage` so that the `cert` (or `csr`) can be used for signing and verifying data other than certificates or CRLs (`digitalSignature`) and also can be used for encrypting and decrypting data other than cryptographic keys (`dataEncipherment`).

`keyusage=digitalSignature,dataEncipherment`

Example 2: The same as above (Example 1), but with the critical bit set.

`keyusage=critical:digitalSignature,dataEncipherment`

`keyvalue=y | n`

This option displays the key value in hex format for the symmetric keys in the file-based and PKCS#11 keystores. The valid values are `y` and `n`. The default value is `n`.

`label=key-label | cert-label`

For the `gencert` subcommand, this option specifies the label of the private key and self-signed certificate in the PKCS#11 token.

For the `genscr` subcommand, this option specifies the label of the private key in the PKCS#11 token.

For the `list` subcommand, this option specifies the label of the X.509 Certificate (when `objtype=key`) or the private key (when `objtype=cert`) in the PKCS#11 token to refine the list.

For the `delete` subcommand, this option specifies the label of the X.509 Certificate (when `objtype=key`) or the private key (when `objtype=cert`) to delete a designated object from the PKCS#11 token.

`listcurves`

This causes the list of supported Elliptic Curve names to be displayed. This option is only available with the `gencert`, `gencsr`, or `genkeypair` subcommands.

`lifetime=number-hour | number-day | number-year`

Specifies the validity period a certificate is valid. The certificate life time can be specified by *number-hour*, *number-day*, or *number-year*. Only one format can be specified. The default is 1-year. Examples of this option might be: `lifetime=1-hour`, `lifetime=2-day`, `lifetime=3-year`

`newlabel=token label`

This option is only used by the `inittoken` command. This is used to change the label assigned to the token that is being initialized. See the `token` option for details about the format of the token name to be used.

`nickname=cert-nickname`

For the `gencert` subcommand, this option is required to specify the certificate's nickname for NSS keystore.

For the `list` subcommand, this option specifies the nickname of the certificate in the NSS token to display its content. For the `delete` subcommand, to delete a CRL from the NSS token, this option is used to specify the nickname of the issuer's certificate. For the `delete` subcommand, to delete a certificate from the NSS token, this option specifies the nickname of the certificate. For the `import` subcommand, to import a specified input file to the NSS token, this option is required to specify the nickname of the resulting certificate.

`objtype=cert | key | crl`

Specifies the class of the object: `cert`, `key`, or `crl`. For the `download` subcommand, if this option is not specified, default to `crl`.

`objtype=public | private | both`

Specifies the type of object: private object, public object, or both. This option only applies to `list` and `delete` subcommands for the PKCS#11 token when `objtype=key` is specified. The default value is `public`.

For the `list` subcommand, the `label` option can be combined with this option to further refine the list of keys. For the `delete` subcommand, this option can be used to narrow the keys to be deleted to only public, or private ones. Alternately, the `label` option can be omitted to indicate that all public, private, or both type of keys are to be deleted. The use of `public`,

private and both as choices for the `objtype` parameter are only applicable with the PKCS#11 keystore in order to maintain compatibility with earlier versions of the `pktool` command.

`outcert=cert-fn`

Specifies the output certificate filename to write to. This option is required for the file based plugin such as OpenSSL. Option `outkey=key-fn` is required with this option.

`outcrl=output-crl-fn`

Specifies the output CRL filename to write to.

`outcsr=csr-fn`

Specifies the output CSR filename to write to.

`outfile=output-fn`

For the `export` subcommand, this option specifies the output filename to be created. For the `import` subcommand, this option specifies the output filename of the certificate or CRL. It only applies to the file based plugin such as OpenSSL. For the `download` subcommand, if this option is not specified, the downloaded file name is the basename of the URL string.

`outformat=pem | der | pkcs12`

For the `import` subcommand, this option specifies the output format of the certificate or key that is extracted from a specified PKCS#12 file into the file based plugin. The valid values are: `pem` or `der`. The default is `pem`. When importing a CRL to the CRL file based keystore, this option specifies the output format of the CRL. The valid values are: `pem` or `der`. The default is `der`. For the `export` subcommand, this option specifies the format of the specified output file to be created. The supported formats are: `pem`, `der` or `pkcs12`. The default is `pkcs12`.

`outkey=key-fn`

Specifies the output private key filename to which to write. This option is only required when using the files keystore.

`prefix=DBprefix`

Specifies the NSS database prefix. This option only applies to the NSS token.

`print=y | n`

This option is used in the `genkey` subcommand and it applies to the PKCS11 and File-based keystores. If `print=y`, the `genkey` subcommand prints out the key value of the generated key in a single line of hex. The default value is `n`. For the PKCS11 keystore, if a symmetric key is created with `sensitive=y` or `extractable=n`, the key value is not displayed, even the `print` option is set to `y`. The key is still created, but a warning like `cannot reveal the key value` is issued.

`sensitive=y | n`

Specifies the resulting symmetric key in the PKCS#11 token is sensitive or not sensitive. The valid values are: `y` and `n`. The default value is `n`.

`serial=hex-serial-number`

Specifies a unique serial number for a certificate. The serial number must be specified as a hex value. Example: `0x0102030405060708090a0b0c0d0e0f`

`subject=subject-DN`

Specifies a particular certificate owner for a certificate or certificate request. An example `subject=` setting might be:

```
subject=O=Sun Microsystems Inc., \
OU=Solaris Security Technologies Group, \
L=Ashburn, ST=VA, C=US, CN=John Smith
```

`token=token[:manuf[:serial]]`

When a token label contains trailing spaces, this option does not require them to be typed as a convenience to the user.

Colon separate token identification string `token:manuf:serial`. If any of the parts have a literal `: char` then it needs to be escaped using a backslash (`\`). If no `:` is found then the entire string (up to 32 chars) is taken as the token label. If only one `:` is found then the string is the token label and the manufacturer. When `keystore=nss` is specified, default to NSS internal token if this option is not specified. When `keystore=pkcs11` is specified, default to `pkcs11_soft` token if this option is not specified.

`trust=trust-value`

Specifies the certificate trust attributes. This is only for NSS certificates and that the standard NSS syntax applies.

`usertype=user | so`

Specifies the type of user for which the `setpin` command is being performed. The default is for a standard user, but `so` can be specified in order to set the PIN for the security officer of the token.

`url=url_string`

Specifies the URL to download a CRL or a certificate file.

`verifycrl=y | n`

When importing a CRL to NSS keystore, this option specifies whether the CRL verification is performed. The valid values are: `y` and `n`. The default value is `n`.

`http_proxy=proxy_str`

Specifies the proxy server hostname and port number. The format can be either `http://hostname[:port]` or `hostname[:port]`. If this option is not specified, the `download` subcommand checks the `http_proxy` environment variable. The command line option has a higher priority than the environment variable.

Examples EXAMPLE 1 Generating a Self-Signed Certificate

The following example creates the certificate and stores it in the keystore indicated in the command:

EXAMPLE 1 Generating a Self-Signed Certificate *(Continued)*

```
$ pktool gencert keystore=nss nickname=WebServerCert \
  subject="O=Sun Microsystems Inc., OU=Solaris Security Technologies Group, \
  L=Ashburn, ST=VA, C=US, CN=John Smith" dir=/etc/certs \
  keytype=rsa keylen=2048 hash=sha512
```

EXAMPLE 2 Generating a Certificate Signing Request

The following example creates the CSR and stores it in the keystore indicated in the command:

```
$ pktool gencsr keystore=nss subject="O=Sun Microsystems Inc., \
  OU=Solaris Security Technologies Group, L=Ashburn, ST=VA, C=US, \
  CN=John Smith" keytype=rsa keylen=2048 hash=sha256 outcsr=csr.dat
```

EXAMPLE 3 Importing a Certificate

The following example imports a certificate object from the specified input file into the keystore indicated in the command:

```
$ pktool import keystore=nss objtype=cert infile=mycert.pem \
  nickname=mycert
```

Exit Status The following exit values are returned:

- 0
Successful completion.
- >0
An error occurred.

Name plabel – get the label of a process

Synopsis /usr/bin/plabel [-sS] [*pid*...]

Description `plabel`, a `proc` tools command, gets the label of a process. If the *pid* is not specified, the label displayed is that of the `plabel` command. When options are not specified, the output format of the label is displayed in default format.

Options

- s Display the label that is associated with *pid* in short form.
- S Display the label that is associated with *pid* in long form.

Exit Status `plabel` exits with one of the following values:

- 0 Successful completion.
- 1 Unsuccessful completion because of a usage error.
- 2 Inability to translate label.
- 3 Inability to allocate memory.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/trusted |
| Interface Stability | See below. |

The `plabel` utility is Committed. The output is Not-an-Interface.

See Also [proc\(1\)](#), [getplabel\(3TSOL\)](#), [attributes\(5\)](#)

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name plgrp – observe and affect home lgroup and lgroup affinities of threads

Synopsis plgrp [-F] [-h] *pid* | *core* [/lwps] ...

plgrp [-F] -i *pid*[/lwps] ...

plgrp [-F] -a *lgroup_list* *pid*[/lwps] ...

plgrp [-F] [-I default | none | future]
-H *lgroup_list* *pid*[/lwps] ...

plgrp [-F] [-I default | none | future] -H *lgroup_list* -e *command* [*arguments*]

plgrp [-F] [-I default | none | future]
-A *lgroup_list*/none | weak | strong [,...] *pid*[/lwps] ...

plgrp [-F] [-I default | none | future]
-A *lgroup_list*/none | weak |strong [,...] -e *command* [*arguments*]

plgrp [-F] -I default | none | future *pid*[/lwps]

plgrp [-F] -I default | none | future -e *command* [*arguments*] ...

Description plgrp displays or sets the home lgroup and lgroup affinities for one or more processes, threads, or LWPs.

An lgroup represents the set of CPU and memory-like hardware devices that are at most some distance (latency) apart from each other. Each lgroup in the system is identified by a unique lgroup ID. The lgroups are organized into a hierarchy to facilitate finding the nearest resources. See `lgrpinfo(1)` for more about lgroups and the lgroup hierarchy.

By default, each thread is assigned a home lgroup upon creation. When the system needs to allocate a CPU or memory resource for a thread, it searches the lgroup hierarchy from the thread's home lgroup for the nearest available resources to the thread's home.

Typically, the home lgroup for a thread is the lgroup for which the thread has the most affinity. Initially, the system chooses a home lgroup for each thread, but leaves the thread's affinity for that lgroup set to none. If a thread sets a stronger affinity for an lgroup in its processor set other than its home, the thread is rehomed to that lgroup as long as the thread is not bound to a CPU. The thread can be re-homed to the lgroup in its processor set with the next highest affinity when the affinity (if any) for its home lgroup is removed (set to none).

The different levels of lgroup affinities and their semantics are fully described in [lgrp_affinity_set\(3LGRP\)](#).

Usage

Specifying lgroups *lgroup_list* is a comma separated list of one or more of the following:

- *lgroup_ID*
- Range of *lgroup_ID*s specified as
<start *lgroup_ID*>-<end *lgroup_ID*>

- all
- root
- leaves

The `all` keyword represents all `lgroup` IDs in the system. The `root` keyword represents the ID of the root `lgroup`. The `leaves` keyword represents the IDs of all leaf `lgroups`, that is, `lgroups` which do not have any children.

Specifying Processes and Threads

`plgrp` takes one or more space separated processes or threads as arguments. Processes and threads can be specified in a manner similar to the `proc(1)` tools. A process ID can be specified as an integer `pid` or `/proc/pid`. Shell expansions can be used to specify processes when `/proc/pid` is used. For example, `/proc/*` can be used to specify all the processes in the system. If a process ID is given alone, then all the threads of the process are included as arguments to `plgrp`.

A thread can be explicitly specified with its process ID and thread ID given together as `pid/lwpid`. Multiple threads of a process can be selected at once by using the hyphen (-) and comma (,). For example, `pid/1,2,7-9` specifies threads 1, 2, 7, 8, and 9 of the process with `pid` as its process ID.

Options The following options are supported:

- a *lgroup_list* Display `lgroup` affinities of specified processes or threads for the specified *lgroup_list*.
- A *lgroup_list/none|weak|strong[, . . .]* Set affinity of specified processes or threads for the specified *lgroup_list*.
A comma separated list of *lgroups/affinity* assignments can be given to set several affinities at once.
- F Force by grabbing the target process even if another process has control. Caution should be exercised when using the -F flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only when the primary controlling process (typically a debugger) has stopped the victim process, but isn't doing anything during the application of this `proc` tool. See **WARNINGS** for more details.
- e Create a new process, apply `plgrp` to that process, and execute the specified command and arguments.

| | |
|-----------------------------------|--|
| -h | Get home lgroup of specified processes and/or threads. If no options are specified, this is the default. |
| -H <i>lgroup_list</i> | Set home lgroup of specified processes and threads.

This sets a strong affinity for the desired lgroup to re-home the threads. If more than one lgroup is specified, plgrp tries to home the threads to the lgroups in a round robin fashion. |
| -i | Display lgroup affinity inheritance of the specified processes or threads. |
| -I <i>default none future</i> | Set lgroup affinity inheritance for the specified processes or threads. |

Operands The following operands are supported:

lwps Specifies thread. See USAGE.
pid Specifies process ID. See USAGE.

Examples EXAMPLE 1 Getting the Home lgroup for the Shell

The following example gets the home lgroup for the shell:

```
% plgrp $$
PID/LWPID  HOME
3401/1     1
```

EXAMPLE 2 Setting the Home lgroup of Multiple Threads to the Root lgroup

The following example sets the home lgroup of multiple threads to the root lgroup:

```
% plgrp -H root 'pgrep firefox'
PID/LWPID  HOME
918/1      1 => 0
934/1      2 => 0
934/2      1 => 0
934/3      2 => 0
934/625    1 => 0
934/626    2 => 0
934/624    2 => 0
934/623    2 => 0
934/630    1 => 0
```

EXAMPLE 3 Executing plgrp with Root lgroup as the Home lgroup of Multiple Threads

The following example executes `firefox` with `root` as the home lgroup of multiple threads:

```
% plgrp -H root -e /usr/bin/firefox
```

EXAMPLE 4 Getting Two Threads' Affinities for lgroups 0-2

The following example gets two threads' affinities for lgroups 1–2:

```
% plgrp -a 0-2 101398/1 101337/1
PID/LWPID   HOME   AFFINITY
101398/1     1      0-2/none
101337/1     1      0-2/none
```

EXAMPLE 5 Setting lgroup Affinities

The following example sets lgroup affinities:

```
% plgrp -A 0/weak,1/none,2/strong 101398
PID/LWPID   HOME      AFFINITY
101398/1     1 => 2     0,2/none => 2/strong,0/weak
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Syntax error. Nothing was changed.
- 2 Non-fatal error or interrupt. Something might have changed.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/core-os |
| Interface Stability | See below. |

The command syntax and output formats are Uncommitted.

See Also [lgrpinfo\(1\)](#), [madv.so.1\(1\)](#), [pmadvise\(1\)](#), [pmap\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [prstat\(1M\)](#), [lgrp_affinity_get\(3LGRP\)](#), [lgrp_affinity_set\(3LGRP\)](#), [lgrp_affinity_inherit_get\(3LGRP\)](#), [lgrp_affinity_inherit_set\(3LGRP\)](#), [lgrp_home\(3LGRP\)](#), [liblgrp\(3LIB\)](#), [proc\(4\)](#), [attributes\(5\)](#)

Warnings Like the [proc\(1\)](#) tools, the `plgrp` utility stops its target processes while inspecting them and reports the results when invoked with any option.

There are conditions under which processes can deadlock. A process can do nothing while it is stopped. Stopping a heavily used process in a production environment (even for a short amount of time) can cause severe bottlenecks and even hangs of these processes, making them to be unavailable to users. Thus, stopping a UNIX process in a production environment should be avoided. See [proc\(1\)](#).

A process that is stopped by this tool might be identified by issuing the following command:

```
/usr/bin/ps -efLL
```

and looking for a T in the first column of the output. Certain processes, for example, sched, can show the T status by default most of the time.

Name plimit – get or set the resource limits of running processes

Synopsis plimit [-km] *pid*...
 plimit {-cdfnstv} *soft,hard*... *pid*...

Description If one or more of the *cdfnstv* options is specified, *plimit* sets the soft (current) limit and/or the hard (maximum) limit of the indicated resource(s) in the processes identified by the process-ID list, *pid*. Otherwise *plimit* reports the resource limits of the processes identified by the process-ID list, *pid*.

Only the owner of a process or the super-user is permitted either to get or to set the resource limits of a process. Only the super-user can increase the hard limit.

Options The following options are supported:

- k On output, show file sizes in kilobytes (1024 bytes) rather than in 512-byte blocks.
- m On output, show file and memory sizes in megabytes (1024*1024 bytes).

The remainder of the options are used to change specified resource limits. They each accept an argument of the form:

soft,hard

where *soft* specifies the soft (current) limit and *hard* specifies the hard (maximum) limit. If the hard limit is not specified, the comma may be omitted. If the soft limit is an empty string, only the hard limit is set. Each limit is either the literal string *unlimited*, or a number, with an optional scaling factor, as follows:

nk *n* kilobytes
nm *n* megabytes (minutes for CPU time)
nh *n* hours (for CPU time only)
mm:ss minutes and seconds (for CPU time only)

The soft limit cannot exceed the hard limit.

- c *soft,hard* Set core file size limits (default unit is 512-byte blocks).
- d *soft,hard* Set data segment (heap) size limits (default unit is kilobytes).
- f *soft,hard* Set file size limits (default unit is 512-byte blocks).
- n *soft,hard* Set file descriptor limits (no default unit).
- s *soft,hard* Set stack segment size limits (default unit is kilobytes).
- t *soft,hard* Set CPU time limits (default unit is seconds).
- v *soft,hard* Set virtual memory size limits (default unit is kilobytes).

Operands The following operands are supported.

pid Process ID list.

Exit Status p-limit returns the exit value zero on success, non-zero on failure (such as no such process, permission denied, or invalid option).

Files /proc/pid/* process information and control files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | system/core-os |

See Also [ulimit\(1\)](#), [proc\(1\)](#), [getrlimit\(2\)](#), [setrlimit\(2\)](#), [proc\(4\)](#), [attributes\(5\)](#),

Name pmapadvise – applies advice about memory to a process

Synopsis pmapadvise -o *option*[,*option*] [-F] [-l] [-v] *pid*...

Description pmapadvise applies advice about how memory is used in the specified process using [madvise\(3C\)](#).

pmapadvise allows users to apply advice to a specific sub-range at a specific instant in time. pmapadvise differs from [madv.so.1\(1\)](#) in that [madv.so.1\(1\)](#) applies the advice throughout execution of the target program to all segments of a specified type.

Options The following options are supported:

-F Force by grabbing the target process even if another process has control.

You should exercise caution when using the -F option. See [proc\(1\)](#).

-l Show unresolved dynamic linker map names.

-o Specify advice to apply in the following form:

```
private=advice
shared=advice
heap=advice
stack=advice
address[:length]=advice
```

where the `advice` can be one of the following:

```
normal
random
sequential
willneed
dontneed
free
access_lwp
access_many
access_many_pset
access_default
```

An `address` and `length` can be given to specify a subrange to apply the advice. The `address` should be hexadecimal and the `length` should be in bytes by default.

If `length` is not specified and the starting address refers to the start of a segment, the advice is applied to that segment. `length` can be qualified by K, M, G, T, P, or E to specify kilobytes, megabytes, gigabytes, terabytes, or exabytes respectively as the unit of measure.

-v Print verbose output. Display output as [pmap\(1\)](#) does, showing what advice is being applied where. This can be useful when the advice is being applied to a named region (for example, private, shared, and so forth) to get feedback on exactly where the advice

is being applied.

`pmapadvise` tries to process all legal options. If an illegal address range is specified, an error message is printed and the offending option is skipped. `pmapadvise` quits without processing any options and prints a usage message when there is a syntax error.

If conflicting advice is given on a region, the order of precedence is from most specific advice to least, that is, most general. In other words, advice specified for a particular address range takes precedence over advice for heap and stack which in turn takes precedence over advice for private and shared memory.

Moreover, the advice in each of the following groups are mutually exclusive from the other advice within the same group:

```
MADV_NORMAL, MADV_RANDOM, MADV_SEQUENTIAL
MADV_WILLNEED, MADV_DONTNEED, MADV_FREE
MADV_ACCESS_DEFAULT, MADV_ACCESS_LWP, MADV_ACCESS_MANY
```

Operands The following operands are supported:

pid Process ID.

Examples **EXAMPLE 1** Applying Advice to a Segment at Specified Address

The following example applies advice to a segment at a specified address:

```
% pmap $$
100666: tcsh
00010000    312K r-x-- /usr/bin/tcsh
0006C000    48K rwx-- /usr/bin/tcsh
00078000    536K rwx-- [ heap ]
FF100000    856K r-x-- /lib/libc.so.1
FF1E6000    32K rwx-- /lib/libc.so.1
FF1EE000     8K rwx-- /lib/libc.so.1
FF230000    168K r-x-- /lib/libcurses.so.1
FF26A000    32K rwx-- /lib/libcurses.so.1
FF272000     8K rwx-- /lib/libcurses.so.1
FF280000    576K r-x-- /lib/libnsl.so.1

FF3EE000     8K rwx-- /lib/ld.so.1
FFBE6000    104K rw--- [ stack ]
%
% pmapadvise -o 78000=access_lwp $$
```

EXAMPLE 1 Applying Advice to a Segment at Specified Address (Continued)

%

EXAMPLE 2 Using the `-v` OptionThe following example displays verbose output from `pmadvise`:

```
% pmadvise -o heap=access_lwp,stack=access_default -v $$
1720:  -sh
00010000    88K r-x-- /usr/sbin/sh
00036000     8K rwx-- /usr/sbin/sh
00038000    16K rwx-- [ heap ]           <= access_lwp
FF250000    24K r-x-- /lib/libgen.so.1
FF266000     8K rwx-- /lib/libgen.so.1
FF272000     8K rwx-- [ anon ]
FF280000   840K r-x-- /lib/libc.so.1
FF362000    32K rwx-- /lib/libc.so.1
FF36A000    16K rwx-- /lib/libc.so.1
FF390000    64K rwx-- [ anon ]
FF3B0000   168K r-x-- /lib/ld.so.1
FF3EA000     8K rwx-- /lib/ld.so.1
FF3EC000     8K rwx-- /lib/ld.so.1
FFBF0000     8K rw--- [ stack ]           <= access_default
```

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Files /proc/* Process files
 /usr/prob/lib/* proc tools support files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/core-os |
| Interface Stability | See below. |

The command syntax is Committed. The output formats are Uncommitted.

See Also [madv.so.1\(1\)](#), [pmap\(1\)](#), [proc\(1\)](#), [madvise\(3C\)](#), [attributes\(5\)](#)

Name pmap – display information about the address space of a process

Synopsis /usr/bin/pmap [-rslF] [-A *address_range*] [*pid* | *core*]...
 /usr/bin/pmap -L [-rslF] [-A *address_range*] [*pid*] ...
 /usr/bin/pmap -x [-aslF] [-A *address_range*] [*pid* | *core*]...
 /usr/bin/pmap -S [-alF] [-A *address_range*] [*pid* | *core*]...

Description The pmap utility prints information about the address space of a process.

Options The following options are supported:

- a Prints anonymous and swap reservations for shared mappings.
- A *address_range* Specifies the subrange of address space to display. *address_range* is specified in one of the following forms:
 - start_addr*
A single address limits the output to the segment (or the page if the -L option is present) containing that address. If the specified address corresponds to the starting address of a segment, the output always includes the whole segment even when the -L option is specified.
 - start_addr*,
An address followed by comma without the end address limits the output to all segments (or pages if the -L option is present) starting from the one containing the specified address.
 - start_addr*,*end_addr*
An address range specified by the start address and end addresses limits the output to all segments (or pages if the -L option is present) starting from the segment or page containing the start address through the segment or page containing the end address.
 - ,*end_addr*
An address range started with comma without the start address limits the output to all segments (or pages if the -L option is present) starting from the first one present until the segment (or page if the -L option is present) containing the specified address.
- F Force. Grabs the target process even if another process has control.
See USAGE.
- l Shows unresolved dynamic linker map names.
- L Prints lgroup containing physical memory that backs virtual memory.
- r Prints the process's reserved addresses.
- s Prints HAT page size information.

- S Displays swap reservation information per mapping. See USAGE for more information.
- x Displays additional information per mapping. See USAGE for more information.

Usage The `pmap` utility prints information about the address space of a process.

Process Mappings

```
/usr/bin/pmap [ -rsLF ] [-A address_range] [ pid | core ] ...
```

By default, `pmap` displays all of the mappings in the virtual address order they are mapped into the process. The mapping size, flags, and mapped object name are shown.

The `-A` option can be used to limit the output to a specified address range. The specified addresses are rounded up or down to a segment boundary and the output includes the segments bounded by those addresses.

Process Lgroup Mappings

```
/usr/bin/pmap -L [ -rsLF ] [-A address_range] pid ...
```

The `-L` option can be used to determine the lgroup containing the physical memory backing the specified virtual memory. When used with the `-A` option, the specified addresses are rounded up or down to a page boundary and the output is limited to the page or pages bounded by those addresses.

This can be used in conjunction with [plgrp\(1\)](#) to discover whether the home lgroup of a thread of interest is the same as where the memory is located and whether there should be memory locality for the thread. The [lgrpinfo\(1\)](#) command can also be useful with this `pmap` option. It displays the lgroup hierarchy, contents, and characteristics which gives more information about the lgroups that the memory is distributed across and their relationship to each other and any other lgroups of interest.

In addition, the thread and memory placement can be changed by using [plgrp\(1\)](#), [pmapadvise\(1\)](#), or [madv.so.1\(1\)](#).

Process anon/locked mapping details

```
/usr/bin/pmap -x [ -aslF ] [-A address_range] [ pid | core ] ...
```

The `-x` option displays additional information per mapping. The size of each mapping, the amount of resident physical memory (RSS), the amount of anonymous memory, and the amount of memory locked is shown with this option. This does not include anonymous memory taken by kernel address space due to this process.

Swap Reservations

```
/usr/bin/pmap -S [ -alF ] [-A address_range] [ pid | core ] ...
```

The `-S` option displays swap reservation information per mapping.

Caution should be exercised when using the `-F` flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the `proc` tool in question.

Display Formats One line of output is printed for each mapping within the process, unless the `--s` or `--L` option is specified. With `-s` option, one line is printed for a contiguous mapping of each hardware translation page size. With `-L` option one line is printed for a contiguous mapping belonging to the same lgroup. With both `-L` and `-s` options, one line is printed for a contiguous mapping of each hardware translation page size belonging to the same lgroup. The column headings are shown in parentheses below.

| | |
|--------------------------------|---|
| Virtual Address (Address) | The first column of output represents the starting virtual address of each mapping. Virtual addresses are displayed in ascending order. |
| Virtual Mapping Size (Kbytes) | The virtual size in kilobytes of each mapping. |
| Resident Physical Memory (RSS) | The amount of physical memory in kilobytes that is resident for each mapping, including that which is shared with other address spaces. |
| Anonymous Memory (Anon) | The number of pages, counted by using the system page size, of anonymous memory associated with the specified mapping. Anonymous memory shared with other address spaces is not included, unless the <code>-a</code> option is specified. |

| | |
|----------------------------|--|
| | <p>Anonymous memory is reported for the process heap, stack, for 'copy on write' pages with mappings mapped with <code>MAP_PRIVATE</code> (see mmap(2)).</p> |
| Locked (Locked) | <p>The number of pages locked within the mapping. Typical examples are memory locked with <code>mlock()</code> and System V shared memory created with <code>SHM_SHARE_MMU</code>.</p> |
| Permissions/Flags (Mode) | <p>The virtual memory permissions are shown for each mapping. Valid permissions are:</p> <ul style="list-style-type: none">r: The mapping can be read by the process.w: The mapping can be written by the process.x: Instructions that reside within the mapping can be executed by the process. <p>Flags showing additional information for each mapping can be displayed:</p> <ul style="list-style-type: none">s: The mapping is shared such that changes made in the observed address space are committed to the mapped file, and are visible from all other processes sharing the mapping.R: Swap space is not reserved for this mapping. Mappings created with <code>MAP_NORESERVE</code> and System V ISM shared memory mappings do not reserve swap space.*: The data for the mapping is not present in the core file (only applicable when applied to a core file). See coreadm(1M) for information on configuring core file content. |
| Lgroup (Lgrp) | <p>The lgroup containing the physical memory that backs the specified mapping.</p> |
| Mapping Name (Mapped File) | <p>A descriptive name for each mapping. The following major types of names are displayed for mappings:</p> <ul style="list-style-type: none">▪ <i>A mapped file</i>: For mappings between a process and a file, the <code>pmap</code> command attempts to resolve the file name for each mapping. If the file name cannot be resolved, <code>pmap</code> displays the major and minor number of the device containing the file, and the file system inode number of the file. |

- *Anonymous memory*: Memory not relating to any named object or file within the file system is reported as [anon].

The pmap command displays common names for certain known anonymous memory mappings:

| | |
|----------------------------|---|
| [heap] | The mapping is the process heap. |
| [stack] | The mapping is the main stack. |
| [stack tid= <i>n</i>] | The mapping is the stack for thread <i>n</i> . |
| [altstack tid= <i>n</i>] | The mapping is used as the alternate signal stack for thread <i>n</i> . |

If the common name for the mapping is unknown, pmap displays [anon] as the mapping name.

- *System V Shared Memory*: Mappings created using System V shared memory system calls are reported with the names shown below:

| | |
|------------------------|--|
| shmid= <i>n</i> : | The mapping is a System V shared memory mapping. The shared memory identifier that the mapping was created with is reported. |
| ism shmid= <i>n</i> : | The mapping is an “Intimate Shared Memory” variant of System V shared memory. ISM mappings are created with the SHM_SHARE_MMU flag set, in accordance with shmat(2) (see shmop(2)). |
| dism shmid= <i>n</i> : | The mapping is a pageable variant of ISM. Pageable ISM is created with the SHM_PAGEABLE flag set in accordance with shmat(2) (see shmop(2)). |

- *Other*: Mappings of other objects, including devices such as frame buffers. No mapping name is shown for other mapped objects.

Page Size (Pgsz)

The page size in kilobytes that is used for hardware address translation for this mapping. See [memcntl\(2\)](#) for further information.

Swap Space (Swap)

The amount of swap space in kilobytes that is reserved for this mapping. That is, swap space that is deducted from the total available pool of reservable swap space that is displayed with the command `swap -s`. See [swap\(1M\)](#).

Examples **EXAMPLE 1** Displaying Process Mappings

By default, `pmap` prints one line for each mapping within the address space of the target process. The following example displays the address space of a typical bourne shell:

```
example$ pmap 102905
102905:    sh
00010000   192K r-x-- /usr/bin/ksh
00040000    8K rwx-- /usr/bin/ksh
00042000   40K rwx-- [ heap ]
FF180000   664K r-x-- /usr/lib/libc.so.1
FF236000   24K rwx-- /usr/lib/libc.so.1
FF23C000    8K rwx-- /usr/lib/libc.so.1
FF250000    8K rwx-- [ anon ]
FF260000   16K r-x-- /usr/lib/en_US.ISO8859-1.so.2
FF272000   16K rwx-- /usr/lib/en_US.ISO8859-1.so.2
FF280000   560K r-x-- /usr/lib/libnsl.so.1
FF31C000   32K rwx-- /usr/lib/libnsl.so.1
FF324000   32K rwx-- /usr/lib/libnsl.so.1
FF350000   16K r-x-- /usr/lib/libmp.so.2
FF364000    8K rwx-- /usr/lib/libmp.so.2
FF380000   40K r-x-- /usr/lib/libsocket.so.1
FF39A000    8K rwx-- /usr/lib/libsocket.so.1
FF3A0000    8K r-x-- /usr/lib/libdl.so.1
FF3B0000    8K rwx-- [ anon ]
FF3C0000   152K r-x-- /usr/lib/ld.so.1
FF3F6000    8K rwx-- /usr/lib/ld.so.1
FFBFC000   16K rw--- [ stack ]
total      1864
```

EXAMPLE 2 Displaying Memory Allocation and Mapping Types

The `-x` option can be used to provide information about the memory allocation and mapping types per mapping. The amount of resident, non-shared anonymous, and locked memory is shown for each mapping:

```
example$ pmap -x 102908
102908:  sh
Address  Kbytes    RSS   Anon  Locked Mode  Mapped File
00010000     88     88    -    -  r-x--  sh
00036000     8      8     8    -  rwx--  sh
00038000    16     16    16    -  rwx--  [ heap ]
FF260000    16     16    -    -  r-x--  en_US.ISO8859-1.so.2
FF272000    16     16    -    -  rwx--  en_US.ISO8859-1.so.2
FF280000   664    624    -    -  r-x--  libc.so.1
FF336000    32     32     8    -  rwx--  libc.so.1
FF380000    24     24    -    -  r-x--  libgen.so.1
FF396000     8      8    -    -  rwx--  libgen.so.1
FF3A0000     8      8    -    -  r-x--  libdl.so.1
FF3B0000     8      8     8    -  rwx--  [ anon ]
FF3C0000   152    152    -    -  r-x--  ld.so.1
FF3F6000     8      8     8    -  rwx--  ld.so.1
FFBFE000     8      8     8    -  rw---  [ stack ]
-----
total Kb   1056   1016    56    -
```

The amount of incremental memory used by each additional instance of a process can be estimated by using the resident and anonymous memory counts of each mapping.

In the above example, the bourne shell has a resident memory size of 1032Kbytes. However, a large amount of the physical memory used by the shell is shared with other instances of shell. Another identical instance of the shell shares physical memory with the other shell where possible, and allocate anonymous memory for any non-shared portion. In the above example, each additional bourne shell uses approximately 56Kbytes of additional physical memory.

A more complex example shows the output format for a process containing different mapping types. In this example, the mappings are as follows:

```
00010000: Executable text, mapped from 'maps' program
00020000: Executable data, mapped from 'maps' program
00022000: Program heap

03000000: A mapped file, mapped MAP_SHARED
04000000: A mapped file, mapped MAP_PRIVATE
```

EXAMPLE 2 Displaying Memory Allocation and Mapping Types *(Continued)*

0500000: A mapped file, mapped MAP_PRIVATE | MAP_NORESERVE

0600000: Anonymous memory, created by mapping /dev/zero

0700000: Anonymous memory, created by mapping /dev/zero
with MAP_NORESERVE

0800000: A DISM shared memory mapping, created with SHM_PAGEABLE
with 8MB locked via mlock(2)

0900000: A DISM shared memory mapping, created with SHM_PAGEABLE,
with 4MB of its pages touched.

0A00000: A DISM shared memory mapping, created with SHM_PAGEABLE,
with none of its pages touched.

0B00000: An ISM shared memory mapping, created with SHM_SHARE_MMU

example\$ pmap -x 15492

15492: ./maps

| Address | Kbytes | RSS | Anon | Locked | Mode | Mapped File |
|----------|--------|-------|-------|--------|-------|---------------------|

EXAMPLE 3 Displaying Page Size Information

The `-s` option can be used to display the hardware translation page sizes for each portion of the address space. (See `memcntl(2)` for further information on Solaris multiple page size support).

In the example below, we can see that the majority of the mappings are using an 8K-Byte page size, while the heap is using a 4M-Byte page size.

Notice that non-contiguous regions of resident pages of the same page size are reported as separate mappings. In the example below, the `libc.so` library is reported as separate mappings, since only some of the `libc.so` text is resident:

```
example$ pmap -xs 15492
15492: ./maps
Address  Kbytes    RSS    Anon  Locked  Pgsz  Mode   Mapped File
00010000     8        8      -    -    8K  r-x--  maps

EXAMPLE 4 Displaying Swap Reservations

The `-S` option can be used to describe the swap reservations for a process. The amount of swap space reserved is displayed for each mapping within the process. Swap reservations are reported as zero for shared mappings, since they are accounted for only once system wide.

```
example$ pmap -S 15492
15492: ./maps
Address Kbytes Swap Mode Mapped File
00010000      8 - r-x-- maps
00020000      8      8 rwx-- maps
00022000 20344 20344 rwx-- [ heap ]
03000000  1024 - rw-s- dev:0,2 ino:4628487
04000000  1024 1024 rw--- dev:0,2 ino:4628487

0A000000  8192 - rwx-s- [ dism shmid=0x2]
0B000000  8192 - rwx-sR [ ism shmid=0x3]
FF280000  680 - r-x-- libc.so.1
FF33A000   32  32 rwx-- libc.so.1
FF3A0000    8 - r-x-- libdl.so.1
FF3B0000    8      8 rwx-- [ anon ]
FF3C0000  152 - r-x-- ld.so.1
FF3F6000    8      8 rwx-- ld.so.1
FFBFA000   24  24 rwx-- [ stack ]
-----
total Kb  50456  23496
```

The swap reservation information can be used to estimate the amount of virtual swap used by each additional process. Each process consumes virtual swap from a global virtual swap pool. Global swap reservations are reported by the 'avail' field of the `swap(1M)` command.

EXAMPLE 5 Labeling Stacks in a Multi-threaded Process

```
example$ pmap 121969
121969: ./stacks
00010000      8K r-x-- /tmp/stacks

Exit Status The following exit values are returned:

0 Successful operation.
non-zero An error has occurred.

Files /proc/* process files
/usr/proc/lib/* proc tools supporting files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/core-os |
| Interface Stability | See below. |

The command syntax is Committed. The -L option and the output formats are Uncommitted.

See Also [ldd\(1\)](#), [lgrpinfo\(1\)](#), [madv.so.1\(1\)](#), [mdb\(1\)](#), [plgrp\(1\)](#), [pmadvise\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [coreadm\(1M\)](#), [prstat\(1M\)](#), [swap\(1M\)](#), [mmap\(2\)](#), [memcntl\(2\)](#), [meminfo\(2\)](#), [shmop\(2\)](#), [dlopen\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#)

-
- Name** pm-updatemanager – application to update packages
- Synopsis** /usr/bin/pm-updatemanager [*options*]
 /usr/bin/pm-updatemanager [-h | --help] [-d | --debug]
 [-R *dir* | --image-dir *dir*]
- Description** pm-updatemanager checks for and installs available updates for the packages installed on the system.
- Note** – If the package/pkg, package/pkg/package-manager, or package/pkg/update-manager packages need to be updated, pm-updatemanager first updates these packages and then restarts to carry out any remaining updates.
- Options** The following options are supported:
- h
 - help
Display a usage message.
 - d
 - debug
Run pm-updatemanager in debug mode.
 - R *dir*
 - image-dir *dir*
Operate on the image rooted at *dir*, rather than on the image discovered automatically.
- Examples** **EXAMPLE 1** Update the Current Image
- Invoke pm-updatemanager on the current image. This checks for and installs all available updates for packages installed in the current image.
- ```
$ /usr/lib/pm-launch pm-updatemanager
```
- This is the same command that the desktop menu option System>Administration>Update Manager invokes.
- EXAMPLE 2** Update a Specified Image
- Invoke pm-updatemanager on the image stored at /aux0/example\_root.
- ```
$ /usr/lib/pm-launch pm-updatemanager -R /aux0/example_root
```
- Exit Status** The following exit values are returned:
- 0 Everything worked.
 - 1 An error occurred.
 - 2 Invalid command line options were specified.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | package/pkg/update-manager |
| Interface Stability | Uncommitted |

See Also [packagemanager\(1\)](#), [pkg\(1\)](#), [pkg\(5\)](#)

<http://hub.opensolaris.org/bin/view/Project+pkg/>

Notes When operating on an image you do not own, `pm-updatemanager` needs to be invoked with enough privilege. You will normally invoke `pm-updatemanager` using `/usr/lib/pm-launch` under these circumstances.

Name ppgsz – set preferred page size for stack, heap, and/or other anonymous segments

Synopsis /usr/bin/ppgsz [-F] -o *option*[,*option*] *cmd* | -p *pid*...

Description The ppgsz utility sets the preferred page size for stack, heap, and/or other anonymous segments for the target process(es), that is, the launched *cmd* or the process(es) in the pid list. ppgsz stops the target process(es) while changing the page size. See [memcntl\(2\)](#).

Options The following options are supported:

-F Force. Sets the preferred page size options(s) for target process(es) even if controlled by other process(es). Caution should be exercised when using the -F flag. See [proc\(1\)](#).

-o *option*[,*option*] The *options* are:

heap=size This option specifies the preferred page size for the heap of the target process(es). *heap* is defined to be the bss (uninitialized data) and the brk area that immediately follows the bss (see [brk\(2\)](#)). The preferred heap page size is set for the existing heap and for any additional heap memory allocated in the future. See NOTES.

stack=size This option specifies the preferred page size for the stack of the target process(es). The preferred stack page size is set for the existing stack and newly allocated parts of the stack as it expands.

anon=size This option specifies the preferred page size for all existing MAP_PRIVATE anonymous segments of the target process(es), other than *heap* and *stack*, which are large enough to fit at least one aligned page of the specified size. For the segments that are large enough, the preferred page size is set starting at the first size-aligned address in the segment. The anon preferred pagesize is not applied to MAP_PRIVATE anonymous segments created in the future. See MAP_ANON in [mmap\(2\)](#).

Anonymous memory refers to MAP_PRIVATE pages that are not directly associated with a file in some filesystem. The ppgsz command uses [memcntl\(2\)](#) to set the preferred page size for anonymous segments. See MC_HAT_ADVICE in [memcntl\(2\)](#).

At least one of the above options must be specified.

size must be a supported page size (see [pagesize\(1\)](#)) or 0, in which case the system will select an appropriate page size. See [memcntl\(2\)](#).

size defaults to bytes and can be specified in octal (0), decimal, or hexadecimal (0x). The numeric value can be qualified with K, M, G, or T to specify Kilobytes, Megabytes, Gigabytes, or Terabytes, respectively. 4194304, 0x400000, 4096K, 0x1000K, and 4M are different ways to specify 4 Megabytes.

-p *pid*

Sets the preferred page size option(s) for the target process(es) in the process-id (*pid*) list following the -p option. The pid list can also consist of names in the /proc directory. Only the process owner or the super-user is permitted to set page size.

cmd is interpreted if -p is not specified. ppgsz launches *cmd* and applies page size option(s) to the new process.

The heap and stack preferred page sizes are inherited. Child process(es) created (see [fork\(2\)](#)) from the launched process or the target process(es) in the pid list after ppgsz completes will inherit the preferred heap and stack page sizes. The preferred page sizes of all segments are set back to the default system page size on [exec\(2\)](#) (see [getpagesize\(3C\)](#)). The preferred page size for all other anonymous segments is not inherited by children of the launched or target process(es).

Examples EXAMPLE 1 Setting the preferred heap and stack page size

The following example sets the preferred heap page size to 4M and the preferred stack page size to 512K for all ora—owned processes running commands that begin with ora:

```
example% ppgsz -o heap=4M,stack=512K -p 'pgrep -u ora '^ora''
```

EXAMPLE 2 Setting the preferred anonymous page size

The following example sets the preferred page size of existing qualifying anonymous segments to 512k for process ID 953:

```
example% ppgsz -o anon=512k -p 953
```

Exit Status If *cmd* is specified and successfully invoked (see [exec\(2\)](#)), the exit status of ppgsz will be the exit status of *cmd*. Otherwise, ppgsz will exit with one of the following values:

- 0 Successfully set preferred page size(s) for processes in the pid list.
- 125 An error occurred in ppgsz. Errors include: invalid argument, invalid page size(s) specified, and failure to set preferred page size(s) for one or more processes in the pid list or *cmd*.

126 `cmd` was found but could not be invoked.

127 `cmd` could not be found.

Files `/proc/*` Process files.
`/usr/lib/ld/map.bssalign` A template link-editor `mapfile` for aligning bss (see NOTES).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------|
| Availability | system/extended-system-utilities |
| Interface Stability | Committed |

See Also [ld\(1\)](#), [mpss.so.1\(1\)](#), [pagesize\(1\)](#), [pgrep\(1\)](#), [pmap\(1\)](#), [proc\(1\)](#), [brk\(2\)](#), [exec\(2\)](#), [fork\(2\)](#), [mementl\(2\)](#), [mmap\(2\)](#), [sbrk\(2\)](#), [getpagesize\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#)

Linker and Libraries Guide

Notes Due to resource constraints, the setting of the preferred page size does not necessarily guarantee that the target process(es) will get the preferred page size. Use [pmap\(1\)](#) to view the *actual* heap and stack page sizes of the target process(es) (see `pmap -s` option).

Large pages are required to be mapped at addresses that are multiples of the size of the large page. Given that the heap is typically not large page aligned, the starting portions of the heap (below the first large page aligned address) are mapped with the system memory page size. See [getpagesize\(3C\)](#).

To provide a heap that will be mapped with a large page size, an application can be built using a link-editor ([ld\(1\)](#)) `mapfile` containing the bss segment declaration directive. Refer to the section Mapfile Option in the *Linker and Libraries Guide* for more details of this directive and the template `mapfile` provided in `/usr/lib/ld/map.bssalign`. Users are cautioned that an alignment specification may be machine-specific and may lose its benefit on different hardware platforms. A more flexible means of requesting the most optimal underlying page size may evolve in future releases.

[mpss.so.1\(1\)](#), a pre-loadable shared object, can also be used to set the preferred stack and/or heap page sizes.

Name ppriv – inspect or modify process privilege sets and attributes

Synopsis /usr/bin/ppriv -e [-D | -N] [-M] [-s *spec*] [-X | -r *rule*] *command* [*arg*]...
/usr/bin/ppriv [-vn] [-S] [-D | -N] [-s *spec*] [-X | -r *rule*]
[*pid* | *core*]...
/usr/bin/ppriv -l [-vn] [*privilege-specification* | *extended-policy*]...

Description The first invocation of the ppriv command runs the *command* specified with the privilege sets and flags modified according to the arguments on the command line.

The second invocation examines or changes the privilege state of running process and core files.

The third invocation lists the privileges defined and information about specified privileges or privileges set specifications.

Options The following options are supported:

- D Turns on privilege debugging for the processes or command supplied.
- e Interprets the remainder of the arguments as a command line and runs the command line with specified privilege attributes and sets.
- l Lists all currently defined privileges on stdout.
- M When a system is configured with Trusted Extensions, this option turns on the NET_MAC_AWARE and NET_MAC_AWARE_INHERIT process attributes.

A process with these attributes and the net_mac_aware privilege can communicate with lower-level remote peers.
- n Show port numbers and users as numbers. Normally, ppriv shows port numbers and users as symbols. This option is only applicable when displaying Extended Policies.
- N Turns off privilege debugging for the processes or command supplied.
- s *spec* Modifies a process's privilege sets according to *spec*, a specification with the format [AEILP] [+ -=] *privsetspec*, containing no spaces, where:
 - AEILP Indicates one or more letters indicating which privilege sets to change. These are case insensitive, for example, either a or A indicates all privilege sets.

For definitions of the single letter abbreviations for privilege sets, see [privileges\(5\)](#).
 - + -= Indicates a modifier to respectively add (+), remove (-), or assign (=) the listed privileges to the specified set(s) in *privsetspec*.

privsetspec Indicates a comma-separated privilege set specification (priv1,priv2, and so on), as described in [priv_str_to_set\(3C\)](#).

Modifying the same set with multiple `-s` options is possible as long as there is either precisely one assignment to an individual set or any number of additions and removals. That is, assignment and addition or removal for one set are mutually exclusive.

`-r rule` Install an Extended Policy. See [privileges\(5\)](#).

Multiple rules can be specified. The new rules are added to the existing policy. To replace an existing policy, first remove it with `-X`, and then add the new policy with `-r`.

`-S` Short. Reports the shortest possible output strings for sets. The default is portable output. See [priv_str_to_set\(3C\)](#).

`-X` Disable the Extended Policy.

`-v` Verbose. Reports privilege sets using privilege names.

Usage The `ppriv` utility examines processes and core files and prints or changes their privilege sets.

`ppriv` can run commands with privilege debugging on or off or with fewer privileges than the invoking process.

When executing a sub process, the only sets that can be modified are L and I. Privileges can only be removed from L and I as `ppriv` starts with P=E=I.

`ppriv` can also be used to remove privileges from processes or to convey privileges to other processes. In order to control a process, the effective set of the `ppriv` utility must be a super set of the controlled process's E, I, and P. The utility's limit set must be a super set of the target's limit set. If the target's process uids do not match, the {PRIV_PROC_OWNER} privilege must be asserted in the utility's effective set. If the controlled processes have any uid with the value 0, more restrictions might exist. See [privileges\(5\)](#).

Examples **EXAMPLE 1** Obtaining the Process Privileges of the Current Shell

The following example obtains the process privileges of the current shell:

```
example$ ppriv $$
387:  -sh
flags = <none>
      E: basic
      I: basic
      P: basic
      L: all
```

EXAMPLE 2 Removing a Privilege From Your Shell's Inheritable and Effective Set

The following example removes a privilege from your shell's inheritable and effective set.

```
example$ ppriv -s EI-proc_session $$
```

The subprocess can still inspect the parent shell but it can no longer influence the parent because the parent has more privileges in its Permitted set than the `ppriv` child process:

```
example$ truss -p $$
truss: permission denied: 387
```

```
example$ ppriv $$
387:  -sh
flags = <none>
      E: basic,!proc_session
      I: basic,!proc_session
      P: basic
      L: all
```

EXAMPLE 3 Running a Process with Privilege Debugging

The following example runs a process with privilege debugging:

```
example$ ppriv -e -D cat /etc/shadow
cat[418]: missing privilege "file_dac_read" (euid = 21782),
          needed at ufs_access+0x3c
cat: cannot open /etc/shadow
```

The privilege debugging error messages are sent to the controlling terminal of the current process. The needed at address specification is an artifact of the kernel implementation and it can be changed at any time after a software update.

The system call number can be mapped to a system call using `/etc/name_to_sysnum`.

EXAMPLE 4 Listing the Privileges Available in the Current Zone

The following example lists the privileges available in the current zone (see [zones\(5\)](#)). When run in the global zone, all defined privileges are listed.

```
example$ ppriv -l zone
... listing of all privileges elided ...
```

EXAMPLE 5 Examining a Privilege Aware Process

The following example examines a privilege aware process:

```
example$ ppriv -S 'pgrep rpcbind'
```

```
928:  /usr/sbin/rpcbind
```

EXAMPLE 5 Examining a Privilege Aware Process (Continued)

```

flags = PRIV_AWARE
      E: net_privaddr,proc_fork,sys_nfs
      I: none
      P: net_privaddr,proc_fork,sys_nfs
      L: none

```

See [setpflags\(2\)](#) for explanations of the flags.

EXAMPLE 6 Running a Process Under an Extended Policy

The following example runs a process under an extended policy:

```

example$ ppriv -r '{file_write}:/home/casper/.mozilla/*' \
          -r '{file_write}:/tmp/*,{proc_exec}:/usr/*' -e firefox

```

See [privileges\(5\)](#).

EXAMPLE 7 Examining a Process that Has been Started

The following example examines the process that was started in example 6:

```

example$ ppriv 101272
101272: /usr/lib/firefox/firefox-bin
flags = PRIV_XPOLICY
Extended policies:
{file_write}:/home/casper/.mozilla/*
{file_write}:/tmp/*
{proc_exec}:/usr/*
E: basic,!file_write,!proc_exec
I: basic,!file_write,!proc_exec
P: basic,!file_write,!proc_exec
L: all

```

Exit Status The following exit values are returned:

0 Successful operation.

non-zero An error has occurred.

Files /proc/* Process files
 /etc/name_to_sysnum system call name to number mapping

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | system/core-os |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | See below. |

The invocation is Committed. The output is Uncommitted.

Name pr – print files

Synopsis /usr/bin/pr [+ *page*] [-column] [-adFmrt] [-e [*char*] [*gap*]]
 [-h *header*] [-i [*char*] [*gap*]] [-l *lines*]
 [-n [*char*] [*width*]] [-o *offset*] [-s [*char*]]
 [-w *width*] [-fp] [*file*]...

/usr/xpg4/bin/pr [+ *page*] [-column | -c *column*] [-adFmrt]
 [-e [*char*] [*gap*]] [-h *header*] [-i [*char*] [*gap*]]
 [-l *lines*] [-n [*char*] [*width*]] [-o *offset*]
 [-s [*char*]] [-w *width*] [-fp] [*file*]...

Description The pr utility is a printing and pagination filter. If multiple input files are specified, each is read, formatted, and written to standard output. By default, the input is separated into 66-line pages, each with:

- a 5-line header that includes the page number, date, time and the path name of the file
- a 5-line trailer consisting of blank lines

If standard output is associated with a terminal, diagnostic messages will be deferred until the pr utility has completed processing.

When options specifying multi-column output are specified, output text columns will be of equal width; input lines that do not fit into a text column will be truncated. By default, text columns are separated with at least one blank character.

Options The following options are supported. In the following option descriptions, *column*, *lines*, *offset*, *page*, and *width* are positive decimal integers; *gap* is a non-negative decimal integer. Some of the option-arguments are optional, and some of the option-arguments cannot be specified as separate arguments from the preceding option letter. In particular, the -s option does not allow the option letter to be separated from its argument, and the options -e, -i, and -n require that both arguments, if present, not be separated from the option letter.

The following options are supported for both /usr/bin/pr and /usr/xpg4/bin/pr:

| | |
|-----------------|---|
| + <i>page</i> | Begins output at page number <i>page</i> of the formatted input. |
| - <i>column</i> | Produces multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with -m. The -e and -i options will be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the -l option). When used with -t, use the minimum number of lines to write the output. |
| -a | Modifies the effect of the - <i>column</i> option so that the columns are filled across the page in a round-robin order (for example, when |

- column* is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so forth).
- d Produces output that is double-spaced; append an extra NEWLINE character following every NEWLINE character found in the input.
 - e [*char*] [*gap*] Expands each input TAB character to the next greater column position specified by the formula $n * \textit{gap} + 1$, where n is an integer > 0 . If *gap* is 0 or is omitted, it defaults to 8. All TAB characters in the input will be expanded into the appropriate number of SPACE characters. If any non-digit character, *char*, is specified, it will be used as the input tab character.
 - f Uses a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters. Pauses before beginning the first page if the standard output is associated with a terminal.
 - h *header* Uses the string *header* to replace the contents of the *file* operand in the page header.
 - l *lines* Overrides the 66-line default and reset the page length to *lines*. If *lines* is not greater than the sum of both the header and trailer depths (in lines), pr will suppress both the header and trailer, as if the -t option were in effect.
 - m Merges files. Standard output will be formatted so pr writes one line from each file specified by *file*, side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations support merging of at least nine files.
 - n [*char*] [*width*] Provides *width*-digit line numbering (default for *width* is 5). The number will occupy the first *width* column positions of each text column of default output or each line of -m output. If *char* (any non-digit character) is given, it will be appended to the line number to separate it from whatever follows (default for *char* is a TAB character).
 - o *offset* Each line of output will be preceded by offset $\langle \text{space} \rangle s$. If the -o option is not specified, the default offset is 0. The space taken will be in addition to the output line width (see -w option below).
 - p Pauses before beginning each page if the standard output is directed to a terminal (pr will write an ALERT character to standard error and wait for a carriage-return character to be read on /dev/tty).
 - r Writes no diagnostic reports on failure to open files.

- s [*char*] Separates text columns by the single character *char* instead of by the appropriate number of SPACE characters (default for *char* is the TAB character).
- t Writes neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quits writing after the last line of each file without spacing to the end of the page.
- w *width* Sets the width of the line to *width* column positions for multiple text-column output only. If the -w option is not specified and the -s option is not specified, the default width is 72. If the -w option is not specified and the -s option is specified, the default width is 512.

For single column output, input lines will not be truncated.

`/usr/bin/pr` The following options are supported for `/usr/bin/pr` only:

- F Folds the lines of the input file. When used in multi-column mode (with the -a or -m options), lines will be folded to fit the current column's width. Otherwise, they will be folded to fit the current line width (80 columns).
- i [*char*][*gap*] In output, replaces SPACE characters with TAB characters wherever one or more adjacent SPACE characters reach column positions $gap+1$, $2*gap+1$, $3*gap+1$, and so forth. If *gap* is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, *char*, is specified, it will be used as the output TAB character.

`/usr/xpg4/bin/pr` The following options are supported for `/usr/xpg4/bin/pr` only:

- F Uses a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters.
- i [*char*][*gap*] In output, replaces multiple SPACE characters with TAB characters wherever two or more adjacent SPACE characters reach column positions $gap+1$, $2*gap+1$, $3*gap+1$, and so forth. If *gap* is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, *char*, is specified, it will be used as the output TAB character.

Operands The following operand is supported:

- file* A path name of a file to be written. If no *file* operands are specified, or if a *file* operand is -, the standard input will be used.

Examples **EXAMPLE 1** Printing a numbered list of all files in the current directory

```
example% ls -a | pr -n -h "Files in $(pwd)."
```

EXAMPLE 2 Printing files in columns

This example prints `file1` and `file2` as a double-spaced, three-column listing headed by `file list`:

```
example% pr -3d -h "file list" file1 file2
```

EXAMPLE 3 Writing files with expanded column tabs

The following example writes `file1` on `file2`, expanding tabs to columns 10, 19, 28, ...

```
example% pr -e9 -t <file1 >file2
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `pr`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name praliases – display system mail aliases

Synopsis praliases [-C *configfile*] [-f *aliasfile*] [*key*]

Description The praliases utility displays system mail aliases. When no key is given, praliases displays the current system aliases, one per line, in no particular order. The form is *key: value*. If a key is given, only that key is looked up and the appropriate *key: value* is displayed if found.

Options The following options are supported:

-C *configfile* Specifies a sendmail configuration file.

-f *aliasfile* Reads the specified file *aliasfile* instead of the default sendmail system aliases file.

Operands The following operands are supported:

key A specific alias key to look up.

Exit Status The following exit values are returned:

0 Successful operation.

>0 An error occurred.

Files

| | |
|-----------------------|---|
| /etc/mail/aliases | Default sendmail system aliases file |
| /etc/mail/aliases.db | Database versions of the /etc/mail/aliases file |
| /etc/mail/aliases.dir | |
| /etc/mail/aliases.pag | Database versions of the /etc/mail/aliases file |
| /etc/mail/sendmail.cf | Default sendmail configuration file |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------------|
| Availability | service/network/smtp/sendmail |

See Also [mailq\(1\)](#), [newaliases\(1M\)](#), [sendmail\(1M\)](#), [attributes\(5\)](#)

Name prctl – get or set the resource controls of running processes, tasks, and projects

Synopsis prctl [-P] [-t [basic | privileged | system]]
[-n *name* [-srx] [-v *value*] [-e | -d *action*] [-p *pid*]]
[-i *idtype*] *id*...

Description The `prctl` utility allows the examination and modification of the resource controls associated with an active process, task, or project on the system. It allows access to the basic and privileged limits and the current usage on the specified entity.

See [resource_controls\(5\)](#) for a description of the resource controls supported in the current release of the Solaris operating system.

Options If none of the `-s`, `-r`, `-x`, `-v`, `-d`, or `-e` options are specified, the invocation is considered a get operation. Otherwise, it is considered a modify operation.

The following options are supported:

`-d` | `-e` *action* Disables (`-d`) or enables (`-e`) the specified *action* on the resource control value specified by `-v`, `-t`, and `-p`. If any of the `-v`, `-t`, or `-p` options are unspecified, they match any value, privilege, or recipient pid. For example, specifying only `-v` modifies the first resource control with matching value, matching any privilege and recipient pid. If no matching resource control value is found, a new value is added as if `-s` were specified.

Actions:

`all` This action is only available with `-d`. It disables all actions. This fails on resource control values that have the `deny` global flag.

`deny` Indicates that the resource control attempts to deny granting the resource to the process, task, project, or zone on a request for resources in excess of the resource control value. `deny` actions can not be enabled if the resource control has the `no-deny` global flag. `deny` actions can not be disabled if the resource control has the `deny` global flag.

| | | |
|------------------------|----------------------------|--|
| | <code>signal</code> | This action is only available with <code>-d</code> . It deactivates the <code>signal</code> action. |
| | <code>signal=signum</code> | In the <code>signal=signum</code> action, <i>signum</i> is a signal number (or string representation of a signal). Setting a <code>signal</code> action on a resource control with the <code>no-local-action</code> global flag fails. A limited set of signals can be sent. See NOTES for additional details. |
| <code>-i idtype</code> | | Specifies the type of the id operands. Valid <i>idtypes</i> are <code>process</code> , <code>task</code> , <code>project</code> , or <code>zone</code> . Also allowed are <code>pid</code> , <code>taskid</code> , <code>projid</code> , and <code>zoneid</code> . The default id type, if the <code>-i</code> option is omitted, is <code>process</code> .

For a modify operation, the entity to which id operands are members is the target entity. For instance, setting a project resource control on an <code>-i process</code> sets the resource control on the project to which each given process argument is a member.

For a get operation, the resource controls are listed for all entities to which the id operands are members. For example, <code>-i task taskid</code> lists the task, project, and zone resource controls for the task, and for the project and zone to which that task is a member. |
| <code>-n name</code> | | Specifies the name of the resource control to get or set. If the <i>name</i> is unspecified, all resource controls are retrieved. |
| <code>-p pid</code> | | When manipulating (using <code>-s</code> , <code>-r</code> , <code>-x</code> , <code>-d</code> , or <code>-e</code>) a basic task project, or zone resource control values, a recipient <i>pid</i> can be specified using <code>-p</code> . When setting a new basic resource control or controls on a task, project, or zone, the <code>-p</code> option is required if the <code>-i idtype</code> option argument is not <code>process</code> . |
| <code>-P</code> | | Display resource control values in space delimited format. |
| <code>-r</code> | | Replaces the first resource control value (matching with the <code>-t privilege</code>) with the new value specified through the <code>-v</code> option. |

| | |
|----------------------------------|---|
| -s | <p>Set a new resource control value.</p> <p>This option requires the <code>-v</code> option.</p> <p>If you do not specify the <code>-t</code> option, basic privilege is used. If you want to set a basic task, process, or zone rctl, <code>-p</code> is required. If <code>-e</code> or <code>-d</code> are also specified, the action on the new rctl is set as well.</p> <p>For compatibility with prior releases, this option is implied if <code>-v</code> is specified, without any of <code>-e</code>, <code>-d</code>, <code>-r</code>, or <code>-x</code>.</p> <p>See resource_controls(5) for a description of unit modifiers and scaling factors you can use to express large values when setting a resource control value.</p> |
| -t [basic privileged system] | <p>Specifies which resource control type to set. Unless the “lowerable” flag is set for a resource control, only invocations by users (or setuid programs) who have privileges equivalent to those of root can modify privileged resource controls. See rctlblk_set_value(3C) for a description of the <code>RCTL_GLOBAL_LOWERABLE</code> flag. If the type is not specified, <code>basic</code> is assumed. For a get operation, the values of all resource control types, including <code>system</code>, are displayed if no type is specified.</p> |
| -v <i>value</i> | <p>Specifies the value for the resource control for a set operation. If no <i>value</i> is specified, then the modification (deletion, action enabling or disabling) is carried out on the lowest-valued resource control with the given type.</p> <p>See resource_controls(5) for a description of unit modifiers and scaling factors you can use to express large values when setting a resource control value.</p> |
| -x | <p>Deletes the specified resource control value. If the delete option is not provided, the default operation of <code>prctl</code> is to modify a resource control value of matching value and privilege, or insert a new value with the given privilege. The matching criteria are discussed more fully in setrctl(2).</p> |

If none of the `-d`, `-e`, `-v`, or `-x` options is specified, the invocation is considered a get operation.

Operands The following operand is supported:

id The ID of the entity (process, task, project, or zone) to interrogate. If the invoking user's credentials are unprivileged and the entity being interrogated possesses different credentials, the operation fails. If no *id* is specified, an error message is returned.

Examples EXAMPLE 1 Displaying Current Resource Control Settings

The following example displays current resource control settings for a task to which the current shell belongs:

```
example$ ps -o taskid -p $$
TASKID
8
example$ prctl -i task 8
136150: /bin/ksh
NAME PRIVILEGE VALUE FLAG ACTION RECIPIENT
task.max-cpu-time
  usage 8s
  system 18.4Es inf none -

usage           0B
privileged      508MB   -  deny  -

```

EXAMPLE 2 Displaying, Replacing, and Verifying the Value of a Specific Control

The following examples displays, replaces, and verifies the value of a specific control on an existing project:

```

example# prctl -n project.cpu-shares -i project group.staff
project: 10: group.staff
NAME    PRIVILEGE    VALUE    FLAG    ACTION    RECIPIENT
project.cpu-shares
usage           1
privileged      1        -  none  -
system          65.5K    max  none  -

example# prctl -n project.cpu-shares -v 10 -r -i project group.staff
example# prctl -n project.cpu-shares -i project group.staff
project: 10: group.staff
NAME    PRIVILEGE    VALUE    FLAG    ACTION    RECIPIENT
project.cpu-shares
usage           10
privileged      10        -  none  -
system          65.5K    max  none  -

```

EXAMPLE 3 Adjusting Resources

The following example uses the `project.max-locked-memory` resource.

First, use `id -p` to find out which project the current shell is a member of:

```
/home/garfield> id -p
uid=77880(garfield) gid=10(staff) projid=10(group.staff)
```

Using the target project, identify the resource limit value before the change:

```
/home/garfield> prctl -n project.max-locked-memory -i project \
group.staff
project 10: group.staff
project.max-locked-memory
privileged          256MB      - deny          -
system             16.0EB    max deny          -
```

current limit is 256 Megabytes.

Next, adjust the `project.max-locked-memory` limit to 300 Megabytes for the target project:

```
# prctl -n project.max-locked-memory -v 300M -r -i project group.staff
```

The resource limit value after the change shows a new value of 300 Megabytes:

```
# prctl -n project.max-locked-memory -i project group.staff
project 10:group.staff
project.max-locked-memory
usage              200MG
privileged         300MB      - deny          -
system             16.0EB    max deny          -
```

EXAMPLE 4 Modifying CPU Caps for a Project

The `prctl` command can use the `project.cpu-cap` resource control (see [resource_controls\(5\)](#)) to set and modify CPU caps for a project. (The same resource control can be used in the `/etc/project` file. See [project\(4\)](#)) The following command modifies the CPU cap to limit user `.smith` to three CPUs:

```
# prctl -r -t privileged -n project.cpu-cap -v 300 -i project user.smith
```

The `prctl -r` option, used above, is used to dynamically change a CPU cap for a project or zone. For example, the following command will change the cap set in the preceding command to 80 percent:

```
# prctl -r -t privileged -n project.cpu-cap -v 80 -i project user.smith
```

To remove a CPU cap, enter:

```
# prctl -x -n project.cpu-cap $$
```

EXAMPLE 5 Modifying CPU Caps for a Zone

The `prctl` command can use the `zone.cpu-cap` resource control (see [resource_controls\(5\)](#)) to set and modify CPU caps for a zone. (The same resource control can be manipulated using the [zonecfg\(1M\)](#) command.) The following command modifies the CPU cap to limit the global zone to 80 percent of a CPU:

```
# prctl -t privileged -n zone.cpu-cap -v 80 -i zone global
```

The cap can be lowered to 50% using:

```
# prctl -r -t privileged -n zone.cpu-cap -v 50 -i zone global
```

Exit Status The following exit values are returned:

- 0 Success.
- 1 Fatal error encountered.
- 2 Invalid command line options were specified.

Files `/proc/pid/*` Process information and control files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/core-os |
| Interface Stability | See below. |

The command-line syntax is Committed. The human-readable output is Uncommitted. The parseable output is Committed.

See Also [rctladm\(1M\)](#), [zonecfg\(1M\)](#), [setrctl\(2\)](#), [rctlblk_get_local_action\(3C\)](#), [project\(4\)](#), [attributes\(5\)](#), [resource_controls\(5\)](#)

Notes The valid signals that can be set on a resource control block allowing local actions are SIGABRT, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Additionally, CPU time related controls can issue the SIGXCPU signal, and file size related controls can send the SIGXFSZ signal.

Name preap – force a defunct process to be reaped by its parent

Synopsis preap [-F] *pid*...

Description A defunct (or zombie) process is one whose exit status has yet to be reaped by its parent. The exit status is reaped by way of the `wait(3C)`, `waitid(2)`, or `waitpid(3C)` system call. In the normal course of system operation, zombies can occur, but are typically short-lived. This can happen if a parent exits without having reaped the exit status of some or all of its children. In that case, those children are reparented to PID 1. See `init(1M)`, which periodically reaps such processes.

An irresponsible parent process can not exit for a very long time and thus leave zombies on the system. Since the operating system destroys nearly all components of a process before it becomes defunct, such defunct processes do not normally impact system operation. However, they do consume a small amount of system memory.

preap forces the parent of the process specified by *pid* to `waitid(3C)` for *pid*, if *pid* represents a defunct process.

preap attempts to prevent the administrator from unwisely reaping a child process which might soon be reaped by the parent, if:

- The process is a child of `init(1M)`.
- The parent process is stopped and might wait on the child when it is again allowed to run.
- The process has been defunct for less than one minute.

Options The following option is supported:

-F Forces the parent to reap the child, overriding safety checks.

Operands The following operand is supported:

pid Process ID list.

Usage Caution should be exercised when using the -F flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the proc tool in question.

Exit Status The following exit values are returned by preap, which prints the exit status of each target process reaped:

0 Successfully operation.

non-zero Failure, such as no such process, permission denied, or invalid option.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------------------|
| Availability | system/extended-system-utilities |

See Also [proc\(1\)](#), [init\(1M\)](#), [waitid\(2\)](#), [wait\(3C\)](#), [waitpid\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#)

Warnings `preap` should be applied sparingly and only in situations in which the administrator or developer has confirmed that defunct processes are not reaped by the parent process. Otherwise, applying `preap` can damage the parent process in unpredictable ways.

Name print – shell built-in function to output characters to the screen or window

Synopsis

```
/usr/bin/print print [-CRenprsv] [-f format] [-u fd] [string...]
```

```
ksh88 print [-Rnprsu [n]] [arg]...
```

```
ksh print [-CRenprsv] [-f format] [-u fd] [string...]
```

Description

ksh88 The shell output mechanism. With no options or if the - option is specified, the arguments that follow are printed on standard output as described by [echo\(1\)](#). If the - option is specified, anything that follows it is processed as an argument, even if it begins with a -.

/usr/bin/print, ksh By default, print writes each string operand to standard output and appends a NEWLINE character.

Unless, the -r, -R, or -f option is specified, each \ character in each string operand is processed specially as follows:

\a Alert character.

\b Backspace character.

\c Terminate output without appending NEWLINE. The remaining string operands are ignored.

\E Escape character (ASCII octal 033).

\f FORM FEED character.

\n NEWLINE character.

\t Tab character.

\v Vertical tab character.

\\ Backslash character.

\0x The 8-bit character whose ASCII code is the 1-, 2-, or 3-digit octal number *x*.

Options

ksh88 The following options are supported by ksh88:

-n Suppresses new-line from being added to the output.

-r -R Raw mode. Ignore the escape conventions of echo. The -R option prints all subsequent arguments and options other than -n.

-p Cause the arguments to be written onto the pipe of the process spawned with |& instead of standard output.

- s Cause the arguments to be written onto the history file instead of standard output.
- u [*n*] Specify a one digit file descriptor unit number *n* on which the output is placed. The default is 1.

`/usr/bin/print`, `ksh` The following options are supported by `/usr/man/print` and `ksh`:

- e Unless `-f` is specified, process `\` sequences in each string operand as described above. This is the default behavior.

If both `-e` and `-r` are specified, the last one specified is the one that is used.
- f *format* Write the string arguments using the format string *format* and do not append a NEWLINE. See `printf(1)` for details on how to specify format.

When the `-f` option is specified and there are more string operands than format specifiers, the format string is reprocessed from the beginning. If there are fewer string operands than format specifiers, then outputting ends at the first unneeded format specifier.
- n Do not append a NEWLINE character to the output.
- p Write to the current co-process instead of standard output.
- r
- R Do not process `\` sequences in each string operand as described above.

If both `-e` and `-r` are specified, the last one specified is the one that is used.
- s Write the output as an entry in the shell history file instead of standard output.
- u *fd* Write to file descriptor number *fd* instead of standard output. The default value is 1.
- v Treat each string as a variable name and write the value in `%B` format. Cannot be used with `-f`.
- C Treat each string as a variable name and write the value in `##B` format. Cannot be used with `-f`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 Output file is not open for writing.

Attributes See `attributes(5)` for descriptions of the following attributes:

Diagnostics If a *variable* is specified and it is not defined in the environment, printenv returns an exit status of 1.

Name printf – write formatted output

Synopsis

`/usr/bin/printf` printf *format* [*argument*]...

`ksh` printf *format* [*string*...]

Description

`/usr/bin/printf` The `printf` utility writes each string operand to standard output using *format* to control the output format.

Operands

`/usr/bin/printf` The following operands are supported by `/usr/bin/printf`:

format A string describing the format to use to write the remaining operands. The *format* operand is used as the *format* string described on the [formats\(5\)](#) manual page, with the following exceptions:

- A SPACE character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.
- A character in the format string is treated as a character, not as a SPACE character.
- In addition to the escape sequences described on the [formats\(5\)](#) manual page (`\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`), `\ddd`, where *ddd* is a one-, two- or three-digit octal number, is written as a byte with the numeric value specified by the octal number.
- The program does not precede or follow output from the `d` or `u` conversion specifications with blank characters not specified by the *format* operand.
- The program does not precede output from the `o` conversion specification with zeros not specified by the *format* operand.
- An additional conversion character, `b`, is supported as follows. The argument is taken to be a string that can contain backslash-escape sequences. The following backslash-escape sequences are supported:
 - the escape sequences listed on the [formats\(5\)](#) manual page (`\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`), which are converted to the characters they represent
 - `\0ddd`, where *ddd* is a zero-, one-, two- or three-digit octal number that is converted to a byte with the numeric value specified by the octal number
 - `\c`, which is written and causes `printf` to ignore any remaining characters in the string operand containing it, any remaining string operands and any additional characters in the *format* operand.

The interpretation of a backslash followed by any other sequence of characters is unspecified.

Bytes from the converted string are written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it is taken to be infinite, so all bytes up to the end of the converted string are written. For each specification that consumes an argument, the next argument operand is evaluated and converted to the appropriate type for the conversion as specified below. The *format* operand is reused as often as necessary to satisfy the argument operands. Any extra *c* or *s* conversion specifications are evaluated as if a null string argument were supplied; other extra conversion specifications are evaluated as if a zero argument were supplied. If the *format* operand contains no conversion specifications and *argument* operands are present, the results are unspecified. If a character sequence in the *format* operand begins with a *%* character, but does not form a valid conversion specification, the behavior is unspecified.

argument The strings to be written to standard output, under the control of *format*. The *argument* operands are treated as strings if the corresponding conversion character is *b*, *c* or *s*. Otherwise, it is evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign is allowed.
- If the leading character is a single- or double-quote, the value is the numeric value in the underlying codeset of the character following the single- or double-quote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does not exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

ksh The *format* operands support the full range of ANSI C/C99/XPG6 formatting specifiers as well as additional specifiers:

%b Each character in the string operand is processed specially, as follows:

- \a* Alert character.
- \b* Backspace character.
- \c* Terminate output without appending NEWLINE. The remaining string operands are ignored.
- \E* Escape character (ASCII octal 033).
- \f* FORM FEED character.

| | |
|------------------|--|
| <code>\n</code> | NEWLINE character. |
| <code>\t</code> | TAB character. |
| <code>\v</code> | Vertical tab character. |
| <code>\\</code> | Backslash character. |
| <code>\0x</code> | The 8-bit character whose ASCII code is the 1-, 2-, or 3-digit octal number <i>x</i> . |
| <code>%B</code> | Treat the argument as a variable name and output the value without converting it to a string. This is most useful for variables of type <code>-b</code> . |
| <code>%H</code> | Output string with characters <code><</code> , <code>&</code> , <code>></code> , <code>"</code> , and non-printable characters, properly escaped for use in HTML and XML documents. |
| <code>%P</code> | Treat <i>string</i> as an extended regular expression and convert it to a shell pattern. |
| <code>%q</code> | Output <i>string</i> quoted in a manner that it can be read in by the shell to get back the same string. However, empty strings resulting from missing string operands are not quoted. |
| <code>%R</code> | Treat <i>string</i> as a shell pattern expression and convert it to an extended regular expression. |
| <code>%T</code> | Treat <i>string</i> as a date/time string and format it. The <code>T</code> can be preceded by (<i>dformat</i>), where <i>dformat</i> is a date format as defined by the <code>date(1)</code> command. |
| <code>%Z</code> | Output a byte whose value is <code>0</code> . |

When performing conversions of *string* to satisfy a numeric format specifier, if the first character of *string* is `"` or `'`, the value is the numeric value in the underlying code set of the character following the `"` or `'`. Otherwise, *string* is treated like a shell arithmetic expression and evaluated.

If a *string* operand cannot be completely converted into a value appropriate for that format specifier, an error occurs, but remaining *string* operands continue to be processed.

In addition to the format specifier extensions, the following extensions of ANSI C/C99/XPG6 are permitted in format specifiers:

- The escape sequences `\E` and `\e` expand to the escape character which is octal 033 in ASCII.
- The escape sequence `\cx` expands to CTRL-*x*.
- The escape sequence `\C[.name.]` expands to the collating element *name*.
- The escape sequence `\x{hex}` expands to the character corresponding to the hexadecimal value *hex*.
- The format modifier flag `=` can be used to center a field to a specified width. When the output is a terminal, the character width is used rather than the number of bytes.

- Each of the integral format specifiers can have a third modifier after width and precision that specifies the base of the conversion from 2 to 64. In this case, the # modifier causes *base#* to be prepended to the value.
- The # modifier can be used with the d specifier when no base is specified to cause the output to be written in units of 1000 with a suffix of one of k M G T P E.
- The # modifier can be used with the i specifier to cause the output to be written in units of 1024 with a suffix of one of Ki Mi Gi Ti Pi Ei.

If there are more *string* operands than format specifiers, the format string is reprocessed from the beginning. If there are fewer *string* operands than format specifiers, then *string* specifiers are treated as if empty strings were supplied, numeric conversions are treated as if 0 was supplied, and time conversions are treated as if now was supplied.

`/usr/bin/printf` is equivalent to ksh's `printf` built-in and `print -f`, which allows additional options to be specified.

Usage

`/usr/bin/printf` The `printf` utility, like the [printf\(3C\)](#) function on which it is based, makes no special provision for dealing with multi-byte characters when using the `%c` conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

Field widths and precisions cannot be specified as `*`.

The `%b` conversion specification is not part of the ISO C standard; it has been added here as a portable way to process backslash escapes expanded in string operands as provided by the `echo` utility. See also the USAGE section of the [echo\(1\)](#) manual page for ways to use `printf` as a replacement for all of the traditional versions of the `echo` utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the `printf` utility reports an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion are to be reported as errors.

It is not considered an error if an argument operand is not completely used for a `c` or `s` conversion or if a string operand's first or second character is used to get the numeric value of a character.

Examples

`/usr/bin/printf` EXAMPLE 1 Printing a Series of Prompts
Examples

The following example alerts the user, then prints and reads a series of prompts:

```
example% printf "\aPlease fill in the following: \nName: "  
read name
```

EXAMPLE 1 Printing a Series of Prompts (Continued)

```
printf "Phone number: "
read phone
```

EXAMPLE 2 Printing a Table of Calculations

The following example prints a table of calculations. It reads out a list of right and wrong answers from a file, calculates the percentage correctly, and prints them out. The numbers are right-justified and separated by a single tab character. The percentage is written to one decimal place of accuracy:

```
example% while read right wrong ; do
    percent=$(echo "scale=1;($right*100)/($right+$wrong)" | bc)
    printf "%2d right\t%2d wrong\t(%%s%%)\n" \
        $right $wrong $percent
done < database_file
```

EXAMPLE 3 Printing number strings

The command:

```
example% printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
    1  21
   3214321
54321  0
```

The *format* operand is used three times to print all of the given strings and that a 0 was supplied by `printf` to satisfy the last `%4d` conversion specification.

EXAMPLE 4 Tabulating Conversion Errors

The following example tabulates conversion errors.

The `printf` utility tells the user when conversion errors are detected while producing numeric output. These results would be expected on an implementation with 32-bit twos-complement integers when `%d` is specified as the *format* operand:

| Arguments | Standard | Diagnostic |
|-------------|-------------|--|
| 5a | 5 | printf: 5a not completely converted |
| 9999999999 | 2147483647 | printf: 9999999999: Results too large |
| -9999999999 | -2147483648 | printf: -9999999999: Results too large |
| ABC | 0 | printf: ABC expected numeric value |

The value shown on standard output is what would be expected as the return value from the function `strtol(3C)`. A similar correspondence exists between `%u` and `strtoul(3C)`, and `%e`, `%f` and `%g` and `strtod(3C)`.

EXAMPLE 5 Printing Output for a Specific Locale

The following example prints output for a specific locale. In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

```
example% printf "%d\n" 3 +3 -3 \'3 \'+3 \'-3"
```

produces:

| | |
|----|---|
| 3 | Numeric value of constant 3 |
| 3 | Numeric value of constant 3 |
| -3 | Numeric value of constant -3 |
| 51 | Numeric value of the character '3' in the ISO/IEC 646:1991 standard codeset |
| 43 | Numeric value of the character '+' in the ISO/IEC 646:1991 standard codeset |
| 45 | Numeric value of the character '-' in the SO/IEC 646:1991 standard codeset |

In a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the `wchar_t` representation of the character.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

ksh Examples The following examples illustrate the use of the `ksh93` version of `printf`.

EXAMPLE 6 Alternative floating point representation 1

The `printf` utility supports an alternative floating point representation (see `printf(3C)` entry for the `"%a"/"%A"`), which allows the output of floating-point values in a format that avoids the usual base16 to base10 rounding errors.

```
example% printf "%a\n" 2 3.1 NaN
```

produces:

```
0x1.00000000000000000000000000000000p+01
0x1.8cccccccccccccccccccccdp+01
nan
```

EXAMPLE 7 Alternative floating point representation 2

The following example shows two different representations of the same floating-point value.

```
example% x=2 ; printf "%f == %a\n" x x
```

produces:

```
2.000000 == 0x1.00000000000000000000000000000000p+01
```

EXAMPLE 8 Output of unicode values

The following command will print the EURO unicode symbol (code-point 0x20ac).

```
example% LC_ALL=en_US.UTF-8 printf "\u[20ac]\n"
```

produces:

```
<euro>
```

where <euro> represents the EURO currency symbol character.

EXAMPLE 9 Convert unicode character to unicode code-point value

The following command will print the hexadecimal value of a given character.

```
example% export LC_ALL=en_US.UTF-8
```

```
example% printf "%x\n" "'<euro>"
```

where <euro> represents the EURO currency symbol character (code-point 0x20ac).

produces:

```
20ac
```

EXAMPLE 10 Print the numeric value of an ASCII character

```
example% printf "%d\n" "'A"
```

produces:

```
65
```

EXAMPLE 11 Print the language-independent date and time format

To print the language-independent date and time format, the following statement could be used:

```
example% printf "format" weekday month day hour min
```

For example,

```
$ printf format "Sunday" "July" 3 10 2
```

For American usage, format could be the string:

EXAMPLE 11 Print the language-independent date and time format *(Continued)*

```
"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

Whereas for EU usage, format could be the string:

```
"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

Note that the '\$' characters must be properly escaped, such as

```
"%1\$s, %3\$d. %2\$s, %4\$d:%5\$.2d\n"
```

 in this case

producing the message:

```
Sunday, 3. July, 10:02
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `printf`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, and `NLSPATH`.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/printf	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	text/locale
	CSI	Enabled
	Interface Stability	Committed
	Standard	See standards(5) .

ksh	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/core-os
	Interface Stability	Uncommitted

See Also [awk\(1\)](#), [bc\(1\)](#), [date\(1\)](#), [echo\(1\)](#), [ksh\(1\)](#), [printf\(3C\)](#), [strtod\(3C\)](#), [strtol\(3C\)](#), [strtoul\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [formats\(5\)](#), [standards\(5\)](#)

Notes Using format specifiers (characters following '%') which are not listed in the [printf\(3C\)](#) or this manual page will result in undefined behavior.

Using escape sequences (the character following a backslash ('\')) which are not listed in the [printf\(3C\)](#) or this manual page will result in undefined behavior.

Floating-point values follow C99, XPG6 and IEEE 754 standard behavior and can handle values the same way as the platform's `|long double|` datatype.

Floating-point values handle the sign separately which allows signs for values like NaN (for example, `-nan`), Infinite (for example, `-inf`) and zero (for example, `-0.0`).

Name prioctl – display or set scheduling parameters of specified processes and LWPs

Synopsis prioctl -l
prioctl -d [-i *idtype*] [*idlist*]
prioctl -s [-c *class*] [*class-specific options*]
[-i *idtype*] [*idlist*]
prioctl -e [-c *class*] [*class-specific options*] *command*
[*argument(s)*]

Description The `prioctl` command displays or sets scheduling parameters of the specified processes or LWPs. It can also be used to display the current configuration information for the system's process scheduler or execute a command with specified scheduling parameters.

Processes and LWPs fall into distinct classes with a separate scheduling policy applied to each class. The classes currently supported are the real-time class, time-sharing class, interactive class, fair-share class, and the fixed priority class. The characteristics of these classes and the class-specific options they accept are described below in the USAGE section under the headings Real-Time Class, Time-Sharing Class, Inter-Active Class, Fair-Share Class, and Fixed-Priority Class. With appropriate permissions, the `prioctl` command can change the class and other scheduling parameters associated with a running process or LWPs.

In the default configuration, a runnable real-time process or LWP runs before any other process. Therefore, inappropriate use of real-time processes or LWPs can have a dramatic negative impact on system performance.

If an *idlist* is present, it must appear last on the command line and the elements of the list must be separated by white space. If no *idlist* is present, an *idtype* argument of `pid`, `ppid`, `pgid`, `sid`, `taskid`, `class`, `uid`, `gid`, `projid`, or `zoneid` specifies the process ID, parent process ID, process group ID, session ID, task ID, class, user ID, group ID, project ID, or zone ID, respectively, of the `prioctl` command itself.

The command

```
prioctl -d [-i idtype] [idlist]
```

displays the class and class-specific scheduling parameters of the processes specified by *idtype* and *idlist*.

The command

```
prioctl -s [-c class] [class-specific options] \  
[-i idtype] [idlist]
```

sets the class and class-specific parameters of the specified processes to the values given on the command line. The `-c class` option specifies the class to be set. (The valid *class* arguments are RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority.)

The class-specific parameters to be set are specified by the class-specific options as explained under the appropriate heading below. If the `-c class` option is omitted, *idtype* and *idlist* must specify a set of processes or LWPs which are all in the same class, otherwise an error results. If no class-specific options are specified, the process's class-specific parameters are set to the default values for the class specified by `-c class` (or to the default parameter values for the process's current class if the `-c class` option is also omitted).

To change the scheduling parameters of a process or LWP using `prioctl` the real or effective user ID (respectively, groupID) of the user invoking `prioctl` must match the real or effective user ID (respectively, groupID) of the receiving process or LWP, or the effective user ID of the user must be super-user. These are the minimum permission requirements enforced for all classes. An individual class can impose additional permissions requirements when setting processes to that class or when setting class-specific scheduling parameters.

When *idtype* and *idlist* specify a set of processes (with or without a list of LWPs), `prioctl` acts on the processes in the set in an implementation-specific order. If `prioctl` encounters an error for one or more of the target processes, it can or cannot continue through the set of processes, depending on the nature of the error.

If the error is related to permissions, `prioctl` prints an error message and then continues through the process set, resetting the parameters for all target processes for which the user has appropriate permissions. If `prioctl` encounters an error other than permissions, it does not continue through the process set but prints an error message and exits immediately.

A special `sys` scheduling class exists for the purpose of scheduling the execution of certain special system processes (such as the swapper process). It is not possible to change the class of any process to `sys`. In addition, any processes or LWPs in the `sys` class that are included in the set of processes specified by *idtype* and *idlist* are disregarded by `prioctl`. For example, if *idtype* were `uid`, an *idlist* consisting of a zero would specify all processes with a UID of 0, except processes in the `sys` class and (if changing the parameters using the `-s` option) the `init` process.

The `init` process (process ID 1) is a special case. In order for the `prioctl` command to change the class or other scheduling parameters of the `init` process, *idtype* must be `pid` and *idlist* must be consist of only a 1. The `init` process can be assigned to any class configured on the system, but the time-sharing class is almost always the appropriate choice. Other choices can be highly undesirable; see the [Oracle Solaris Administration: Common Tasks](#) for more information.

The command

```
prioctl -e [-c class] [class-specific options] command \
    [argument...]
```

executes the specified command with the class and scheduling parameters specified on the command line (*arguments* are the arguments to the command). If the `-c class` option is omitted the command is run in the user's current class.

Options The following options are supported:

-c *class*

Specifies the *class* to be set. (The valid *class* arguments are RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority.) If the specified class is not already configured, it is automatically configured.

-d

Displays the scheduling parameters associated with a set of processes.

-e

Executes a specified command with the class and scheduling parameters associated with a set of processes.

-i *idtype*

This option, together with the *idlist* arguments (if any), specifies one or more processes or LWPs to which the `prioctl` command is to apply. The interpretation of *idlist* depends on the value of *idtype*. If the -i *idtype* option is omitted when using the -d or -s options the default *idtype* of pid is assumed.

The valid *idtype* arguments and corresponding interpretations of *idlist* are as follows:

-i all

The `prioctl` command applies to all existing processes. No *idlist* should be specified (if one is specified, it is ignored). The permission restrictions described below still apply.

-i ctid

idlist is a list of process contract IDs. The `prioctl` command applies to all processes with a process contract ID equal to an ID from the list.

-i class

idlist consists of a single class name (RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority). The `prioctl` command applies to all processes in the specified class.

-i gid

idlist is a list of group IDs. The `prioctl` command applies to all processes with an effective group ID equal to an ID from the list.

-i pgid

idlist is a list of process group IDs. The `prioctl` command applies to all processes in the specified process groups.

-i *pid[/lwps]*

idlist is a list of process IDs with each ID possibly followed by a forward slash (/) and a list of comma-separated LWP IDs. A range of LWP IDs can be indicated by a hyphen (-) separating the first and final items in the range.

- i *ppid*
idlist is a list of parent process IDs. The `prioctl` command applies to all processes whose parent process ID is in the list.
- i *projid*
idlist is a list of project IDs. The `prioctl` command applies to all processes with an effective project ID equal to an ID from the list.
- i *sid*
idlist is a list of session IDs. The `prioctl` command applies to all processes in the specified sessions.
- i *taskid*
idlist is a list of task IDs. The `prioctl` command applies to all processes in the specified tasks.
- i *uid*
idlist is a list of user IDs. The `prioctl` command applies to all processes with an effective user ID equal to an ID from the list.
- i *zoneid*
idlist is a list of zone IDs. The `prioctl` command applies to all processes with an effective zone ID equal to an ID from the list.
- l
Displays a list of the classes currently configured in the system along with class-specific information about each class. The format of the class-specific information displayed is described under `USAGE`.
- s
Sets the scheduling parameters associated with a set of processes.

The valid class-specific options for setting real-time parameters are:

- p *rtpri*
Sets the real-time priority of the specified processes and LWPs to *rtpri*.
- t *tqntm* [- *r res*]
Sets the time quantum of the specified processes to *tqntm*. You can optionally specify a resolution as explained below.
- q *tqsig*
Sets the real-time time quantum signal of the specified processes and LWPs to *tqsig*.

The valid class-specific options for setting time-sharing parameters are:

- m *tsuprilim*
Sets the user priority limit of the specified processes and LWPs to *tsuprilim*.
- p *tsupri*
Sets the user priority of the specified processes and LWPs to *tsupri*.

The valid class-specific options for setting inter-active parameters are:

-m *iauprilm*
Sets the user priority limit of the specified processes and LWPs to *iauprilm*.

-p *iaupri*
Sets the user priority of the specified processes and LWPs to *iaupri*.

The valid class-specific options for setting fair-share parameters are:

-m *fssuprilm*
Sets the user priority limit of the specified processes and LWPs to *fssuprilm*.

-p *fssupri*
Sets the user priority of the specified processes and LWPs to *fssupri*.

The valid class-specific options for setting fixed-priority parameters are:

-m *fxuprilm*
Sets the user priority limit of the specified processes and LWPs to *fxuprilm*.

-p *fxupri*
Sets the user priority of the specified processes and LWPs to *fxupri*.

-t *tqntm*
[- r *res*] Sets the time quantum of the specified processes and LWPs to *tqntm*. You can optionally specify a resolution as explained below.

Usage

Real-Time Class The real-time class provides a fixed priority preemptive scheduling policy for those processes requiring fast and deterministic response and absolute user/application control of scheduling priorities. If the real-time class is configured in the system, it should have exclusive control of the highest range of scheduling priorities on the system. This ensures that a runnable real-time process is given CPU service before any process belonging to any other class.

The real-time class has a range of real-time priority (*rtpri*) values that can be assigned to processes within the class. Real-time priorities range from 0 to *x*, where the value of *x* is configurable and can be displayed for a specific installation that has already configured a real-time scheduler, by using the command

```
prioctl -l
```

The real-time scheduling policy is a fixed priority policy. The scheduling priority of a real-time process never changes except as the result of an explicit request by the user/application to change the *rtpri* value of the process.

For processes in the real-time class, the *rtpri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *rtpri* value completely determines the scheduling priority of a real-time process relative to other processes within its class. Numerically higher

rtpri values represent higher priorities. Since the real-time class controls the highest range of scheduling priorities in the system, it is guaranteed that the runnable real-time process with the highest *rtpri* value is always selected to run before any other process in the system.

In addition to providing control over priority, `prioctl` provides for control over the length of the time quantum allotted to processes in the real-time class. The time quantum value specifies the maximum amount of time a process can run, assuming that it does not complete or enter a resource or event wait state (`sleep`). Notice that if another process becomes runnable at a higher priority, the currently running process can be preempted before receiving its full time quantum.

The command

```
prioctl -d [-i idtype] [idlist]
```

displays the real-time priority, time quantum (in millisecond resolution), and time quantum signal value for each real-time process in the set specified by *idtype* and *idlist*.

Any combination of the `-p`, `-t [-r]`, and `-q` options can be used with `prioctl -s` or `prioctl -e` for the real-time class. If an option is omitted and the process is currently real-time, the associated parameter is unaffected. If an option is omitted when changing the class of a process to real-time from some other class, the associated parameter is set to a default value. The default value for *rtpri* is 0 and the default for time quantum is dependent on the value of *rtpri* and on the system configuration; see `rt_dptbl(4)`.

When using the `-t tqntm` option, you can optionally specify a resolution using the `-r res` option. (If no resolution is specified, millisecond resolution is assumed.) If *res* is specified, it must be a positive integer between 1 and 1,000,000,000 inclusively and the resolution used is the reciprocal of *res* in seconds. For example, specifying `-t 10 -r 100` would set the resolution to hundredths of a second and the resulting time quantum length would be 10/100 seconds (one tenth of a second). Although very fine (nanosecond) resolution can be specified, the time quantum length is rounded up by the system to the next integral multiple of the system clock's resolution. Requests for time quantum of zero or quantum greater than the (typically very large) implementation-specific maximum quantum result in an error.

The real-time time quantum signal can be used to notify runaway real-time processes about the consumption of their time quantum. Those processes, which are monitored by the real-time time quantum signal, receive the configured signal in the event of time quantum expiration. The default value (0) of the time quantum signal *tqsig* denotes no signal delivery. A positive value denotes the delivery of the signal specified by the value. Like `kill(1)` and other commands operating on signals, the `-q tqsig` option is also able to handle symbolically named signals, like XCPU or KILL.

In order to change the class of a process to real-time (from any other class), the user invoking `prioctl` must have super-user privilege. In order to change the *rtpri* value or time quantum of a real-time process, the user invoking `prioctl` must either be super-user, or must currently be in the real-time class (shell running as a real-time process) with a real or effective user ID matching the real or effective user ID of the target process.

The real-time priority, time quantum, and time quantum signal are inherited across the `fork(2)` and `exec(2)` system calls. When using the time quantum signal with a user defined signal handler across the `exec(2)` system call, the new image must install an appropriate user defined signal handler before the time quantum expires. Otherwise, unpredictable behavior would result.

Time-Sharing Class The time-sharing scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics. The objectives of the time-sharing policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs, while providing a degree of user/application control over scheduling.

The time-sharing class has a range of time-sharing user priority (*tsupri*) values that can be assigned to processes within the class. User priorities range from $-x$ to $+x$, where the value of x is configurable. The range for a specific installation can be displayed by using the command

```
priocntl -l
```

The purpose of the user priority is to provide some degree of user/application control over the scheduling of processes in the time-sharing class. Raising or lowering the *tsupri* value of a process in the time-sharing class raises or lowers the scheduling priority of the process. It is not guaranteed, however, that a time-sharing process with a higher *tsupri* value runs before one with a lower *tsupri* value. This is because the *tsupri* value is just one factor used to determine the scheduling priority of a time-sharing process. The system can dynamically adjust the internal scheduling priority of a time-sharing process based on other factors such as recent CPU usage.

In addition to the system-wide limits on user priority (displayed with `priocntl -l`), there is a per process user priority limit (*tsuprilim*), which specifies the maximum *tsupri* value that can be set for a given process.

The command

```
priocntl -d [-i idtype] [idlist]
```

displays the user priority and user priority limit for each time-sharing process in the set specified by *idtype* and *idlist*.

Any time-sharing process can lower its own *tsuprilim* (or that of another process with the same user ID). Only a time-sharing process with super-user privilege can raise a *tsuprilim*. When changing the class of a process to time-sharing from some other class, super-user privilege is required in order to set the initial *tsuprilim* to a value greater than zero.

Any time-sharing process can set its own *tsupri* (or that of another process with the same user ID) to any value less than or equal to the process's *tsuprilim*. Attempts to set the *tsupri* above the *tsuprilim* (and/or set the *tsuprilim* below the *tsupri*) result in the *tsupri* being set equal to the *tsuprilim*.

Any combination of the `-m` and `-p` options can be used with `prioctl -s` or `prioctl -e` for the time-sharing class. If an option is omitted and the process is currently time-sharing, the associated parameter is normally unaffected. The exception is when the `-p` option is omitted and `-m` is used to set a *tsuprilim* below the current *tsupri*. In this case, the *tsupri* is set equal to the *tsuprilim* which is being set. If an option is omitted when changing the class of a process to time-sharing from some other class, the associated parameter is set to a default value. The default value for *tsuprilim* is 0 and the default for *tsupri* is to set it equal to the *tsuprilim* value which is being set.

The time-sharing user priority and user priority limit are inherited across the `fork(2)` and `exec(2)` system calls.

Inter-Active Class The inter-active scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics while providing good responsiveness for user interaction. The objectives of the inter-active policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs. The priorities of processes in the inter-active class can be changed in the same manner as those in the time-sharing class, though the modified priorities continue to be adjusted to provide good responsiveness for user interaction.

The inter-active user priority limit, *iaupri*, is equivalent to *tsupri*. The inter-active per process user priority, *iauprilim*, is equivalent to *tsuprilim*.

Inter-active class processes that have the *iamode* (“interactive mode”) bit set are given a priority boost value of 10, which is factored into the user mode priority of the process when that calculation is made, that is, every time a process's priority is adjusted. This feature is used by the X windowing system, which sets this bit for those processes that run inside of the current active window to give them a higher priority.

Fair-Share Class The fair-share scheduling policy provides a fair allocation of system CPU resources among projects, independent of the number of processes they own. Projects are given “shares” to control their entitlement to CPU resources. Resource usage is remembered over time, so that entitlement is reduced for heavy usage, and increased for light usage, with respect to other projects. CPU time is scheduled among processes according to their owner's entitlements, independent of the number of processes each project owns.

The FSS scheduling class supports the notion of per-process user priority and user priority limit for compatibility with the time-share scheduler. The fair share scheduler attempts to provide an evenly graded effect across the whole range of user priorities. Processes with negative *fssupri* values receive time slices less frequently than normal, while processes with positive *fssupri* values receive time slices more frequently than normal. Notice that user priorities do not interfere with shares. That is, changing a *fssupri* value of a process is not going to affect its project's overall CPU usage which only relates to the amount of shares it is allocated compared to other projects.

The priorities of processes in the fair-share class can be changed in the same manner as those in the time-share class.

Fixed-Priority Class The fixed-priority class provides a fixed priority preemptive scheduling policy for those processes requiring that the scheduling priorities do not get dynamically adjusted by the system and that the user/application have control of the scheduling priorities.

The fixed-priority class shares the same range of scheduling priorities with the time-sharing class, by default. The fixed-priority class has a range of fixed-priority user priority (*fxupri*) values that can be assigned to processes within the class. User priorities range from 0 to *x*, where the value of *x* is configurable. The range for a specific installation can be displayed by using the command

```
prioctl -l
```

The purpose of the user priority is to provide user/application control over the scheduling of processes in the fixed-priority class. For processes in the fixed-priority class, the *fxupri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *fxupri* value completely determines the scheduling priority of a fixed-priority process relative to other processes within its class. Numerically higher *fxupri* values represent higher priorities.

In addition to the system-wide limits on user priority (displayed with `prioctl -l`), there is a per process user priority limit (*fxuprilim*), which specifies the maximum *fxupri* value that can be set for a given process.

Any fixed-priority process can lower its own *fxuprilim* (or that of another process with the same user ID). Only a process with super-user privilege can raise a *fxuprilim*. When changing the class of a process to fixed-priority from some other class, super-user privilege is required in order to set the initial *fxuprilim* to a value greater than zero.

Any fixed-priority process can set its own *fxupri* (or that of another process with the same user ID) to any value less than or equal to the process's *fxuprilim*. Attempts to set the *fxupri* above the *fxuprilim* (or set the *fxuprilim* below the *fxupri*) result in the *fxupri* being set equal to the *fxuprilim*.

In addition to providing control over priority, `prioctl` provides for control over the length of the time quantum allotted to processes in the fixed-priority class. The time quantum value specifies the maximum amount of time a process can run, before surrendering the CPU, assuming that it does not complete or enter a resource or event wait state (sleep). Notice that if another process becomes runnable at a higher priority, the currently running process can be preempted before receiving its full time quantum.

Any combination of the `-m`, `-p`, and `-t` options can be used with `prioctl -s` or `prioctl -e` for the fixed-priority class. If an option is omitted and the process is currently fixed-priority, the associated parameter is normally unaffected. The exception is when the `-p` option is omitted and the `-m` option is used to set a *fxuprilim* below the current *fxupri*. In this case, the *fxupri* is set equal to the *fxuprilim* which is being set. If an option is omitted when changing the class of a process to fixed-priority from some other class, the associated parameter is set to a default value. The default value for *fxuprilim* is 0. The default for *fxupri* is to set it equal to the *fxuprilim* value which is being set. The default for time quantum is dependent on the *fxupri* and on the system configuration. See `fx_dptbl(4)`.

The time quantum of processes in the fixed-priority class can be changed in the same manner as those in the real-time class.

The fixed-priority user priority, user priority limit, and time quantum are inherited across the `fork(2)` and `exec(2)` system calls.

Examples The following are real-time class examples:

EXAMPLE 1 Setting the Class

The following example sets the class of any non-real-time processes selected by *idtype* and *idlist* to real-time and sets their real-time priority to the default value of 0. The real-time priorities of any processes currently in the real-time class are unaffected. The time quantum of all of the specified processes are set to 1/10 seconds.

```
example% prioctl -s -c RT -t 1 -r 10 -i idtype idlist
```

EXAMPLE 2 Executing a Command in Real-time

The following example executes *command* in the real-time class with a real-time priority of 15 and a time quantum of 20 milliseconds:

```
example% prioctl -e -c RT -p 15 -t 20 command
```

EXAMPLE 3 Executing a Command in Real-time with a Specified Quantum Signal

The following example executes *command* in the real-time class with a real-time priority of 11, a time quantum of 250 milliseconds, and where the specified real-time quantum signal is SIGXCPU:

```
example% prioctl -e -c RT -p 11 -t 250 -q XCPU command
```

The following are time-sharing class examples:

EXAMPLE 4 Setting the Class of non-time-sharing Processes

The following example sets the class of any non-time-sharing processes selected by *idtype* and *idlist* to time-sharing and sets both their user priority limit and user priority to 0. Processes already in the time-sharing class are unaffected.

```
example% prioctl -s -c TS -i idtype idlist
```

EXAMPLE 5 Executing a Command in the Time-sharing Class

The following example executes *command* with the arguments *arguments* in the time-sharing class with a user priority limit of 0 and a user priority of -15:

```
example% prioctl -e -c TS -m 0 -p -15 command [arguments]
```

EXAMPLE 6 Executing a Command in Fixed-Priority Class

The following example executes a command in the fixed-priority class with a user priority limit of 20 and user priority of 10 and time quantum of 250 milliseconds:

```
example% priocntl -e -c FX -m 20 -p 10 -t 250 command
```

EXAMPLE 7 Changing the Priority of a Specific LWP

The following example sets the user priority limit of 20 and user priority of 15 for the LWP 5 in process 500:

```
example% priocntl -s -m 20 -p 15 500/5
```

Exit Status The following exit values are returned:

For options -d, -l, and -s:

0
Successful operation.

1
Error condition.

For option -e:

Return of the Exit Status of the executed command denotes successful operation. Otherwise,

1
Command could not be executed at the specified priority.

Oracle Solaris Administration: Common Tasks

Diagnostics `priocntl` prints the following error messages:

Process(es) not found
None of the specified processes exists.

Specified processes from different classes
The -s option is being used to set parameters, the -c class option is not present, and processes from more than one class are specified.

Invalid option or argument

An unrecognized or invalid option or option argument is used.

Name proc, pflags, pcred, pldd, psig, pstack, pfiles, pwdx, pstop, prun, pwait, ptime – proc tools

Synopsis /usr/bin/pflags [-r] *pid* | *core* [/lwp] ...
 /usr/bin/pcred [*pid* | *core*]...
 /usr/bin/pcred [-u *user/uid*] [-g *group/gid*] [-G *grouplist*] *pid*...
 /usr/bin/pcred -l *login pid*...
 /usr/bin/pldd [-Fl] [*pid* | *core*]...
 /usr/bin/psig [-n] *pid*...
 /usr/bin/pstack [-F] *pid* | *core* [/lwp] ...
 /usr/bin/pfiles [-Fn] *pid*...
 /usr/bin/pwdx *pid*...
 /usr/bin/pstop *pid*[/lwp] ...
 /usr/bin/prun *pid*[/lwp] ...
 /usr/bin/pwait [-v] *pid*...
 /usr/bin/ptime [-Fm] [-p] *pid*...
 /usr/bin/ptime [-m]*command* [*arg*]...

Description The proc tools are utilities that exercise features of /proc (see [proc\(4\)](#)). Most of them take a list of process-ids (*pid*). The tools that do take process-ids also accept /proc/*nnn* as a process-id, so the shell expansion /proc/* can be used to specify all processes in the system.

Some of the proc tools can also be applied to core files (see [core\(4\)](#)). The tools that apply to core files accept a list of either process IDs or names of core files or both.

Some of the proc tools can operate on individual threads. Users can examine only selected threads by appending */thread-id* to the process-id or core. Multiple threads can be selected using the - and , delimiters. For example /1,2,7-9 examines threads 1, 2, 7, 8, and 9.

See WARNINGS.

pflags Print the /proc tracing flags, the pending and held signals, and other /proc status information for each process or specified lwps in each process.

pcred Print or set the credentials (effective, real, saved UIDs and GIDs) of each process.

pldd List the dynamic libraries linked into each process, including shared objects explicitly attached using `dlopen(3C)`. See also `ldd(1)`.

psig List the signal actions and handlers of each process. See `signal.h(3HEAD)`.

pstack Print a hex+symbolic stack trace for each process or specified lwps in each process.

- pfiles** Report **fstat(2)** and **fcntl(2)** information for all open files in each process. For network endpoints, the local (and peer if connected) address information is also provided. For sockets, the socket type, socket options and send and receive buffer sizes are also provided. In addition, a path to the file is reported if the information is available from `/proc/pid/path`. This is not necessarily the same name used to open the file. See **proc(4)** for more information.
- pwdx** Print the current working directory of each process.
- ps top** Stop each process or the specified lwps (**PR_REQUESTED stop**).
- prun** Set running each process or the specified lwps (the inverse of **ps top**).
- pwait** Wait for all of the specified processes to terminate.
- ptime** Time the *command*, like **time(1)**, but using microstate accounting for reproducible precision. Unlike **time(1)**, children of the command are not timed.
- If the `-p pid` version is used, display a snapshot of timing statistics for the specified *pid*.

Options The following general options are supported:

- F Force. Grabs the target process even if another process has control.
- n (**psig** and **pfiles** only) Sets non-verbose mode. **psig** displays signal handler addresses rather than names. **pfiles** does not display verbose information for each file descriptor. Instead, **pfiles** limits its output to the information that would be retrieved if the process applied **fstat(2)** to each of its file descriptors.
- r (**pf1ags** only) If the process is stopped, displays its machine registers.
- v (**pwait** only) Verbose. Reports terminations to standard output.

In addition to the general options, **pc red** supports the following options:

- g *group/gid* Sets the real, effective, and saved group ids (GIDs) of the target processes to the specified value.
- G *grouplist* Sets the supplementary GIDs of the target process to the specified list of groups. The supplementary groups should be specified as a comma-separated list of group names ids. An empty list clears the supplementary group list of the target processes.
- l *login* Sets the real, effective, and saved UIDs of the target processes to the UID of the specified login. Sets the real, effective, and saved GIDs of the target processes to the GID of the specified login. Sets the supplementary group list to the supplementary groups list of the specified login.
- u *user/uid* Sets the real, effective, and saved user ids (UIDs) of the target processes to the specified value.

In addition to the general options, `pldd` supports the following option:

`-l` Shows unresolved dynamic linker map names.

In addition to the general options, `ptime` supports the following options:

`-m` Display the full set of microstate accounting statistics.

The displayed fields are as follows:

`real` Wall clock time.
`user` User level CPU time.
`sys` System call CPU time.
`trap` Other system trap CPU time.
`tfllt` Text page fault sleep time.
`dfltt` Data page fault sleep time.
`kfltt` Kernel page fault sleep time.
`lock` User lock wait sleep time.
`slp` All other sleep time.
`lat` CPU latency (wait) time.
`stop` Stopped time.

`-p pid` Displays a snapshot of timing statistics for the specified *pid*.

To set the credentials of another process, a process must have sufficient privilege to change its user and group ids to those specified according to the rules laid out in [setuid\(2\)](#) and it must have sufficient privilege to control the target process.

Usage These proc tools stop their target processes while inspecting them and reporting the results: `profiles`, `pldd`, and `psstack`. A process can do nothing while it is stopped. Thus, for example, if the X server is inspected by one of these proc tools running in a window under the X server's control, the whole window system can become deadlocked because the proc tool would be attempting to print its results to a window that cannot be refreshed. Logging in from another system using [ssh\(1\)](#) and killing the offending proc tool would clear up the deadlock in this case.

See WARNINGS.

Caution should be exercised when using the `-F` flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the proc tool in question.

Some of the proc tools can also be applied to core files, as shown by the synopsis above. A core file is a snapshot of a process's state and is produced by the kernel prior to terminating a process with a signal or by the [gcore\(1\)](#) utility. Some of the proc tools can need to derive the name of the executable corresponding to the process which dumped core or the names of shared libraries associated with the process. These files are needed, for example, to provide symbol table information for [pstack\(1\)](#). If the proc tool in question is unable to locate the needed executable or shared library, some symbol information is unavailable for display. Similarly, if a core file from one operating system release is examined on a different operating system release, the run-time link-editor debugging interface (`librtld_db`) cannot be able to initialize. In this case, symbol information for shared libraries is not available.

Exit Status The following exit values are returned:

0 Successful operation.
non-zero An error has occurred.

Files /proc/* process files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The human readable output is Uncommitted. The options are Committed.

See Also [gcore\(1\)](#), [ldd\(1\)](#), [pargs\(1\)](#), [pgrep\(1\)](#), [pkill\(1\)](#), [plimit\(1\)](#), [pmap\(1\)](#), [preap\(1\)](#), [ps\(1\)](#), [ptree\(1\)](#), [ppgsz\(1\)](#), [pwd\(1\)](#), [rlogin\(1\)](#), [ssh\(1\)](#), [time\(1\)](#), [truss\(1\)](#), [wait\(1\)](#), [fcntl\(2\)](#), [fstat\(2\)](#), [setuid\(2\)](#), [dlopen\(3C\)](#), [signal.h\(3HEAD\)](#), [core\(4\)](#), [proc\(4\)](#), [process\(4\)](#), [attributes\(5\)](#), [zones\(5\)](#)

Warnings The following proc tools stop their target processes while inspecting them and reporting the results: `pfiles`, `pldd`, and `pstack`. However, even if `pstack` operates on an individual thread, it stops the whole process.

A process or thread can do nothing while it is stopped. Stopping a heavily used process or thread in a production environment, even for a short amount of time, can cause severe bottlenecks and even hangs of these processes or threads, causing them to be unavailable to users. Some databases could also terminate abnormally. Thus, for example, a database server under heavy load could hang when one of the database processes or threads is traced using the above mentioned proc tools. Because of this, stopping a UNIX process or thread in a production environment should be avoided.

A process or thread being stopped by these tools can be identified by issuing `/usr/bin/ps -efl` and looking for “T” in the first column. Notice that certain processes, for example “sched”, can show the “T” status by default most of the time.

The process ID returned for locked files on network file systems might not be meaningful.

Name prof – display profile data

Synopsis prof [-ChsVz] [-a | c | n | t] [-o | x] [-g | l] [-m *mdata*]
[*prog*]

Description The `prof` command interprets a profile file produced by the `monitor` function. The symbol table in the object file *prog* (`a.out` by default) is read and correlated with a profile file (`mon.out` by default). For each external text symbol the percentage of time spent executing between the address of that symbol and the address of the next is printed, together with the number of times that function was called and the average number of milliseconds per call.

Options The mutually exclusive options `-a`, `-c`, `-n`, and `-t` determine the type of sorting of the output lines:

- a Sort by increasing symbol address.
- c Sort by decreasing number of calls.
- n Sort lexically by symbol name.
- t Sort by decreasing percentage of total time (default).

The mutually exclusive options `-o` and `-x` specify the printing of the address of each symbol monitored:

- o Print each symbol address (in octal) along with the symbol name.
- x Print each symbol address (in hexadecimal) along with the symbol name.

The mutually exclusive options `-g` and `-l` control the type of symbols to be reported. The `-l` option must be used with care; it applies the time spent in a static function to the preceding (in memory) global function, instead of giving the static function a separate entry in the report. If all static functions are properly located, this feature can be very useful. If not, the resulting report may be misleading.

Assume that A and B are global functions and only A calls static function S. If S is located immediately after A in the source code (that is, if S is properly located), then, with the `-l` option, the amount of time spent in A can easily be determined, including the time spent in S. If, however, both A and B call S, then, if the `-l` option is used, the report will be misleading; the time spent during B's call to S will be attributed to A, making it appear as if more time had been spent in A than really had. In this case, function S cannot be properly located.

- g List the time spent in static (non-global) functions separately. The `-g` option function is the opposite of the `-l` function.
- l Suppress printing statically declared functions. If this option is given, time spent executing in a static function is allocated to the closest global function loaded before the static function in the executable. This option is the default. It is the opposite of the `-g` function and should be used with care.

The following options may be used in any combination:

- C Demangle C++ symbol names before printing them out.
- h Suppress the heading normally printed on the report. This is useful if the report is to be processed further.
- m *mdata* Use file *mdata* instead of *mon.out* as the input profile file.
- s Print a summary of several of the monitoring parameters and statistics on the standard error output.
- V Print *prof* version information on the standard error output.
- z Include all symbols in the profile range, even if associated with zero number of calls and zero time.

A single function may be split into subfunctions for profiling by means of the `MARK` macro. See [prof\(5\)](#).

Environment Variables	PROFDIR	The name of the file created by a profiled program is controlled by the environment variable <code>PROFDIR</code> . If <code>PROFDIR</code> is not set, <i>mon.out</i> is produced in the directory current when the program terminates. If <code>PROFDIR=string</code> , <i>string/pid.progname</i> is produced, where <i>progname</i> consists of <code>argv[0]</code> with any path prefix removed, and <i>pid</i> is the process ID of the program. If <code>PROFDIR</code> is set, but null, no profiling output is produced.
Files	<i>mon.out</i>	default profile file
	<i>a.out</i>	default namelist (object) file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/base-developer-utilities

See Also [gprof\(1\)](#), [exit\(2\)](#), [pcsample\(2\)](#), [profil\(2\)](#), [malloc\(3C\)](#), [malloc\(3MALLOC\)](#), [monitor\(3C\)](#), [attributes\(5\)](#), [prof\(5\)](#)

Notes If the executable image has been stripped and does not have the `.symtab` symbol table, `gprof` reads the global dynamic symbol tables `.dynam` and `.SUNW_ldynam`, if present. The symbols in the dynamic symbol tables are a subset of the symbols that are found in `.symtab`. The `.dynam` symbol table contains the global symbols used by the runtime linker. `.SUNW_ldynam` augments the information in `.dynam` with local function symbols. In the case where `.dynam` is found and `.SUNW_ldynam` is not, only the information for the global symbols is available. Without local symbols, the behavior is as described for the `-a` option.

The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may *beat* with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.

Only programs that call `exit` or return from `main` are guaranteed to produce a profile file, unless a final call to `monitor` is explicitly coded.

The times for static functions are attributed to the preceding external text symbol if the `-g` option is not used. However, the call counts for the preceding function are still correct; that is, the static function call counts are not added to the call counts of the external function.

If more than one of the options `-t`, `-c`, `-a`, and `-n` is specified, the last option specified is used and the user is warned.

`LD_LIBRARY_PATH` must not contain `/usr/lib` as a component when compiling a program for profiling. If `LD_LIBRARY_PATH` contains `/usr/lib`, the program will not be linked correctly with the profiling versions of the system libraries in `/usr/lib/libp`. See [gprof\(1\)](#).

Functions such as `mcount()`, `_mcount()`, `moncontrol()`, `_moncontrol()`, `monitor()`, and `_monitor()` may appear in the `prof` report. These functions are part of the profiling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unprofiled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.

64-bit profiling 64-bit profiling may be used freely with dynamically linked executables, and profiling information is collected for the shared objects if the objects are compiled for profiling. Care must be applied to interpret the profile output, since it is possible for symbols from different shared objects to have the same name. If duplicate names are seen in the profile output, it is better to use the `-s` (summary) option, which prefixes a module id before each symbol that is duplicated. The symbols can then be mapped to appropriate modules by looking at the modules information in the summary.

If the `-a` option is used with a dynamically linked executable, the sorting occurs on a per-shared-object basis. Since there is a high likelihood of symbols from differed shared objects to have the same value, this results in an output that is more understandable. A blank line separates the symbols from different shared objects, if the `-s` option is given.

32-bit profiling 32-bit profiling may be used with dynamically linked executables, but care must be applied. In 32-bit profiling, shared objects cannot be profiled with `prof`. Thus, when a profiled, dynamically linked program is executed, only the *main* portion of the image is sampled. This means that all time spent outside of the *main* object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with `prof`. If desired, the program should be linked to the profiled version of a library (or to the standard archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the `/usr/lib/libp` directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some `libc` routine, say, `malloc()`. Suppose `malloc()` is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes 10 units of time, more than any other routine in the *main* (profiled) portion of the image. In this case, `prof` will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A. The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

Name profiles – list and manage rights profiles

Synopsis profiles [-l] [-a | *user ...*] [-S *repository*]
 profiles -p *profiles* [-S *repository*]
 profiles -p *profiles* [-S *repository*] *subcommand*
 profiles -p *profiles* [-S *repository*] -f *command_file*
 profiles help

Description The profiles utility creates and modifies the configuration of a rights profile in the [prof_attr\(4\)](#) or [exec_attr\(4\)](#) databases in the local files name service or LDAP name service. A rights profile configuration consists of a profile name and a number of properties.

The following synopsis of the profiles subcommand is for interactive usage:

```
profiles -p profile [-S repository] [subcommand]
```

The profiles command prints on standard output the names of the rights profiles that have been assigned to you or to the optionally-specified user or role name. Profiles are a bundling mechanism used to enumerate the commands and authorizations needed to perform a specific function. Along with each listed executable are the process attributes, such as the effective user and group IDs, with which the process runs when started by a privileged command interpreter. See the [pfexec\(1\)](#) man page. Profiles can contain other profiles defined in [prof_attr\(4\)](#).

Multiple profiles can be combined to construct the appropriate access control. When profiles are assigned, the authorizations are added to the existing set. If the same command appears in multiple profiles, the first occurrence, as determined by the ordering of the profiles is used for process-attribute settings. For convenience, a wildcard can be specified to match all commands.

The special profile “Stop” shortcuts the evaluations of further profiles. Profiles seen after the “Stop” profile are not evaluated nor are they used to find additional commands. This profile can be used to sidestep profiles listed in `/etc/security/policy.conf` with the PROF_GRANTED key and the authorizations listed with AUTH_GRANTED in that file.

When profiles are interpreted, the profile list is loaded from [user_attr\(4\)](#). If any default profiles are defined in `/etc/security/policy.conf` (see [policy.conf\(4\)](#)), the list of default profiles are added to the list loaded from [user_attr\(4\)](#). Matching entries in [prof_attr\(4\)](#) provide the authorizations list, and matching entries in [exec_attr\(4\)](#) provide the commands list.

Properties When invoked with the -p option, the properties of the specified profile, as well as the properties of its associated executable files can be managed. However, to maintain system integrity, those profiles that are maintained by Solaris can not modified by this command. Such profiles can only be modified via the [pkg\(1\)](#) command during a system update.

Optionally, other profiles can also be delivered by the [pkg\(1\)](#) command as not modifiable.

To prevent privilege escalation, the property values are restricted based on the user's authorizations. At a minimum, an administrator needs to be granted the Rights Management profile. Additionally, to modify security-related properties controlled by delegate authorizations, an administrator must be granted Rights Delegation profile. See [exec_attr\(4\)](#), [prof_attr\(4\)](#), and the following summary for details.

Property values can be simple strings, or comma-separated lists of simple strings. Simple strings containing white space must be double quoted.

The profiles command operates in both profile and command contexts. The profile context is the initial state, in which the various profile properties can be managed. The following table summarizes the properties in the profile context:

Property Name	Value Type	Required Authorizations
name	simple	none
auths	list of simple	solaris.auth.{assign/delegate}
profiles	list of simple	solaris.profile.{assign/delegate}
privs	list of simple	solaris.privilege.{assign/delegate}
limitpriv	list of simple	solaris.privilege.{assign/delegate}
defaultpriv	list of simple	solaris.privilege.{assign/delegate}
always_audit	list of simple	solaris.audit.assign
never_audit	list of simple	solaris.audit.assign
desc	simple	none
help	simple	none
pam_policy	simple	solaris.account.setpolicy
cmd	simple/new context	none

The command context is entered by specifying the cmd property. While in the command context, the properties of the current command can be managed.

The following table summarizes the properties in the command context:

Property Name	Value Type	Required Authorizations
id	simple	none
privs	list of simple	solaris.privilege.{assign/delegate}
limitprivs	list of simple	solaris.privilege.{assign/delegate}
euid	simple	solaris.profile.cmd.setuid
uid	simple	solaris.profile.cmd.setuid
egid	simple	solaris.group.{assign/delegate}
gid	simple	solaris.group.{assign/deleg}

The values that can be specified in the profile context properties are described in the following list. . An equal sign (=) is required between the property and its values as specified in the following list.

always_audit

The audit flags specifying event classes to always audit. Only the first occurrence of this property, either in the user's [user_attr\(4\)](#) entry, or in the ordered list of assigned profiles is applied at login and su.

auths

One or more comma-separated authorizations to be added to the new profile. If the wildcard character (*) is used in an authorization name, the name must be enclosed in double quotes (").

cmd

The fully qualified path to an executable file or the asterisk (*) symbol, which is used to specify all commands. An asterisk that replaces the filename component in a pathname indicates all files in a particular directory.

This is a special property that is used to enter the command context to manage the security properties of a command.

Either numeric IDs and names can be used for these IDs.

id

This property is initially set to the value that was specified by the previous **cmd** property, but can be modified. When used in conjunction with the **select** subcommand, the properties of an existing command can be cloned for subsequent editing.

pam_policy

The PAM policy to apply to a user. **pam_policy** must be either an absolute pathname to a [pam.conf\(4\)](#)-formatted file or the name of a [pam.conf\(4\)](#)-formatted file located in `/etc/security/pam_policy`. See [pam_user_policy\(5\)](#) for more information.

privs

The set of privileges to be applied to the inheritable set of the executable process. The default is basic.

limitprivs

The set of privileges to be applied to the limit set of the executable process. The default is all.

euid

The effective user ID of the process that executes with the command.

uid

The real user ID of the process that executes with the command.

egid

The effective group ID of the process that executes with the command.

gid

The real group ID of the process that executes with the command.

defaultpriv

The default set of privileges assigned to a user's set of processes. Only the first occurrence of this property, either in the user's `user_attr(4)` entry, or in the ordered list of assigned profiles is applied at login and su.

desc

The description of the new profile. The text must be enclosed in quotation marks.

help

The help file name for the new profile. The help file is copied to the `/usr/lib/help/profiles/locale/<locale>` directory. Where `<locale>` is the value of the user's language locale, or C if none is specified. Specifying this property is only applicable in the files repository.

limitpriv

The maximum set of privileges a user or any process started by the user, whether through `su(1M)` or any other means, can obtain. Only the first occurrence of this property, either in the user's `user_attr(4)` entry, or in the ordered list of assigned profiles is applied at login and su.

name

The name of the profile. The initial value for the name is specified using `-p` option on the command line. If the name is changed, the current profile properties are applied to the newly named profile. In this way an existing profile can be cloned for subsequent editing. The name must not match an existing profile.

never_audit

The audit flags specifying event classes to never audit. Only the first occurrence of this property, either in the user's `user_attr(4)` entry, or in the ordered list of assigned profiles is applied at login and su.

privs

The set of privileges that can be specified using the `P` option of the `pfexec(1)` command.

profiles

One or more comma-separated supplementary profiles to be added to the new profile.

Options The following options are supported:

-a

Lists all the profile names in the specified repository. If no repository is specified, it follows whatever is configured for `prof_attr` in `nsswitch.conf(4)`.

-f *command_file*

Specifies the name of profiles command file. *command_file* is a text file of profiles subcommands, one per line.

-l

Provides information about the Rights Profile and lists the commands and their special process attributes such as user and group IDs.

-p profile

Specifies the profile name.

-S repository

The valid repositories are `files` and `ldap`. *repository* specifies which name service is updated. The default *repository* is `files`.

Sub-commands When invoked with the `-p` option, subcommands can be provided on the command line or interactively. Multiple subcommands, separated by semicolons can be specified on the command line by enclosing the entire set in quotation marks. The lack of subcommands implies an interactive session, during which auto-completion of subcommands can be invoked by using the TAB key.

The `add` and `select` subcommands can be used to select a specific command, at which point the context changes to that of the command. During an interactive session, the command context is identified by the command basename in the prompt string. The `end` and `cancel` subcommands are used to complete the command specification, at which time the context is reverted to the `profile` context.

Subcommands that can result in destructive actions or loss of work have a `-F` option to force the action. If input is from a terminal device, the user is prompted when appropriate. This could occur if a subcommand is given without the `-F` option. Otherwise, the action is disallowed, with a diagnostic message written to standard error.

The `property-value` can be a simple value, or a list of simple values for those properties which accept lists. The following subcommands are supported:

`add cmd=pathname`

In the `profile` context, begins the specification for a given command. The context is changed to the `commandtype`.

`add property-name=property-value`

Adds the specified values to the current property values. This subcommand can only be applied to properties that accept lists.

`cancel`

End the command specification and reset context to `profile`. Abandons any partially specified resources. `cancel` is only applicable in the `command` context.

`clear property name`

Clear the value for the property.

`commit`

Commit the current configuration from memory to stable storage. The configuration must be committed for the changes to take effect. Until the in-memory configuration is committed, you can remove changes with the `revert` subcommand. The `commit` operation is attempted automatically upon completion of a `profiles` session. Since a configuration must be correct to be committed, this operation automatically does a `verify`.

`delete [-F]`

Delete the specified profile from memory and stable storage. This operation is not permitted if the profile is included as a subprofile of another profile in the same repository. Instead, a list of profiles which include this profile is supplied from which the user must manually remove this profile prior to deleting it. Specify the `-F` option to force the action. If the deletion is allowed, its action is instantaneous and the session is terminated.

`end`

End the command specification. This subcommand is only applicable in the `command` context. The `profiles` command verifies that the current command is completely specified. If so, it is added to the in-memory configuration (see `commit` for saving this to stable storage) and the context reverts to the `profile` context. If the specification is incomplete, it issues an appropriate error message.

`exit [-F]`

Exit the profiles session. A `commit` is automatically attempted if needed. You can also use an EOF character to exit profiles. The `-F` option can be used to force the action.

`export [-f output-file]`

Print configuration to standard output. Use the `-f` option to print the configuration to `output-file`. This option produces output in a form suitable for use in a command file option.

`help [usage] [subcommands] [properties] [<subcommand.>] [<properties>]`

Print general help or help about specific topic.

`info [property-name]`

Display information about the current profile or the specified property.

`remove cmd=fullpath`

Removes the specified command from the profile. This subcommand is only valid in the `profile` context.

`remove [-F] cmd`

Removes all the commands from the profile. A confirmation is required, unless you use the `-F` option. This subcommand is only valid in the `profile` context.

`remove property-name=property-value`

Remove the specified values from the property. This can only be applied to properties that accept lists.

`revert [-F]`

Revert the configuration back to the last committed state. The `-F` option can be used to force the action.

`select cmd=fullpath`

Select the command which matches the given pathname criteria, for modification. This subcommand is applicable only in the `profile` context.

`set property-name=property-value`

Set a given property name to the given value. Some properties (for example, name and desc) are only valid in the profile context, while others are only valid in the command context.

This subcommand is applicable in both the profile and command contexts.

`verify`

Verify the current configuration for correctness:

- The required properties are specified.
- The values are valid for each keyword.
- The user is authorized to specify the values.

Examples EXAMPLE 1 Using the profiles Command

The output of the `profiles` command has the following form:

```
example% profiles tester01 tester02
tester01 : Audit Management, All Commands
tester02 : Device Management, All Commands
example%
```

EXAMPLE 2 Using the list Option

```
example% profiles -l tester01 tester02
tester01 :
  Audit Management:
    /usr/sbin/audit          euid=root
    /usr/sbin/auditconfig   euid=root   egid=sys
  All Commands:
    *
tester02 :
  Device Management:
    /usr/bin/allocate:      euid=root
    /usr/bin/deallocate:   euid=root
  All Commands
    *
example%
```

EXAMPLE 3 Creating a New Profile

The following creates a new User Manager profile in LDAP. new profile description is Manage users and groups, and the authorization assigned is `solaris.user.manage`. The supplementary profile assigned is Mail Management. The help file name is `RtUserMgmt.html`.

```
example% profiles -p "User Manager" -S ldap
profiles:User Manager> set desc="Manage users and groups"
profiles:User Manager> set help=RtUserMgmt.html
profiles:User Manager> set auths=solaris.user.manage
profiles:User Manager> set profiles="Mail Management"
profiles:User Manager> exit
```

EXAMPLE 4 Displaying Information Regarding the Current Configuration

The following command displays information regarding the User Manager profile:

```
example% profiles -p "User Manager" -S ldap info
name=User Manager
desc=Manage users and groups
auths=solaris.user.manage
profiles=Mail Management
help=RtUserMgmt.html
```

EXAMPLE 5 Deleting a Profile

The following command deletes the User Manager profile from LDAP:

```
example% profiles -p "User Manager" -S ldap delete -F
```

EXAMPLE 6 Modifying a Profile

The following modifies the User Manager profile in LDAP. The new profile description is Manage world, the new authorization assignment is solaris.user.* authorizations, and the new supplementary profile assignment is All.

```
example% profiles -p "User Manager" -S ldap
profiles:User Manager> set desc="Manage world"
profiles:User Manager> set auths="solaris.user.*"
profiles:User Manager> set profiles=All
profiles:User Manager> exit
```

EXAMPLE 7 Creating an exec_attr Database Entry

The following command creates a new exec_attr entry for the User Manager profile in LDAP. The /usr/bin/cp entry is added. The command has an effective user ID of 0 and an effective group ID of 0.

```
example% profiles -p "User Manager" -S ldap
profiles:User Manager> add cmd=/usr/bin/cp
profiles:User Manager:cp> set euid=0
profiles:User Manager:cp> set egid=0
profiles:User Manager:cp> end
profiles:User Manager> exit
example%
```

EXAMPLE 8 Deleting an exec_attr Database Entry

The following example deletes an exec_attr database entry for the User Manager profile from LDAP. The entry designated for the command /usr/bin/cp is deleted.

```
example% profiles -p "User Manager" -S ldap
profiles:User Manager> remove cmd=/usr/bin/cp
profiles:User Manager> exit
example%
```

EXAMPLE 9 Modifying an `exec_attr` Database Entry

The following modifies the attributes of the `exec_attr` database entry for the User Manager profile in LDAP. The `/usr/bin/cp` entry is modified to execute with the real user ID of 0 and the real group ID of 0.

```
example% profiles -p "User Manager" -S ldap
profiles:User Manager> select cmd=/usr/bin/cp
profiles:User Manager:cp> clear euid
profiles:User Manager:cp> clear egid
profiles:User Manager:cp> set uid=0
profiles:User Manager:cp> set gid=0
profiles:User Manager:cp> end
profiles:User Manager> exit
example%
```

Exit Status The following exit values are returned:

```
0
    Successful completion.
1
    An error occurred.
```

Files `/etc/security/exec_attr`
`/etc/security/prof_attr`
`/etc/user_attr`
`/etc/security/policy.conf`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [auths\(1\)](#), [pexec\(1\)](#), [pkg\(1\)](#), [roles\(1\)](#), [getprofattr\(3C\)](#), [auth_attr\(4\)](#), [exec_attr\(4\)](#), [nsswitch.conf\(4\)](#), [pam.conf\(4\)](#), [policy.conf\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [audit_flags\(5\)](#), [attributes\(5\)](#), [pam_user_policy\(5\)](#), [privileges\(5\)](#)

Name projects – print project membership of user

Synopsis projects [-dv] [*user*]
projects -l [*projectname* [*projectname*]. . .]

Description The `projects` command prints on standard output the projects to which the invoking user or an optionally specified user belongs. Each user belongs to some set of projects specified in the [project\(4\)](#) file and possibly in the associated NIS maps and LDAP databases for project information.

Options The following options are supported:

- d Prints only default project.
- l Prints verbose info on each project *projectname*. If no *projectnames* are given, info on all projects is printed.
- v Prints project descriptions along with project names.

Operands The following operand is supported:

projectname Display information for the specified project.
user Displays project memberships for the specified user.

Examples EXAMPLE 1 Displaying Membership for a Specified User

```
example$ projects paul  
default beatles wings  
example$ projects ringo  
default beatles  
example$ projects -d paul  
beatles
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 A fatal error occurred during execution.
- 2 Invalid command line options were specified.

Files /etc/project Local database containing valid project definitions for this machine.

Attributes See [attributes\(5\)](#) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Stability	See below.

The invocation is Committed. The human-readable output is Uncommitted.

See Also [getdefaultproj\(3PROJECT\)](#), [getproject\(3PROJECT\)](#), [project\(4\)](#), [attributes\(5\)](#)

Name ps – report process status

Synopsis ps [-aAcdefjHLLPyZ] [-g *grplist*] [-h *lgrplist*]
[-n *namelist*] [-o *format*]... [-p *proclist*]
[-s *sidlist*] [-t *term*] [-u *uidlist*] [-U *uidlist*]
[-G *gidlist*] [-z *zonelist*]

Description The ps command prints information about active processes. Without options, ps prints information about processes that have the same effective user ID and the same controlling terminal as the invoker. The output contains only the process ID, terminal identifier, cumulative execution time, and the command name. Otherwise, the information that is displayed is controlled by the options.

Some options accept lists as arguments. Items in a list can be either separated by commas or else enclosed in quotes and separated by commas or spaces. Values for *proclist* and *grplist* must be numeric.

The ps command tries to determine whether it is called natively or using the command syntax expected by ps(1B). In the latter case, the ps command behaves exactly as described in ps(1B).

Options The following options are supported:

-a

Lists information about all processes most frequently requested: all those except session leaders and processes not associated with a terminal.

-A

Lists information for all processes. Identical to -e, below.

-c

Prints information in a format that reflects scheduler properties as described in [prioctl\(1\)](#). The -c option affects the output of the -f and -l options, as described below.

-d

Lists information about all processes except session leaders.

-e

Lists information about every process now running.

When the -e option is specified, options -z, -t, -u, -U, -g, -G, -p, -g, -s and -a options have no effect.

-f

Generates a full listing. (See below for significance of columns in a full listing.)

-g *grplist*

Lists only process data whose group leader's ID number(s) appears in *grplist*. (A group leader is a process whose process ID number is identical to its process group ID number.)

-
- G *gidlist*
Lists information for processes whose real group ID numbers are given in *gidlist*. The *gidlist* must be a single argument in the form of a blank- or comma-separated list.
 - h *lgrplist*
Lists only the processes homed to the specified *lgrplist*. Nothing is listed for any invalid group specified in *lgrplist*.
 - H
Prints the home lgroup of the process under an additional column header, LGRP.
 - j
Prints session ID and process group ID.
 - l
Generates a long listing. (See below.)
 - L
Prints information about each light weight process (*lwp*) in each selected process. (See below.)
 - n *namelist*
Specifies the name of an alternative system *namelist* file in place of the default. This option is accepted for compatibility, but is ignored.
 - o *format*
Prints information according to the format specification given in *format*. This is fully described in DISPLAY FORMATS. Multiple -o options can be specified; the format specification is interpreted as the space-character-separated concatenation of all the *format* option-arguments.
 - p *proclist*
Lists only process data whose process ID numbers are given in *proclist*.
 - P
Prints the number of the processor to which the process or lwp is bound, if any, under an additional column header, PSR.
 - s *sidlist*
Lists information on all session leaders whose IDs appear in *sidlist*.
 - t *term*
Lists only process data associated with *term*. Terminal identifiers are specified as a device file name, and an identifier. For example, *term/a*, or *pts/0*.
 - u *uidlist*
Lists only process data whose effective user ID number or login name is given in *uidlist*. In the listing, the numerical user ID is printed unless you give the -f option, which prints the login name.

-U *uidlist*

Lists information for processes whose real user ID numbers or login names are given in *uidlist*. The *uidlist* must be a single argument in the form of a blank- or comma-separated list.

-y

Under a long listing (-l), omits the obsolete F and ADDR columns and includes an RSS column to report the resident set size of the process. Under the -y option, both RSS and SZ (see below) is reported in units of kilobytes instead of pages.

-z *zonelist*

Lists only processes in the specified zones. Zones can be specified either by name or ID. This option is only useful when executed in the global zone.

-Z

Prints the name of the zone with which the process is associated under an additional column header, ZONE. The ZONE column width is limited to 8 characters. Use ps -eZ for a quick way to see information about every process now running along with the associated zone name. Use

```
ps -eo zone,uid,pid,ppid,time,comm,...
```

to see zone names wider than 8 characters.

The following options are used by the /usr/ucb/ps command (see [ps\(1B\)](#)). They are supported in /usr/bin/ps, allowing the latter to emulate UCB behavior. The UCB options do not use a hyphen. You cannot mix these options with the options described above.

r

Restricts output to running and runnable processes.

S

Displays accumulated CPU time used by this process and all of its reaped children.

v

Displays a version of the output containing virtual memory. This includes fields SIZE, %CPU, %MEM, and RSS, described below.

w

Uses a wide output format, that is, 132 columns rather than 80. If the option letter is repeated, that is, -ww, this option uses arbitrarily wide output. This information is used to decide how much of long commands to print. *Note:* The wide output option can be viewed only by a superuser or the user who owns the process.

x

Includes processes with no controlling terminal.

num

A process number may be given, in which case the output is restricted to that process. This option must be supplied last.

Many of the options shown are used to select processes to list. If any are specified, the default list is ignored and `ps` selects the processes represented by the inclusive OR of all the selection-criteria options.

Display Formats Under the `-f` option, `ps` tries to determine the command name and arguments given when the process was created by examining the user block. Failing this, the command name is printed, as it would have appeared without the `-f` option, in square brackets.

The column headings and the meaning of the columns in a `ps` listing are given below; the letters `f` and `l` indicate the option (`full` or `long`, respectively) that causes the corresponding heading to appear; `all` means that the heading always appears. *Note:* These two options determine only what information is provided for a process; they do not determine which processes are listed.

F(l)

Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.

S(l)

The state of the process:

O

Process is running on a processor.

S

Sleeping: process is waiting for an event to complete.

R

Runnable: process is on run queue.

T

Process is stopped, either by a job control signal or because it is being traced.

W

Waiting: process is waiting for CPU usage to drop to the CPU-caps enforced limits.

Z

Zombie state: process terminated and parent not waiting.

UID (f,l)

The effective user ID number of the process (the login name is printed under the `-f` option).

PID(all)

The process ID of the process (this datum is necessary in order to kill a process).

PPID(f,l)

The process ID of the parent process.

C(f,l)

Processor utilization for scheduling (obsolete). Not printed when the `-c` option is used.

CLS(f,l)

Scheduling class. Printed only when the `-c` option is used.

PRI(l)

The priority of the process. Without the `-c` option, higher numbers mean lower priority. With the `-c` option, higher numbers mean higher priority.

NI(l)

Nice value, used in priority computation. Not printed when the `-c` option is used. Only processes in the certain scheduling classes have a nice value.

ADDR(l)

The memory address of the process, `0` unless running with all privilege.

SZ(l)

The total size of the process in virtual memory, including all mapped files and devices, in pages. See [pagesize\(1\)](#).

WCHAN(l)

The address of an event for which the process is sleeping. Only visible when running with all privilege, otherwise it is `0`. To determine if a process is sleeping, check the `S` column.

STIME(f)

The starting time of the process, given in hours, minutes, and seconds. (A process begun more than twenty-four hours before the `ps` inquiry is executed is given in months and days.)

TTY(all)

The controlling terminal for the process (the message, `?`, is printed when there is no controlling terminal).

TIME(all)

The cumulative execution time for the process.

LTIME(all)

The execution time for the lwp being reported.

CMD(all)

The command name (the full command name and its arguments, up to a limit of 80 characters, are printed under the `-f` option).

The following two additional columns are printed when the `-j` option is specified:

PGID

The process ID of the process group leader.

SID

The process ID of the session leader.

The following two additional columns are printed when the `-L` option is specified:

LWP

The lwp ID of the lwp being reported.

NLWP

The number of lwps in the process (if `-f` is also specified).

Under the `-L` option, one line is printed for each lwp in the process and the time-reporting fields `STIME` and `LTIME` show the values for the lwp, not the process. A traditional single-threaded process contains only one lwp.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked `<defunct>`.

-o format The `-o` option allows the output format to be specified under user control.

The format specification must be a list of names presented as a single argument, blank- or comma-separated. Each variable has a default header. The default header can be overridden by appending an equals sign and the new text of the header. The rest of the characters in the argument is used as the header text. The fields specified are written in the order specified on the command line, and should be arranged in columns in the output. The field widths are selected by the system to be at least as wide as the header text (default or overridden value). If the header text is null, such as `-o user=`, the field width is at least as wide as the default header text. If all header text fields are null, no header line is written.

The following names are recognized in the POSIX locale:

user

The effective user ID of the process. This is the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

ruser

The real user ID of the process. This is the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

group

The effective group ID of the process. This is the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

rgroup

The real group ID of the process. This is the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

pid

The decimal value of the process ID.

ppid

The decimal value of the parent process ID.

pgid

The decimal value of the process group ID.

pcpu

The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of “recently” in this context is unspecified. The CPU time available is determined in an unspecified manner.

vsz

The total size of the process in virtual memory, in kilobytes.

nice

The decimal value of the system scheduling priority of the process. See [nice\(1\)](#).

etime

In the POSIX locale, the elapsed time since the process was started, in the form:

[[dd-]hh:]mm:ss

where

dd

is the number of days

hh

is the number of hours

mm

is the number of minutes

ss

is the number of seconds

The *dd* field is a decimal integer. The *hh*, *mm* and *ss* fields is two-digit decimal integers padded on the left with zeros.

time

In the POSIX locale, the cumulative CPU time of the process in the form:

[dd-]hh:mm:ss

The *dd*, *hh*, *mm*, and *ss* fields is as described in the *etime* specifier.

tty

The name of the controlling terminal of the process (if any) in the same format used by the [who\(1\)](#) command.

comm

The name of the command being executed (*argv[0]* value) as a string.

args

The command with all its arguments as a string. The implementation might truncate this value to the field width; it is implementation-dependent whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it

was passed to the command when it started, or is a version of the arguments as they might have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of `ps`. The Solaris implementation limits the string to 80 bytes; the string is the version of the argument list as it was passed to the command when it started.

The following names are recognized in the Solaris implementation:

`f`

Flags (hexadecimal and additive) associated with the process.

`s`

The state of the process.

`c`

Processor utilization for scheduling (obsolete).

`uid`

The effective user ID number of the process as a decimal integer.

`ruid`

The real user ID number of the process as a decimal integer.

`gid`

The effective group ID number of the process as a decimal integer.

`rgid`

The real group ID number of the process as a decimal integer.

`projid`

The project ID number of the process as a decimal integer.

`project`

The project ID of the process as a textual value if that value can be obtained; otherwise, as a decimal integer.

`zoneid`

The zone ID number of the process as a decimal integer.

`zone`

The zone ID of the process as a textual value if that value can be obtained; otherwise, as a decimal integer.

`sid`

The process ID of the session leader.

`taskid`

The task ID of the process.

`class`

The scheduling class of the process.

- `pri`
The priority of the process. Higher numbers mean higher priority.
- `opri`
The obsolete priority of the process. Lower numbers mean higher priority.
- `lwp`
The decimal value of the lwp ID. Requesting this formatting option causes one line to be printed for each lwp in the process.
- `nlwp`
The number of lwps in the process.
- `psr`
The number of the processor to which the process or lwp is bound.
- `pset`
The ID of the processor set to which the process or lwp is bound.
- `addr`
The memory address of the process.
- `osz`
The total size of the process in virtual memory, in pages.
- `wchan`
The address of an event for which the process is sleeping (if `-`, the process is running).
- `stime`
The starting time or date of the process, printed with no blanks.
- `rss`
The resident set size of the process, in kilobytes. The `rss` value reported by `ps` is an estimate provided by `proc(4)` that might underestimate the actual resident set size. Users who wish to get more accurate usage information for capacity planning should use `pmap(1) -x` instead.
- `pmem`
The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.
- `fname`
The first 8 bytes of the base name of the process's executable file.
- `ctid`
The contract ID of the process contract the process is a member of as a decimal integer.
- `lgrp`
The home lgroup of the process.

Only `comm` and `args` are allowed to contain blank characters; all others, including the Solaris implementation variables, are not.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

Format Specifier	Default Header	Format Specifier	Default Header
args	COMMAND	ppid	PPID
comm	COMMAND	rgroup	RGROUP
etime	ELAPSED	ruser	RUSER
group	GROUP	time	TIME
nice	NI	tty	TT
pcpu	%CPU	user	USER
pgid	PGID	vsz	VSZ
pid	PID		

The following table lists the Solaris implementation format specifiers and the default header used with each.

Format Specifier	Default Header	Format Specifier	Default Header
addr	ADDR	projid	PROJID
c	C	project	PROJECT
class	CLS	psr	PSR
f	F	rgid	RGID
fname	COMMAND	rss	RSS
gid	GID	ruid	RUID
lgrp	LGRP	s	S
lwp	LWP	sid	SID
nlwp	NLWP	stime	STIME
opri	PRI	taskid	TASKID
osz	SZ	uid	UID
pmem	%MEM	wchan	WCHAN

Format	Default	Format	Default
Specifier	Header	Specifier	Header
pri	PRI	zone	ZONE
ctid	CTID	zoneid	ZONEID

Examples EXAMPLE 1 Using ps Command

The command:

```
example% ps -o user,pid,ppid=MOM -o args
```

writes the following in the POSIX locale:

```
USER  PID  MOM  COMMAND
helene 34   12  ps -o uid,pid,ppid=MOM -o args
```

The contents of the COMMAND field need not be the same due to possible truncation.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of ps: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, LC_TIME, and NLSPATH.

COLUMNS

Override the system-selected horizontal screen size, used to determine the number of text columns to display.

Exit Status The following exit values are returned:

- 0
Successful completion.
- >0
An error occurred.

Files /dev/pts/*
/dev/term/*
terminal ("tty") names searcher files
/etc/passwd
UID information supplier
/proc/*
process control files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled (see USAGE)
Interface Stability	Committed
Standard	See standards(5) .

See Also [kill\(1\)](#), [lgrpinfo\(1\)](#), [nice\(1\)](#), [pagesize\(1\)](#), [pmap\(1\)](#), [priocntl\(1\)](#), [who\(1\)](#), [ps\(1B\)](#), [getty\(1M\)](#), [proc\(4\)](#), [ttysrch\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [resource_controls\(5\)](#), [standards\(5\)](#), [zones\(5\)](#)

Notes Things can change while `ps` is running. The snapshot it gives is true only for a split-second, and it might not be accurate by the time you see it. Some data printed for defunct processes is irrelevant.

If no options to select processes are specified, `ps` reports all processes associated with the controlling terminal. If there is no controlling terminal, there is no report other than the header.

`ps -ef` or `ps -o stime` might not report the actual start of a tty login session, but rather an earlier time, when a `getty` was last respawned on the tty line.

On prior releases the `ADDR` and `WCHAN` fields might have contained the kernel memory address of the process and/or event it was waiting on. These fields are now always `0` unless requested by a process running with all privilege. The values can still be obtained using the `::ps` and `::thread dcmds` within `mdb`.

`ps` is CSI-enabled except for login names (usernames).

Name ps – display the status of current processes

Synopsis /usr/ucb/ps [-] [aceglnrSuUvwx] [-t *term*] [*num*]

Description The `ps` command displays information about processes. Normally, only those processes that are running with your effective user ID and are attached to a controlling terminal (see [termio\(7I\)](#)) are shown. Additional categories of processes can be added to the display using various options. In particular, the `-a` option allows you to include processes that are not owned by you (that do not have your user ID), and the `-x` option allows you to include processes without controlling terminals. When you specify both `-a` and `-x`, you get processes owned by anyone, with or without a controlling terminal. The `-r` option restricts the list of processes printed to running and runnable processes.

`ps` displays in tabular form the process ID, under PID; the controlling terminal (if any), under TT; the cpu time used by the process so far, including both user and system time, under TIME; the state of the process, under S; and finally, an indication of the COMMAND that is running.

The state is given by a single letter from the following:

- 0 Process is running on a processor.
- S Sleeping. Process is waiting for an event to complete.
- R Runnable. Process is on run queue.
- Z Zombie state. Process terminated and parent not waiting.
- T Traced. Process stopped by a signal because parent is tracing it.

Options The following options must all be combined to form the first argument. The `ps` command accepts the arguments without the leading (-) for historical reasons

- a Includes information about processes owned by others.
- c Displays the command name rather than the command arguments.
- e Displays the environment as well as the arguments to the command.
- g Displays all processes. Without this option, `ps` only prints interesting processes. Processes are deemed to be uninteresting if they are process group leaders. This normally eliminates top-level command interpreters and processes waiting for users to login on free terminals.
- l Displays a long listing, with fields F, PPID, CP, PRI, NI, SZ, RSS, and WCHAN as described below.
- n Produces numerical output for some fields. In a user listing, the USER field is replaced by a UID field.
- r Restricts output to running and runnable processes.

- S Displays accumulated CPU time used by this process and all of its reaped children.
- t *term* Lists only process data associated with the terminal, *term*. Terminal identifiers may be specified in one of two forms: the device's file name (for example, `tty04` or `term/14`) or, if the device's file name starts with `tty`, just the digit identifier (for example, `04`).
- u Displays user-oriented output. This includes fields `USER`, `%CPU`, `%MEM`, `SZ`, `RSS`, and `START` as described below.
- U Obsolete. This option no longer has any effect. It causes `ps` to exit without printing the process listing.
- v Displays a version of the output containing virtual memory. This includes fields `SIZE`, `%CPU`, `%MEM`, and `RSS`, described below.
- w Uses a wide output format, that is, 132 columns rather than 80. If the option letter is repeated, that is, `-ww`, this option uses arbitrarily wide output. This information is used to decide how much of long commands to print. *Note*: The wide output option can be viewed only by a superuser or the user who owns the process.
- x Includes processes with no controlling terminal.
- num* A process number may be given, in which case the output is restricted to that process. This option must be supplied last.

Display Formats Fields that are not common to all output formats:

- `USER` Name of the owner of the process.
- `%CPU` CPU use of the process. This is a decaying average over up to a minute of previous (real) time.
- `NI` Process scheduling increment (see [getpriority\(3C\)](#)).
- `SIZE` The total size of the process in virtual memory, including all mapped files and devices, in kilobyte units.
- `SZ` Same as `SIZE`.
- `RSS` Real memory (resident set) size of the process, in kilobyte units.
- `UID` Numerical user-ID of process owner.
- `PPID` Numerical ID of parent of process.
- `CP` Short-term CPU utilization factor (used in scheduling).
- `PRI` The priority of the process (higher numbers mean lower priority).

- START** The starting time of the process, given in hours, minutes, and seconds. A process begun more than 24 hours before the ps inquiry is executed is given in months and days.
- WCHAN** The address of an event for which the process is sleeping (if blank, the process is running).
- %MEM** The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.
- F** Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked <defunct> ; otherwise, ps tries to determine the command name and arguments given when the process was created by examining the user block.

Files /dev/tty*

/etc/passwd UID information supplier

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	compatibility/ucb

See Also [kill\(1\)](#), [ps\(1\)](#), [whodo\(1M\)](#), [getpriority\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#), [termio\(7I\)](#)

Notes Things can change while ps is running. The picture ps gives is only a close approximation to the current state. Some data printed for defunct processes is irrelevant.

Name ptree – print process trees

Synopsis /usr/bin/ptree [-a] [-c] [-z *zone*] [*pid* | *user*]. . .

Description The `ptree` utility prints the process trees containing the specified *pids* or *users*, with child processes indented from their respective parent processes. An argument of all digits is taken to be a process-ID, otherwise it is assumed to be a user login name. The default is all processes.

Options The following options are supported:

- a All. Print all processes, including children of process 0.
- c Contracts. Print process contract memberships in addition to parent-child relationships. See [process\(4\)](#). This option implies the -a option.
- z *zone* Zones. Print only processes in the specified *zone*. Each zone ID can be specified as either a zone name or a numerical zone ID.

This option is only useful when executed in the global zone.

Operands The following operands are supported:

- pid* Process-id or a list of process-ids. `ptree` also accepts `/proc/nnn` as a process-id, so the shell expansion `/proc/*` can be used to specify all processes in the system.
- user* Username or list of usernames. Processes whose effective user IDs match those given are displayed.

Examples EXAMPLE 1 Using `ptree`

The following example prints the process tree (including children of process 0) for processes which match the command name `ssh`:

```
$ ptree -a 'pgrep ssh'
  1      /usr/sbin/init
    100909 /usr/lib/ssh/sshd
      569150 /usr/lib/ssh/sshd
        569157 /usr/lib/ssh/sshd
          569159 -ksh
            569171 bash
              569173 /bin/ksh
                569193 bash
```

Exit Status The following exit values are returned:

- 0 Successful operation.
- non-zero An error has occurred.

Files /proc/* process files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The human readable output is Uncommitted The options are Committed.

See Also [gcore\(1\)](#), [ltd\(1\)](#), [pargs\(1\)](#), [pgrep\(1\)](#), [pkill\(1\)](#), [plimit\(1\)](#), [pmap\(1\)](#), [preap\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [ppgsz\(1\)](#), [pwd\(1\)](#), [rlogin\(1\)](#), [time\(1\)](#), [truss\(1\)](#), [wait\(1\)](#), [fcntl\(2\)](#), [fstat\(2\)](#), [setuid\(2\)](#), [dlopen\(3C\)](#), [signal.h\(3HEAD\)](#), [core\(4\)](#), [proc\(4\)](#), [process\(4\)](#), [attributes\(5\)](#), [zones\(5\)](#)

-
- Name** pvs – display the internal version information of dynamic objects
- Synopsis** pvs [-Cdlnorsv] [-I *index-expr*] [-N *name*] *file...*
- Description** The pvs utility displays any internal version information contained within an ELF file. Commonly, these files are dynamic executables and shared objects, and possibly relocatable objects. This version information can fall into one of two categories:
- version definitions
 - version dependencies
- Version *definitions* describe the interfaces that are made available by an ELF file. Each version definition is associated to a set of global symbols provided by the file. Version definitions can be assigned to a file during its creation by the link-editor using the -M option and the associated *mapfile* directives. See the *Linker and Libraries Guide* for more details.
- Version *dependencies* describe the binding requirements of dynamic objects on the version definitions of any shared object dependencies. When a dynamic object is built with a shared object, the link-editor records information within the dynamic object indicating that the shared object is a dependency. This dependency must be satisfied at runtime. If the shared object also contains version *definitions*, then those version definitions that satisfy the global symbol requirements of the dynamic object are also recorded in the dynamic object being created. At process initialization, the runtime linker uses any version *dependencies* as a means of validating the interface requirements of the dynamic objects used to construct the process.
- Options** The following options are supported. If neither the -d or -r options are specified, both are enabled.
- C Demangles C++ symbol names.
 - d Prints version definition information.
 - I *index-expr* Qualifies the versions to examine with a specific version index or index range. For example, the version with index 3 in an object can be displayed using:

```
example% pvs -I 3 filename
```

An *index-expr* can be a single non-negative integer value that specifies a specific version, as shown in the previous example. Alternatively, an *index-expr* can consist of two such values separated by a colon (:), indicating a range of versions. The following example displays the versions 3, 4, and 5 in a file:

```
example% pvs -I 3:5 filename
```

When specifying an index range, the second value can be omitted to indicate the final item in the file. For example, the following statement lists all versions from the tenth to the end:

```
example% pvs -I 10: filename
```

See Matching Options for additional information about the matching options (-I, -N).

- l Prints any symbols that have been reduced from global to local binding due to versioning. By convention, these symbol entries are located in the *.symtab* section, and fall between the *FILE* symbol representing the output file, and the *FILE* symbol representing the first input file used to generate the output file. These reduced symbol entries are assigned the fabricated version definition `_LOCAL_`. No reduced symbols will be printed if the file has been stripped (see `strip(1)`), or if the symbol entry convention cannot be determined.

Use of the -l option implicitly enables the -s option
- n Normalizes version definition information. By default, all version definitions within the object are displayed. However, version definitions can inherit other version definitions. Under normalization, only the head of each inheritance list is displayed.
- N *name* When used with the -d option, -N prints only the information for the given version definition *name* and any of its inherited version definitions.

When used with the -r option, -N prints only the information for the given dependency file *name*. It is possible to qualify a specific version from the dependency file by including the version in parenthesis following the file name:

example% `pvs -N 'dependency (version)' filename`
- See Matching Options for additional information about the matching options (-I, -N).
- o Creates one-line version definition output. By default, file, version definitions, and any symbol output is indented to ease human inspection. This option prefixes each output line with the file and version definition name and can be more useful for analysis with automated tools.
- r Prints version dependency (requirements) information.
- s Prints the symbols associated with each version definition. Any data symbols from versions defined by the object are accompanied with the size, in bytes, of the data item.
- v Verbose output. Indicates any weak version definitions, and any version definition inheritance. When used with the -N and -d options, the inheritance of the base version definition is also shown. When used with the -s option, the version symbol definition is also shown.

Operands The following operands are supported.

file The ELF file about which internal version information is displayed.

Usage

Matching Options The **-I** and **-N** options are collectively referred to as the *matching options*. These options are used to narrow the range of versions to examine, by index or by name.

Any number and type of matching option can be mixed in a given invocation of **pvs**. In this case, **pvs** displays the superset of all versions matched by any of the matching options used. This feature allows for the selection of complex groupings of items using the most convenient form for specifying each item.

Examples **EXAMPLE 1** Displaying version definitions

The following example displays the version definitions of `libelf.so.1`:

```
% pvs -d /lib/libelf.so.1
    libelf.so.1;
    SUNW_1.1
```

EXAMPLE 2 Creating a one-liner display

A normalized, one-liner display, suitable for creating a *mapfile* version control directive, can be created using the **-n** and **-o** options:

```
% pvs -don /lib/libelf.so.1
/lib/libelf.so.1 - SUNW_1.1;
```

EXAMPLE 3 Displaying version requirements

The following example displays the version requirements of `ldd` and `pvs`:

```
% pvs -r /usr/bin/ldd /usr/bin/pvs
/usr/bin/ldd:
    libelf.so.1 (SUNW_1.1);
    libc.so.1 (SUNW_1.1);
/usr/bin/pvs:
    libelf.so.1 (SUNW_1.1);
    libc.so.1 (SUNW_1.1);
```

EXAMPLE 4 Determining a dependency symbol version

The following example displays the shared object from which the `ldd` command expects to find the `printf` function at runtime, as well as the version it belongs to:

```
% pvs -ors /usr/bin/ldd | grep ' printf'
/usr/bin/ldd - libc.so.1 (SYSVABI_1.3): printf;
```

EXAMPLE 5 Determine all dependency symbols from a specific version

The `-N` option can be used to obtain a list of all the symbols from a dependency that belong to a specific version. To determine the symbols that `ldd` will find from version `SYSVABI_1.3` of `libc.so.1`:

```
% pvs -s -N 'libc.so.1 (SYSVABI_1.3)' /usr/bin/ldd
```

```
libc.so.1 (SYSVABI_1.3):
    _exit;
    strstr;
    printf;
    __fpstart;
    strncmp;
    lseek;
    strcmp;
    getopt;
    execl;
    close;
    fflush;
    wait;
    strerror;
    putenv;
    sprintf;
    getenv;
    open;
    perror;
    fork;
    strlen;
    geteuid;
    access;
    setlocale;
    atexit;
    fprintf;
    exit;
    read;
    malloc;
```

Note that the specific list of symbols used by `ldd` may change between Solaris releases.

EXAMPLE 6 Display base defined version by index

By convention, the base global version defined by an object has the name of the object. For example, the base version of `pvs` is named `'pvs'`. The base version of any object is always version index 1. Therefore, the `-I` option can be used to display the base version of any object without having to specify its name:

```
% pvs -v -I 1 /usr/bin/pvs
    pvs [BASE];
```

Exit Status If the requested version information is not found, a non-zero value is returned. Otherwise, a 0 value is returned.

Version information is determined not found when any of the following is true:

- the `-d` option is specified and no version definitions are found.
- the `-r` option is specified and no version requirements are found.
- neither the `-d` nor `-r` option is specified and no version definitions or version requirements are found.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	developer/base-developer-utilities

See Also [elfdump\(1\)](#), [ld\(1\)](#), [ldd\(1\)](#), [strip\(1\)](#), [elf\(3ELF\)](#), [attributes\(5\)](#)

Linker and Libraries Guide

Name pwd – return working directory name

Synopsis /usr/bin/pwd

Description The pwd utility writes an absolute path name of the current working directory to standard output.

Both the Bourne shell, [sh\(1\)](#), and the Korn shells, [ksh\(1\)](#) and [ksh88\(1\)](#), also have a built-in pwd command.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of pwd: LANG, LC_ALL, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

If an error is detected, output will not be written to standard output, a diagnostic message will be written to standard error, and the exit status will not be 0.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	Committed
Standard	See standards(5) .

See Also [cd\(1\)](#), [ksh\(1\)](#), [ksh88\(1\)](#), [sh\(1\)](#), [shell_builtins\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics pwd: cannot determine current directory!

Consult your network administrator.

Notes If you move the current directory or one above it, pwd may not give the correct response. Use the [cd\(1\)](#) command with a full path name to correct this situation.

Name radadrngen – code generator

Synopsis /usr/bin/radadrngen [-N] spec.xml
 /usr/bin/radadrngen [-N] -c *dir* [-r [-m] [-s]] spec.xml
 /usr/bin/radadrngen [-N] -j *dir* [-i] spec.xml
 /usr/bin/radadrngen [-N] {-o *docbook* | *docbook-man* | *man* | *rmdoc*} spec.xml
 /usr/bin/radadrngen -d baseline.xml spec.xml

Description The radadrngen command is the ADR IDL processing tool. Its primary purpose is to generate language bindings for the rad server and the various rad client environments. It can also generate documentation, and audit changes to interfaces for consistency with their versions.

All invocations validate the given spec.xml against the ADR schema.

Options The following options are supported:

Common Options -N
 Do not limit what types can be nullable. This restriction is in place to facilitate mapping to languages where certain types are not naturally nullable. This option relaxes this restriction for uses where it is both permissible and advantageous for all types to be nullable.

C Definition Options -c *dir*
 Generate C definitions for the types and interfaces defined in the input file. Files will be created under *dir*.

-r
 Generate C server-side definitions that reference entry points using the prescribed entry-point naming scheme.

-m
 Do not generate separate definitions for inherited interfaces. By default, new definitions are generated for inherited interfaces, replicating the definitions in the inherited interface.

-s
 Generate C stubs for entry points referenced by the definitions created by the -r option.

Java Definition Options -j *dir*
 Generate Java interfaces for the types and interfaces defined in the input file. The Java source tree will be created under *dir*.

-i
 Generate concrete implementation classes for the interfaces created for structured types.

Documentation Generation Options -o *format*
 Generate documentation, in the given format, for the interface definition in spec.xml. Documentation can be improved by decorating the various parts of the interface definition with *summary* and *doc* elements.

Valid formats:

docbook
standard docbook format

docbook-man
man page content in docbook format, a precursor to man format, below

man
a man page, in [nt]roff format

rmdoc
spec.xml, with the *summary* and *doc* elements removed

Interface Comparison Options -d baseline.xml
Compare the interfaces defined by baseline.xml and spec.xml and verify that the version of the modified interface is consistent with the differences found. An error message is displayed if the versions are inconsistent.

Operands The following operand must be specified on the command line:

spec.xml
The path to the API specification for which type and interface definitions must be generated.

Files /usr/share/lib/xml/rng/radadr.rng.1
The core ADR RelaxNG schema definition.

/usr/share/lib/xml/rng/radadr-doc.rng.1
The ADR RelaxNG schema definition for documentation elements.

Name ranlib – convert archives to random libraries

Synopsis ranlib *archive*

Description The ranlib utility was used in SunOS 4.x to add a table of contents to archive libraries, which converted each archive to a form that could be linked more rapidly. This is no longer needed, as the ar(1) command automatically provides all the functionality ranlib used to provide.

This script is provided as a convenience for software developers who need to maintain Makefiles that are portable across a variety of operating systems.

Exit Status ranlib has exit status 0.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/base-developer-utilities

See Also ar(1), ar.h(3HEAD), attributes(5)

Name rcapstat – report resource cap enforcement daemon statistics

Synopsis rcapstat [-g] [-p | -z] [-T u | d] [*interval* [*count*]]

Description The rcapstat command reports on the projects or zones capped by [rcapd\(1M\)](#). Each report contains statistics that pertain to the project or zone and paging statistics. Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. rcapd pages out the most infrequently used pages.

The paging statistics in the first report issued show the activity since the daemon was started. Subsequent reports reflect the activity since the last report was issued.

Reports are issued every *interval* seconds up to the quantity specified by *count*, or forever if *count* is not specified.

Options The following options are supported:

-g Global statistics. Reports the minimum memory utilization for memory cap enforcement (see [rcapadm\(1M\)](#)) and reports current memory utilization as a percentage of installed physical memory.

-p Report statistics for capped projects. This is the default if no option is specified.

-T u | d Display a time stamp.

Specify u for a printed representation of the internal representation of time. See [time\(2\)](#). Specify d for standard date format. See [date\(1\)](#).

-z Report statistics for capped zones.

Output The following list defines the column headings in the rcapstat report and provides information about how to interpret the report.

id The project ID or zone ID of the capped project or zone.

project The project name.

zone The zone name.

nproc The number of processes in the project or zone since the last report.

vm The total of all anonymous mappings that reserve disk or memory swap.

rss The total resident set size (RSS) of the project or zone's processes, in kilobytes (K), megabytes (M), or gigabytes (G). The count does not account for shared pages.

cap The RSS cap for the project or zone. See [rcapd\(1M\)](#) for information about how to specify memory caps.

at The total amount of memory that rcapd attempted to page out.

Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. rcapd pages out the most infrequently used pages.

<code>avgat</code>	The average amount of memory that <code>rcapd</code> attempted to page out during each sample cycle. The rate at which <code>rcapd</code> samples RSS can be set with <code>rcapadm(1M)</code> .
<code>pg</code>	An estimate of the total amount of memory that <code>rcapd</code> successfully paged out.
<code>avgpg</code>	An estimate of the average amount of memory that <code>rcapd</code> successfully paged out during each sample cycle. The rate at which <code>rcapd</code> samples process RSS sizes can be set with <code>rcapadm</code> .

Operands The following operands are supported:

<i>interval</i>	Specifies the reporting interval in seconds. The default interval is 5 seconds.
<i>count</i>	Specifies the number of reports to produce. By default, <code>rcapstat</code> reports statistics until a termination signal is received or until the <code>rcapd</code> process exits.

Examples **EXAMPLE 1** Using `rcapstat` to Report Cap and Project Information

Caps are defined for two projects associated with two users. `user1` has a cap of 50 megabytes and `user2` has a cap of 10 megabytes.

The following command produces five reports at 5-second sampling intervals.

```
example# rcapstat 5 5
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1    24 123M  35M 50M 50M  0K 3312K  0K
 78194 user2     1 2368K 1856K 10M  0K  0K  0K  0K
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1    24 123M  35M 50M  0K  0K  0K  0K
 78194 user2     1 2368K 1856K 10M  0K  0K  0K  0K
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1    24 123M  35M 50M  0K  0K  0K  0K
 78194 user2     1 2368K 1928K 10M  0K  0K  0K  0K
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1    24 123M  35M 50M  0K  0K  0K  0K
 78194 user2     1 2368K 1928K 10M  0K  0K  0K  0K
```

The first three lines of output constitute the first report, which contains the cap and project information for the two projects and paging statistics since `rcapd` was started. The `at` and `pg` columns are a number greater than zero for `user1` and zero for `user2`, which indicates that at some time in the daemon's history, `user1` exceeded its cap but `user2` did not.

The subsequent reports show no significant activity.

EXAMPLE 2 Using rcapstat to Monitor the RSS of a Project

```
example% rcapstat 5 5
  id project  nproc   vm  rss  cap   at avgat   pg  avgpg
376565  user1    57 209M 46M  10M 440M 220M 5528K 2764K
376565  user1    57 209M 44M  10M 394M 131M 4912K 1637K
376565  user1    56 207M 43M  10M 440M 147M 6048K 2016K
376565  user1    56 207M 42M  10M 522M 174M 4368K 1456K
376565  user1    56 207M 44M  10M 482M 161M 3376K 1125K
```

The project user1 has an RSS in excess of its physical memory cap. The nonzero values in the pg column indicate that rcapd is consistently paging out memory as it attempts to meet the cap by lowering the physical memory utilization of the project's processes. However, rcapd is unsuccessful, as indicated by the varying rss values that do not show a corresponding decrease. This means that the application's resident memory is being actively used, forcing rcapd to affect the working set. Under this condition, the system continues to experience high page fault rates, and associated I/O, until the working set size (WSS) is reduced, the cap is raised, or the application changes its memory access pattern. Notice that a page fault occurs when either a new page must be created, or the system must copy in a page from the swap device.

EXAMPLE 3 Determining the Working Set Size of a Project

This example is a continuation of Example 1, and it uses the same project.

```
example% rcapstat 5 5
  id project  nproc   vm  rss  cap   at avgat   pg  avgpg
376565  user1    56 207M 44M  10M 381M 191M   15M 7924K
376565  user1    56 207M 46M  10M 479M 160M 2696K  898K
376565  user1    56 207M 46M  10M 424M 141M 7280K 2426K
376565  user1    56 207M 43M  10M 401M 201M 4808K 2404K
376565  user1    56 207M 43M  10M 456M 152M 4800K 1600K
376565  user1    56 207M 44M  10M 486M 162M 4064K 1354K
376565  user1    56 207M 52M 100M 191M  95M 1944K  972K
376565  user1    56 207M 55M 100M   0K   0K   0K   0K
376565  user1    56 207M 56M 100M   0K   0K   0K   0K
376565  user1    56 207M 56M 100M   0K   0K   0K   0K
376565  user1    56 207M 56M 100M   0K   0K   0K   0K
376565  user1    56 207M 56M 100M   0K   0K   0K   0K
```

By inhibiting cap enforcement, either by raising the cap of a project or by changing the minimum physical memory utilization for cap enforcement (see rcapadm(1M)), the resident set can become the working set. The rss column might stabilize to show the project WSS, as shown in the previous example. The WSS is the minimum cap value that allows the project's processes to operate without perpetually incurring page faults.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid command-line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-caps

See Also [rcapadm\(1M\)](#), [rcapd\(1M\)](#), [attributes\(5\)](#)

Physical Memory Control Using the Resource Capping Daemon in System Administration Guide: Resource Management

Notes If the interval specified to `rcapstat` is shorter than the reporting interval specified to `rcapd` (with `rcapadm(1M)`), the output for some intervals can be zero. This is because `rcapd` does not update statistics more frequently than the interval specified with `rcapadm`, and this interval is independent of (and less precise than) the sampling interval used by `rcapstat`.

Name rcp – remote file copy

Synopsis rcp [-p] [-a] [-K] [-x] [-PN | -PO] [-k *realm*] *filename1 filename2*
 rcp [-pr] [-a] [-K] [-x] [-PN | -PO] [-k *realm*] *filename... directory*

Description The rcp command copies files between machines. Each *filename* or *directory* argument is either a remote file name of the form:

hostname:path

or a local file name (containing no : (colon) characters, or / (backslash) before any : (colon) characters).

The *hostname* can be an IPv4 or IPv6 address string. See [inet\(7P\)](#) and [inet6\(7P\)](#). Since IPv6 addresses already contain colons, the *hostname* should be enclosed in a pair of square brackets when an IPv6 address is used. Otherwise, the first occurrence of a colon can be interpreted as the separator between *hostname* and *path*. For example,

```
[1080::8:800:200C:417A]:tmp/file
```

If a *filename* is not a full path name, it is interpreted relative to your home directory on *hostname*. A *path* on a remote host can be quoted using \ , " , or ' , so that the metacharacters are interpreted remotely. Please notice that the kerberized versions of rcp are not IPv6-enabled.

rcp does not prompt for passwords. It either uses Kerberos authentication which is enabled through command-line options or your current local user name must exist on *hostname* and allow remote command execution by [rsh\(1\)](#).

The rcp session can be kerberized using any of the following Kerberos specific options : -a, -PN or -PO, -x, and -k *realm*. Some of these options (-a, -x and -PN or -PO) can also be specified in the [appdefaults] section of [krb5.conf\(4\)](#). The usage of these options and the expected behavior is discussed in the OPTIONS section below. If Kerberos authentication is used, authorization to the account is controlled by rules in [krb5_auth_rules\(5\)](#). If this authorization fails, fallback to normal rcp using rhosts occurs only if the -PO option is used explicitly on the command line or is specified in [krb5.conf\(4\)](#). If authorization succeeds, remote copy succeeds without any prompting of password. Also notice that the -PN or -PO, -x, and -k *realm* options are just supersets of the -a option.

rcp handles third party copies, where neither source nor target files are on the current machine. Hostnames can also take the form

username@hostname:filename

to use *username* rather than your current local user name as the user name on the remote host. rcp also supports Internet domain addressing of the remote host, so that:

username@host.domain:filename

specifies the username to be used, the hostname, and the domain in which that host resides. File names that are not full path names are interpreted relative to the home directory of the user named *username*, on the remote host.

Options The following options are supported:

- a This option explicitly enables Kerberos authentication and trusts the `.k5login` file for access-control. If the authorization check by `in.rshd(1M)` on the server-side succeeds and if the `.k5login` file permits access, the user is allowed to carry out the `rcp` transfer.
- k *realm* Causes `rcp` to obtain tickets for the remote host in *realm* instead of the remote host's realm as determined by `krb5.conf(4)`.
- K *realm* This option explicitly disables Kerberos authentication. It can be used to override the `autoLogin` variable in `krb5.conf(4)`.
- p Attempts to give each copy the same modification times, access times, modes, and ACLs if applicable as the original file.
- PO
- PN Explicitly requests new (-PN) or old (-PO) version of the Kerberos “rcmd” protocol. The new protocol avoids many security problems prevalent in the old one and is regarded much more secure, but is not interoperable with older (MIT/SEAM) servers. The new protocol is used by default, unless explicitly specified using these options or through `krb5.conf(4)`. If Kerberos authorization fails when using the old “rcmd” protocol, there is fallback to regular, non-kerberized `rcp`. This is not the case when the new, more secure “rcmd” protocol is used.
- r Copies each subtree rooted at *filename*; in this case the destination must be a directory.
- x Causes the information transferred between hosts to be encrypted. Notice that the command is sent unencrypted to the remote system. All subsequent transfers are encrypted.

Usage See `largefile(5)` for the description of the behavior of `rcp` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

The `rcp` command is IPv6-enabled. See `ip6(7P)`. IPv6 is not currently supported with Kerberos V5 authentication.

For the kerberized `rcp` session, each user can have a private authorization list in a file `.k5login` in their home directory. Each line in this file should contain a Kerberos principal name of the form *principal/instance@realm*. If there is a `~/k5login` file, then access is granted to the account if and only if the originator user is authenticated to one of the principals named in the `~/k5login` file. Otherwise, the originating user is granted access to the account if and

only if the authenticated principal name of the user can be mapped to the local account name using the *authenticated-principal-name* → *local-user-name* mapping rules. The `.k5login` file (for access control) comes into play only when Kerberos authentication is being done.

Exit Status The following exit values are returned:

0 All files were copied successfully.

>0 An error occurred.

See the NOTES section for caveats on the exit code.

Files `$HOME/.profile`

`$HOME/.k5login` File containing Kerberos principals that are allowed access

`/etc/krb5/krb5.conf` Kerberos configuration file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients
CSI	Enabled

See Also [cpio\(1\)](#), [ftp\(1\)](#), [rlogin\(1\)](#), [rsh\(1\)](#), [setfacl\(1\)](#), [tar\(1\)](#), [tar\(1\)](#), [in.rshd\(1M\)](#), [hosts.equiv\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [krb5_auth_rules\(5\)](#), [inet\(7P\)](#), [inet6\(7P\)](#), [ip6\(7P\)](#)

Notes `rcp` is meant to copy between different hosts. Attempting to `rcp` a file onto itself, as with:

```
example% rcp tmp/file myhost:/tmp/file
```

results in a severely corrupted file.

`rcp` might not correctly fail when the target of a copy is a file instead of a directory.

`rcp` can become confused by output generated by commands in a `$HOME/.profile` on the remote host.

`rcp` requires that the source host have permission to execute commands on the remote host when doing third-party copies.

`rcp` does not properly handle symbolic links. Use `tar` or `cpio` piped to `rsh` to obtain remote copies of directories containing symbolic links or named pipes. See [tar\(1\)](#) and [cpio\(1\)](#).

If you forget to quote metacharacters intended for the remote host, you get an incomprehensible error message.

`rcp` fails if you copy ACLs to a file system that does not support ACLs.

rcp is CSI-enabled except for the handling of username, hostname, and domain.

When rcp is used to perform third-party copies where either of the remote machines is not running Solaris, the exit code cannot be relied upon. That is, errors could occur when success is reflected in the exit code, or the copy could be completely successful even though an error is reflected in the exit code.

Name read – read a line from standard input

Synopsis

```
/usr/bin/read /usr/bin/read [-r] var...  
sh read name...  
csh set variable= $<  
ksh88 read [-prsu [n]] [name ? prompt] [name]...  
ksh read [-ACprs] [-d delim] [-n nsize] [-N nsize] [-t timeout]  
      [-u unit] [vname?prompt] [vname... ]
```

Description

`/usr/bin/read` The read utility reads a single line from standard input.

By default, unless the `-r` option is specified, backslash (`\`) acts as an escape character. If standard input is a terminal device and the invoking shell is interactive, read prompts for a continuation line when:

- The shell reads an input line ending with a backslash, unless the `-r` option is specified.
- A here-document is not terminated after a `NEWLINE` character is entered.

The line is split into fields as in the shell. The first field is assigned to the first variable `var`, the second field to the second variable `var`, and so forth. If there are fewer `var` operands specified than there are fields, the leftover fields and their intervening separators is assigned to the last `var`. If there are fewer fields than `vars`, the remaining `vars` is set to empty strings.

The setting of variables specified by the `var` operands affects the current shell execution environment. If it is called in a sub-shell or separate utility execution environment, such as one of the following:

```
(read foo)  
nohup read ...  
find . -exec read ... \;
```

It does not affect the shell variables in the caller's environment.

The standard input must be a text file.

- sh One line is read from the standard input and, using the internal field separator, IFS (normally space or tab), to delimit word boundaries, the first word is assigned to the first `name`, the second word to the second `name`, and so on, with leftover words assigned to the last `name`. Lines can be continued using `\newLine`. Characters other than `NEWLINE` can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to `names`, and no interpretation is done on the character that follows the backslash. The return code is `0`, unless an end-of-file is encountered.
- csh The notation:

```
set variable = $<
```

loads one line of standard input as the value for *variable*. (See `cs(1)`).

ksh88 The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (`\`), is used to remove any special meaning for the next character and for line continuation. In raw mode, the `-r`, the `,` and the `\` character are not treated specially. The first field is assigned to the first *name*, the second field to the second *name*, and so on, with leftover fields assigned to the last *name*. The `-p` option causes the input line to be taken from the input pipe of a process spawned by the shell using `|&`. If the `-s` flag is present, the input is saved as a command in the history file. The flag `-u` can be used to specify a one digit file descriptor unit *n* to read from. The file descriptor can be opened with the `exec` special command. The default value of *n* is `0`. If *name* is omitted, `REPLY` is used as the default *name*. The exit status is `0` unless the input file is not open for reading or an end-of-file is encountered. An end-of-file with the `-p` option causes cleanup for this process so that another can be spawned. If the first argument contains a `?`, the remainder of this word is used as a *prompt* on standard error when the shell is interactive. The exit status is `0` unless an end-of-file is encountered.

ksh `read` reads a line from standard input and breaks it into fields using the characters in the value of the IFS variable as separators. The escape character, `\`, is used to remove any special meaning for the next character and for line continuation unless the `-r` option is specified.

If there are more variables than fields, the remaining variables are set to empty strings. If there are fewer variables than fields, the leftover fields and their intervening separators are assigned to the last variable. If no *var* is specified, the variable `REPLY` is used.

When *var* has the binary attribute and `-n` or `-N` is specified, the bytes that are read are stored directly into *var*.

If you specify `?prompt` after the first *var*, `read` displays a prompt on standard error when standard input is a terminal or pipe.

Options

`/usr/bin/read`, **ksh88** The following option is supported by `/usr/bin/read` and **ksh88**:

`-r` Do not treat a backslash character in any special way. Considers each backslash to be part of the input line.

ksh The following options are supported by **ksh**:

`-A` Unset *var*, and create an indexed array containing each field in the line starting at index `0`.

`-C` Unset *var* and read *var* as a compound variable.

`-d delim` Read until delimiter *delim* instead of to the end of line.

`-n nsize` Read at most *nsize* bytes. Binary field size is in bytes.

- N *nsize* Read exactly *nsize* bytes. Binary field size is in bytes.
- p Read from the current co-process instead of standard input. An end of file causes read to disconnect the co-process so that another can be created.
- r Do not treat \ specially when processing the input line.
- s Save a copy of the input as an entry in the shell history file.
- t *timeout* Specify a *timeout* in seconds when reading from a terminal or pipe.
- u *fd* Read from file descriptor number *fd* instead of standard input. The default value is 0.
- v When reading from a terminal, display the value of the first variable and use it as a default value.

Operands The following operand is supported:

var The name of an existing or non-existing shell variable.

Examples EXAMPLE 1 Using the read Command

The following example for `/usr/bin/read` prints a file with the first field of each line moved to the end of the line:

```
example% while read -r xx yy
do
    printf "%s %s\n" "$yy" "$xx"
done < input_file
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of read: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

IFS Determines the internal field separators used to delimit fields.

PS2 Provides the prompt string that an interactive shell writes to standard error when a line ending with a backslash is read and the -r option was not specified, or if a here-document is not terminated after a NEWLINE character is entered.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 End-of-file was detected or an error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

See Also [csh\(1\)](#), [ksh\(1\)](#), [ksh88\(1\)](#), [line\(1\)](#), [set\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name readonly – shell built-in function to protect the value of the given variable from reassignment

Synopsis

```
sh  readonly [name]...
ksh88 **readonly [name [= value]]...
      **readonly -p
ksh  ++readonly [-p] [name [= value]]...
```

Description

sh The given *names* are marked `readonly` and the values of these *names* may not be changed by subsequent assignment. If no arguments are given, a list of all `readonly` names is printed.

ksh88 The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.

When `-p` is specified, `readonly` writes to the standard output the names and values of all read-only variables, in the following format:

```
"readonly %s=%s\n", name, value
```

if *name* is set, and:

```
"readonly $s\n", name
```

if *name* is unset.

The shell formats the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same value and `readonly` attribute-setting results in a shell execution environment in which:

1. Variables with values set at the time they were output do not have the `readonly` attribute set.
2. Variables that were unset at the time they were output do not have a value at the time at which the saved output is re-input to the shell.

On this manual page, [ksh88\(1\)](#) commands that are preceded by one or two `**` (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by `**` that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the `=` sign and word splitting and file name generation are not performed.

ksh `readonly` sets the `readonly` attribute on each of the variables specified by name which prevents their values from being changed. If `=value` is specified, the variable name is set to `value` before the variable is made `readonly`.

If no names are specified then the names and values of all `readonly` variables are written to standard output.

`readonly` is built-in to the shell as a declaration command so that field splitting and pathname expansion are not performed on the arguments. Tilde expansion occurs on `value`.

-p Causes the output to be in a form of `readonly` commands that can be used as input to the shell to recreate the current set of `readonly` variables.

On this manual page, [ksh\(1\)](#) commands that are preceded by one or two + symbols are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. They are not valid function names.
5. Words, following a command preceded by ++ that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and field splitting and file name generation are not performed.

Exit Status

ksh The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Name refer – expand and insert references from a bibliographic database

Synopsis refer [-ben] [-ar] [-cstring] [-kx] [-\lm,n] [-p filename]
[-skeys] filename...

Description refer is a preprocessor for `nroff(1)`, or `troff(1)`, that finds and formats references. The input files (standard input by default) are copied to the standard output, except for lines between `‘. [’` and `‘.]’` command lines. Such lines are assumed to contain keywords as for `lookbib(1)`, and are replaced by information from a bibliographic data base. The user can avoid the search, override fields from it, or add new fields. The reference data, from whatever source, is assigned to a set of `troff` strings. Macro packages such as `ms(5)` print the finished reference text from these strings. A flag is placed in the text at the point of reference. By default, the references are indicated by numbers.

When refer is used with `eqn(1)`, `neqn`, or `tbl(1)`, refer should be used first in the sequence, to minimize the volume of data passed through pipes.

- Options**
- b Bare mode — do not put any flags in text (neither numbers or labels).
 - e Accumulate references instead of leaving the references where encountered, until a sequence of the form:

```
. [
$LIST$
.]
```

 is encountered, and then write out all references collected so far. Collapse references to the same source.
 - n Do not search the default file.
 - ar Reverse the first *r* author names (Jones, J. A. instead of J. A. Jones). If *r* is omitted, all author names are reversed.
 - cstring Capitalize (with SMALL CAPS) the fields whose key-letters are in *string*.
 - kx Instead of numbering references, use labels as specified in a reference data line beginning with the characters `%x`; By default, *x* is L.
 - \lm,n Instead of numbering references, use labels from the senior author's last name and the year of publication. Only the first *m* letters of the last name and the last *n* digits of the date are used. If either of *m* or *n* is omitted, the entire name or date, respectively, is used.
 - p filename Take the next argument as a file of references to be searched. The default file is searched last.
 - skeys Sort references by fields whose key-letters are in the *keys* string, and permute reference numbers in the text accordingly. Using this option implies the `-e` option. The key-letters in *keys* may be followed by a number indicating how many such fields are used, with a + sign taken as a very large number. The

default is AD, which sorts on the senior author and date. To sort on all authors and then the date, for instance, use the options '-sA+T'.

Files /usr/lib/refer directory of programs
 /usr/lib/refer/papers directory of default publication lists and indexes

See Also [addbib\(1\)](#), [eqn\(1\)](#), [indxbib\(1\)](#), [lookbib\(1\)](#), [nroff\(1\)](#), [roffbib\(1\)](#), [sortbib\(1\)](#), [tbl\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#)

Name regcmp – regular expression compile

Synopsis regcmp [-] *filename*...

Description The regcmp command performs a function similar to regcmp and, in most cases, precludes the need for calling regcmp from C programs. Bypassing regcmp saves on both execution time and program size. The command regcmp compiles the regular expressions in *filename* and places the output in *filename.i*.

Options – If the `-` option is used, the output is placed in *filename.c*. The format of entries in *filename* is a name (C variable) followed by one or more blanks followed by one or more regular expressions enclosed in double quotes. The output of regcmp is C source code. Compiled regular expressions are represented as extern char vectors. *filename.i* files may thus be #included in C programs, or *filename.c* files may be compiled and later loaded. In the C program that uses the regcmp output, `regex(abc, line)` applies the regular expression named `abc` to `line`. Diagnostics are self-explanatory.

Examples EXAMPLE 1 Using the regcmp command.

```
name    "( [A-Za-z] [A-Za-z0-9_ ]*)$0"
telno   "\({0,1}([2-9][01][1-9])$0\){0,1}*"
        "([2-9][0-9]{2})$1[ -]{0,1}"
        "([0-9]{4})$2"
```

The three arguments to `telno` shown above must all be entered on one line.

In the C program that uses the regcmp output,

```
    regex(telno, line, area, exch, rest)
```

applies the regular expression named `telno` to `line`.

Environment Variables A general description of the usage of the LC_* environmental variables can be found in [environ\(5\)](#).

LC_CTYPE Determines how regcmp handles characters. When LC_CTYPE is set to a valid value, regcmp can display and handle text and filenames containing valid characters for that locale.

LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name renice – alter priority of running processes

Synopsis renice [-n *increment*] [-i *idtype*] *ID*...

renice [-n *increment*] [-g | -p | -u] *ID*...

renice *priority* [-p] *pid*... [-g *gid*]... [-p *pid*]...
[-u *user*]...

renice *priority* -g *gid*... [-g *gid*]... [-p *pid*]...
[-u *user*]...

renice *priority* -u *user*... [-g *gid*]... [-p *pid*]...
[-u *user*]...

Description The renice command alters the scheduling priority of one or more running processes. By default, the processes to be affected are specified by their process IDs.

If the first operand is a number within the valid range of priorities (−20 to 20), renice will treat it as a *priority* (as in all but the first synopsis form). Otherwise, renice will treat it as an *ID* (as in the first synopsis form).

Altering Process Priority Users other than the privileged user may only alter the priority of processes they own, and can only monotonically increase their “nice value” within the range 0 to 19. This prevents overriding administrative fiats. The privileged user may alter the priority of any process and set the priority to any value in the range −20 to 19. Useful priorities are: 19 (the affected processes will run only when nothing else in the system wants to); 0 (the “base” scheduling priority);, and any negative value (to make things go very fast). 20 is an acceptable nice value, but will be rounded down to 19.

Options renice supports the following option features:

- The first operand, *priority*, must precede the options and can have the appearance of a multi-digit option.
- The -g, -p, and -u options can each take multiple option-arguments.
- The *pid* option-argument can be used without its -p option.
- The -i option can be used to specify the *ID* type for the ID list. This is preferred in specifying *ID* type over the use of the -g | -p | -u syntax, which is now obsolete. See NOTES.

The following options are supported:

- g Interprets all operands or just the *gid* arguments as unsigned decimal integer process group IDs.
- i This option, together with the *ID* list arguments, specifies a class of processes to which the renice command is to apply. The interpretation of the ID list depends on the value of *idtype*. The valid *idtype* arguments are: pid, pgid, uid, gid, sid, taskid, projid, and zoneid.

- n *increment* Specifies how the system scheduling priority of the specified process or processes is to be adjusted. The *increment* option-argument is a positive or negative decimal integer that will be used to modify the system scheduling priority of the specified process or processes. Positive *increment* values cause a lower system scheduling priority. Negative *increment* values may require appropriate privileges and will cause a higher system scheduling priority.
- p Interprets all operands or just the *pid* arguments as unsigned decimal integer process IDs. The -p option is the default if no options are specified.
- u Interprets all operands or just the *user* argument as users. If a user exists with a user name equal to the operand, then the user ID of that user will be used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it will be used as the numeric user ID of the user.

Operands The following operands are supported:

- ID* A process ID, process group ID, or user name/user ID, depending on the option selected.
- priority* The value specified is taken as the actual system scheduling priority, rather than as an increment to the existing system scheduling priority. Specifying a scheduling priority higher than that of the existing process may require appropriate privileges.

Examples **EXAMPLE 1** Adjusting the scheduling priority of process IDs

Adjust the system scheduling priority so that process IDs 987 and 32 would have a lower scheduling priority:

```
example% renice -n 5 -p 987 32
```

EXAMPLE 2 Adjusting the scheduling priority of group IDs

Adjust the system scheduling priority so that group IDs 324 and 76 would have a higher scheduling priority, if the user has the appropriate privileges to do so:

```
example% renice -n -4 -g 324 76
```

EXAMPLE 3 Adjusting the scheduling priority of a user ID and user name

Adjust the system scheduling priority so that numeric user ID 8 and user sas would have a lower scheduling priority:

```
example% renice -n 4 -u 8 sas
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `renice`: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLS_PATH.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /etc/passwd map user names to user IDs

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Standard	See standards(5) .

See Also [nice\(1\)](#), [passwd\(1\)](#), [prioctl\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes The renice syntax

```
renice [-n increment] [-i idtype] ID ...
```

is preferred over the old syntax

```
renice [-n increment] [-g | -p | -u] ID ...
```

which is now obsolete.

If you make the priority very negative, then the process cannot be interrupted.

To regain control you must make the priority greater than 0.

Users other than the privileged user cannot increase scheduling priorities of their own processes, even if they were the ones that decreased the priorities in the first place.

The `prioctl` command subsumes the function of `renice`.

Name rlogin – remote login

Synopsis rlogin [-8EL] [-ec] [-A] [-K] [-x] [-PN | -PO] [-f | -F] [-a]
[-l *username*] [-k *realm*] *hostname*

Description The rlogin utility establishes a remote login session from your terminal to the remote machine named *hostname*. The user can choose to kerberize the rlogin session using Kerberos V5 and also protect the data being transferred.

Hostnames are listed in the *hosts* database, which can be contained in the */etc/hosts* file, the Network Information Service (NIS) *hosts* map, the Internet domain name server, or a combination of these. Each host has one official name (the first name in the database entry), and optionally one or more nicknames. Either official hostnames or nicknames can be specified in *hostname*.

The user can opt for a secure rlogin session which uses Kerberos V5 for authentication. Encryption of the session data is also possible. The rlogin session can be kerberized using any of the following Kerberos specific options: -A, -PN or -PO, -x, -f or -F, and -k *realm*. Some of these options (-A, -x, -PN or -PO, and -f or -F) can also be specified in the [appdefaults] section of *krb5.conf(4)*. The usage of these options and the expected behavior is discussed in the OPTIONS section below. If Kerberos authentication is used, authorization to the account is controlled through rules in *krb5_auth_rules(5)*. If this authorization fails, fallback to normal rlogin using *rhosts* occurs only if the -PO option is used explicitly on the command line or is specified in *krb5.conf(4)*. Also notice that the -PN or -PO, -x, -f or -F, and -k *realm* options are just supersets of the -A option.

The remote terminal type is the same as your local terminal type, as given in your environment TERM variable. The terminal or window size is also copied to the remote system if the server supports the option. Changes in size are reflected as well. All echoing takes place at the remote site, so that (except for delays) the remote login is transparent. Flow control using Control-S and Control-Q and flushing of input and output on interrupts are handled properly.

Options The following options are supported:

- 8 Passes eight-bit data across the net instead of seven-bit data.
- a Forces the remote machine to ask for a password by sending a null local username.
- A Explicitly enables Kerberos authentication and trusts the *.k5login* file for access-control. If the authorization check by *in.rlogind(1M)* on the server-side succeeds and if the *.k5login* file permits access, the user is allowed to login without supplying a password.
- ec Specifies a different escape character, *c*, for the line used to disconnect from the remote host.
- E Stops any character from being recognized as an escape character.

- f Forwards a copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. This is a non-forwardable ticket granting ticket. You must forward a ticket granting ticket if you need to authenticate yourself to other Kerberized network services on the remote host. An example is if your home directory on the remote host is NFS mounted via Kerberos V5. If your local credentials are not forwarded in this case, you can not access your home directory. This option is mutually exclusive with the -F option.
- F Forwards a forwardable copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. The -F option provides a superset of the functionality offered by the -f option. For example, with the -f option, after you connected to the remote host, any attempt to invoke `/usr/bin/ftp`, `/usr/bin/telnet`, `/usr/bin/rlogin`, or `/usr/bin/rsh` with the -f or -F options would fail. Thus, you would be unable to push your single network sign on trust beyond one system. This option is mutually exclusive with the -f option.
- k *realm* Causes `rlogin` to obtain tickets for the remote host in *realm* instead of the remote host's realm as determined by `krb5.conf(4)`.
- K This option explicitly disables Kerberos authentication. It can be used to override the `autoLogin` variable in `krb5.conf(4)`.
- l *username* Specifies a different *username* for the remote login. If you do not use this option, the remote username used is the same as your local username.
- L Allows the `rlogin` session to be run in "litout" mode.
- PN
- PO Explicitly requests the new (-PN) or old (-PO) version of the Kerberos 'rcmd' protocol. The new protocol avoids many security problems prevalent in the old one and is considered much more secure, but is not interoperable with older (MIT/SEAM) servers. The new protocol is used by default, unless explicitly specified using these options or by using `krb5.conf(4)`. If Kerberos authorization fails when using the old 'rcmd' protocol, there is fallback to regular, non-kerberized `rlogin`. This is not the case when the new, more secure 'rcmd' protocol is used.
- x Turns on DES encryption for all data passed through the `rlogin` session. This reduces response time and increases CPU utilization.

Escape Sequences Lines that you type which start with the tilde character (~) are "escape sequences." The escape character can be changed using the -e option.

- ~. Disconnects from the remote host. This is not the same as a logout, because the local host breaks the connection with no warning to the remote end.

- `~susp` Suspends the login session, but only if you are using a shell with Job Control. `susp` is your “suspend” character, usually Control-Z. See [tty\(1\)](#).
- `~dsusp` Suspends the input half of the login, but output is still able to be seen (only if you are using a shell with Job Control). `dsusp` is your “deferred suspend” character, usually Control-Y. See [tty\(1\)](#).

Operands *hostname* The remote machine on which *rlogin* establishes the remote login session.

Usage For the kerberized *rlogin* session, each user can have a private authorization list in a file, `.k5login`, in his home directory. Each line in this file should contain a Kerberos principal name of the form *principal/instance@realm*. If there is a `~/.k5login` file, access is granted to the account if and only if the originating user is authenticated to one of the principals named in the `~/.k5login` file. Otherwise, the originating user is granted access to the account if and only if the authenticated principal name of the user can be mapped to the local account name using the *authenticated-principal-name* → *local-user-name* mapping rules. The `.k5login` file (for access control) comes into play only when Kerberos authentication is being done.

For the non-secure *rlogin* session, each remote machine can have a file named `/etc/hosts.equiv` containing a list of trusted host names with which it shares user names. Users with the same user name on both the local and remote machine can *rlogin* from the machines listed in the remote machine's `/etc/hosts.equiv` file without supplying a password. Individual users can set up a similar private equivalence list with the file `.rhosts` in their home directories. Each line in this file contains two names, that is, a host name and a user name, separated by a space. An entry in a remote user's `.rhosts` file permits the user named *username* who is logged into *hostname* to log in to the remote machine as the remote user without supplying a password. If the name of the local host is not found in the `/etc/hosts.equiv` file on the remote machine, and the local user name and host name are not found in the remote user's `.rhosts` file, then the remote machine prompts for a password. Host names listed in the `/etc/hosts.equiv` and `.rhosts` files must be the official host names listed in the hosts database. Nicknames can not be used in either of these files.

For security reasons, the `.rhosts` file must be owned by either the remote user or by root.

Files <code>/etc/passwd</code>	Contains information about users' accounts.
<code>/usr/hosts/*</code>	For <i>hostname</i> version of the command.
<code>/etc/hosts.equiv</code>	List of trusted hostnames with shared user names.
<code>/etc/nologin</code>	Message displayed to users attempting to login during machine shutdown.
<code>\$HOME/.rhosts</code>	Private list of trusted hostname/username combinations.
<code>\$HOME/.k5login</code>	File containing Kerberos principals that are allowed access.
<code>/etc/krb5/krb5.conf</code>	Kerberos configuration file.

`/etc/hosts` Hosts database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients

See Also [rsh\(1\)](#), [stty\(1\)](#), [tty\(1\)](#), [in.rlogind\(1M\)](#), [hosts\(4\)](#), [hosts.equiv\(4\)](#), [krb5.conf\(4\)](#), [nologin\(4\)](#), [attributes\(5\)](#), [krb5_auth_rules\(5\)](#)

Diagnostics The following message indicates that the machine is in the process of being shutdown and logins have been disabled:

```
NO LOGINS: System going down in N minutes
```

Notes When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP.) The functionality of the two remains the same. Only the name has changed.

This implementation can only use the TCP network service.

Name rm, rmdir – remove directory entries

Synopsis /usr/bin/rm [-f] [-i] *file*...
 /usr/bin/rm -rR [-f] [-i] *dirname*... [*file*]...
 /usr/xpg4/bin/rm [-fiRr] *file*...
 /usr/bin/rmdir [-ps] *dirname*...

Description

/usr/bin/rm
 /usr/xpg4/bin/rm
 The `rm` utility removes the directory entry specified by each *file* argument. If a file has no write permission and the standard input is a terminal, the full set of permissions (in octal) for the file are printed followed by a question mark. This is a prompt for confirmation. If the answer is affirmative, the file is deleted, otherwise the file remains.

If *file* is a symbolic link, the link is removed, but the file or directory to which it refers is not deleted. Users do not need write permission to remove a symbolic link, provided they have write permissions in the directory.

If multiple *files* are specified and removal of a *file* fails for any reason, `rm` writes a diagnostic message to standard error, do nothing more to the current *file*, and go on to any remaining *files*.

If the standard input is not a terminal, the utility operates as if the `-f` option is in effect.

/usr/bin/rmdir
 The `rmdir` utility removes the directory entry specified by each *dirname* operand, which must refer to an empty directory.

Directories are processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of `rmdir`, the subdirectory must be specified before the parent directory so that the parent directory is empty when `rmdir` tries to remove it.

Options The following options are supported for `/usr/bin/rm` and `/usr/xpg4/bin/rm`:

`-r` Recursively removes directories and subdirectories in the argument list. The directory is emptied of files and removed. The user is normally prompted for removal of any write-protected files which the directory contains. The write-protected files are removed without prompting, however, if the `-f` option is used, or if the standard input is not a terminal and the `-i` option is not used.

Symbolic links that are encountered with this option is not traversed.

If the removal of a non-empty, write-protected directory is attempted, the utility always fails (even if the `-f` option is used), resulting in an error message.

`-R` Same as `-r` option.

`/usr/bin/rm` The following options are supported for `/usr/bin/rm` only:

- f Removes files (even if write-protected) in a directory without prompting the user. In a write-protected directory, however, files are never removed (whatever their permissions are) and no messages are displayed.
- i Interactive. With this option, `rm` prompts for confirmation before removing any files. It overrides the `-f` option and remains in effect even if the standard input is not a terminal.

`/usr/xpg4/bin/rm` The following options are supported for `/usr/xpg4/bin/rm` only:

- f Does not prompt for confirmation. Does not write diagnostic messages or modify the exit status in the case of non-existent operands. Any previous occurrences of the `-i` option is ignored.
- i Prompts for confirmation. Any occurrences of the `-f` option is ignored.

`/usr/bin/rmdir` The following options are supported for `/usr/bin/rmdir` only:

- p Allows users to remove the directory *dirname* and its parent directories which become empty. A message is printed to standard error if all or part of the path could not be removed.
- s Suppresses the message printed on the standard error when `-p` is in effect.

Operands The following operands are supported:

- file* Specifies the pathname of a directory entry to be removed.
- dirname* Specifies the pathname of an empty directory to be removed.

Usage See [largefile\(5\)](#) for the description of the behavior of `rm` and `rmdir` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples The following examples are valid for the commands shown.

`/usr/bin/rm`, **EXAMPLE 1** Removing Directories
`/usr/xpg4/bin/rm`

The following command removes the directory entries `a.out` and `core`:

```
example% rm a.out core
```

EXAMPLE 2 Removing a Directory without Prompting

The following command removes the directory `junk` and all its contents, without prompting:

```
example% rm -rf junk
```

`/usr/bin/rmdir` **EXAMPLE 3** Removing Empty Directories

If a directory `a` in the current directory is empty, except that it contains a directory `b`, and `a/b` is empty except that it contains a directory `c`, the following command removes all three directories:

```
example% rmdir -p a/b/c
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `rm` and `rmdir`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Affirmative responses are processed using the extended regular expression defined for the `yesexpr` keyword in the `LC_MESSAGES` category of the user's locale. The locale specified in the `LC_COLLATE` category defines the behavior of ranges, equivalence classes, and multi-character collating elements used in the expression defined for `yesexpr`. The locale specified in `LC_CTYPE` determines the locale for interpretation of sequences of bytes of text data a characters, the behavior of character classes used in the expression defined for the `yesexpr`. See [locale\(5\)](#).

Exit Status The following exit values are returned:

- `0` If the `-f` option was not specified, all the named directory entries were removed; otherwise, all the existing named directory entries were removed.
- `>0` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

<code>/usr/bin/rm</code> <code>/usr/bin/rmdir</code>	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/core-os
	CSI	Enabled

<code>/usr/xpg4/bin/rm</code>	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/xopen/xcu4
	CSI	Enabled
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [rmdir\(2\)](#), [unlink\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Diagnostics It is forbidden to remove the files “.” and “..” in order to avoid the consequences of inadvertently doing something like the following:

```
example% rm -r .*
```

It is forbidden to remove the file “/” in order to avoid the consequences of inadvertently doing something like:

```
example% rm -rf $x/$y
```

or

```
example% rm -rf /$y
```

when \$x and \$y expand to empty strings.

Notes A `-` permits the user to mark explicitly the end of any command line options, allowing `rm` to recognize file arguments that begin with a `-`. As an aid to BSD migration, `rm` accepts `--` as a synonym for `-`. This migration aid may disappear in a future release. If a `--` and a `-` both appear on the same command line, the second is interpreted as a file.

Name rmformat – removable rewritable media format utility

Synopsis rmformat [-DeHUv] [-b *label*] [-c *blockno*]
 [-Fquick | long | force] [-s *filename*] [*devname*]
 rmformat -V read | write *devname*
 rmformat -l [*devname*]

Description The `rmformat` utility is used to format, label, partition, and perform other miscellaneous functions on removable, rewritable media that include PCMCIA memory and `ata` cards. The `rmformat` utility should also be used with all USB mass storage devices, including USB hard drives. This utility can also be used for the verification and surface analysis and for repair of the bad sectors found during verification if the drive or the driver supports bad block management.

After formatting, `rmformat` writes the label, which covers the full capacity of the media as one slice on PCMCIA memory cards. The partition information can be changed with the help of other options provided by `rmformat`.

Options The following options are supported:

-b *label*

Labels the media with a SUNOS label. A SUNOS volume label name is restricted to 8 characters. For media size greater than 1 TB, an EFI label is created. For writing a DOS Volume label, the user should use `mkfs_pcfs(1M)`.

-c *blockno*

Corrects and repairs the given block. This correct and repair option may not be applicable to all devices supported by `rmformat`, as some devices may have a drive with bad block management capability and others may have this option implemented in the driver. If the drive or driver supports bad block management, a best effort is made to rectify the bad block. If the bad block still cannot be rectified, a message is displayed to indicate the failure to repair. The block number can be provided in decimal, octal, or hexadecimal format.

The normal PCMCIA memory and `ata` cards do not support bad block management.

-e

Ejects the media upon completion. This feature may not be available if the drive does not support motorized eject.

-F quick | long | force

Formats the media.

The `quick` option starts a format without certification or format with limited certification of certain tracks on the media.

The `long` option starts a complete format. For some devices this might include the certification of the whole media by the drive itself.

The `force` option to format is provided to start a long format without user confirmation before the format is started.

On PCMCIA memory cards, all options start a long format.

`-l`

Lists all removable devices. By default, without any options, `rmformat` also lists all removable devices. If the `dev_name` is given, `rmformat` lists the device associated with the `dev_name`. The output shows the device pathname, vendor information, and the device type.

`-s filename`

Enables the user to lay out the partition information in the SUNOS label.

The user should provide a file as input with information about each slice in a format providing byte offset, size required, tags, and flags, as follows:

```
slices: n = offset, size [, flags, tags]
```

where *n* is the slice number, *offset* is the byte offset at which the slice *n* starts, and *size* is the required size for slice *n*. Both *offset* and *size* must be a multiple of 512 bytes. These numbers can be represented as decimal, hexadecimal, or octal numbers. No floating point numbers are accepted. Details about maximum number of slices can be obtained from the [Oracle Solaris Administration: Common Tasks](#).

To specify the *size* or *offset* in kilobytes, megabytes, or gigabytes, add KB, MB, GB, respectively. A number without a suffix is assumed to be a byte offset. The flags are represented as follows:

```
wm = read-write, mountable  
wu = read-write, unmountable  
ru = read-only, unmountable
```

The tags are represented as follows: `unassigned`, `boot`, `root`, `swap`, `usr`, `backup`, `stand`, `var`, `home`, `alternates`.

The tags and flags can be omitted from the four tuple when finer control on those values is not required. It is required to omit both or include both. If the tags and flags are omitted from the four tuple for a particular slice, a default value for each is assumed. The default value for flags is `wm` and for tags is `unassigned`.

Either full tag names can be provided or an abbreviation for the tags can be used. The abbreviations can be the first two or more letters from the standard tag names. `rmformat` is case insensitive in handling the defined tags & flags.

Slice specifications are separated by :

For example:

```
slices: 0 = 0, 30MB, "wm", "home" :
        1 = 30MB, 51MB :
        2 = 0, 100MB, "wm", "backup" :
        6 = 81MB, 19MB
```

rmformat does the necessary checking to detect any overlapping partitions or illegal requests to addresses beyond the capacity of the media under consideration. There can be only one slice information entry for each slice *n*. If multiple slice information entries for the same slice *n* are provided, an appropriate error message is displayed. The slice 2 is the backup slice covering the whole disk capacity. The pound sign character, #, can be used to describe a line of comments in the input file. If the line starts with #, then rmformat ignores all the characters following # until the end of the line.

Partitioning some of the media with very small capacity is permitted, but be cautious in using this option on such devices.

-U

Performs umount on any file systems and then formats. See [mount\(1M\)](#). This option unmounts all the mounted slices and issues a long format on the device requested.

-V read | write

Verifies each block of media after format. The write verification is a destructive mechanism. The user is queried for confirmation before the verification is started. The output of this option is a list of block numbers, which are identified as bad.

The read verification only verifies the blocks and report the blocks which are prone to errors.

The list of block numbers displayed can be used with the -c option for repairing.

Operands The following operand is supported:

devname

devname can be provided as absolute device pathname or relative pathname for the device from the current working directory or the nickname, such as *cdrom* or *rmdisk*.

For systems without volume management running, the user can also provide the absolute device pathname as */dev/rdisk/c?t?d?s?* or the appropriate relative device pathname from the current working directory.

Examples **EXAMPLE 1** Formatting Removable Media for a PCFS File System

The following example shows how to create an alternate *fdisk* partition:

```
example$ rmformat -F quick /dev/rdisk/c0t4d0s2:c
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
example$ su
# fdisk /dev/rdisk/c0t4d0s2:c
# mkfs -F pcfs /dev/rdisk/c0t4d0s2:c
```

EXAMPLE 1 Formatting Removable Media for a PCFS File System (Continued)

```
Construct a new FAT file system on /dev/rdisk/c0t4d0s2:c: (y/n)? y
#
```

Files /dev/aliases

Directory providing symbolic links to the character devices for the different media under the control of volume management using appropriate alias.

/dev/dsk

Directory providing block device access for the PCMCIA memory and ata cards and removable media devices.

/dev/rdisk

Directory providing character device access for the PCMCIA memory and ata cards and removable media devices.

/dev/aliases/pcm s

Symbolic link to the character device for the PCMCIA memory card in socket S , where S represents a PCMCIA socket number.

/dev/aliases/rmdisk 0

Symbolic link to the generic removable media device that is not a CD-ROM, DVD-ROM, PCMCIA memory card, and so forth.

/dev/rdisk

Directory providing character device access for the PCMCIA memory and ata cards and other removable devices.

/dev/dsk

Directory providing block device access for the PCMCIA memory and ata cards and other removable media devices.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTE VALUE
Availability	system/storage/media-volume-manageR

See Also [cpio\(1\)](#), [eject\(1\)](#), [tar\(1\)](#), [volcheck\(1\)](#), [volrmmount\(1\)](#), [format\(1M\)](#), [mkfs_pcfs\(1M\)](#), [mount\(1M\)](#), [newfs\(1M\)](#), [prtvtoc\(1M\)](#), [rmmount\(1M\)](#), [rpc.smsvervd\(1M\)](#), [attributes\(5\)](#), [scsa2usb\(7D\)](#), [sd\(7D\)](#), [pcfs\(7FS\)](#), [udfs\(7FS\)](#)

Oracle Solaris Administration: Common Tasks

Notes A rewritable media or PCMCIA memory card or PCMCIA ata card containing a `ufs` file system created on a SPARC-based system (using [newfs\(1M\)](#)) is not identical to a rewritable media or PCMCIA memory card containing a `ufs` file system created on an x86 based system.

Do not interchange any removable media containing `ufs` between these platforms; use `cpio(1)` or `tar(1)` to transfer files on memory cards between them. For interchangeable filesystems refer to `pcfs(7FS)` and `udfs(7FS)`.

`rmformat` might not list all removable devices in virtualization environments.

Bugs Currently, bad sector mapping is not supported on PCMCIA memory cards. Therefore, memory card is unusable if `rmformat` finds an error (bad sector).

Name rmmount, rmumount – mounts and unmounts removable media

Synopsis rmmount [-u] [-o *options*] [*nickname* | *device*] [*mount_point*]

rmmount [-d] [-l]

rmumount [*nickname* | *mount_point* | *device*]

rmumount [-d] [-l]

Description The rmmount and rmumount utilities mount and unmount removable or hot-pluggable volumes. The optional argument can identify the volume by its volume label, mount point or block device path.

rmmount can also take additional mount options if the user has sufficient privileges to override the default mount options.

Unmounting removable media does not result in its ejection. Use [eject\(1\)](#) to optionally unmount and eject the media.

Options The following options are supported for rmmount and rmumount:

-d Display the device path of the default device. This device is used if no arguments are supplied.

-l Display the paths and nicknames of mountable devices.

The following options are supported for rmmount only:

-o *options* Display mount options. This option can only be used by users that have privileges to override the system default options.

-u Unmounts the volume as opposed to mounting it.

Operands The following operands are supported:

device Specifies which device to mount or unmount, by the name it appears in the directory /dev.

mount_point Specifies which device to mount or unmount, by the name it appears in the directory /dev.

nickname Specifies which device to mount or unmount, by its nickname as known to this command.

Examples **EXAMPLE 1** Mounting a USB disk

The following example mounts a USB disk with a volume label of PHOTOS:

```
example% rmmount PHOTOS
```

EXAMPLE 2 Unmounting a pcfs Volume

The following example unmounts a pcfs volume by device path:

```
example% rmmount /dev/dsk/c4t0d0p0:1
```

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /media Default mount root.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/media-volume-manager
Interface Stability	Uncommitted

See Also [eject\(1\)](#), [attributes\(5\)](#)

Name roffbib – format and print a bibliographic database

Synopsis roffbib [-e] [-h] [-m *filename*] [-np] [-olist] [-Q] [-ra*N*]
[-s*N*] [-T*term*] [-V] [-x] [*filename*] ...

Description roffbib prints out all records in a bibliographic database, in bibliography format rather than as footnotes or endnotes. Generally it is used in conjunction with [sortbib\(1\)](#):

```
example% sortbib database | roffbib
```

Options roffbib accepts all options understood by [nroff\(1\)](#) except -i and -q.

- e Produce equally-spaced words in adjusted lines using full terminal resolution.
- h Use output tabs during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.
- m *filename* Prepend the macro file `/usr/share/lib/tmac/tmac.name` to the input files. There should be a space between the -m and the macro filename. This set of macros will replace the ones defined in `/usr/share/lib/tmac/tmac.bib`.
- np Number first generated page *p*.
- olist Print only page numbers that appear in the comma-separated *list* of numbers and ranges. A range *N–M* means pages *N* through *M*; an initial -*N* means from the beginning to page *N*; a final *N–* means from page *N* to end.
- Q Queue output for the phototypesetter. Page offset is set to 1 inch.
- ra*N* Set register *a* (one-character) to *N*. The command-line argument -r*N*1 will number the references starting at 1.

Four command-line registers control formatting style of the bibliography, much like the number registers of [ms\(5\)](#). The flag -rv2 will double space the bibliography, while -rv1 will double space references but single space annotation paragraphs. The line length can be changed from the default 6.5 inches to 6 inches with the -rL6i argument, and the page offset can be set from the default of 0 to one inch by specifying -r01i (capital O, not zero).
- s*N* Halt prior to every *N* pages for paper loading or changing (default *N*=1). To resume, enter NEWLINE or RETURN.
- T*term* Specify *term* as the terminal type.
- V Send output to the Versatec. Page offset is set to 1 inch.
- x If abstracts or comments are entered following the %X field key, roffbib will format them into paragraphs for an annotated bibliography. Several %X fields may be given if several annotation paragraphs are desired.

Files /usr/share/lib/tmac/tmac.bib file of macros used by nroff/troff

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools

See Also [addbib\(1\)](#), [indxbib\(1\)](#), [lookbib\(1\)](#), [nroff\(1\)](#) [refer\(1\)](#), [sortbib\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#)

Bugs Users have to rewrite macros to create customized formats.

Name roles – print roles granted to a user

Synopsis roles [*user*]...

Description The command `roles` prints on standard output the roles that you or the optionally-specified user have been granted. Roles are special accounts that correspond to a functional responsibility rather than to an actual person (referred to as a normal user).

Each user may have zero or more roles. Roles have most of the attributes of normal users and are identified like normal users in [passwd\(4\)](#) and [shadow\(4\)](#). Each role must have an entry in the [user_attr\(4\)](#) file that identifies it as a role. Roles can have their own authorizations and profiles. See [auths\(1\)](#) and [profiles\(1\)](#).

Roles are not allowed to log into a system as a primary user. Instead, a user must log in as him— or herself and assume the role. The actions of a role are attributable to the normal user. When auditing is enabled, the audited events of the role contain the audit ID of the original user who assumed the role.

A role may not assume itself or any other role. Roles are not hierarchical. However, rights profiles (see [prof_attr\(4\)](#)) are hierarchical and can be used to achieve the same effect as hierarchical roles.

Role assumption can be performed using [su\(1M\)](#), [ssh\(1\)](#), or some other service that supports the `PAM_AUSER` variable. Successful assumption requires both role authentication and membership. Role authentication can require either the user's password or the role's password, depending on the setting of the `roleauth` property in the role's [user_attr\(4\)](#) entry. By default, the role's password is required. Roles are typically assigned a profile shell. By convention, a profile shell is specified by preceding the standard shell's name with `pf`, for example, `pfbash`. Role assignments are specified in [user_attr\(4\)](#).

Examples EXAMPLE 1 Sample Output

The output of the `roles` command has the following form:

```
example% roles tester01 tester02tester01 : admin
tester02 : secadmin, root
example%
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Name rpcgen – an RPC protocol compiler

Synopsis rpcgen *infile*

```
rpcgen [-a] [-A] [-b] [-C] [-D name [= value]] [-i size]
      [-I [-K seconds]] [-L] [-M] [-N] [-T] [-v]
      [-Y pathname] infile
```

```
rpcgen [-c | -h | -l | -m | -t | -Sc | -Ss | -Sm]
      [-o outfile] [infile]
```

```
rpcgen [-s nettype] [-o outfile] [infile]
```

```
rpcgen [-n netid] [-o outfile] [infile]
```

Description The rpcgen utility is a tool that generates C code to implement an RPC protocol. The input to rpcgen is a language similar to C known as RPC Language (Remote Procedure Call Language).

The rpcgen utility is normally used as in the first synopsis where it takes an input file and generates three output files. If the *infile* is named *proto.x*, then rpcgen generates a header in *proto.h*, XDR routines in *proto_xdr.c*, server-side stubs in *proto_svc.c*, and client-side stubs in *proto_clnt.c*. With the -T option, it also generates the RPC dispatch table in *proto_tbl.i*.

rpcgen can also generate sample client and server files that can be customized to suit a particular application. The -Sc, -Ss, and -Sm options generate sample client, server and makefile, respectively. The -a option generates all files, including sample files. If the *infile* is *proto.x*, then the client side sample file is written to *proto_client.c*, the server side sample file to *proto_server.c* and the sample makefile to *makefile.proto*.

The server created can be started both by the port monitors (for example, *inetd*) or by itself. When it is started by a port monitor, it creates servers only for the transport for which the file descriptor 0 was passed. The name of the transport must be specified by setting up the environment variable *PM_TRANSPORT*. When the server generated by rpcgen is executed, it creates server handles for all the transports specified in the *NETPATH* environment variable, or if it is unset, it creates server handles for all the visible transports from the */etc/netconfig* file. Note: the transports are chosen at run time and not at compile time. When the server is self-started, it backgrounds itself by default. A special define symbol *RPC_SVC_FG* can be used to run the server process in foreground.

The second synopsis provides special features which allow for the creation of more sophisticated RPC servers. These features include support for user-provided *#defines* and RPC dispatch tables. The entries in the RPC dispatch table contain:

- pointers to the service routine corresponding to that procedure
- a pointer to the input and output arguments
- the size of these routines

A server can use the dispatch table to check authorization and then to execute the service routine. A client library can use the dispatch table to deal with the details of storage management and XDR data conversion.

The other three synopses shown above are used when one does not want to generate all the output files, but only a particular one. See the EXAMPLES section below for examples of rpcgen usage. When rpcgen is executed with the `-s` option, it creates servers for that particular class of transports. When executed with the `-n` option, it creates a server for the transport specified by *netid*. If *infile* is not specified, rpcgen accepts the standard input.

All the options mentioned in the second synopsis can be used with the other three synopses, but the changes are made only to the specified output file.

The C preprocessor `cc -E` is run on the input file before it is actually interpreted by rpcgen. For each type of output file, rpcgen defines a special preprocessor symbol for use by the rpcgen programmer:

RPC_HDR	defined when compiling into headers
RPC_XDR	defined when compiling into XDR routines
RPC_SVC	defined when compiling into server-side stubs
RPC_CLNT	defined when compiling into client-side stubs
RPC_TBL	defined when compiling into RPC dispatch tables

Any line beginning with “%” is passed directly into the output file, uninterpreted by rpcgen, except that the leading “%” is stripped off. To specify the path name of the C preprocessor, use the `-Y` flag.

For every data type referred to in *infile*, rpcgen assumes that there exists a routine with the string `xdr_` prepended to the name of the data type. If this routine does not exist in the RPC/XDR library, it must be provided. Providing an undefined data type allows customization of XDR routines.

Server Error Reporting By default, errors detected by `proto_svc.c` is reported to standard error and/or the system log.

This behavior can be overridden by compiling the file with a definition of `RPC_MSGOUT`, for example, `-DRPC_MSGOUT=mymsgfunc`. The function specified is called to report errors. It must conform to the following `printf`-like signature:

```
extern void RPC_MSGOUT(const char *fmt, ...);
```

Options The following options are supported:

`-a` Generates all files, including sample files.

-
- A Enables the Automatic MT mode in the server main program. In this mode, the RPC library automatically creates threads to service client requests. This option generates multithread-safe stubs by implicitly turning on the -M option. Server multithreading modes and parameters can be set using the `rpc_control(3NSL)` call. rpcgen generated code does not change the default values for the Automatic MT mode.
- b Backward compatibility mode. Generates transport-specific RPC code for older versions of the operating system.
- c Compiles into XDR routines.
- C Generates header and stub files which can be used with ANSIC compilers. Headers generated with this flag can also be used with C++ programs.
- Dname[=value] Defines a symbol *name*. Equivalent to the `#define` directive in the source. If no *value* is given, *value* is defined as 1. This option can be specified more than once.
- h Compiles into C data-definitions (a header). The -T option can be used in conjunction to produce a header which supports RPC dispatch tables.
- i size Size at which to start generating inline code. This option is useful for optimization. The default *size* is 5.
- I Compiles support for `inetd(1M)` in the server side stubs. Such servers can be self-started or can be started by `inetd`. When the server is self-started, it backgrounds itself by default. A special define symbol `RPC_SVC_FG` can be used to run the server process in foreground, or the user can simply compile without the -I option.
- If there are no pending client requests, the `inetd` servers exit after 120 seconds (default). The default can be changed with the -K option. All of the error messages for `inetd` servers are always logged with `syslog(3C)`.
- Note:* This option is supported for backward compatibility only. It should always be used in conjunction with the -b option which generates backward compatibility code. By default (that is, when -b is not specified), rpcgen generates servers that can be invoked through portmonitors.
- K seconds By default, services created using rpcgen and invoked through port monitors wait 120 seconds after servicing a request before exiting. That interval can be changed using the -K flag. To create a server that exits immediately upon servicing a request, use -K 0. To create a server that never exits, the appropriate argument is -K -1.

- When monitoring for a server, some portmonitors, *always* spawn a new process in response to a service request. If it is known that a server are used with such a monitor, the server should exit immediately on completion. For such servers, rpcgen should be used with `-K 0`.
- l Compiles into client-side stubs.
 - L When the servers are started in foreground, uses `syslog(3C)` to log the server errors instead of printing them on the standard error.
 - m Compiles into server-side stubs, but do not generate a “main” routine. This option is useful for doing callback-routines and for users who need to write their own “main” routine to do initialization.
 - M Generates multithread-safe stubs for passing arguments and results between rpcgen-generated code and user written code. This option is useful for users who want to use threads in their code.
 - N This option allows procedures to have multiple arguments. It also uses the style of parameter passing that closely resembles C. So, when passing an argument to a remote procedure, you do not have to pass a pointer to the argument, but can pass the argument itself. This behavior is different from the old style of rpcgen-generated code. To maintain backward compatibility, this option is not the default.
 - n *netid* Compiles into server-side stubs for the transport specified by *netid*. There should be an entry for *netid* in the `netconfig` database. This option can be specified more than once, so as to compile a server that serves multiple transports.
 - o *outfile* Specifies the name of the output file. If none is specified, standard output is used (`-c`, `-h`, `-l`, `-m`, `-n`, `-s`, `-Sc`, `-Sm`, `-Ss`, and `-t` modes only).
 - s *nettype* Compiles into server-side stubs for all the transports belonging to the class *nettype*. The supported classes are `netpath`, `visible`, `circuit_n`, `circuit_v`, `datagram_n`, `datagram_v`, `tcp`, and `udp` (see `rpc(3NSL)` for the meanings associated with these classes). This option can be specified more than once. *Note:* The transports are chosen at run time and not at compile time.
 - Sc Generates sample client code that uses remote procedure calls.
 - Sm Generates a sample Makefile which can be used for compiling the application.
 - Ss Generates sample server code that uses remote procedure calls.
 - t Compiles into RPC dispatch table.
 - T Generates the code to support RPC dispatch tables.

The options `-c`, `-h`, `-l`, `-m`, `-s`, `-Sc`, `-Sm`, `-Ss`, and `-t` are used exclusively to generate a particular type of file, while the options `-D` and `-T` are global and can be used with the other options.

- `-v` Displays the version number.
- `-Y pathname` Gives the name of the directory where `rpcgen` starts looking for the C preprocessor.

Operands The following operand is supported:

infile input file

Examples EXAMPLE 1 Generating the output files and dispatch table

The following entry

```
example% rpcgen -T prot.x
```

generates all the five files: `prot.h`, `prot_clnt.c`, `prot_svc.c`, `prot_xdr.c`, and `prot_tbl.i`.

EXAMPLE 2 Sending headers to standard output

The following example sends the C data-definitions (header) to the standard output:

```
example% rpcgen -h prot.x
```

EXAMPLE 3 Sending a test version

To send the test version of the `-DTEST`, server side stubs for all the transport belonging to the class `datagram_n` to standard output, use:

```
example% rpcgen -s datagram_n -DTEST prot.x
```

EXAMPLE 4 Creating server side stubs

To create the server side stubs for the transport indicated by `netid` `tcp`, use:

```
example% rpcgen -n tcp -o prot_svc.c prot.x
```

Exit Status `0` Successful operation.

`>0` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/base-developer/utilities

The `rpcgen` chapter in the *ONC+ Developer's Guide* manual.

Name rpm2cpio – convert Red Hat Package (RPM) to cpio archive

Synopsis rpm2cpio [*file.rpm*]

Description The rpm2cpio utility converts the .rpm file specified as its sole argument to a cpio archive on standard output. (See NOTES.) If no argument is given, an rpm stream is read from standard input. In both cases, rpm2cpio will fail and print a usage message if the standard output is a terminal. Therefore, the output is usually redirected to a file or piped through the [cpio\(1\)](#) utility.

Examples EXAMPLE 1 Converting an rpm file

```
example% rpm2cpio Device3Dfx-1.1-2.src.rpm | cpio -itv
CPIO archive found!
-rw-r--r-- 1 root root 2635 Sep 13 16:39 1998, 3dfx.gif
-rw-r--r-- 1 root root 11339 Sep 27 16:03 1998, Dev3Dfx.tar.gz
-rw-r--r-- 1 root root 1387 Sep 27 16:04 1998, Device3Dfx-1.1-2.spec
31 blocks
```

EXAMPLE 2 Converting from standard input

```
example% rpm2cpio < Device3Dfx-1.1-2.src.rpm | cpio -itv
CPIO archive found!
-rw-r--r-- 1 root root 2635 Sep 13 16:39 1998, 3dfx.gif
-rw-r--r-- 1 root root 11339 Sep 27 16:03 1998, Dev3Dfx.tar.gz
-rw-r--r-- 1 root root 1387 Sep 27 16:04 1998, Device3Dfx-1.1-2.spec
31 blocks
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	package/rpm

See Also [cpio\(1\)](#), [attributes\(5\)](#)

Notes rpm2cpio handles versions 3 and 4 RPMs.

Name rsh, remsh, remote_shell – remote shell

Synopsis rsh [-n] [-a] [-K] [-PN | -PO] [-x] [-f | -F] [-l *username*]
 [-k *realm*] *hostname* *command*

rsh *hostname* [-n] [-a] [-K] [-PN | -PO] [-x] [-f | -F]
 [-l *username*] [-k *realm*] *command*

remsh [-n] [-a] [-K] [-PN | -PO] [-x] [-f | -F] [-l *username*]
 [-k *realm*] *hostname* *command*

remsh *hostname* [-n] [-a] [-K] [-PN | -PO] [-x] [-f | -F]
 [-l *username*] [-k *realm*] *command*

hostname [-n] [-a] [-PN | -PO] [-x] [-f | -F]
 [-l *username*] [-k *realm*] *command*

Description The rsh utility connects to the specified *hostname* and executes the specified *command*. rsh copies its standard input to the remote command, the standard output of the remote command to its standard output, and the standard error of the remote command to its standard error. Interrupt, quit, and terminate signals are propagated to the remote command. rsh normally terminates when the remote command does.

The user can opt for a secure session of rsh which uses Kerberos V5 for authentication. Encryption of the network session traffic is also possible. The rsh session can be kerberized using any of the following Kerberos specific options: -a, -PN or -PO, -x, -f or -F, and -k *realm*. Some of these options (-a, -x, -PN or -PO, and -f or -F) can also be specified in the [appdefaults] section of [krb5.conf\(4\)](#). The usage of these options and the expected behavior is discussed in the OPTIONS section below. If Kerberos authentication is used, authorization to the account is controlled by rules in [krb5_auth_rules\(5\)](#). If this authorization fails, fallback to normal rsh using [rhosts](#) occurs only if the -PO option is used explicitly on the command line or is specified in [krb5.conf\(4\)](#). Also, the -PN or -PO, -x, -f or -F, and -k *realm* options are just supersets of the -a option.

If you omit *command*, instead of executing a single command, rsh logs you in on the remote host using [rlogin\(1\)](#).

rsh does not return the exit status code of *command*.

Shell metacharacters which are not quoted are interpreted on the local machine, while quoted metacharacters are interpreted on the remote machine. See [EXAMPLES](#).

If there is no locale setting in the initialization file of the login shell ([.cshrc](#), ...) for a particular user, rsh always executes the command in the “C” locale instead of using the default locale of the remote machine.

The command is sent unencrypted to the remote system. All subsequent network session traffic is encrypted. See -x.

Options The following options are supported:

- a Explicitly enable Kerberos authentication and trusts the `.k5login` file for access-control. If the authorization check by `in.rshd(1M)` on the server-side succeeds and if the `.k5login` file permits access, the user is allowed to carry out the command.
- f Forward a copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. This is a non-forwardable ticket granting ticket. Forward a ticket granting ticket if you need to authenticate yourself to other Kerberized network services on the remote host. An example would be if your home directory on the remote host is NFS mounted by way of Kerberos V5. If your local credentials are not forwarded in this case, you cannot access your home directory. This option is mutually exclusive with the `-F` option.
- F Forward a forwardable copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. The `-F` option provides a superset of the functionality offered by the `-f` option. For example, with the `-f` option, if after you connected to the remote host, your remote command attempted to invoke `/usr/bin/ftp`, `/usr/bin/telnet`, `/usr/bin/rlogin`, or `/usr/bin/rsh`, with the `-f` or `-F` options, the attempt would fail. Thus, you would be unable to push your single network sign on trust beyond one system. This option is mutually exclusive with the `-f` option.
- k *realm* Causes `rsh` to obtain tickets for the remote host in *realm* instead of the remote host's realm as determined by `krb5.conf(4)`.
- K This option explicitly disables Kerberos authentication. It can be used to override the `autoLogin` variable in `krb5.conf(4)`.
- l *username* Uses *username* as the remote username instead of your local username. In the absence of this option, the remote username is the same as your local username.
- n Redirect the input of `rsh` to `/dev/null`. You sometimes need this option to avoid unfortunate interactions between `rsh` and the shell which invokes it. For example, if you are running `rsh` and invoke a `rsh` in the background without redirecting its input away from the terminal, it blocks even if no reads are posted by the remote command. The `-n` option prevents this.
- PO
- PN Explicitly request new (`-PN`) or old (`-PO`) version of the Kerberos “`rcmd`” protocol. The new protocol avoids many security problems prevalent in the old one and is regarded much more secure, but is not interoperable with older (MIT/SEAM) servers. The new protocol is used by default, unless explicitly specified using these options or through `krb5.conf(4)`. If Kerberos

authorization fails when using the old “rcmd” protocol, there is fallback to regular, non-kerberized rsh. This is not the case when the new, more secure “rcmd” protocol is used.

-x Cause the network session traffic to be encrypted. See DESCRIPTION.

The type of remote shell (sh, rsh, or other) is determined by the user's entry in the file `/etc/passwd` on the remote system.

Operands The following operand is supported:

command The command to be executed on the specified *hostname*.

Usage See [largefile\(5\)](#) for the description of the behavior of rsh and remsh when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

The rsh and remsh commands are IPv6-enabled. See [ip6\(7P\)](#). IPv6 is not currently supported with Kerberos V5 authentication.

Hostnames are given in the *hosts* database, which can be contained in the `/etc/hosts` file, the Internet domain name database, or both. Each host has one official name (the first name in the database entry) and optionally one or more nicknames. Official hostnames or nicknames can be given as *hostname*.

If the name of the file from which rsh is executed is anything other than rsh, rsh takes this name as its *hostname* argument. This allows you to create a symbolic link to rsh in the name of a host which, when executed, invokes a remote shell on that host. By creating a directory and populating it with symbolic links in the names of commonly used hosts, then including the directory in your shell's search path, you can run rsh by typing *hostname* to your shell.

If rsh is invoked with the basename remsh, rsh checks for the existence of the file `/usr/bin/remsh`. If this file exists, rsh behaves as if remsh is an alias for rsh. If `/usr/bin/remsh` does not exist, rsh behaves as if remsh is a host name.

For the kerberized rsh session, each user can have a private authorization list in a file `.k5login` in their home directory. Each line in this file should contain a Kerberos principal name of the form *principal/instance@realm*. If there is a `~/k5login` file, then access is granted to the account if and only if the originater user is authenticated to one of the principals named in the `~/k5login` file. Otherwise, the originating user is granted access to the account if and only if the authenticated principal name of the user can be mapped to the local account name using the *authenticated-principal-name* → *local-user-name* mapping rules. The `.k5login` file (for access control) comes into play only when Kerberos authentication is being done.

For the non-secure rsh session, each remote machine can have a file named `/etc/hosts.equiv` containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine can run rsh from the machines listed in the remote machine's `/etc/hosts.equiv` file. Individual users can set up a

similar private equivalence list with the file `.rhosts` in their home directories. Each line in this file contains two names: a hostname and a username separated by a space. The entry permits the user named `username` who is logged into `hostname` to use `rsh` to access the remote machine as the remote user. If the name of the local host is not found in the `/etc/hosts.equiv` file on the remote machine, and the local username and hostname are not found in the remote user's `.rhosts` file, then the access is denied. The hostnames listed in the `/etc/hosts.equiv` and `.rhosts` files must be the official hostnames listed in the `hosts` database; nicknames can not be used in either of these files.

You cannot log in using `rsh` as a trusted user from a trusted hostname if the trusted user account is locked.

`rsh` does not prompt for a password if access is denied on the remote machine unless the *command* argument is omitted.

Examples **EXAMPLE 1** Using `rsh` to Append Files

The following command appends the remote file `lizard.file` from the machine called `lizard` to the file called `example.file` on the machine called `example`:

```
example% rsh lizard cat lizard.file >> example.file
```

The following command appends the file `lizard.file` on the machine called `lizard` to the file `lizard.file2` which also resides on the machine called `lizard`:

```
example% rsh lizard cat lizard.file ">>" lizard.file2
```

Exit Status

The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Files	<code>/etc/hosts</code>	Internet host table
	<code>/etc/hosts.equiv</code>	Trusted remote hosts and users
	<code>/etc/passwd</code>	System password file
	<code>\$HOME/.k5login</code>	File containing Kerberos principals that are allowed access
	<code>/etc/krb5/krb5.conf</code>	Kerberos configuration file

Attributes

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients
CSI	Enabled

See Also [on\(1\)](#), [rlogin\(1\)](#), [ssh\(1\)](#), [telnet\(1\)](#), [vi\(1\)](#), [in.rshd\(1M\)](#), [hosts\(4\)](#), [hosts.equiv\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [krb5_auth_rules\(5\)](#), [largefile\(5\)](#), [ip6\(7P\)](#)

Notes When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

You cannot run an interactive command (such as [vi\(1\)](#)). Use `rlogin` if you wish to do this.

Stop signals stop the local `rsh` process only. This is arguably wrong, but currently hard to fix for reasons too complicated to explain here.

The current local environment is not passed to the remote shell.

Sometimes the `-n` option is needed for reasons that are less than obvious. For example, the command:

```
example% rsh somehost dd if=/dev/nrmt0 bs=20b | tar xvpBf -
```

puts your shell into a strange state. Evidently, the `tar` process terminates before the `rsh` process. The `rsh` command then tries to write into the "broken pipe" and, instead of terminating neatly, proceeds to compete with your shell for its standard input. Invoking `rsh` with the `-n` option avoids such incidents.

This bug occurs only when `rsh` is at the beginning of a pipeline and is not reading standard input. Do not use the `-n` option if `rsh` actually needs to read standard input. For example:

```
example% tar cf - . | rsh sundial dd of=/dev/rmt0 obs=20b
```

does not produce the bug. If you were to use the `-n` option in a case like this, `rsh` would incorrectly read from `/dev/null` instead of from the pipe.

For most purposes, [ssh\(1\)](#) is preferred over `rsh`.

Name runat – execute command in extended attribute name space

Synopsis /usr/bin/runat *file* [*command*]

Description The runat utility is used to execute shell commands in a file's hidden attribute directory. Effectively, this utility changes the current working directory to be the hidden attribute directory associated with the file argument and then executes the specified command in the bourne shell (/bin/sh). If no command argument is provided, an interactive shell is spawned. The environment variable \$SHELL defines the shell to be spawned. If this variable is undefined, the default shell, /bin/sh, is used.

The file argument can be any file, including a directory, that can support extended attributes. It is not necessary that this file have any attributes, or be prepared in any way, before invoking the runat command.

Operands The following operands are supported:

file Any file, including a directory, that can support extended attributes.

command The command to be executed in an attribute directory.

Errors A non-zero exit status will be returned if runat cannot access the *file* argument, or the *file* argument does not support extended attributes.

Usage See [fsattr\(5\)](#) for a detailed description of extended file attributes.

The process context created by the runat command has its current working directory set to the hidden directory containing the file's extended attributes. The parent of this directory (the "." entry) always refers to the file provided on the command line. As such, it may not be a directory. Therefore, commands (such as pwd) that depend upon the parent entry being well-formed (that is, referring to a directory) may fail.

In the absence of the *command* argument, runat will spawn a new interactive shell with its current working directory set to be the provided file's hidden attribute directory. Notice that some shells (such as zsh and tcsh) are not well behaved when the directory parent is not a directory, as described above. These shells should not be used with runat.

Examples EXAMPLE 1 Using runat to list extended attributes on a file

```
example% runat file.1 ls -l
example% runat file.1 ls
```

EXAMPLE 2 Creating extended attributes

```
example% runat file.2 cp /tmp/attrdata attr.1
example% runat file.2 cat /tmp/attrdata > attr.1
```

EXAMPLE 3 Copying an attribute from one file to another

```
example% runat file.2 cat attr.1 | runat file.1 "cat > attr.1"
```

EXAMPLE 4 Using runat to spawn an interactive shell

```
example% runat file.3 /bin/sh
```

This spawns a new shell in the attribute directory for `file.3`. Notice that the shell will not be able to determine what your current directory is. To leave the attribute directory, either exit the spawned shell or change directory (`cd`) using an absolute path.

Recommended methods for performing basic attribute operations:

```
display          runat file ls [options]
read             runat file cat attribute
create/modify    runat file cp absolute-file-path attribute
delete           runat file rm attribute
permission changes
                 runat file chmod mode attribute
                 runat file chgrp group attribute
                 runat file chown owner attribute
```

interactive shell

```
runat file /bin/sh
or set your $SHELL to /bin/sh and
runat file
```

The above list includes commands that are known to work with runat. While many other commands may work, there is no guarantee that any beyond this list will work. Any command that relies on being able to determine its current working directory is likely to fail. Examples of such commands follow:

EXAMPLE 5 Using man in an attribute directory

```
example% runat file.1 man runat
>getcwd: Not a directory
```

EXAMPLE 6 Spawning a tcsh shell in an attribute directory

```
example% runat file.3 /usr/bin/tcsh
tcsh: Not a directory
tcsh: Trying to start from "/home/user"
```

A new tcsh shell has been spawned with the current working directory set to the user's home directory.

EXAMPLE 7 Spawning a zsh shell in an attribute directory

```
example% runat file.3 /usr/bin/zsh
example%
```

While the command appears to have worked, zsh has actually just changed the current working directory to '/'. This can be seen by using `/bin/pwd`:

```
example% /bin/pwd
/
```

Environment Variables SHELL Specifies the command shell to be invoked by runat.

Exit Status The following exit values are returned:

- 125 The attribute directory of the file referenced by the *file* argument cannot be accessed.
- 126 The exec of the provided *command* argument failed.

Otherwise, the exit status returned is the exit status of the shell invoked to execute the provided command.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	Committed

See Also [open\(2\)](#), [attributes\(5\)](#), [fsattr\(5\)](#)

Notes It is not always obvious why a command fails in runat when it is unable to determine the current working directory. The errors resulting can be confusing and ambiguous (see the `tcsh` and `zsh` examples above).

Name rup – show host status of remote machines (RPC version)

Synopsis rup [-hlt]
rup [*host*]...

Description rup gives a status similar to `uptime` for remote machines. It broadcasts on the local network, and displays the responses it receives.

Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

When *host* arguments are given, rather than broadcasting rup will only query the list of specified hosts.

A remote host will only respond if it is running the `rstatd` daemon, which is normally started up from `inetd(1M)`.

In the absence of a name service, such as LDAP or NIS, rup displays host names as numeric IP addresses.

Options

- h Sort the display alphabetically by host name.
- l Sort the display by load average.
- t Sort the display by up time.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients

See Also [ruptime\(1\)](#), [inetd\(1M\)](#), [attributes\(5\)](#)

Installing Oracle Solaris 11.1 Systems

Bugs Broadcasting does not work through gateways.

Name rup – show host status of remote machines (RPC version)

Synopsis rup [-hlt]
rup [*host*] . . .

Description rup gives a status similar to `uptime` for remote machines. It broadcasts on the local network, and displays the responses it receives.

Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

When *host* arguments are given, rather than broadcasting rup only queries the list of specified hosts.

A remote host will only respond if it is running the `rstatd` daemon, which is normally started up from [inetd\(1M\)](#).

Options

- h Sort the display alphabetically by host name.
- l Sort the display by load average.
- t Sort the display by up time.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/extended-system-utilities

See Also [ruptime\(1\)](#), [inetd\(1M\)](#), [attributes\(5\)](#)

Bugs Broadcasting does not work through gateways.

Name ruptime – show host status of local machines

Synopsis ruptime [-ar] [-l | -t | -u]

Description The ruptime utility gives a status line like uptime (see [uptime\(1\)](#)) for each machine on the local network; these are formed from packets broadcast by each host on the network approximately every three minutes.

Machines for which no status report has been received for 11 minutes are shown as being down.

Normally, the listing is sorted by host name, but this order can be changed by specifying one of the options listed below.

Options The following options are supported:

- a Counts even those users who have been idle for an hour or more.
- r Reverses the sorting order.
- l | -t | -u These options are mutually exclusive. The use of one overrides the previous one(s).
 - l Sorts the display by load average.
 - t Sorts the display by up time.
 - u Sorts the display by number of users.

Files /var/spool/rwho/whod.* data files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients

See Also [uptime\(1\)](#), [rwho\(1\)](#), [in.rwhod\(1M\)](#), [attributes\(5\)](#)

Name rusage – print resource usage for a command

Synopsis /usr/ucb/rusage *command*

Description The rusage command is similar to [time\(1\)](#). It runs the given *command*, which must be specified; that is, *command* is not optional as it is in the C shell's timing facility. When the command is complete, rusage displays the real (wall clock), the system CPU, and the user CPU times which elapsed during execution of the command, plus other fields in the rusage structure, all on one long line. Times are reported in seconds and hundredths of a second.

Examples EXAMPLE 1 The format of rusage output

The example below shows the format of rusage output.

```
example% rusage wc /usr/share/man/man1/csh (1)
3045 13423 78071 /usr/share/man/man1/csh (1)
2.26 real 0.80 user 0.36 sys 11 pf 38 pr 0 sw 11 rb 0 wb 16 vcx 37
      icx 24 mx 0 ix 1230 id 9 is
example%
```

Each of the fields identified corresponds to an element of the rusage structure, as described in [getrusage\(3C\)](#), as follows:

real		elapsed real time
user	ru_utime	user time used
sys	ru_stime	system time used
pf	ru_majflt	page faults requiring physical I/O
pr	ru_minflt	page faults not requiring physical I/O
sw	ru_nswap	swaps
rb	ru_inblock	block input operations
wb	ru_oublock	block output operations
vcx	ru_nvcsw	voluntary context switches
icx	ru_nivcsw	involuntary context switches
mx	ru_maxrss	maximum resident set size
ix	ru_ixrss	currently 0
id	ru_idrss	integral resident set size
is	ru_isrss	currently 0

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

See Also [csh\(1\)](#), [time\(1\)](#), [getrusage\(3C\)](#), [attributes\(5\)](#)

Bugs When the command being timed is interrupted, the timing values displayed may be inaccurate.

Name rusers – who is logged in on remote machines

Synopsis rusers [-ahilu] host...

Description The rusers command produces output similar to [who\(1\)](#), but for remote machines. The listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

The default is to print out the names of the users logged in. When the `-l` flag is given, additional information is printed for each user:

userid hostname:terminal login_date login_time idle_time login_host

If *hostname* and *login host* are the same value, the *login_host* field is not displayed. Likewise, if *hostname* is not idle, the *idle_time* is not displayed.

A remote host will only respond if it is running the rusersd daemon, which may be started up from [inetd\(1M\)](#).

In the absence of a name service, such as LDAP or NIS, rusers displays host names as numeric IP addresses.

- Options**
- a Give a report for a machine even if no users are logged on.
 - h Sort alphabetically by host name.
 - i Sort by idle time.
 - l Give a longer listing in the style of [who\(1\)](#).
 - u Sort by number of users.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients

See Also [who\(1\)](#), [inetd\(1M\)](#), [attributes\(5\)](#)

Name rwho – who is logged in on local machines

Synopsis rwho [-a]

Description The rwho command produces output similar to [who\(1\)](#), but for all machines on your network. If no report has been received from a machine for 5 minutes, rwho assumes the machine is down, and does not report users last known to be logged into that machine.

If a user has not typed to the system for a minute or more, rwho reports this idle time. If a user has not typed to the system for an hour or more, the user is omitted from the output of rwho unless the -a flag is given.

Options -a Report all users whether or not they have typed to the system in the past hour.

Files /var/spool/rwho/whod.* information about other machines

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also [finger\(1\)](#), [ruptime\(1\)](#), [who\(1\)](#), [in.rwhod\(1M\)](#), [attributes\(5\)](#)

Notes rwho does not work through gateways.

The directory /var/spool/rwho must exist on the host from which rwho is run.

This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

The rwho service daemon, [in.rwhod\(1M\)](#), must be enabled for this command to return useful results.

Name sar – system activity reporter

Synopsis sar [-aAbcdgkmpqruvw] [-o *filename*] *t* [*n*]

 sar [-aAbcdgkmpqruvw] [-e *time*] [-f *filename*] [-i *sec*]
 [-s *time*]

Description In the first instance, the `sar` utility samples cumulative activity counters in the operating system at *n* intervals of *t* seconds, where *t* should be 5 or greater. If *t* is specified with more than one option, all headers are printed together and the output can be difficult to read. (If the sampling interval is less than 5, the activity of `sar` itself can affect the sample.) If the `-o` option is specified, it saves the samples in *filename* in binary format. The default value of *n* is 1.

In the second instance, no sampling interval is specified. `sar` extracts data from a previously recorded *filename*, either the one specified by the `-f` option or, by default, the standard system activity daily data file `/var/adm/sa/sadd` for the current day *dd*. The starting and ending times of the report can be bounded using the `-e` and `-s` arguments with *time* specified in the form *hh[:mm[:ss]]*. The `-i` option selects records at *sec* second intervals. Otherwise, all intervals found in the data file are reported.

Options The following options modify the subsets of information reported by `sar`.

-a Reports use of file access system routines: `iget/s`, `namei/s`, `dirblk/s`

-A Reports all data. Equivalent to `-abcdgkmpqruvw`.

-b Reports buffer activity:

<code>bread/s</code> , <code>bwrit/s</code>	transfers per second of data between system buffers and disk or other block devices.
<code>lread/s</code> , <code>lwrit/s</code>	accesses of system buffers.
<code>%rcache</code> , <code>%wcache</code>	cache hit ratios, that is, $(1 - \text{bread}/\text{lread})$ as a percentage.
<code>pread/s</code> , <code>pwrit/s</code>	transfers using raw (physical) device mechanism.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

-c Reports system calls:

<code>scall/s</code>	system calls of all types.
<code>sread/s</code> , <code>swrit/s</code> , <code>fork/s</code> , <code>exec/s</code>	specific system calls.
<code>rchar/s</code> , <code>wchar/s</code>	characters transferred by read and write system calls. No incoming or outgoing <code>exec(2)</code> and <code>fork(2)</code> calls are reported.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

-d Reports activity for each block device (for example, disk or tape drive) with the exception of XDC disks and tape drives. When data is displayed, the device specification *dsk-* is generally used to represent a disk drive. The device specification used to represent a tape drive is machine dependent. The activity data reported is:

%busy, avque	portion of time device was busy servicing a transfer request, average number of requests outstanding during that time.
read/s, write/s, blks/s	number of read/write transfers from or to device, number of bytes transferred in 512-byte units.
await	average wait time in milliseconds.
avserv	average service time in milliseconds.

For more general system statistics, use [iostat\(1M\)](#), [sar\(1M\)](#), or [vmstat\(1M\)](#).

See *System Administration Guide: Advanced Administration* for naming conventions for disks.

-e time Selects data up to *time*. Default is 18:00.

-f filename Uses *filename* as the data source for *sar*. Default is the current daily data file `/var/adm/sa/sadd`.

-g Reports paging activities:

pgout/s	page-out requests per second.
ppgout/s	pages paged-out per second.
pgfree/s	pages per second placed on the free list by the page stealing daemon.
pgscan/s	pages per second scanned by the page stealing daemon.
%ufs_ipf	the percentage of UFS inodes taken off the freelist by <i>iget</i> which had reusable pages associated with them. These pages are flushed and cannot be reclaimed by processes. Thus, this is the percentage of <i>igets</i> with page flushes.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

- i *sec* Selects data at intervals as close as possible to *sec* seconds.
- k Reports kernel memory allocation (KMA) activities:
- sml_mem, alloc, fail information about the memory pool reserving and allocating space for small requests: the amount of memory in bytes KMA has for the small pool, the number of bytes allocated to satisfy requests for small amounts of memory, and the number of requests for small amounts of memory that were not satisfied (failed).
- lg_mem, alloc, fail information for the large memory pool (analogous to the information for the small memory pool).
- ovsz_alloc, fail the amount of memory allocated for oversize requests and the number of oversize requests which could not be satisfied (because oversized memory is allocated dynamically, there is not a pool).
- m Reports message and semaphore activities:
- msg/s, sema/s primitives per second.
- If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.
- o *filename* Saves samples in file, *filename*, in binary format.
- p Reports paging activities:
- atc/s page faults per second that are satisfied by reclaiming a page currently in memory (attaches per second).
- pgin/s page-in requests per second.
- ppgin/s pages paged-in per second.
- pflt/s page faults from protection errors per second (illegal access to page) or “copy-on-writes”.
- vflt/s address translation page faults per second (valid page not in memory).
- slock/s faults per second caused by software lock requests requiring physical I/O.
- If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

- q Reports average queue length while occupied, and percent of time occupied:
runq-sz, %runocc Run queue of kernel threads in memory and runnable
swpq-sz, %swpocc Swap queue of processes
- r Reports unused memory pages and disk blocks:
freemem average pages available to user processes.
freeswap disk blocks available for page swapping.
- s *time* Selects data later than *time* in the form *hh[:mm]*. Default is 08:00.
- u Reports CPU utilization (the default):
%usr, %sys, %wio, %idle portion of time running in user mode, running
in system mode, idle with some process waiting
for block I/O, and otherwise idle.
- If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.
- v Reports status of process, i-node, file tables:
proc-sz, inod-sz, file-sz, lock-sz entries/size for each table, evaluated once
at sampling point.
ov overflows that occur between sampling
points for each table.
- w Reports system swapping and switching activity:
swpin/s, swpot/s, bswin/s, bswot/s number of transfers and number of
512-byte units transferred for swapins
and swapouts (including initial loading
of some programs).
pswch/s process switches.
- If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.
- y Reports TTY device activity:
rawch/s, canch/s, outch/s input character rate, input character rate
processed by canon, output character rate.
rcvin/s, xmtin/s, mdmin/s receive, transmit and modem interrupt rates.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

Examples EXAMPLE 1 Viewing System Activity

The following example displays today's CPU activity so far:

```
example% sar
```

EXAMPLE 2 Watching System Activity Evolve

To watch CPU activity evolve for 10 minutes and save data:

```
example% sar -o temp 60 10
```

EXAMPLE 3 Reviewing Disk and Tape Activity

To later review disk and tape activity from that period:

```
example% sar -d -f temp
```

Files `/var/adm/sa/sadd` daily data file, where *dd* are digits representing the day of the month

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

Oracle Solaris Administration: Common Tasks

Notes The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

Name sccs – front end for the Source Code Control System (SCCS)

Synopsis /usr/bin/sccs [-r] [-d*rootprefix*] [-p*subdir*] *subcommand*
 [*option*]... [*file*]...
 /usr/xpg4/bin/sccs [-r] [-d *rootprefix*] [-p *subdir*] *subcommand*
 [*option*]... [*file*]...

Description The sccs command is a comprehensive, straightforward front end to the various utility programs of the Source Code Control System (SCCS).

sccs applies the indicated *subcommand* to the history file associated with each of the indicated files.

The name of an SCCS history file is derived by prepending the 's.' prefix to the filename of a working copy. The sccs command normally expects these 's.' files to reside in an SCCS subdirectory. Thus, when you supply sccs with a *file* argument, it normally applies the subcommand to a file named s.*file* in the SCCS subdirectory. If *file* is a path name, sccs looks for the history file in the SCCS subdirectory of that file's parent directory. If *file* is a directory, however, sccs applies the subcommand to every s.*file* file it contains. Thus, the command:

```
example% sccs get program.c
```

would apply the get subcommand to a history file named SCCS/s.*program.c*, while the command:

```
example% sccs get SCCS
```

would apply it to every s.*file* in the SCCS subdirectory.

Options for the sccs command itself must appear before the *subcommand* argument. Options for a given subcommand must appear after the *subcommand* argument. These options are specific to each subcommand, and are described along with the subcommands themselves (see Subcommands below).

Running Setuid The sccs command also includes the capability to run "setuid" to provide additional protection. However, this does not apply to subcommands such as [sccs-admin\(1\)](#), since this would allow anyone to change the authorizations of the history file. Commands that would do so always run as the real user.

Options The following options are supported:

```
/usr/bin/sccs -drootprefix
```

```
/usr/xpg4/bin/sccs -d rootprefix
```

Defines the root portion of the path name for SCCS history files. The default root portion is the current directory. *rootprefix* is prepended to the entire *file* argument, even if *file* is an absolute path name. -d overrides any directory specified by the PROJECTDIR environment variable (see ENVIRONMENT VARIABLES below).

```
/usr/bin/sccs -psubdir
```

`/usr/xpg4/bin/sccs -psubdir`

Defines the (sub)directory within which a history file is expected to reside. SCCS is the default. (See EXAMPLES below).

`-r`

Runs `sccs` with the real user ID, rather than set to the effective user ID.

Operands The following operands are supported:

file

a file passed to *subcommand*

option

an option or option-argument passed to *subcommand*

subcommand

one of the subcommands listed in Usage

Usage The usage for `sccs` is described below.

Subcommands Many of the following `sccs` subcommands invoke programs that reside in `/usr/bin`. Many of these subcommands accept additional arguments that are documented in the reference page for the utility program the subcommand invokes.

`admin`

Modify the flags or checksum of an SCCS history file. Refer to [sccs-admin\(1\)](#) for more information about the `admin` utility. While `admin` can be used to initialize a history file, you might find that the `create` subcommand is simpler to use for this purpose.

`/usr/bin/sccs cdc -rsid [-y[comment]]`

`/usr/xpg4/bin/sccs cdc -rsid | -rsid [-y[comment]]`

Annotate (change) the delta commentary. Refer to [sccs-cdc\(1\)](#). The `fix` subcommand can be used to replace the delta, rather than merely annotating the existing commentary.

`-r sid | -rsid`

Specify the SCCS delta ID (SID) to which the change notation is to be added. The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the *release* and *level* fields, and for branch deltas, the *branch* and *sequence* fields. For instance, the SID for the initial delta is normally 1.1.

`-y“[comment]”`

Specify the comment with which to annotate the delta commentary. If `-y` is omitted, `sccs` prompts for a comment. A null *comment* results in an empty annotation.

`/usr/bin/sccs check [-b] [-u[username]]`

`/usr/xpg4/bin/sccs check [-b] [-u username] [-U]`

Check for files currently being edited. Like `info` and `tell`, but returns an exit code, rather than producing a listing of files. `check` returns a non-zero exit status if anything is being edited.

`-b`

Ignore branches.

`-u[username] | -u [username] | -U`

Check only files being edited by you. When *username* is specified, check only files being edited by that user. For `/usr/xpg4/bin/sccs`, the `-U` option is equivalent to `-u <current_user>`.

`clean [-b]`

Remove everything in the current directory that can be retrieved from an SCCS history. Does not remove files that are being edited.

`-b`

Do not check branches to see if they are being edited. ‘`clean -b`’ is dangerous when branch versions are kept in the same directory.

`comb`

Generate scripts to combine deltas. Refer to [sccs-comb\(1\)](#).

`create`

Create (initialize) history files. `create` performs the following steps:

- Renames the original source file to `,program.c` in the current directory.
- Create the history file called `s.program.c` in the SCCS subdirectory.
- Performs an ‘`sccs get`’ on `program.c` to retrieve a read-only copy of the initial version.

`deledit [-s] [-y[comment]]`

Equivalent to an ‘`sccs delta`’ and then an ‘`sccs edit`’. `deledit` checks in a delta, and checks the file back out again, but leaves the current working copy of the file intact.

`-s`

Silent. Do not report delta numbers or statistics.

`-y[comment]`

Supply a comment for the delta commentary. If `-y` is omitted, `delta` prompts for a comment. A null *comment* results in an empty comment field for the delta.

`delget [-s] [-y[comment]]`

Perform an ‘`sccs delta`’ and then an ‘`sccs get`’ to check in a delta and retrieve read-only copies of the resulting new version. See the `deledit` subcommand for a description of `-s` and `-y`. `sccs` performs a `delta` on all the files specified in the argument list, and then a `get` on all the files. If an error occurs during the `delta`, the `get` is not performed.

`delta [-s] [-y[comment]]`

Check in pending changes. Records the line-by-line changes introduced while the file was checked out. The effective user ID must be the same as the ID of the person who has the file checked out. Refer to [sccs-delta\(1\)](#). See the `deledit` subcommand for a description of `-s`

and `-y`.

```
/usr/bin/sccs diff [-C] [-I] [-cdate-time] [-rsid] diff-options
```

```
/usr/xpg4/bin/sccs diff [-C] [-I] [-c date-time | -cdate-time ]
[-r sid | -rsid] diff-options
```

Compare (in [diff\(1\)](#) format) the working copy of a file that is checked out for editing, with a version from the SCCS history. Use the most recent checked-in version by default. The `diffs` subcommand accepts the same options as `diff`.

Any `-r`, `-c`, `-i`, `-x`, and `-t` options are passed to subcommand `get`. A `-C` option is passed to `diff` as `-c`. An `-I` option is passed to `diff` as `-i`.

```
-c date-time | -cdate-time
```

Use the most recent version checked in before the indicated date and time for comparison. `date-time` takes the form: `yy[mm[dd[hh[mm[ss]]]]]`. Omitted units default to their maximum possible values; that is `-c7502` is equivalent to `-c750228235959`.

```
-r sid | -rsid
```

Use the version corresponding to the indicated delta for comparison.

`edit`

Retrieve a version of the file for editing. '`sccs edit`' extracts a version of the file that is writable by you, and creates a `p`.file in the SCCS subdirectory as lock on the history, so that no one else can check that version in or out. ID keywords are retrieved in unexpanded form. `edit` accepts the same options as `get`, below. Refer to [sccs-get\(1\)](#) for a list of ID keywords and their definitions.

`enter`

Similar to `create`, but omits the final '`sccs get`'. This can be used if an '`sccs edit`' is to be performed immediately after the history file is initialized.

```
/usr/bin/sccs fix -rsid
```

```
/usr/xpg4/bin/sccs fix -r sid | -rsid
```

Revise a (leaf) delta. Remove the indicated delta from the SCCS history, but leave a working copy of the current version in the directory. This is useful for incorporating trivial updates for which no audit record is needed, or for revising the delta commentary. `fix` must be followed by a `-r` option, to specify the SID of the delta to remove. The indicated delta must be the most recent (leaf) delta in its branch. Use `fix` with caution since it does not leave an audit trail of differences (although the previous commentary is retained within the history file).

```
/usr/bin/sccs get [-ekmps] [-Gnewname] [-cdate-time] [-r[sid] ]
```

```

/usr/xpg4/bin/sccs get [-ekmps] [-G newname | -Gnewname]
                    [-c date-time | -cdate-time] [-r sid | -rsid]
    Retrieve a version from the SCCS history. By default, this is a read-only working copy of the
    most recent version. ID keywords are in expanded form. Refer to sccs-get\(1\), which
    includes a list of ID keywords and their definitions.

    -c date-time | -cdate-time
        Retrieve the latest version checked in prior to the date and time indicated by the
        date-time argument. date-time takes the form: yy[mm[dd[ hh[mm[ss] ] ] ] ].

    -e
        Retrieve a version for editing. Same as sccs edit.

    -G newname | -Gnewname
        Use newname as the name of the retrieved version.

    -k
        Retrieve a writable copy but do not check out the file. ID keywords are unexpanded.

    -m
        Precede each line with the SID of the delta in which it was added.

    -p
        Produce the retrieved version on the standard output. Reports that would normally go
        to the standard output (delta IDs and statistics) are directed to the standard error.

    -r sid | -rsid
        Retrieve the version corresponding to the indicated SID. For /usr/bin/sccs, if no sid is
        specified, the latest sid for the specified file is retrieved.

    -s
        Silent. Do not report version numbers or statistics.

sccs -help message-code | sccs-command
sccs -help stuck
    Supply more information about SCCS diagnostics. sccs -help displays a brief explanation
    of the error when you supply the code displayed by an SCCS diagnostic message. If you
    supply the name of an SCCS command, it prints a usage line. sccs -help also recognizes the
    keyword stuck. Refer to sccs-help\(1\).

```

```

/usr/bin/sccs info [-b] [-u[username] ]
/usr/xpg4/bin/sccs info [-b] [-u[ username] ] -U]
    Display a list of files being edited, including the version number checked out, the version to
    be checked in, the name of the user who holds the lock, and the date and time the file was
    checked out.

    -b
        Ignore branches.

```

`-u[username] | -u [username] | -U`

List only files checked out by you. When *username* is specified, list only files checked out by that user. For `/usr/xpg4/bin/sccs`, the `-U` option is equivalent to `-u <current_user>`.

`print`

Print the entire history of each named file. Equivalent to an `'sccs prs -e'` followed by an `'sccs get -p -m'`.

`/usr/bin/sccs prs [-el] [-cdate-time] [-rsid]`

`/usr/xpg4/bin/sccs prs [-el] [-c date-time | -cdate-time] [-r sid | -rsid]`

Peruse (display) the delta table, or other portion of an `s.` file. Refer to [sccs-prs\(1\)](#).

`-c date-time | -cdate-time`

Specify the latest delta checked in before the indicated date and time. The *date-time* argument takes the form: `yy[mm[dd[hh[mm[ss]]]]]`.

`-e`

Display delta table information for all deltas earlier than the one specified with `-r` (or all deltas if none is specified).

`-l`

Display information for all deltas later than, and including, that specified by `-c` or `-r`.

`-r sid | -rsid`

Specify a given delta by SID.

`prt [-y]` Display the delta table, but omit the MR field (see [sccsfile\(4\)](#) for more information on this field). Refer to [sccs-prt\(1\)](#).

`-y` Display the most recent delta table entry. The format is a single output line for each file argument, which is convenient for use in a pipeline with [awk\(1\)](#) or [sed\(1\)](#).

`/usr/bin/sccs rmdel -rsid`

`/usr/xpg4/bin/sccs rmdel -r sid`

Remove the indicated delta from the history file. That delta must be the most recent (leaf) delta in its branch. Refer to [sccs-rmdel\(1\)](#).

`sact`

Show editing activity status of an SCCS file. Refer to [sccs-sact\(1\)](#).

`sccsdiff -r old-sid -r new-sid diff-options`

Compare two versions corresponding to the indicated SIDs (deltas) using `diff`. Refer to [sccs-sccsdiff\(1\)](#).

`/usr/bin/sccs tell [-b] [-u[username]]`

```

/usr/xpg4/bin/sccs tell [-b] [-u [username] | -U]
    Display the list of files that are currently checked out, one file per line.

    -b
        Ignore branches.

    -u[username] | -u [username] | -U
        List only files checked out to you. When username is specified, list only files checked out
        to that user. For /usr/xpg4/bin/sccs, the -U option is equivalent to -u <current_user>.

unedit
    “Undo” the last edit or ‘get -e’, and return the working copy to its previous condition.
    unedit backs out all pending changes made since the file was checked out.

unget
    Same as unedit. Refer to sccs-unget\(1\).

val
    Validate the history file. Refer to sccs-val\(1\).

what
    Display any expanded ID keyword strings contained in a binary (object) or text file. Refer
    to what\(1\) for more information.

```

Examples EXAMPLE 1 Checking out, editing, and checking in a file

To check out a copy of `program.c` for editing, edit it, and then check it back in:

```

example% sccs edit program.c
1.1
new delta 1.2
14 lines

```

```

example% vi program.c
your editing session

```

```

example% sccs delget program.c
comments? clarified cryptic diagnostic
1.2
3 inserted
2 deleted
12 unchanged
1.2
15 lines

```

EXAMPLE 2 Defining the root portion of the command pathname

sccs converts the command:

```

example% sccs -d/usr/src/include get stdio.h

```

to:

EXAMPLE 2 Defining the root portion of the command pathname *(Continued)*

```
/usr/bin/get /usr/src/include/SCCS/s.stdio.h
```

EXAMPLE 3 Defining the resident subdirectory

The command:

```
example% sccs -pprivate get include/stdio.h
```

becomes:

```
/usr/bin/get include/private/s.stdio.h
```

EXAMPLE 4 Initializing a history file

To initialize the history file for a source file named `program.c`, make the SCCS subdirectory, and then use `'sccs create'`:

```
example% mkdir SCCS  
example% sccs create program.c  
program.c:  
1.1  
14 lines
```

After verifying the working copy, you can remove the backup file that starts with a comma:

```
example% diff program.c ,program.c  
example% rm ,program.c
```

EXAMPLE 5 Retrieving a file from another directory

To retrieve a file from another directory into the current directory:

```
example% sccs get /usr/src/sccs/cc.c
```

or:

```
example% sccs -p/usr/src/sccs/ get cc.c
```

EXAMPLE 6 Checking out all files

To check out all files under SCCS in the current directory:

```
example% sccs edit SCCS
```

EXAMPLE 7 Checking in all files

To check in all files currently checked out to you:

```
example% sccs delta 'sccs tell -u'
```

EXAMPLE 8 Entering multiple lines of comments

If using `-y` to enter a comment, for most shells, enclose the comment in single or double quotes. In the following example, `Myfile` is checked in with a two-line comment:

```
example% sccs deledit Myfile -y"Entering a
multi-line comment"
No id keywords (cm7)
1.2
2 inserted
0 deleted
14 unchanged
1.2
new delta 1.3
```

Displaying the SCCS history of `Myfile`:

```
example% sccs prt Myfile

SCCS/s.Myfile:

D 1.2  01/04/20  16:37:07  me 2 1   00002/00000/00014
Entering a
multi-line comment

D 1.1  01/04/15  13:23:32  me 1 0   00014/00000/00000
date and time created 01/04/15 13:23:32 by me
```

If `-y` is not used and `sccs` prompts for a comment, the newlines must be escaped using the backslash character (`\`):

```
example% sccs deledit Myfile
comments? Entering a \
multi-line comment
No id keywords (cm7)
1.2
0 inserted
0 deleted
14 unchanged
1.2
new delta 1.3
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `sccs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

PROJECTDIR If contains an absolute path name (beginning with a slash), `sccs` searches for SCCS history files in the directory given by that variable.

If `PROJECTDIR` does not begin with a slash, it is taken as the name of a user, and `sccs` searches the `src` or source subdirectory of that user's home directory for history files. If such a directory is found, it is used. Otherwise,

the value is used as a relative path name.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files	SCCS	SCCS subdirectory
	SCCS/d. <i>file</i>	temporary file of differences
	SCCS/p. <i>file</i>	lock (permissions) file for checked-out versions
	SCCS/q. <i>file</i>	temporary file
	SCCS/s. <i>file</i>	SCCS history file
	SCCS/x. <i>file</i>	temporary copy of the s. <i>file</i>
	SCCS/z. <i>file</i>	temporary lock file
	/usr/bin/*	SCCS utility programs

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/bin/sccs	Availability	developer/build/make

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/xpg4/bin/sccs	Availability	developer/xopen/xcu4
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [awk\(1\)](#), [diff\(1\)](#), [sccs-admin\(1\)](#), [sccs-cdc\(1\)](#), [sccs-comb\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-rmdel\(1\)](#), [sccs-sact\(1\)](#), [sccs-sccsdiff\(1\)](#), [sccs-unget\(1\)](#), [sccs-val\(1\)](#), [sed\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name sccs-admin, admin – create and administer SCCS history files

Synopsis /usr/bin/admin [-bhnz] [-a *username* | *groupid*]...
 [-d *flag*] ... [-e *username* | *groupid*]...
 [-f *flag* [*value*]] ... [-i [*filename*]] [-m *mr-list*]
 [-rrelease] [-t [*description-file*]] [-y [*comment*]] *s.filename*...

Description The `admin` command creates or modifies the flags and other parameters of SCCS history files. Filenames of SCCS history files begin with the `s.` prefix, and are referred to as `s.` files, or history files.

The named `s.` file is created if it does not exist already. Its parameters are initialized or modified according to the options you specify. Parameters not specified are given default values when the file is initialized, otherwise they remain unchanged.

If a directory name is used in place of the `s.filename` argument, the `admin` command applies to all `s.` files in that directory. Unreadable `s.` files produce an error. The use of `'-'` as the `s.filename` argument indicates that the names of files are to be read from the standard input, one `s.` file per line.

Options The following options are supported:

- a *username* | *groupid* Adds a user name, or a numerical group ID, to the list of users who may check deltas in or out. If the list is empty, any user is allowed to do so.
- b Forces encoding of binary data. Files that contain ASCII NUL or other control characters, or that do not end with a NEWLINE, are recognized as binary data files. The contents of such files are stored in the history file in encoded form. See [uuencode\(1C\)](#) for details about the encoding. This option is normally used in conjunction with `-i` to force `admin` to encode initial versions not recognized as containing binary data.
- d *flag* Deletes the indicated *flag* from the SCCS file. The `-d` option may be specified only for existing `s.` files. See `-f` for the list of recognized flags.
- e *username* | *groupid* Erases a user name or group ID from the list of users allowed to make deltas.
- f *flag* [*value*] Sets the indicated *flag* to the (optional) *value* specified. The following flags are recognized:
 - b
Enables branch deltas. When `b` is set, branches can be created using the `-b` option of the SCCS `get` command (see [sccs-get\(1\)](#)).

cceil

Sets a ceiling on the releases that can be checked out. *ceil* is a number less than or equal to 9999. If *c* is not set, the ceiling is 9999.

dsid

Specifies the default delta number, or SID, to be used by an SCCS get command.

ffloor

Sets a floor on the releases that can be checked out. The floor is a number greater than 0 but less than 9999. If *f* is not set, the floor is 1.

i

Treats the 'No id keywords (ge6)' message issued by an SCCS get or delta command as an error rather than a warning.

j

Allows concurrent updates.

*la**l release[, release...]*

Locks the indicated list of releases against deltas. If *a* is used, this flag locks out deltas to all releases. An SCCS 'get -e' command fails when applied against a locked release.

mmodule

Supplies a value for the module name to which the `sccs-admin.1` keyword is to expand. If the *m* flag is not specified, the value assigned is the name of the SCCS file with the leading `s.` removed.

n

Creates empty releases when releases are skipped. These null (empty) deltas serve as anchor points for branch deltas.

qvalue

Supplies a *value* to which the keyword is to expand when a read-only version is retrieved with the SCCS get command.

snumber

Specifies how many lines of code are scanned for the SCCS keyword.

ttype

Supplies a value for the module type to which the keyword is to expand.

- v*[*program*]
 Specifies a validation *program* for the MR numbers associated with a new delta. The optional *program* specifies the name of an MR number validity checking *program*. If this flag is set when creating an SCCS file, the *-m* option must also be used, in which case the list of MRs may be empty.
- y*[*value*, [*value*]]
 Specifies the SCCS keywords to be expanded. If no *value* is specified, no keywords will be expanded.
- h* Checks the structure of an existing *s*. file (see [sccsfile\(4\)](#)), and compares a newly computed check-sum with one stored in the first line of that file. *-h* inhibits writing on the file and so nullifies the effect of any other options.
- i* [*filename*]
 Initializes the history file with text from the indicated file. This text constitutes the initial delta, or set of checked-in changes. If *filename* is omitted, the initial text is obtained from the standard input. Omitting the *-i* option altogether creates an empty *s*. file. You can only initialize one *s*. file with text using *-i*. This option implies the *-n* option.
- m mr-list*
 Inserts the indicated Modification Request (MR) numbers into the commentary for the initial version. When specifying more than one MR number on the command line, *mr-list* takes the form of a quoted, space-separated list. A warning results if the *v* flag is not set or the MR validation fails.
- n* Creates a new SCCS history file.
- r release*
 Specifies the release for the initial delta. *-r* may be used only in conjunction with *-i*. The initial delta is inserted into release 1 if this option is omitted. The level of the initial delta is always 1. Initial deltas are named 1.1 by default.
- t* [*description-file*]
 Inserts descriptive text from the file *description-file*. When *-t* is used in conjunction with *-n*, or *-i* to initialize a new *s*.file, the *description-file* must be supplied. When modifying the description for an existing file: a *-t* option without a *description-file* removes the descriptive text, if any; a *-t* option with a *description-file* replaces the existing text.
- y* [*comment*]
 Inserts the indicated *comment* in the "Comments:" field for the initial delta. Valid only in conjunction with *-i* or *-n*. If *-y* option is omitted, a default comment line is inserted that notes the date and time the history file was created.

-z Recomputes the file check-sum and stores it in the first line of the `s` file. *Caution:* It is important to verify the contents of the history file (see [sccs-val\(1\)](#), and the `print` subcommand in [sccs\(1\)](#)), since using `-z` on a truly corrupted file may prevent detection of the error.

Examples **EXAMPLE 1** Preventing SCCS keyword expansion

In the following example, 10 lines of `file` will be scanned and only the `W`, `Y`, `X` keywords will be interpreted:

```
example% sccs admin -fs10 file
example% sccs admin -fyW,Y,X file
example% get file
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `alias` and `unalias`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLS_PATH`.

Exit Status The following exit values are returned:

0 Successful completion.
1 An error occurred.

Files `s.*` history file
 `SCCS/s.*` history file in SCCS subdirectory
 `z.*` temporary lock file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make
Interface Stability	Committed
Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-cdc\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-rmdel\(1\)](#), [sccs-val\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the `sccs-help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Warnings The last component of all SCCS filenames must have the `'s.'` prefix. New SCCS files are given mode 444 (see [chmod\(1\)](#)). All writing done by `admin` is to a temporary file with an `x.` prefix, created with mode 444 for a new SCCS file, or with the same mode as an existing SCCS file. After successful execution of `admin`, the existing `s.` file is removed and replaced with the `x.` file. This ensures that changes are made to the SCCS file only when no errors have occurred.

It is recommended that directories containing SCCS files have permission mode 755, and that the `s` files themselves have mode 444. The mode for directories allows only the owner to modify the SCCS files contained in the directories, while the mode of the `s` files prevents all modifications except those performed using SCCS commands.

If it should be necessary to patch an SCCS file for any reason, the mode may be changed to 644 by the owner to allow use of a text editor. However, extreme care must be taken when doing this. The edited file should *always* be processed by an `'admin -h'` command to check for corruption, followed by an `'admin -z'` command to generate a proper check-sum. Another `'admin -h'` command is recommended to ensure that the resulting `s` file is valid.

`admin` also uses a temporary lock `s` file, starting with the `'z.'` prefix, to prevent simultaneous updates to the `s` file. See [sccs-get\(1\)](#) for further information about the `'z` file'.

Name `sccs-cdc, cdc` – change the delta commentary of an SCCS delta

Synopsis `cdc -rsid [-mmr-list] [-y [comment]] s.filename...`

Description `cdc` annotates the delta commentary for the SCCS delta ID (SID) specified by the `-r` option in each named `s.file`.

If the `v` flag is set in the `s.file`, you can also use `cdc` to update the Modification Request (MR) list.

If you checked in the delta, or, if you own the file and directory and have write permission, you can use `cdc` to annotate the commentary.

Rather than replacing the existing commentary, `cdc` inserts the new comment you supply, followed by a line of the form:

```
*** CHANGED *** yy/mm/dd hh/mm/ss username
```

above the existing commentary.

If a directory is named as the `s.filename` argument, the `cdc` command applies to all `s.file` in that directory. Unreadable `s.file` produce an error; processing continues with the next file (if any). If `'-'` is given as the `s.filename` argument, each line of the standard input is taken as the name of an SCCS history file to be processed, and the `-m` and `-y` options must be used.

- Options**
- `-rsid` Specify the SID of the delta to change.
 - `-mmr-list` Specify one or more MR numbers to add or delete. When specifying more than one MR on the command line, `mmr-list` takes the form of a quoted, space-separated list. To delete an MR number, precede it with a `!` character (an empty MR list has no effect). A list of deleted MRs is placed in the comment section of the delta commentary. If `-m` is not used and the standard input is a terminal, `cdc` prompts with `MRs?` for the list (before issuing the `comment s?` prompt). `-m` is only useful when the `v` flag is set in the `s.file`. If that flag has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, `cdc` terminates and the delta commentary remains unchanged.
 - `-y[comment]` Use `comment` as the annotation in the delta commentary. The previous comments are retained; the `comment` is added along with a notation that the commentary was changed. A null `comment` leaves the commentary unaffected. If `-y` is not specified and the standard input is a terminal, `cdc` prompts with `comment s?` for the text of the notation to be added. An unescaped NEWLINE character terminates the annotation text.

Examples EXAMPLE 1 Changing the annotated commentary

The following command:

```
example% cdc -r1.6 -y"corrected commentary" s.program.c
```

produces the following annotated commentary for delta 1.6 in s.program.c:

```
D 1.6 88/07/05 23:21:07 username 9 0 00001/00000/00000
MRs:
COMMENTS:
corrected commentary
*** CHANGED *** 88/07/07 14:09:41 username
performance enhancements in main()
```

Files z.file temporary lock file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make

See Also [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-comb\(1\)](#), [sccs-delta\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-rmdel\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

Diagnostics Use the `sccs-help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Name sccs-comb, comb – combine SCCS deltas

Synopsis comb [-os] [-csid-list] [-psid] *s.filename*...

Description comb generates a shell script (see [sh\(1\)](#)) that you can use to reconstruct the indicated *s*. files. This script is written to the standard output.

If a directory name is used in place of the *s.filename* argument, the comb command applies to all *s*. files in that directory. Unreadable *s*. files produce an error; processing continues with the next file (if any). The use of – as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s*. file per line.

If no options are specified, comb preserves only the most recent (leaf) delta in a branch, and the minimal number of ancestors needed to preserve the history.

Options The following options are supported:

- o For each get -e generated, access the reconstructed file at the release of the delta to be created. Otherwise, the reconstructed file is accessed at the most recent ancestor. The use of -o can decrease the size of the reconstructed *s*. file. It can also alter the shape of the delta tree of the original file.
- s Generate scripts to gather statistics, rather than combining deltas. When run, the shell scripts report: the file name, size (in blocks) after combining, original size (also in blocks), and the percentage size change, computed by the formula:
$$100 * (original - combined) / original$$
This option can be used to calculate the space that is saved, before actually doing the combining.
- csid-list Include the indicated list of deltas. All other deltas are omitted. *sid-list* is a comma-separated list of SCCS delta IDs (SIDs). To specify a range of deltas, use a – separator instead of a comma, between two SIDs in the list.
- pSID The SID of the oldest delta to be preserved.

Files *s*. COMB reconstructed SCCS file
comb????? temporary file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make

See Also [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-cdc\(1\)](#), [sccs-delta\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-rmdel\(1\)](#), [sccs-sccsdiff\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

Diagnostics Use the `sccs -help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Bugs `comb` might rearrange the shape of the tree of deltas. It might not save any space; in fact, it is possible for the reconstructed file to actually be larger than the original.

Name `sccs-delta, delta` – make a delta to an SCCS file

Synopsis `/usr/bin/delta [-dnps] [-g sid-list | -gsid-list]
 [-m mr-list | -mmr-list] [-r sid | -rsid]
 [-y [comment]] s.filename...`

`/usr/xpg4/bin/delta [-dnps] [-g sid-list | -gsid-list]
 [-m mr-list | -mmr-list] [-r sid | -rsid]
 [-y [comment]] s.filename...`

Description The `delta` utility checks in a record of the line-by-line differences made to a checked-out version of a file under SCCS control. These changes are taken from the writable working copy that was retrieved using the SCCS `get` command (see [sccs-get\(1\)](#)). This working copy does not have the ‘s.’ prefix, and is also referred to as a g-file.

If a directory name is used in place of the *s.filename* argument, the `delta` command applies to all s. files in that directory. Unreadable s. files produce an error; processing continues with the next file (if any). The use of ‘-’ as the *s.filename* argument indicates that the names of files are to be read from the standard input, one s. file per line (requires -y, and in some cases, -m).

`delta` can issue prompts on the standard output depending upon the options specified and the flags that are set in the s. file (see [sccs-admin\(1\)](#), and the -m and -y options below, for details).

`/usr/xpg4/bin/delta` The SID of the delta is not echoed to stdout.

Options The following options are supported:

- d Use command [diff\(1\)](#) instead of [bdiff\(1\)](#). Returns exit status 2 if *s.filename* argument is not specified.
- n Retain the edited g-file, which is normally removed at the completion of processing.
- p Display line-by-line differences (in [diff\(1\)](#) format) on the standard output.
- s Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error).
- g *sid-list* | -gsid-list Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. *sid-list* is a comma-separated list of SIDs. To specify a range of deltas, use a ‘-’ separator instead of a comma, between two SIDs in the list.
- m *mr-list* | -mmr-list If the SCCS file has the v flag set (see [sccs-admin\(1\)](#)), you must supply one or more Modification Request (MR) numbers for the new delta. When specifying more than one MR number on the command line, *mr-list* takes the form of a quoted, space-separated list. If -m is not used and the standard input is a terminal, `delta` prompts with

MRs? for the list (before issuing the comments? prompt). If the v flag in the s . file has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, de l t a terminates without checking in the changes.

-r *sid* | -r*sid*

When two or more versions are checked out, specify the version to check in. This SID value can be either the SID specified on the get command line, or the SID of the new version to be checked in as reported by get. A diagnostic results if the specified SID is ambiguous, or if one is required but not supplied.

-y[*comment*]

Supply a comment for the delta table (version log). A null comment is accepted, and produces an empty commentary in the log. If -y is not specified and the standard input is a terminal, de l t a prompts with 'comments?'. An unescaped NEWLINE terminates the comment.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of de l t a: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred and the -d option had not been specified.
- 2 An error occurred, the -d option had been specified, and the *s.filename* argument was not specified.

Files

- d . file temporary file of differences
- p . file lock file for a checked-out version
- q . file temporary file
- s . file SCCS history file
- x . file temporary copy of the s . file
- z . file temporary file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/bin/delta	Availability	developer/build/make

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/xpg4/bin/delta	Availability	developer/xopen/xcu4
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [bdiff\(1\)](#), [diff\(1\)](#), [sccs-admin\(1\)](#), [sccs-cdc\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-rmdel\(1\)](#), [sccs-sccsdiff\(1\)](#), [sccs-unget\(1\)](#), [sccs\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the SCCS help command for explanations (see [sccs-help\(1\)](#)).

Warnings Lines beginning with an ASCII SOH character (binary 001) cannot be placed in the SCCS file unless the SOH is escaped. This character has special meaning to SCCS (see [sccsfile\(4\)](#)) and produces an error.

Name sccs-get, get – retrieve a version of an SCCS file

Synopsis /usr/bin/get [-begkmpst] [-l [p]] [-asequence]
 [-c *date-time* | -c*date-time*] [-Gg-file]
 [-i *sid-list* | -i*sid-list*] [-r [*sid*]]
 [-x *sid-list* | -x*sid-list*] *s.filename...*

/usr/xpg4/bin/get [-begkmpst] [-l [p]] [-asequence]
 [-c *date-time* | -c*date-time*] [-Gg-file]
 [-i *sid-list* | -i*sid-list*] [-r *sid* | -r*sid*]
 [-x *sid-list* | -x*sid-list*] *s.filename...*

Description The get utility retrieves a working copy from the SCCS history file, according to the specified options.

For each *s.filename* argument, get displays the SCCS delta ID (SID) and number of lines retrieved.

If a directory name is used in place of the *s.filename* argument, the get command applies to all *s.* files in that directory. Unreadable *s.* files produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s.* file per line.

The retrieved file normally has the same filename base as the *s.* file, less the prefix, and is referred to as the *g*-file.

For each file processed, get responds (on the standard output) with the SID being accessed, and with the number of lines retrieved from the *s.* file.

Options The following options are supported:

- asequence Retrieves the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS comb command (see [sccs-comb\(1\)](#)). For users, -r is an easier way to specify a version. The -a option supersedes the -r option when both are used.
- b Creates a new branch. Used with the -e option to indicate that the new delta should have a SID in a new branch. Instead of incrementing the level for version to be checked in, get indicates in the *p.* file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the *b* flag is not set in the *s.* file, this option is ignored.
- c *date-time* | -c*date-time* Retrieves the latest version checked in prior to the date and time indicated by the *date-time* argument. *date-time* takes the form:

yy[mm[dd[hh[mm[ss]]]]]

Units omitted from the indicated date and time default to their maximum possible values; that is -c7502 is equivalent to -c750228235959. Values of *yy* in the range 69–99 refer to the twentieth century. Values in the range 00–68 refer to the twenty-first century. Any number of non-numeric characters can separate the various 2 digit components. If white-space characters occur, the *date-time* specification must be quoted.

- e Retrieves a version for editing. With this option, *get* places a lock on the *s*.file, so that no one else can check in changes to the version you have checked out. If the *j* flag is set in the *s*.file, the lock is advisory: *get* issues a warning message. Concurrent use of '*get -e*' for different SIDs is allowed. However, *get* does not check out a version of the file if a writable version is present in the directory. All SCCS file protections stored in the *s*.file, including the release ceiling, floor, and authorized user list, are honored by '*get -e*'.
- g Gets the SCCS version ID, without retrieving the version itself. Used to verify the existence of a particular SID.
- Gnewname* Uses *newname* as the name of the retrieved version.
- i *sid-list* | -i*sid-list* Specifies a list of deltas to include in the retrieved version. The included deltas are noted in the standard output message. *sid-list* is a comma-separated list of SIDs. To specify a range of deltas, use a '-' separator instead of a comma, between two SIDs in the list.
- k Suppresses expansion of ID keywords. -k is implied by the -e.
- l [*p*] Retrieves a summary of the delta table (version log) and write it to a listing file, with the 'l.' prefix (called 'l.file'). When -lp is used, write the summary onto the standard output.
- m Precedes each retrieved line with the SID of the delta in which it was added to the file. The SID is separated from the line with a TAB.
- n Precedes each line with the %M% ID keyword and a TAB. When both the -m and -n options are used, the ID keyword precedes the SID, and the line of text.
- p Writes the text of the retrieved version to the standard output. All messages that normally go to the standard output are written to the standard error instead.

- s Suppresses all output normally written on the standard output. However, fatal error messages (which always go to the standard error) remain unaffected.
- t Retrieves the most recently created (top) delta in a given release (for example: -r1).
- /usr/bin/get -r[*sid*] Retrieves the version corresponding to the indicated SID (delta).

The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the *release* and *level* fields, and for branch deltas, the *branch* and *sequence* fields. For instance, if 1.2 is the SID, 1 is the release, and 2 is the level number. If 1.2.3.4 is the SID, 3 is the branch and 4 is the sequence number.

You need not specify the entire SID to retrieve a version with `get`. When you omit `-r` altogether, or when you omit both release and level, `get` normally retrieves the highest release and level. If the `d` flag is set to an SID in the `s` file and you omit the SID, `get` retrieves the default version indicated by that flag.

When you specify a release but omit the level, `get` retrieves the highest level in that release. If that release does not exist, `get` retrieves highest level from the next-highest existing release.

Similarly with branches, if you specify a release, level and branch, `get` retrieves the highest sequence in that branch.

- /usr/xpg4/bin/get -r *sid* | -r*sid* Same as for /usr/bin/get except that SID is mandatory.
- x *sid-list* | -x*sid-list* Excludes the indicated deltas from the retrieved version. The excluded deltas are noted in the standard output message. *sid-list* is a comma-separated list of SIDs. To specify a range of deltas, use a '-' separator instead of a comma, between two SIDs in the list.

Output

/usr/bin/get The output format for /usr/bin/get is as follows:

```
"%s\n%d lines\n", <SID>, <number of lines>
```

/usr/xpg4/bin/get The output format for /usr/xpg4/bin/get is as follows:

```
"%s\n%d\n", <SID>, <number of lines>
```

Usage Usage guidelines are as follows:

ID Keywords In the absence of `-e` or `-k`, `get` expands the following ID keywords by replacing them with the indicated values in the text of the retrieved source.

<i>Keyword</i>	<i>Value</i>
%A%	Shorthand notation for an ID line with data for <code>what(1)</code> : %Z%Y% %M% %I%Z%
%B%	SID branch component
%C%	Current line number. Intended for identifying messages output by the program such as "this shouldn't have happened" type errors. It is <i>not</i> intended to be used on every line to provide sequence numbers.
%D%	Current date: <i>yy/mm/dd</i>
%E%	Date newest applied delta was created: <i>yy/mm/dd</i>
%F%	SCCS s . file name
%G%	Date newest applied delta was created: <i>mm/dd/yy</i>
%H%	Current date: <i>mm/dd/yy</i>
%I%	SID of the retrieved version: %R%. %L%. %B%. %S%
%J%	SID level component
%M%	Module name: either the value of the <code>m</code> flag in the <code>s . file</code> (see <code>scs-admin(1)</code>), or the name of the <code>s . file</code> less the prefix
%P%	Fully qualified <code>s . file</code> name
%Q%	Value of the <code>q</code> flag in the <code>s . file</code>
%R%	SID Release component
%S%	SID Sequence component
%T%	Current time: <i>hh:mm:ss</i>
%U%	Time the newest applied delta was created: <i>hh:mm:ss</i>
%W%	Shorthand notation for an ID line with data for what: %Z%%&;%I%
%Y%	Module type: value of the <code>t</code> flag in the <code>s . file</code>
%Z%	4-character string: '@(#)', recognized by <code>what</code>

ID String The table below explains how the SCCS identification string is determined for retrieving and creating deltas.

Determination of SCCS Identification String				
SID (1) Specified	-b Option Used (2)	Other Conditions	SID Retrieved	SID of Delta to be Created
none (3)	no	R defaults to mR	mR.mL	mR.(mL+1)
none (3)	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1

Determination of SCCS Identification String				
SID (1) Specified	-b Option Used (2)	Other Conditions	SID Retrieved	SID of Delta to be Created
R	no	$R > mR$	mR.mL	R.1 (4)
R	no	$R = mR$	mR.mL	mR.(mL+1)
R	yes	$R > mR$	mR.mL	mR.mL.(mB+1).1
R	yes	$R = mR$	mR.mL	mR.mL.(mB+1).1
R	–	$R < mR$ and R does <i>not</i> exist	hR.mL (5)	hR.mL.(mB+1).1
R	–	Trunk succ. (6) in release $> R$ and R exists	R.mL	R.mL.(mB+1).1
R.L	no	No trunk succ.	R.L	R.(L+1)
R.L	yes	No trunk succ.	R.L	R.L.(mB+1).1
R.L	–	Trunk succ. in release $\geq R$	R.L	R.L.(mB+1).1
R.L.B	no	No branch succ.	R.L.B.mS	R.L.B.(mS+1)
R.L.B	yes	No branch succ.	R.L.B.mS	R.L.(mB+1).1
R.L.B.S	no	No branch succ.	R.L.B.S	R.L.B.(S+1)
R.L.B.S	yes	No branch succ.	R.L.B.S	R.L.(mB+1).1
R.L.B.S	–	Branch succ.	R.L.B.S	R.L.(mB+1).1

- (1) 'R', 'L', 'B', and 'S' are the 'release', 'level', 'branch', and 'sequence' components of the SID, respectively; 'm' means 'maximum'. Thus, for example, 'R.mL' means 'the maximum level number within release R'; 'R.L.(mB+1).1' means 'the first sequence number on the *new* branch (that is, maximum branch number plus one) of level L within release R'. *Note:* If the SID specified is of the form 'R.L', 'R.L.B', or 'R.L.B.S', each of the specified components *must* exist.
- (2) The -b option is effective only if the b flag is present in the file. An entry of '–' means 'irrelevant'.
- (3) This case applies if the d (default SID) flag is *not* present in the file. If the d flag is present in the file, the SID obtained from the d flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.
- (4) Forces creation of the *first* delta in a *new* release.
- (5) 'hR' is the highest *existing* release that is lower than the specified, *nonexistent*, release R.
- (6) Successor.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `get`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Files

- `"g-file"` version retrieved by `get`
- `l.file` file containing extracted delta table info
- `p.file` permissions (lock) file
- `z.file` temporary copy of `s.file`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/get	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	developer/build/make

/usr/xpg4/bin/get	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	developer/xopen/xcu4
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-delta\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-sact\(1\)](#), [sccs-unget\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the `sccs-help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Bugs If the effective user has write permission (either explicitly or implicitly) in the directory containing the SCCS files, but the real user does not, only one file can be named when using `-e`.

Name sccs-help, sccshelp – ask for help regarding SCCS error or warning messages

Synopsis /usr/bin/sccshelp [*argument*]...

Description The sccs-help utility retrieves information to further explain errors messages and warnings from SCCS commands. It also provides some information about SCCS command usage. If no arguments are given, sccs-help prompts for one.

An *argument* may be a message number (which normally appears in parentheses following each SCCS error or warning message), or an SCCS command name. sccs-help responds with an explanation of the message or a usage line for the command.

When all else fails, try /usr/bin/sccshelp stuck.

Files /usr/lib/help directory containing files of message text

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make

See Also [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-cdc\(1\)](#), [sccs-comb\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-rmdel\(1\)](#), [sccs-sact\(1\)](#), [sccs-sccsdiff\(1\)](#), [sccs-unget\(1\)](#), [sccs-val\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

Name sccs-prs, prs – display selected portions of an SCCS history

Synopsis prs [-ae ℓ] [-c*date-time*] [-ddataspec] [-rsid] *s.filename*...

Description The prs utility displays part or all of the SCCS file (see [sccsfile\(4\)](#)) in a user supplied format.

If a directory name is used in place of the *s.filename* argument, the prs command applies to all *s.* files in that directory. Unreadable *s.* files produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s.* file per line.

Options In the absence of options, prs displays the delta table (version log). In the absence of -d, or - ℓ , prs displays the entry for each delta indicated by the other options.

- a Includes all deltas, including those marked as removed (see [sccs-rmdel\(1\)](#)).
- e Requests information for all deltas created *earlier* than, and including, the delta indicated with -r or -c.
- ℓ Requests information for all deltas created *later* than, and including, the delta indicated with -r or -c.

-c*date-time* Either options -e or - ℓ must be used with this option. -c*date-time* displays information on the deltas checked in either prior to and including the date and time indicated by the *date-time* argument (option -e); or later than and including the date and time indicated (option - ℓ). *date-time* takes the form:

yy[*mm*[*dd*[*hh*[*mm*[*ss*]]]]]]

Units omitted from the indicated date and time default to their maximum possible values; that is -c7502 is equivalent to -c750228235959. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the *date-time* specification must be quoted. Values of *yy* in the range 69–99 refer to the twentieth century. Values in the range of 00–68 refer to the twenty-first century.

-ddataspec Produce a report according to the indicated data specification. *dataspec* consists of a (quoted) text string that includes embedded data keywords of the form: ':key:' (see Data Keywords, below). prs expands these keywords in the output it produces. To specify a TAB character in the output, use \t; to specify a NEWLINE in the output, use \n.

-rsid Specifies the SCCS delta ID (SID) of the delta for which information is desired. If no SID is specified, the most recently created delta is used.

Usage Usage of prs is described below.

Data Keywords Data keywords specify which parts of an SCCS file are to be retrieved. All parts of an SCCS file (see [sccsfile\(4\)](#)) have an associated data keyword. A data keyword may appear any number of times in a data specification argument to `-d`. These data keywords are listed in the table below:

<i>Keyword</i>	<i>Data Item</i>	<i>File Section*</i>	<i>Value</i>	<i>Format**</i>
:A:	a format for the what string:	N/A	:Z::Y: :M: :I::Z:	S
:B:	branch number	D	<i>nnnn</i>	S
:BD:	body	B	<i>text</i>	M
:BF:	branch flag	F	yes or no	S
:CB:	ceiling boundary	F	:R:	S
:C:	comments for delta	D	<i>text</i>	M
:D:	date delta created	D	:Dy:/:Dm:/:Dd:	S
:Dd:	day delta created	D	<i>nn</i>	S
:Dg:	deltas ignored (seq #)	D	:DS: :DS: . . .	S
:DI:	seq-no. of deltas included, excluded, ignored	D	:Dn:/:Dx:/:Dg:	S
:DL:	delta line statistics	D	:Li:/:Ld:/:Lu:	S
:Dm:	month delta created	D	<i>nn</i>	S
:Dn:	deltas included (seq #)	D	:DS: :DS: . . .	S
:DP:	predecessor delta seq-no.	D	<i>nnnn</i>	S
:Ds:	default SID	F	:I:	S
:DS:	delta sequence number	D	<i>nnnn</i>	S
:Dt:	delta information	D	:DT: :I: :D: :T: :P: :DS: :DP:	S
:DT:	delta type	D	D or R	S
:Dx:	deltas excluded (seq #)	D	:DS: . . .	S
:Dy:	year delta created	D	<i>nn</i>	S
:F:	s. file name	N/A	<i>text</i>	S
:FB:	floor boundary	F	:R:	S
:FD:	file descriptive text	C	<i>text</i>	M

<i>Keyword</i>	<i>Data Item</i>	<i>File Section*</i>	<i>Value</i>	<i>Format**</i>
:FL:	flag list	F	<i>text</i>	M
:GB:	gotten body	B	<i>text</i>	M
:I:	SCCS delta ID (SID)	D	:R: . :L: . :B: . :S:	S
:J:	joint edit flag	F	yes or no	S
:KF:	keyword error/warning flag	F	yes or no	S
:L:	level number	D	<i>nnnn</i>	S
:Ld:	lines deleted by delta	D	<i>nnnnn</i>	S
:Li:	lines inserted by delta	D	<i>nnnnn</i>	S
:LK:	locked releases	F	:R: . . .	S
:Lu:	lines unchanged by delta	D	<i>nnnnn</i>	S
:M:	module name	F	<i>text</i>	S
:MF:	MR validation flag	F	yes or no	S
:MP:	MR validation program	F	<i>text</i>	S
:MR:	MR numbers for delta	D	<i>text</i>	M
:ND:	null delta flag	F	yes or no	S
:Q:	user defined keyword	F	<i>text</i>	S
:P:	user who created delta	D	<i>username</i>	S
:PN:	s . file's pathname	N/A	<i>text</i>	S
:R:	release number	D	<i>nnnn</i>	S
:S:	sequence number	D	<i>nnnn</i>	S
:T:	time delta created	D	:Th: . :Tm: . :Ts:	S
:Th:	hour delta created	D	<i>nn</i>	S
:Tm:	minutes delta created	D	<i>nn</i>	S
:Ts:	seconds delta created	D	<i>nn</i>	S
:UN:	user names	U	<i>text</i>	M
:W:	a form of what string	N/A	:Z: . :M: \t: I:	S
:Y:	module type flag	F	<i>text</i>	S
:Z:	what string delimiter	N/A	@(#)	S

*B = body, D = delta table, F = flags, U = user names

**S = simple format, M = multi-line format

Examples EXAMPLE 1 Displaying delta entries

The following command displays delta entries:

```
example% prs -e -d":I:\t:P:" program.c
```

produces:

```
1.6  username
1.5  username...
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of prs: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Files /tmp/pr????? temporary file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	developer/build/make
Interface Stability	Committed
Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-cdc\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prt\(1\)](#), [sccs-sact\(1\)](#), [sccs-sccsdiff\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the `sccs-help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Name sccs-prt, prt – display delta table information from an SCCS file

Synopsis prt [-abdefistu] [-cdate-time] [-rdate-time]
 [-ysid] s.filename...

Description prt prints selected portions of an SCCS file. By default, it prints the delta table (version log).

If a directory name is used in place of the *s.filename* argument, the prt command applies to all *s.* files in that directory. Unreadable *s.* files produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s.* file per line.

Options If any option other than -y, -c, or -r is supplied, the name of each file being processed (preceded by one NEWLINE and followed by two NEWLINE characters) appears above its contents.

If none of the -u, -f, -t, or -b options are used, -d is assumed. -s, -i are mutually exclusive, as are -c and -r.

- a Display log entries for all deltas, including those marked as removed.
- b Print the body of the *s.* file.
- d Print delta table entries. This is the default.
- e Everything. This option implies -d, -i, -u, -f, and -t.
- f Print the flags of each named *s.* file.
- i Print the serial numbers of included, excluded, and ignored deltas.
- s Print only the first line of the delta table entries; that is, only up to the statistics.
- t Print the descriptive text contained in the *s.* file.
- u Print the user-names and/or numerical group IDs of users allowed to make deltas.
- cdate-time Exclude delta table entries that are specified cutoff date and time. Each entry is printed as a single line, preceded by the name of the SCCS file. This format (also produced by -r, and -y) makes it easy to sort multiple delta tables in chronological order. When both -y and -c, or -y and -r are supplied, prt stops printing when the first of the two conditions is met.
- rdate-time Exclude delta table entries that are newer than the specified cutoff date and time.
- ysid Exclude delta table entries made prior to the SID specified. If no delta in the table has the specified SID, the entire table is printed. If no SID is specified, the most recent delta is printed.

Usage

- Output Format The following format is used to print those portions of the `s` file that are specified by the various options.
- NEWLINE
 - Type of delta (D or R)
 - SPACE
 - SCCS delta ID (SID)
 - TAB
 - Date and time of creation in the form: *yy/mm/dd hh/mm/ss*
 - SPACE
 - Username the delta's creator
 - TAB
 - Serial number of the delta
 - SPACE
 - Predecessor delta's serial number
 - TAB
 - Line-by-line change statistics in the form: *inserted/deleted/unchanged*
 - NEWLINE
 - List of included deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
 - List of excluded deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
 - List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
 - List of modification requests (MRs), followed by a NEWLINE (only if any MR numbers were supplied).
 - Lines of the delta commentary (if any), followed by a NEWLINE.

Examples EXAMPLE 1 Producing a Display of the Delta Table

The following command produces a one-line display of the delta table entry for the most recent version:

```
example% prt -y program.c
s.program.c: D 1.6 88/07/06 21:39:39 username 5 4 00159/00080/00636
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make

See Also [sccs\(1\)](#), [sccs-cdc\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-sact\(1\)](#), [sccs-sccsdiff\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

Diagnostics Use the `sccs-help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Name sccs-rmdel, rmdel – remove a delta from an SCCS file

Synopsis rmdel -rsid *s.filename*...

Description The rmdel utility removes the delta specified by the SCCS delta ID (SID) supplied with -r. The delta to be removed must be the most recent (leaf) delta in its branch. In addition, the SID must *not* be that of a version checked out for editing: it must not appear in any entry of the version lock file (p.file).

If you created the delta, or, if you own the file and directory and have write permission, you can remove it with rmdel.

If a directory name is used in place of the *s.filename* argument, the rmdel command applies to all *s*. files in that directory. Unreadable *s*. files produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s*. file per line.

Options The following option is supported:

-rsid Remove the version corresponding to the indicated SID (delta).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of rmdel: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Files p.file permissions file
s.file history file
z.file temporary copy of the s.file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make
Interface Stability	Committed
Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-cdc\(1\)](#), [sccs-comb\(1\)](#), [sccs-delta\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-sccsdiff\(1\)](#), [sccs-unget\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the SCCS help command for explanations (see [sccs-help\(1\)](#)).

Name sccs-sact, sact – show editing activity status of an SCCS file

Synopsis sact *s.filename*...

Description The sact utility informs the user of any SCCS files that are checked out for editing.

The output for each named file consists of five fields separated by SPACE characters.

- SID of a delta that currently exists in the SCCS file, to which changes are made to make the new delta
- SID for the new delta to be created
- Username of the person who has the file checked out for editing.
- Date that the version was checked out.
- Time that the version was checked out.

If a directory name is used in place of the *s.filename* argument, the sact command applies to all *s.* files in that directory. Unreadable *s.* files produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s.* file per line.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of sact: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make
Interface Stability	Committed
Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the [sccs-help](#) command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Name sccs-sccsdiff, sccsdiff – compare two versions of an SCCS file

Synopsis sccsdiff [-p] -rsid -rsid [diff-options] s.filename

Description sccsdiff compares two versions of an SCCS file and displays the differences between the two versions. Any number of SCCS files can be specified. The options specified apply to all named s . files.

Options The following options are supported:

-p Pipe output for each file through [pr\(1\)](#).

-rsid Specify a version corresponding to the indicated SCCS delta ID (SID) for comparison. Versions are passed to [diff\(1\)](#) in the order given.

diff-options Pass options to [diff\(1\)](#), including: -b, -c, -e, -f, -h, -u, -C number, -U number, and -D string.

Files /tmp/get????? temporary files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	developer/build/make

See Also [diff\(1\)](#), [sccs\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

Diagnostics *filename*: No differences If the two versions are the same.

Use the sccs-help command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Name sccs-unget, unget – undo a previous get of an SCCS file

Synopsis unget [-ns] [-rsid] *s.filename*...

Description The unget utility undoes the effect of a get -e command executed before the creation of the pending delta.

If a directory name is used in place of the *s.filename* argument, the unget command applies to all *s.* files in that directory. Unreadable *s.* files produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s.* file per line.

Options The following options are supported:

- n Retains the retrieved version, which is otherwise removed.
- s Suppress display of the SCCS delta ID (SID).
- rsid When multiple versions are checked out, this option specifies which pending delta to abort. A diagnostic results if the specified SID is ambiguous, or if it is necessary but omitted from the command line.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of unget: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make
Interface Stability	Committed
Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-rmdel\(1\)](#), [sccs-sact\(1\)](#), [sccs-sccsdiff\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the [sccs-help](#) command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Name sccs-val, val – validate an SCCS file

Synopsis val [-s] [-m *name*] [-rsid] [-y *type*] *s.filename...*

Description The val utility determines if the specified *s*. files meet the characteristics specified by the indicated arguments. val can process up to 50 files on a single command line.

val has a special argument, '-', which reads the standard input until the end-of-file condition is detected. Each line read is independently processed as if it were a command line argument list.

val generates diagnostic messages on the standard output for each command line and file processed and also returns a single 8-bit code upon exit as described below.

The 8-bit code returned by val is a disjunction of the possible errors, that is, it can be interpreted as a bit string where (moving from left to right) the bits set are interpreted as follows:

```
bit 0 = missing file argument
bit 1 = unknown or duplicate option
bit 2 = corrupted s.file
bit 3 = can not open file or file not in s.file format
bit 4 = the SCCS delta ID (SID) is invalid or ambiguous
bit 5 = the SID does not exist
bit 6 = mismatch between Y% and -y argument
bit 7 = mismatch between sccs-val.1 and -m argument
```

val can process two or more files on a given command line, and in turn can process multiple command lines (when reading the standard input). In these cases, an aggregate code is returned which is the logical OR of the codes generated for each command line and file processed.

Options The following options are supported:

```
-s          Silent. Suppresses the normal error or warning messages.
-m name    Compares name with the %M% ID keyword in the s . file.
-rsid       Checks to see if the indicated SID is ambiguous, invalid, or absent from the s . file.
-y type    Compares type with the %Y% ID keyword.
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of val: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Committed
Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the `sccs-help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Name scp – secure copy (remote file copy program)

Synopsis scp [-pqrVBC46] [-F *ssh_config*] [-S *program*] [-P *port*]
 [-c *cipher*] [-i *identity_file*] [-o *ssh_option*]
 [[*user@*]*host1*:]*file1* [...] [[*user@*]*host2*:]*file2*

Description The scp utility copies files between hosts on a network. It uses [ssh\(1\)](#) for data transfer, and uses the same authentication and provides the same security as [ssh\(1\)](#). Unlike [rcp\(1\)](#), scp will ask for passwords or passphrases if they are needed for authentication.

Any file name may contain a host and user specification to indicate that the file is to be copied to/from that host. Copies between two remote hosts are permitted.

Options The following options are supported:

- 4 Forces scp to use IPv4 addresses only.
- 6 Forces scp to use IPv6 addresses only.
- B Selects batch mode. (Prevents asking for passwords or passphrases.)
- c *cipher* Selects the cipher to use for encrypting the data transfer. This option is directly passed to [ssh\(1\)](#).
- C Compression enable. Passes the -C flag to [ssh\(1\)](#) to enable compression.
- F *ssh_config* Specifies an alternative per-user configuration file for [ssh\(1\)](#).
- i *identity_file* Selects the file from which the identity (private key) for RSA authentication is read. This option is directly passed to [ssh\(1\)](#).
- o *ssh_option* The given option is directly passed to [ssh\(1\)](#).
- p Preserves modification times, access times, and modes from the original file.
- P *port* Specifies the port to connect to on the remote host. Notice that this option is written with a capital 'P', because -p is already reserved for preserving the times and modes of the file in [rcp\(1\)](#).
- q Disables the progress meter.
- r Recursively copies entire directories.
- S *program* Specifies the name of the program to use for the encrypted connection. The program must understand [ssh\(1\)](#) options.
- v Verbose mode. Causes scp and [ssh\(1\)](#) to print debugging messages about their progress. This is helpful in debugging connection, authentication, and configuration problems.

Operands The following operands are supported:

host1, host2,... The name(s) of the host from or to which the file is to be copied.

file1, file2,... The file(s) to be copied.

Exit Status The following exit values are returned:

0 Successful completion.

1 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	Committed

See Also [rcp\(1\)](#), [ssh\(1\)](#), [ssh-add\(1\)](#), [ssh-agent\(1\)](#), [ssh-keygen\(1\)](#), [sshd\(1M\)](#), [ssh_config\(4\)](#), [attributes\(5\)](#)

Notes Generally, use of `scp` with password or keyboard-interactive authentication method and two remote hosts does not work. It does work with either the `pubkey`, `hostbased` or `gssapi-keyex` authentication method. For the `pubkey` authentication method, either private keys not protected by a passphrase, or an explicit `ssh agent` forwarding have to be used. The `gssapi-keyex` authentication method works with the `kerberos_v5` GSS-API mechanism, but only if the `GSSAPIDelegateCredentials` option is enabled.

Name script – make record of a terminal session

Synopsis script [-a] [*filename*]

Description The `script` utility makes a record of everything printed on your screen. The record is written to *filename*. If no file name is given, the record is saved in the file `typescript`. See WARNINGS.

The `script` command forks and creates a sub-shell, according to the value of `$SHELL`, and records the text from this session. The script ends when the forked shell exits or when Control-d is typed.

Options The following option is supported:

-a Appends the session record to *filename*, rather than overwriting it.

Notes `script` places everything that appears on the screen in *filename*, including prompts.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	system/core-os
CSI	Enabled

See Also [attributes\(5\)](#)

Warnings `script` can pose a security risk when used in directories that are writable by other users (for example, `/tmp`), especially when run by a privileged user, that is, root. Be sure that `typescript` is not a link before running `script`.

Name sdiff – print differences between two files side-by-side

Synopsis sdiff [-l] [-s] [-o *output*] [-w *n*] *filename1 filename2*

Description sdiff uses the output of the diff command to produce a side-by-side listing of two files indicating lines that are different. Lines of the two files are printed with a blank gutter between them if the lines are identical, a < in the gutter if the line appears only in *filename1*, a > in the gutter if the line appears only in *filename2*, and a | for lines that are different. (See the EXAMPLES section below.)

Options

- l Print only the left side of any lines that are identical.
- s Do not print identical lines.
- o *output* Use the argument *output* as the name of a third file that is created as a user-controlled merge of *filename1* and *filename2*. Identical lines of *filename1* and *filename2* are copied to *output*. Sets of differences, as produced by diff, are printed; where a set of differences share a common gutter character. After printing each set of differences, sdiff prompts the user with a % and waits for one of the following user-typed commands:
 - l Append the left column to the output file.
 - r Append the right column to the output file.
 - s Turn on silent mode; do not print identical lines.
 - v Turn off silent mode.
 - e l Call the editor with the left column.
 - e r Call the editor with the right column.
 - e b Call the editor with the concatenation of left and right.
 - e Call the editor with a zero length file.
 - q Exit from the program.On exit from the editor, the resulting file is concatenated to the end of the *output* file.
- w *n* Use the argument *n* as the width of the output line. The default line length is 130 characters.

Usage See [largefile\(5\)](#) for the description of the behavior of sdiff when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples EXAMPLE 1 An example of the sdiff command.

A sample output of sdiff follows.

EXAMPLE 1 An example of the `sdiff` command. *(Continued)*

```
x | y
a   a
b <
c <
d   d
   > c
```

Environment Variables If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see [environ\(5\)](#)) are not set in the environment, the operational behavior of `sdiff` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" locale determines how `sdiff` behaves.

`LC_CTYPE` Determines how `sdiff` handles characters. When `LC_CTYPE` is set to a valid value, `sdiff` can display and handle text and filenames containing valid characters for that locale.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled

Name sed – stream editor

Synopsis /usr/bin/sed [-n] *script* [*file*]...
/usr/bin/sed [-n] [-e *script*]... [-f *script_file*]...
 [*file*]...
/usr/xpg4/bin/sed [-n] *script* [*file*]...
/usr/xpg4/bin/sed [-n] [-e *script*]... [-f *script_file*]...
 [*file*]...

Description The sed utility is a stream editor that reads one or more text files, makes editing changes according to a script of editing commands, and writes the results to standard output. The script is obtained from either the *script* operand string, or a combination of the option-arguments from the -e *script* and -f *script_file* options.

The sed utility is a text editor. It cannot edit binary files or files containing ASCII NUL (\0) characters or very long lines.

Options The following options are supported:

-e *script* *script* is an edit command for sed. See USAGE below for more information on the format of *script*. If there is just one -e option and no -f options, the flag -e may be omitted.

-f *script_file* Takes the script from *script_file*. *script_file* consists of editing commands, one per line.

-n Suppresses the default output.

Multiple -e and -f options may be specified. All commands are added to the script in the order specified, regardless of their origin.

Operands The following operands are supported:

file A path name of a file whose contents will be read and edited. If multiple *file* operands are specified, the named files will be read in the order specified and the concatenation will be edited. If no *file* operands are specified, the standard input will be used.

script A string to be used as the script of editing commands. The application must not present a *script* that violates the restrictions of a text file except that the final character need not be a NEWLINE character.

Usage A script consists of editing commands, one per line, of the following form:

[*address* [, *address*]] *command* [*arguments*]

Zero or more blank characters are accepted before the first address and before *command*. Any number of semicolons are accepted before the first address.

In normal operation, sed cyclically copies a line of input (less its terminating NEWLINE character) into a *pattern space* (unless there is something left after a D command), applies in sequence all commands whose *addresses* select that pattern space, and copies the resulting pattern space to the standard output (except under -n) and deletes the pattern space. Whenever the pattern space is written to standard output or a named file, sed will immediately follow it with a NEWLINE character.

Some of the commands use a *hold space* to save all or part of the *pattern space* for subsequent retrieval. The *pattern* and *hold spaces* will each be able to hold at least 8192 bytes.

sed Addresses An *address* is either empty, a decimal number that counts input lines cumulatively across files, a \$ that addresses the last line of input, or a context address, which consists of a */regular expression/* as described on the [regexp\(5\)](#) manual page.

A command line with no addresses selects every pattern space.

A command line with one address selects each pattern space that matches the address.

A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second address. Thereafter the process is repeated, looking again for the first address. (If the second address is a number less than or equal to the line number selected by the first address, only the line corresponding to the first address is selected.)

Typically, address are separated from each other by a comma (,). They may also be separated by a semicolon (;).

sed Regular Expressions sed supports the basic regular expressions described on the [regexp\(5\)](#) manual page, with the following additions:

`\cREc` In a context address, the construction `\cREc`, where *c* is any character other than a backslash or NEWLINE character, is identical to `/RE/`. If the character designated by *c* appears following a backslash, then it is considered to be that literal character, which does not terminate the RE. For example, in the context address `\xabc\xdefx`, the second *x* stands for itself, so that the regular expression is `abcxdef`.

`\n` The escape sequence `\n` matches a NEWLINE character embedded in the pattern space. A literal NEWLINE character must not be used in the regular expression of a context address or in the substitute command.

Editing commands can be applied only to non-selected pattern spaces by use of the negation command ! (described below).

sed Editing Commands In the following list of functions the maximum number of permissible addresses for each function is indicated.

The `r` and `w` commands take an optional *rfile* (or *wfile*) parameter, separated from the command letter by one or more blank characters.

Multiple commands can be specified by separating them with a semicolon (;) on the same command line.

The *text* argument consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Each embedded NEWLINE character in the text must be preceded by a backslash. Other backslashes in text are removed and the following character is treated literally. Backslashes in text are treated like backslashes in the replacement string of an `s` command, and may be used to protect initial blanks and tabs against the stripping that is done on every script line. The *rfile* or *wfile* argument must terminate the command line and must be preceded by exactly one blank. The use of the *wfile* parameter causes that file to be initially created, if it does not exist, or will replace the contents of an existing file. There can be at most 10 distinct *wfile* arguments.

Regular expressions match entire strings, not just individual lines, but a NEWLINE character is matched by \n in a sed RE. A NEWLINE character is not allowed in an RE. Also notice that \n cannot be used to match a NEWLINE character at the end of an input line; NEWLINE characters appear in the pattern space as a result of the `N` editing command.

Two of the commands take a *command-list*, which is a list of sed commands separated by NEWLINE characters, as follows:

```
{ command
  command
}
```

The { can be preceded with blank characters and can be followed with white space. The *commands* can be preceded by white space. The terminating } must be preceded by a NEWLINE character and can be preceded or followed by <blank>s. The braces may be preceded or followed by <blank>s. The command may be preceded by <blank>s, but may not be followed by <blank>s.

The following table lists the functions, with the maximum number of permissible addresses.

Max Address	Command	Description
1	a \ <i>text</i>	Append by executing <code>N</code> command or beginning a new cycle. Place <i>text</i> on the output before reading the next input line.
2	b <i>label</i>	Branch to the : command bearing the <i>label</i> . If <i>label</i> is empty, branch to the end of the script. Labels are recognized unique up to eight characters.
2	c \ <i>text</i>	Change. Delete the pattern space. Place <i>text</i> on the output. Start the next cycle.

Max Address	Command	Description
2	d	Delete the pattern space. Start the next cycle.
2	D	Delete the initial segment of the pattern space through the first new-line. Start the next cycle. (See the N command below.)
2	g	Replace the contents of the pattern space by the contents of the hold space.
2	G	Append the contents of the hold space to the pattern space.
2	h	Replace the contents of the hold space by the contents of the pattern space.
2	H	Append the contents of the pattern space to the hold space.
1	i \ <i>text</i>	Insert. Place <i>text</i> on the standard output.
2	l	<code>/usr/bin/sed</code> : List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded.
		<code>/usr/xpg4/bin/sed</code> : List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded. The characters (\, \a, \b, \f, \r, \t, and \v) are written as the corresponding escape sequences. Non-printable characters not in that table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation dependent. Long lines are folded, with the point of folding indicated by writing a backslash followed by a NEWLINE; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line is marked with a \$.
2	n	Copy the pattern space to the standard output if default output is not suppressed. Replace the pattern space with the next line of input.
2	N	Append the next line of input to the pattern space with an embedded new-line. (The current line number changes.) If no next line of input is available, the N command verb shall branch to the end of the script and quit without starting a new cycle and without writing the pattern space.
2	p	Print. Copy the pattern space to the standard output.

Max Address	Command	Description
2	P	Copy the initial segment of the pattern space through the first new-line to the standard output.
1	q	Quit. Branch to the end of the script. Do not start a new cycle.
2	r <i>rfile</i>	Read the contents of <i>rfile</i> . Place them on the output before reading the next input line. If <i>rfile</i> does not exist or cannot be read, it is treated as if it were an empty file, causing no error condition.
2	t <i>label</i>	Test. Branch to the : command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a t. If <i>label</i> is empty, branch to the end of the script.
2	w <i>wfile</i>	Write. Append the pattern space to <i>wfile</i> . The first occurrence of w will cause <i>wfile</i> to be cleared. Subsequent invocations of w will append. Each time the sed command is used, <i>wfile</i> is overwritten.
2	x	Exchange the contents of the pattern and hold spaces.
2	! <i>command</i>	Don't. Apply the <i>command</i> (or group, if <i>command</i> is { }) only to lines <i>not</i> selected by the address(es).
0	: <i>label</i>	This command does nothing; it bears a <i>label</i> for b and t commands to branch to.
1	=	Place the current line number on the standard output as a line.
2	{ <i>command-list</i> }	Execute <i>command-list</i> only when the pattern space is selected.
0		An empty command is ignored.
0	#	If a # appears as the first character on a line of a script file, then that entire line is treated as a comment, with one exception: if a # appears on the first line and the character after the # is an n, then the default output will be suppressed. The rest of the line after #n is also ignored. A script file must contain at least one non-comment line.

Max Addr	Command (Using <i>strings</i>) and Description
2	s/ <i>regular expression/replacement/flags</i>

Max Addr	Command (Using <i>strings</i>) and Description
	<p>Substitute the <i>replacement</i> string for instances of the <i>regular expression</i> in the pattern space. Any character other than backslash or newline can be used instead of a slash to delimit the RE and the replacement. Within the RE and the replacement, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.</p> <p>An ampersand (&) appearing in the <i>replacement</i> will be replaced by the string matching the RE. The special meaning of & in this context can be suppressed by preceding it by backslash. The characters <code>\n</code>, where <i>n</i> is a digit, will be replaced by the text matched by the corresponding backreference expression. For each backslash (\) encountered in scanning <i>replacement</i> from beginning to end, the following character loses its special meaning (if any). It is unspecified what special meaning is given to any character other than &, \ or digits.</p> <p>A line can be split by substituting a NEWLINE character into it. The application must escape the NEWLINE character in the <i>replacement</i> by preceding it with backslash. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.</p> <p><i>flags</i> is zero or more of:</p> <p><i>n n</i>= 1 - 512. Substitute for just the <i>n</i>th occurrence of the <i>regular expression</i>.</p> <p><i>g</i> Global. Substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one. If both <i>g</i> and <i>n</i> are specified, the results are unspecified.</p>
	<p><i>p</i> Print the pattern space if a replacement was made.</p> <p><i>P</i> Copy the initial segment of the pattern space through the first new-line to the standard output.</p> <p><i>w wfile</i> Write. Append the pattern space to <i>wfile</i> if a replacement was made. The first occurrence of <i>w</i> will cause <i>wfile</i> to be cleared. Subsequent invocations of <i>w</i> will append. Each time the sed command is used, <i>wfile</i> is overwritten.</p>
2	<p><i>y/ string1 / string2 /</i></p> <p>Transform. Replace all occurrences of characters in <i>string1</i> with the corresponding characters in <i>string2</i>. <i>string1</i> and <i>string2</i> must have the same number of characters, or if any of the characters in <i>string1</i> appear more than once, the results are undefined. Any character other than backslash or NEWLINE can be used instead of slash to delimit the strings. Within <i>string1</i> and <i>string2</i>, the delimiter itself can be used as a literal character if it is preceded by a backslash. For example, <code>y/abc/ABC/</code> replaces a with A, b with B, and c with C.</p>

See [largefile\(5\)](#) for the description of the behavior of sed when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples EXAMPLE 1 An example sed script

This sed script simulates the BSD `cat -s` command, squeezing excess blank lines from standard input.

```
sed -n '
# Write non-empty lines.
./ {
    p
    d
}
# Write a single empty line, then look for more empty lines.
/^\$/ p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^\$/ {
    N
    s/./ /
    b Empty
}
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
p
,
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of sed: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

	ATTRIBUTETYPE	ATTRIBUTEVALUE
/usr/bin/sed	Availability	system/core-os
	CSI	Not enabled

	ATTRIBUTETYPE	ATTRIBUTEVALUE
/usr/xpg4/bin/sed	Availability	system/xopen/xcu4
	CSI	Enabled
	Interface Stability	Committed

ATTRIBUTETYPE	ATTRIBUTEVALUE
Standard	See standards(5) .

See Also [awk\(1\)](#), [ed\(1\)](#), [grep\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#), [standards\(5\)](#)

Name sed – stream editor

Synopsis sed [-n] [-e *script*] [-f *sfilename*] [*filename*]. . .

Description The sed utility copies the *filenames* (standard input default) to the standard output, edited according to a script of commands.

Options The following options are supported:

- n Suppresses the default output.
- e *script* *script* is an edit command for sed. If there is just one -e option and no -f options, the -e flag may be omitted.
- f *sfilename* Takes the script from *sfilename*.

Usage

sed Scripts sed scripts consist of editing commands, one per line, of the following form:

```
[ address [, address ] ] function [ arguments ]
```

In normal operation, sed cyclically copies a line of input into a *pattern space* (unless there is something left after a D command), sequentially applies all commands with *addresses* matching that pattern space until reaching the end of the script, copies the pattern space to the standard output (except under -n), and finally, deletes the pattern space.

Some commands use a *hold space* to save all or part of the pattern space for subsequent retrieval.

An *address* is either:

- a decimal number linecount, which is cumulative across input files;
- a \$, which addresses the last input line;
- or a context address, which is a */regular expression/* as described on the [regexp\(5\)](#) manual page, with the following exceptions:

<code>\?RE?</code>	In a context address, the construction <code>\?regular expression?</code> , where <code>?</code> is any character, is identical to <code>/regular expression/</code> . <i>Note:</i> in the context address <code>\xabc\xdefx</code> , the second <code>x</code> stands for itself, so that the regular expression is <code>abcxdef</code> .
<code>\n</code>	Matches a NEWLINE embedded in the pattern space.
<code>.</code>	Matches any character except the NEWLINE ending the pattern space.
<code>null</code>	A command line with no address selects every pattern space.
<code>address</code>	Selects each pattern space that matches.

address1 , *address2* Selects the inclusive range from the first pattern space matching *address1* to the first pattern space matching *address2*. Selects only one line if *address1* is greater than or equal to *address2*.

Comments If the first nonwhite character in a line is a '#' (pound sign), sed treats that line as a comment, and ignores it. If, however, the first such line is of the form:

#n

sed runs as if the -n flag were specified.

Functions The maximum number of permissible addresses for each function is indicated in parentheses in the list below.

An argument denoted *text* consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Backslashes in text are treated like backslashes in the replacement string of an s command, and may be used to protect initial SPACE and TAB characters against the stripping that is done on every script line.

An argument denoted *rfilename* or *wfilename* must terminate the command line and must be preceded by exactly one SPACE. Each *wfilename* is created before processing begins. There can be at most 10 distinct *wfilename* arguments.

(1)a\

text Append: place *text* on the output before reading the next input line.

(2)b *label*

Branch to the ':' command bearing the *label*. Branch to the end of the script if *label* is empty.

(2)c\

text Change: delete the pattern space. With 0 or 1 address or at the end of a 2 address range, place *text* on the output. Start the next cycle.

(2)d

Delete the pattern space. Start the next cycle.

(2)D

Delete the initial segment of the pattern space through the first NEWLINE. Start the next cycle.

(2)g

Replace the contents of the pattern space by the contents of the hold space.

(2)G

Append the contents of the hold space to the pattern space.

(2)h

Replace the contents of the hold space by the contents of the pattern space.

(2)H

Append the contents of the pattern space to the hold space.

(1)i\

text Insert: place *text* on the standard output.

-
- (2)l List the pattern space on the standard output in an unambiguous form. Non-printing characters are spelled in two digit ASCII and long lines are folded.
- (2)n Copy the pattern space to the standard output. Replace the pattern space with the next line of input.
- (2)N Append the next line of input to the pattern space with an embedded newline. (The current line number changes.)
- (2)p Print: copy the pattern space to the standard output.
- (2)P Copy the initial segment of the pattern space through the first NEWLINE to the standard output.
- (1)q Quit: branch to the end of the script. Do not start a new cycle.
- (2)r *rfilename* Read the contents of *rfilename*. Place them on the output before reading the next input line.
- (2)s/*regular expression*/*replacement*/*flags* Substitute the *replacement* string for instances of the *regular expression* in the pattern space. Any character may be used instead of '/'. For a fuller description see [regexp\(5\)](#). *flags* is zero or more of:
- n* *n*= 1 – 512. Substitute for just the *n*th occurrence of the *regular expression*.
- g Global: substitute for all nonoverlapping instances of the *regular expression* rather than just the first one.
- p Print the pattern space if a replacement was made.
- w *wfilename* Write: append the pattern space to *wfilename* if a replacement was made.
- (2)t *label* Test: branch to the ':' command bearing the *label* if any substitutions have been made since the most recent reading of an input line or execution of a t. If *label* is empty, branch to the end of the script.
- (2)w *wfilename* Write: append the pattern space to *wfilename*.
- (2)x Exchange the contents of the pattern and hold spaces.

(2)y/string1/string2/	Transform: replace all occurrences of characters in <i>string1</i> with the corresponding character in <i>string2</i> . The lengths of <i>string1</i> and <i>string2</i> must be equal.
(2)! function	Do not: apply the function (or group, if function is '{') only to lines <i>not</i> selected by the address(es).
(0): label	This command does nothing. It bears a <i>label</i> for b and t commands to branch to. <i>Note:</i> The maximum length of <i>label</i> is seven characters.
(1)=	Place the current line number on the standard output as a line.
(2){	Execute the following commands through a matching '}' only when the pattern space is selected. Commands are separated by ';'.
(0)	An empty command is ignored.

Large Files See [largefile\(5\)](#) for the description of the behavior of sed when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Diagnostics	Too many commands	The command list contained more than 200 commands.
	Too much command text	The command list was too big for sed to handle. Text in the a, c, and i commands, text read in by r commands, addresses, regular expressions and replacement strings in s commands, and translation tables in y commands all require sed to store data internally.
	Command line too long	A command line was longer than 4000 characters.
	Too many line numbers	More than 256 decimal number linecounts were specified as addresses in the command list.
	Too many files in w commands	More than 10 different files were specified in w commands or w options for s commands in the command list.
	Too many labels	More than 50 labels were specified in the command list.
	Unrecognized command	A command was not one of the ones recognized by sed.
	Extra text at end of command	A command had extra text after the end.

Illegal line number	An address was neither a decimal number linecount, a \$, nor a context address.
Space missing before filename	There was no space between an r or w command, or the w option for a s command, and the filename specified for that command.
Too many { 's	There were more { than } in the list of commands to be executed.
Too many } 's	There were more } than { in the list of commands to be executed.
No addresses allowed	A command that takes no addresses had an address specified.
Only one address allowed	A command that takes one address had two addresses specified.
"\digit" out of range	The number in a \n item in a regular expression or a replacement string in ans command was greater than 9.
Bad number	One of the endpoints in a range item in a regular expression (that is, an item of the form {n} or {n,m}) was not a number.
Range endpoint too large	One of the endpoints in a range item in a regular expression was greater than 255.
More than 2 numbers given in \{ \}	More than two endpoints were given in a range expression.
} expected after \ }	A \ } appeared in a range expression and was not followed by a }.
First number exceeds second in \{ \}	The first endpoint in a range expression was greater than the second.
Illegal or missing delimiter	The delimiter at the end of a regular expression was absent.
\(\) imbalance	There were more \ (than \) , or more \) than \ (, in a regular expression.
[] imbalance	There were more [] than [) , or more [) than [) , in a regular expression.

First RE may not be null	The first regular expression in an address or in a <code>s</code> command was null (empty).
Ending delimiter missing on substitution	The ending delimiter in a <code>s</code> command was absent.
Ending delimiter missing on string	The ending delimiter in a <code>y</code> command was absent.
Transform strings not the same size	The two strings in a <code>y</code> command were not the same size.
Suffix too large - 512 max	The suffix in a <code>s</code> command, specifying which occurrence of the regular expression should be replaced, was greater than 512.
Label too long	A label in a command was longer than 8 characters.
Duplicate labels	The same label was specified by more than one <code>:</code> command.
File name too long	The filename specified in a <code>r</code> or <code>w</code> command, or in the <code>w</code> option for a <code>s</code> command, was longer than 1024 characters.
Output line too long	An output line was longer than 4000 characters long.
Too many appends or reads after line <i>n</i>	More than 20 <code>a</code> or <code>r</code> commands were to be executed for line <i>n</i> .
Hold space overflowed.	More than 4000 characters were to be stored in the <i>hold space</i> .

Files `usr/ucb/sed` `BSD sed`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

Bugs There is a combined limit of 200 `-e` and `-f` arguments. In addition, there are various internal size limits which, in rare cases, may overflow. To overcome these limitations, either combine or break out scripts, or use a pipeline of `sed` commands.

Name set, unset, setenv, unsetenv, export – shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents

Synopsis

```
sh set [--aefhkntuvx argument...]...
unset [name]...
export [name]...

csh set [var [= value]]
set var [n] = word
unset pattern
setenv [VAR [word]]
unsetenv variable

ksh88 set [ $\pm$ abCefhkmnopstuvx] [ $\pm$ o option]... [ $\pm$ A name]
      [arg]...
unset [-f] name...
**export [name [=value]]...
**export [-p]

ksh +set [ $\pm$ abCefGhkmnoprstuvx] [ $\pm$ o option]... [ $\pm$ A vname]
      [arg]...
+unset [-fnv] vname...
++export [-p] [name[=value]]...
```

Description

sh The set built-in command has the following options:

- - Does not change any of the flags. This option is useful in setting \$1 to -.
- a Marks variables which are modified or created for export.
- e Exits immediately if a command exits with a non-zero exit status.
- f Disables file name generation.
- h Locates and remembers function commands as functions are defined. Function commands are normally located when the function is executed.
- k All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- n Reads commands but does not execute them.
- t Exits after reading and executing one command.

- u Treats unset variables as an error when substituting.
- v Prints shell input lines as they are read.
- x Prints commands and their arguments as they are executed.

Using + rather than – causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags can be found in \$-. The remaining *arguments* are positional parameters and are assigned, in order, to \$1, \$2, If no *arguments* are specified the values of all names are printed.

For each *name*, unset removes the corresponding variable or function value. The variables PATH, PS1, PS2, MAILCHECK, and IF cannot be unset.

With the export built-in, the specified *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are specified, variable names that have been marked for export during the current shell's execution are listed. Function names are *not* exported.

- csh With no arguments, set displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the *var* argument alone, set assigns an empty (null) value to the variable *var*. With arguments of the form *var* = *value* set assigns *value* to *var*, where *value* is one of:

- word* A single word (or quoted string).
- (*wordlist*) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form set *var*[*n*]=*word* replaces the *n*'th word in a multiword value with *word*.

unset removes variables whose names match (filename substitution) *pattern*. All variables are removed by 'unset *'.

With no arguments, setenv displays all environment variables. With the *VAR* argument, setenv sets the environment variable *VAR* to an empty (null) value. (By convention, environment variables are normally specified upper-case names.) With both *VAR* and *word* arguments specified, setenv sets *VAR* to *word*, which must be either a single word or a quoted string. The PATH variable can take multiple *word* arguments, separated by colons (see EXAMPLES). The most commonly used environment variables, USER, TERM, and PATH, are automatically imported to and exported from the csh variables user, term, and path. Use setenv if you need to change these variables. In addition, the shell sets the PWD environment variable from the csh variable cwd whenever the latter changes.

The environment variables LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY take immediate effect when changed within the C shell. See [environ\(5\)](#) for descriptions of these environment variables.

unsetenv removes *variable* from the environment. As with unset, pattern matching is not performed.

ksh88 The flags for the set built-in have meaning as follows:

- A Array assignment. Unsets the variable *name* and assigns values sequentially from the list *arg*. If +A is used, the variable *name* is not unset first.
- a All subsequent variables that are defined are automatically exported.
- b Causes the shell to notify the user asynchronously of background job completions.
- C Prevents existing files from being overwritten by the shell's > redirection operator. The >| redirection operator overrides this noclobber option for an individual file.
- e If a command has a non-zero exit status, executes the ERR trap, if set, and exits. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.
- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs run in a separate process group and a line prints upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Reads commands and checks them for syntax errors, but does not execute them. Ignored for interactive shells.
- +o Writes the current option settings to standard output in a format that is suitable for reinput to the shell as commands that achieve the same option settings.
- o *option* The *option* argument can be one of the following option names:
 - allexport Same as -a.
 - errexit Same as -e.
 - bgnice All background jobs are run at a lower priority. This is the default mode. emacs Puts you in an emacs style in-line editor for command entry.
 - gmacs Puts you in a gmacs style in-line editor for command entry.
 - ignoreeof The shell does not exit on end-of-file. The command `exit` must be used.

keyword	Same as -k.
markdirs	All directory names resulting from file name generation have a trailing / appended.
monitor	Same as -m.
noclobber	Prevents redirection operator > from truncating existing files. Requires the > operator to truncate a file when turned on. Same as -C.
noexec	Same as -n.
noglob	Same as -f.
nolog	Does not save function definitions in history file.
notify	Same as -b.
nounset	Same as -u.
privileged	Same as -p.
verbose	Same as -v.
trackall	Same as -h.
vi	Puts you in insert mode of a vi style in-line editor until you hit escape character 033. This puts you in control mode. A return sends the line.
viraw	Each character is processed as it is typed in vi mode.
xtrace	Same as -x.

If no option name is supplied then the current option settings are printed.

- p Disables processing of the \$HOME/.profile file and uses the file /etc/suid_profile instead of the ENV file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.
- s Sorts the positional parameters lexicographically.
- t Exits after reading and executing one command.
- u Treats unset parameters as an error when substituting.
- v Prints shell input lines as they are read.
- x Prints commands and their arguments as they are executed.
- Turns off -x and -v flags and stops examining arguments for flags.

- Does not change any of the flags. This option is useful in setting \$1 to a value beginning with -. If no arguments follow this flag then the positional parameters are unset.

Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags can be found in \$-. Unless -A is specified, the remaining arguments are positional parameters and are assigned, in order, to \$1 \$2 If no arguments are specified then the names and values of all variables are printed on the standard output.

The variables specified by the list of *names* are unassigned, that is, their values and attributes are erased. `readonly` variables cannot be unset. If the -f flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOU`, and `_` removes their special meaning even if they are subsequently assigned.

When using `unset`, the variables specified by the list of *names* are unassigned, i.e., their values and attributes are erased. `readonly` variables cannot be unset. If the -f flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOU`, and `_` removes their special meaning even if they are subsequently assigned.

With the `export` built-in, the specified *names* are marked for automatic export to the environment of subsequently-executed commands.

When -p is specified, `export` writes to the standard output the names and values of all exported variables in the following format:

```
"export %s=%s\n", name, value
```

if *name* is set, and:

```
"export %s\n", name
```

if *name* is unset.

The shell formats the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same exporting results, except for the following:

1. Read-only variables with values cannot be reset.
2. Variables that were unset at the time they were output are not reset to the unset state if a value is assigned to the variable between the time the state was saved and the time at which the saved output is reinput to the shell.

On this manual page, [ksh88\(1\)](#) commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.

2. I/O redirections are processed after variable assignments.
 3. Errors cause a script that contains them to abort.
 4. Words, following a command preceded by ****** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.
- ksh** `set` sets or unsets options and positional parameters. Options that are specified with a `-` cause the options to be set. Options that are specified with a `+` cause the option to be unset.

`set` without any options or arguments displays the names and values of all shell variables in the order of the collation sequence in the current locale. The values are quoted so that they are suitable for input again to the shell.

If no arguments are specified, not even the end of options argument `--`, the positional parameters are unchanged. Otherwise, unless the `-A` option has been specified, the positional parameters are replaced by the list of arguments. A first argument of `--` is ignored when setting positional parameters.

For backwards compatibility, a `set` command without any options specified, whose first argument is `-` turns off the `-v` and `-x` options. If any additional arguments are specified, they replace the positional parameters.

The options for `set` in `ksh` are:

- `-a` Set the export attribute for each variable whose name does not contain a `.` that you assign a value in the current shell environment.
- `-A name` Assign the arguments sequentially to the array named by *name* starting at subscript `0` rather than to the positional parameters.
- `-b` The shell writes a message to standard error as soon it detects that a background job completes rather than waiting until the next prompt.
- `-B` Enable `{ . . . }` group expansion. On by default.
- `-C` Prevents existing regular files from being overwritten using the `>` redirection operator. The `>|` redirection overrides this `noclobber` option.
- `-e` A simple command that has a non-zero exit status causes the shell to exit unless the simple command is:
 - contained in an `&&` or `||` list
 - the command immediately following `if`, `while`, or `until`
 - contained in the pipeline following `!`
- `-f` Pathname expansion is disabled.

- G Causes ** by itself to also match all sub-directories during pathname expansion.
- h Obsolete. Causes each command whose name has the syntax of an alias to become a tracked alias when it is first encountered.
- H Enable !-style history expansion similar to csh.
- k This is obsolete. All arguments of the form *name=value* are removed and placed in the variable assignment list for the command. Ordinarily, variable assignments must precede command arguments.
- m When enabled, the shell runs background jobs in a separate process group and displays a line upon completion. This mode is enabled by default for interactive shells on systems that support job control.
- n The shell reads commands and checks for syntax errors, but does not execute the command. Usually specified on command invocation.
- o [*option*] If option is not specified, the list of options and their current settings is written to standard output. When invoked with a + the options are written in a format that can be input again to the shell to restore the settings. This option can be repeated to enable or disable multiple options.

The value of *option* must be one of the following:

allexport	Same as -a.
bgnice	All background jobs are run at lower priorities.
braceexpand	Same as -B.
emacs	Enables or disables emacs editing mode.
errexit	Same as -e.
globstar	Equivalent to -G.
gmacs	Enables or disables gmacs. gmacs editing mode is the same as emacs editing mode, except for the handling of CTRL-T.
histexpand	Same as -H.
ignoreeof	The interactive shell does not exit on end-of-file.
keyword	Same as -k.
markdirs	All directory names resulting from file name generation have a trailing / appended.
monitor	Same as -m.

<code>multiline</code>	Use multiple lines when editing lines that are longer than the window width.
<code>noclobber</code>	Same as <code>-C</code> .
<code>noexec</code>	Same as <code>-n</code> .
<code>noglob</code>	Same as <code>-f</code> .
<code>nolog</code>	This has no effect. It is provided for backward compatibility.
<code>notify</code>	Same as <code>-b</code> .
<code>nounset</code>	Same as <code>-u</code> .
<code>pipefail</code>	A pipeline does not complete until all components of the pipeline have completed, and the exit status of the pipeline is the value of the last command to exit with non-zero exit status, or is zero if all commands return zero exit status.
<code>privileged</code>	Same as <code>-p</code> .
<code>showme</code>	Simple commands preceded by a ; are traced as if <code>-x</code> were enabled but not executed.
<code>trackall</code>	Same as <code>-h</code> .
<code>verbose</code>	Same as <code>-v</code> .
<code>vi</code>	Enables or disables <code>vi</code> editing mode.
<code>viraw</code>	Does not use canonical input mode when using <code>vi</code> edit mode
<code>xtrace</code>	Same as <code>-x</code> .
<code>-p</code>	Privileged mode. Disabling <code>-p</code> sets the effective user id to the real user id, and the effective group id to the real group id. Enabling <code>-p</code> restores the effective user and group ids to their values when the shell was invoked. The <code>-p</code> option is on whenever the real and effective user id is not equal or the real and effective group id is not equal. User profiles are not processed when <code>-p</code> is enabled.
<code>-r</code>	Restricted. Enables restricted shell. This option cannot be unset once enabled.
<code>-s</code>	Sort the positional parameters
<code>-t</code>	Obsolete. The shell reads one command and then exits.
<code>-u</code>	If enabled, the shell displays an error message when it tries to expand a variable that is unset.
<code>-v</code>	Verbose. The shell displays its input onto standard error as it reads it.
<code>-x</code>	Execution trace. The shell displays each command after all expansion and before execution preceded by the expanded value of the <code>PS4</code> parameter.

The following exit values are returned by `set` in `ksh`:

0 Successful completion.

>0 An error occurred.

For each *name* specified, `unset` unsets the variable, or function if `-f` is specified, from the current shell execution environment. Read-only variables cannot be unset.

The options for `unset` in `ksh` are:

`-f` Where *name* refers to a function name, the shell unsets the function definition.

`-n` If *name* refers to variable that is a reference, the variable *name* is unset rather than the variable it references. Otherwise, this option is equivalent to the `-v` option.

`-v` Where *name* refers to a variable name, the shell unsets it and removes it from the environment. This is the default behavior.

The following exit values are returned by `unset` in `ksh`:

0 Successful completion. All names were successfully unset.

>0 An error occurred, or one or more *name* operands could not be unset

`export` sets the export attribute on each of the variables specified by name which causes them to be in the environment of subsequently executed commands. If `=value` is specified, the variable *name* is set to *value*.

If no *name* is specified, the names and values of all exported variables are written to standard output.

`export` is built-in to the shell as a declaration command so that field splitting and pathname expansion are not performed on the arguments. Tilde expansion occurs on value.

The options for `export` in `ksh` are:

`-p` Causes the output to be in the form of `export` commands that can be used as input to the shell to recreate the current exports.

The following exit values are returned by `export` in `ksh`:

0 Successful completion.

>0 An error occurred.

On this manual page, `ksh(1)` commands that are preceded by one or two `+` are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.

2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. They are not valid function names.
5. Words, following a command preceded by ++ that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and field splitting and file name generation are not performed.

Examples

`csh` The following example sets the `PATH` variable to search for files in the `/bin`, `/usr/bin`, `/usr/sbin`, and `/usr/ucb/bin` directories, in that order:

```
setenv PATH "/bin:/usr/bin:/usr/sbin:usr/ucb/bin"
```

Name setfacl – modify the Access Control List (ACL) for a file or files

Synopsis setfacl [-r] -s *acl_entries* *file*
setfacl [-r] -md *acl_entries* *file*
setfacl [-r] -f *acl_file* *file*

Description For each file specified, setfacl either replaces its entire ACL, including the default ACL on a directory, or it adds, modifies, or deletes one or more ACL entries, including default entries on directories.

When the setfacl command is used, it can result in changes to the file permission bits. When the user ACL entry for the file owner is changed, the file owner class permission bits are modified. When the group ACL entry for the file group class is changed, the file group class permission bits are modified. When the other ACL entry is changed, the file other class permission bits are modified.

If you use the chmod(1) command to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions can change the effective permissions for additional users and groups who have ACL entries on the file.

A directory can contain default ACL entries. If a file or directory is created in a directory that contains default ACL entries, the newly created file has permissions generated according to the intersection of the default ACL entries and the permissions requested at creation time. The umask(1) are not applied if the directory contains default ACL entries. If a default ACL is specified for a specific user (or users), the file has a regular ACL created. Otherwise, only the mode bits are initialized according to the intersection described above. The default ACL should be thought of as the maximum discretionary access permissions that can be granted.

Use the setfacl command to set ACLs on files in a UFS file system, which supports POSIX-draft ACLS (or aclent_t style ACLs). Use the chmod command to set ACLs on files in a ZFS file system, which supports NFSv4-style ACLS (or ace_t style ACLs).

acl_entries Syntax For the -m and -s options, *acl_entries* are one or more comma-separated ACL entries.

An ACL entry consists of the following fields separated by colons:

<i>entry_type</i>	Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be user (the owner of a file) or mask (the ACL mask).
<i>uid</i> or <i>gid</i>	User name or user identification number. Or, group name or group identification number.
<i>perms</i>	Represents the permissions that are set on <i>entry_type</i> . <i>perms</i> can be indicated by the symbolic characters rwx or a number (the same permissions numbers used with the chmod command).

The following table shows the valid ACL entries (default entries can only be specified for directories):

ACL Entry	Description
<code>u[ser]::perms</code>	File owner permissions.
<code>g[roup]::perms</code>	File group owner permissions.
<code>o[ther]::perms</code>	Permissions for users other than the file owner or members of file group owner.
<code>m[ask]::perms</code>	The ACL mask. The mask entry indicates the maximum permissions allowed for users (other than the owner) and for groups. The mask is a quick way to change permissions on all the users and groups.
<code>u[ser]:uid:perms</code>	Permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.
<code>g[roup]:gid:perms</code>	Permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.
<code>d[efault]:u[ser]::perms</code>	Default file owner permissions.
<code>d[efault]:g[roup]::perms</code>	Default file group owner permissions.
<code>d[efault]:o[ther]::perms</code>	Default permissions for users other than the file owner or members of the file group owner.
<code>d[efault]:m[ask]::perms</code>	Default ACL mask.
<code>d[efault]:u[ser]:uid:perms</code>	Default permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.
<code>d[efault]:g[roup]:gid:perms</code>	Default permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.

For the `-d` option, *acl_entries* are one or more comma-separated ACL entries without permissions. Notice that the entries for file owner, file group owner, ACL mask, and others can not be deleted.

Options The options have the following meaning:

- `-d acl_entries` Deletes one or more entries from the file. The entries for the file owner, the file group owner, and others can not be deleted from the ACL. Notice that deleting an entry does not necessarily have the same effect as removing all permissions from the entry.
- `-f acl_file` Sets a file's ACL with the ACL entries contained in the file named *acl_file*. The same constraints on specified entries hold as with the `-s` option. The

entries are not required to be in any specific order in the file. Also, if you specify a dash (-) for *acl_file*, standard input is used to set the file's ACL.

The character # in *acl_file* can be used to indicate a comment. All characters, starting with the # until the end of the line, are ignored. Notice that if the *acl_file* has been created as the output of the `getfacl(1)` command, any effective permissions, which follow a #, are ignored.

- m *acl_entries* Adds one or more new ACL entries to the file, and/or modifies one or more existing ACL entries on the file. If an entry already exists for a specified *uid* or *gid*, the specified permissions replace the current permissions. If an entry does not exist for the specified *uid* or *gid*, an entry is created. When using the -m option to modify a default ACL, you must specify a complete default ACL (user, group, other, mask, and any additional entries) the first time.
- r Recalculates the permissions for the ACL mask entry. The permissions specified in the ACL mask entry are ignored and replaced by the maximum permissions necessary to grant the access to all additional user, file group owner, and additional group entries in the ACL. The permissions in the additional user, file group owner, and additional group entries are left unchanged.
- s *acl_entries* Sets a file's ACL. All old ACL entries are removed and replaced with the newly specified ACL. The entries need not be in any specific order. They are sorted by the command before being applied to the file.

Required entries:

- Exactly one user entry specified for the file owner.
- Exactly one group entry for the file group owner.
- Exactly one other entry specified.

If there are additional user and group entries:

- Exactly one mask entry specified for the ACL mask that indicates the maximum permissions allowed for users (other than the owner) and groups.
- Must not be duplicate user entries with the same *uid*.
- Must not be duplicate group entries with the same *gid*.

If *file* is a directory, the following default ACL entries can be specified:

- Exactly one default user entry for the file owner.
- Exactly one default group entry for the file group owner.
- Exactly one default mask entry for the ACL mask.
- Exactly one default other entry.

There can be additional default user entries and additional default group entries specified, but there can not be duplicate additional default user entries with the same *uid*, or duplicate default group entries with the same *gid*.

Examples EXAMPLE 1 Adding read permission only

The following example adds one ACL entry to file `abc`, which gives user `shea` read permission only.

```
setfacl -m user:shea:r— abc
```

EXAMPLE 2 Replacing a file's entire ACL

The following example replaces the entire ACL for the file `abc`, which gives `shea` read access, the file owner all access, the file group owner read access only, the ACL mask read access only, and others no access.

```
setfacl -s user:shea:rwx,user::rwx,group::rw-,mask:r--,other:--- abc
```

Notice that after this command, the file permission bits are `rwxr----`. Even though the file group owner was set with read/write permissions, the ACL mask entry limits it to have only read permission. The mask entry also specifies the maximum permissions available to all additional user and group ACL entries. Once again, even though the user `shea` was set with all access, the mask limits it to have only read permission. The ACL mask entry is a quick way to limit or open access to all the user and group entries in an ACL. For example, by changing the mask entry to read/write, both the file group owner and user `shea` would be given read/write access.

EXAMPLE 3 Setting the same ACL on two files

The following example sets the same ACL on file `abc` as the file `xyz`.

```
getfacl xyz | setfacl -f — abc
```

Files `/etc/passwd` password file
`/etc/group` group file

Name setlabel – change effective sensitivity label of files

Synopsis /usr/bin/setlabel *newlabel filename...*

Description In most cases, setlabel moves files into the zone whose label corresponds to *newlabel*. The old file pathname is adjusted so that it is relative to the root pathname of the new zone. If the old pathname for a file's parent directory does not exist as a directory in the new zone, the file is not moved. Once moved, the file might no longer be accessible in the current zone.

However, setlabel behaves differently for files and directories which are on multilevel ZFS file systems. Refer to [zfs\(1M\)](#). In that case, files are not moved, but are re-labeled in place, since multilevel file systems support per-file labels.

Unless *newlabel* and *filename* have been specified, no labels are set.

Labels are defined by the security administrator at your site. The system always displays labels in uppercase. Users can enter labels in any combination of uppercase and lowercase. Incremental changes to labels are supported.

Refer to [setflabel\(3TSOL\)](#) for a complete description of the conditions that are required to satisfy this command, and the privileges that are needed to execute this command.

Exit Status setlabel exits with one of the following values:

- 0 Successful completion.
- 1 Usage error.
- 2 Error in getting, setting or translating the label.

Usage On the command line, enclose the label in double quotes unless the label is only one word. Without quotes, a second word or letter separated by a space is interpreted as a second argument.

```
% setlabel SECRET somefile
% setlabel "TOP SECRET" somefile
```

Use any combination of upper and lowercase letters. You can separate items in a label with blanks, tabs, commas or slashes (/). Do not use any other punctuation.

```
% setlabel "ts a b" somefile
% setlabel "ts,a,b" somefile
% setlabel "ts/a b" somefile
% setlabel " TOP SECRET A B " somefile
```

Examples EXAMPLE 1 Set a Label.

To set *somefile*'s label to SECRET A:

```
example% setlabel "Secret a" somefile
```

EXAMPLE 2 Turn On a Compartment.

Plus and minus signs can be used to modify an existing label. A plus sign turns on the specified compartment for *somefile*'s label.

```
example% setLabel +b somefile
```

EXAMPLE 3 Turn Off a Compartment.

A minus sign turns off the compartments that are associated with a classification. To turn off compartment A in *somefile*'s label:

```
example% setLabel -A somefile
```

If an incremental change is being made to an existing label and the first character of the label is a hyphen (-), a preceding double-hyphen (--) is required.

To turn off compartment -A in *somefile*'s label:

```
example% setLabel -- -A somefile
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	Committed

See Also [zfs\(1M\)](#), [setflabel\(3TSOL\)](#), [label_encodings\(4\)](#), [attributes\(5\)](#)

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This implementation of setting a label is meaningful for the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. For more information, see [label_encodings\(4\)](#).

Name setpgrp – set process group ID

Synopsis setpgrp *command* [*arg*] . . .

Description If the current process is not already a session leader, the setpgrp utility sets the process group ID and session ID to the current process ID and does an exec () of *command* and its argument(s), if any.

Operands The following operands are supported:

command The name of a command to be invoked.

arg An option or argument to *command*.

Exit Status The following exit values are returned:

1 Error executing the setpgrp utility or during exec () of *command*.

Otherwise, the exit status will be that of *command*.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name sftp – secure file transfer program

Synopsis sftp [-lCv] [-B *buffer_size*] [-b *batchfile*] [-F *ssh_config*]
 [-o *ssh_option*] [-P *sftp_server_path*] [-R *num_requests*]
 [-S *program*] [-s *subsystem* | *sftp_server*] *host*

sftp [[*user@*]*host*[:*file* [*file*]]]

sftp [[*user@*]*host*[:*dir*[/]]]

sftp -b *batchfile* [*user@*]*host*

Description The sftp utility is an interactive file transfer program with a user interface similar to ftp(1) that uses the ssh(1) command to create a secure connection to the server.

sftp implements the SSH File Transfer Protocol as defined in IETF draft-ietf-secsh-filexfer. There is no relationship between the protocol used by sftp and the FTP protocol (RFC 959) provided by ftp(1).

The first usage format causes sftp to connect to the specified host and enter an interactive mode. If a username was provided then sftp tries to log in as the specified user. If a directory is provided then sftp tries to change the current directory on the server to the specified directory before entering the interactive mode.

The second usage format retrieves the specified file from the server and copies it to the specified target file or directory on the client. If a username is specified sftp tries to log in as the specified user.

Options The following options are supported:

-b *batchfile*

Batch mode reads a series of commands from an input *batchfile* instead of stdin. Since it lacks user interaction, it should be used in conjunction with non-interactive authentication. A batchfile of - can be used to indicate standard input. sftp aborts if any of the following commands fail: get, put, rm, rename, ln, rm, mkdir, chdir, ls, lchdir, chmod, chown, chgrp, lpwd, and lmkdir. Termination on error can be suppressed on a command by command basis by prefixing the command with a - character (for example, - rm /tmp/blah*).

-B *buffer_size*

Specifies the size of the buffer that sftp uses when transferring files. Larger buffers require fewer round trips at the cost of higher memory consumption. The default is 32768 bytes.

-C

Enables compression, using the -C flag in ssh(1).

-F *ssh_config*

Specifies an alternative per-user configuration file for ssh. This option is directly passed to ssh(1).

- o *ssh_option*
Specifies an option to be directly passed to `ssh(1)`.
- P *sftp_server path*
Executes the specified path as an *sftp-server* and uses a pipe, rather than an `ssh` connection, to communicate with it. This option can be useful in debugging the `sftp` client and server. When the `-P` is specified, the `-S` option is ignored.
- R *num_requests*
Specifies how many requests can be outstanding at any one time. Increasing this can slightly improve file transfer speed but increases memory usage. The default is 64 outstanding requests.
- s *subsystem | sftp_server*
Specifies the SSH2 subsystem or the path for an `sftp` server on the remote host. A path is useful for using `sftp` over protocol version 1, or when the remote `sshd` does not have an `sftp` subsystem configured.
- S *ssh_program path*
Uses the specified program instead of `ssh(1)` to connect to the `sftp` server. When the `-P` option is specified, the `-S` option is ignored. The program must understand `ssh(1)` options.
- v
Raises logging level. This option is also passed to `ssh(1)`.
- 1
Specifies the use of protocol version 1.

Operands The following operands are supported:

hostname | user@hostname
The name of the host to which `sftp` connects and logs into.

Interactive Commands Once in interactive mode, `sftp` understands a set of commands similar to those of `ftp(1)`. Commands are case insensitive and path names can be enclosed in quotes if they contain spaces.

`bye`
Quits `sftp`.

`cd path`
Changes remote directory to *path*.

`chgrp grp path`
Changes group of file *path* to *grp*. *grp* must be a numeric GID.

`chmod mode path`
Changes permissions of file *path* to *mode*.

`chown own path`
Changes owner of file *path* to *own*. *own* must be a numeric UID.

`exit`

Quits `sftp`.

`get [flags] remote-path [local-path]`

Retrieves the *remote-path* and stores it on the local machine. If the local path name is not specified, it is specified the same name it has on the remote machine. If the `-P` flag is specified, then the file's full permission and access time are copied too.

`help`

Displays help text.

Identical to the `?` command.

`lcd path`

Changes local directory to *path*.

`lls [ls-options [path]]`

Displays local directory listing of either *path* or current directory if *path* is not specified.

`mkdir path`

Creates local directory specified by *path*.

`ln oldpath newpath`

Creates a link from *oldpath* to *newpath*.

`lpwd`

Prints local working directory.

`ls [-laflnrSt] [path]`

Displays remote directory listing of either *path* or current directory if *path* is not specified. *path* can contain wildcards.

The `ls` supports the following options:

`-a`

Lists files beginning with a dot (`.`).

`-f`

Does not sort the listing. The default sort order is lexicographical.

`-l`

Displays additional details including permissions and ownership information.

`-n`

Produces a long listing with user and group information presented numerically.

`-r`

Reverses the sort order of the listing.

`-S`

Sorts the listing by file size.

-t
Sorts the listing by last modification time.

-l
Produces single column output.

umask *umask*
Sets local umask to *umask*.

mkdir *path*
Creates remote directory specified by *path*.

put [*flags*] *local-path* [*local-path*]
Uploads *local-path* and stores it on the remote machine. If the remote path name is not specified, it is specified the same name it has on the local machine. If the -P flag is specified, then the file's full permission and access time are copied too.

pwd
Displays remote working directory.

quit
Quits sftp.

rename *oldpath newpath*
Renames remote file from *oldpath* to *newpath*.

rm *path*
Deletes remote file specified by *path*.

rmdir *path*
Removes remote directory specified by *path*.

symlink *oldpath newpath*
Creates a symbolic link from *oldpath* to *newpath*.

version
Displays the sftp protocol version.

[*comment*]
Include a comment. This is useful in batch files.

! [*command*]
If *command* is not specified, escapes to the local shell.

If *command* is specified, executes *command* in the local shell.

?
Displays help text.

Identical to the help command.

Exit Status The following exit values are returned:

0
Successful completion.

>0
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	Committed

See Also [ftp\(1\)](#), [scp\(1\)](#), [ssh\(1\)](#), [ssh-add\(1\)](#), [ssh-keygen\(1\)](#), [sshd\(1M\)](#), [attributes\(5\)](#)

Name sh, jsh – standard and job control shell and command interpreter

Synopsis /usr/sunos/bin/sh [-acefhiknrstuvx] [*argument*]...

/usr/xpg4/bin/sh [± abCefhikmnoqrstuvx]
[± o *option*]... [-c *string*] [*arg*]...

/usr/sunos/bin/jsh [-acefhiknrstuvx] [*argument*]...

Description The /usr/sunos/bin/sh utility is a command programming language that executes commands read from a terminal or a file.

The /usr/xpg4/bin/sh utility is a standards compliant shell. This utility provides all the functionality of [ksh88\(1\)](#), except in cases discussed in [ksh88\(1\)](#) where differences in behavior exist.

The jsh utility is an interface to the shell that provides all of the functionality of sh and enables job control (see Job Control section below).

Note – /usr/bin/sh and /usr/bin/jsh are links to [ksh93](#). See [ksh93\(1\)](#).

Arguments to the shell are listed in the Invocation section below.

Definitions A *blank* is a tab or a space. A *name* is a sequence of ASCII letters, digits, or underscores, beginning with a letter or an underscore. A *parameter* is a name, a digit, or any of the characters *, @, #, ?, -, \$, and !.

Usage

Commands A *simple-command* is a sequence of non-blank *words* separated by *blanks*. The first *word* specifies the name of the command to be executed. Except as specified below, the remaining *words* are passed as arguments to the invoked command. The command name is passed as argument 0 (see [exec\(2\)](#)). The *value* of a *simple-command* is its exit status if it terminates normally, or (octal) 200+*status* if it terminates abnormally. See [signal.h\(3HEAD\)](#) for a list of status values.

A *pipeline* is a sequence of one or more *commands* separated by |. The standard output of each *command* but the last is connected by a [pipe\(2\)](#) to the standard input of the next *command*. Each *command* is run as a separate process. The shell waits for the last *command* to terminate. The exit status of a *pipeline* is the exit status of the last command in the *pipeline*.

A *list* is a sequence of one or more *pipelines* separated by ;, &, &&, or | |, and optionally terminated by ; or &. Of these four symbols, ; and & have equal precedence, which is lower than that of && and | |. The symbols && and | | also have equal precedence. A semicolon (;) causes sequential execution of the preceding *pipeline*, that is, the shell waits for the *pipeline* to finish before executing any commands following the semicolon. An ampersand (&) causes asynchronous execution of the preceding pipeline, that is, the shell does *not* wait for that pipeline to finish. The symbol && (| |) causes the *list* following it to be executed only if the preceding pipeline returns a zero (non-zero) exit status. An arbitrary number of newlines can appear in a *list*, instead of semicolons, to delimit commands.

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last *simple-command* executed in the command.

`for name [in word . . .] do list done` Each time a `for` command is executed, *name* is set to the next *word* taken from the `in word` list. If `in word . . .` is omitted, then the `for` command executes the `do list` once for each positional parameter that is set (see Parameter Substitution section below). Execution ends when there are no more words in the list.

`case word in [pattern [| pattern]) list ; ;] . . . esac`

A `case` command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see File Name Generation section), except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.

`if list ; then list elif list ; then list ;] . . . [else list ;] fi`

The *list* following `if` is executed and, if it returns a zero exit status, the *list* following the first `then` is executed. Otherwise, the *list* following `elif` is executed and, if its value is zero, the *list* following the next `then` is executed. Failing that, the `else list` is executed. If no `else list` or `then list` is executed, then the `if` command returns a zero exit status.

`while list do list done` A `while` command repeatedly executes the `while list` and, if the exit status of the last command in the list is zero, executes the `do list`; otherwise the loop terminates. If no commands in the `do list` are executed, then the `while` command returns a zero exit status; `until` can be used in place of `while` to negate the loop termination test.

`(list)` Execute *list* in a sub-shell.

`{ list ; }` *list* is executed in the current (that is, parent) shell. The `{` must be followed by a space.

`name () { list ; }` Define a function which is referenced by *name*. The body of the function is the *list* of commands between `{` and `}`. The `{` must be followed by a space. Execution of functions is described below (see Execution section). The `{` and `}` are unnecessary if the body of the function is a *command* as defined above, under Commands.

The following words are only recognized as the first word of a command and when not quoted:

`if then else elif fi case esac for while until do done { }`

Comments Lines A word beginning with `#` causes that word and all the following characters up to a newline to be ignored.

Command Substitution The shell reads commands from the string between two grave accents (“”) and the standard output from these commands can be used as all or part of a word. Trailing newlines from the standard output are removed.

No interpretation is done on the string before the string is read, except to remove backslashes (\) used to escape other characters. Backslashes can be used to escape a grave accent (‘) or another backslash (\) and are removed before the command string is read. Escaping grave accents allows nested command substitution. If the command substitution lies within a pair of double quotes (“ . . . ‘ . . . ‘ . . . ”), a backslash used to escape a double quote (\”) is removed. Otherwise, it is left intact.

If a backslash is used to escape a newline character (\newline), both the backslash and the newline are removed (see the later section on Quoting). In addition, backslashes used to escape dollar signs (\\$) are removed. Since no parameter substitution is done on the command string before it is read, inserting a backslash to escape a dollar sign has no effect. Backslashes that precede characters other than \, ‘, “, newline, and \$ are left intact when the command string is read.

Parameter Substitution The character \$ is used to introduce substitutable *parameters*. There are two types of parameters, positional and keyword. If *parameter* is a digit, it is a positional parameter. Positional parameters can be assigned values by set. Keyword parameters (also known as variables) can be assigned values by writing:

```
name=value [ name=value ] . . .
```

Pattern-matching is not performed on *value*. There cannot be a function and a variable with the same *name*.

`${parameter}` The value, if any, of the parameter is substituted. The braces are required only when *parameter* is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If *parameter* is * or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.

`${parameter:-word}` Use Default Values. If *parameter* is unset or null, the expansion of *word* is substituted; otherwise, the value of *parameter* is substituted.

`${parameter:=word}` Assign Default Values. If *parameter* is unset or null, the expansion of *word* is assigned to *parameter*. In all cases, the final value of *parameter* is substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.

`${parameter:?word}` If *parameter* is set and is non-null, substitute its value; otherwise, print *word* and exit from the shell. If *word* is omitted, the message “parameter null or not set” is printed.

`${parameter:+word}` If *parameter* is set and is non-null, substitute *word*; otherwise substitute nothing.

In the above, *word* is not evaluated unless it is to be used as the substituted string, so that, in the following example, `pwd` is executed only if `d` is not set or is null:

```
echo ${d:-'pwd'}
```

If the colon (`:`) is omitted from the above expressions, the shell only checks whether *parameter* is set or not.

The following parameters are automatically set by the shell.

- # The number of positional parameters in decimal.
- Flags supplied to the shell on invocation or by the `set` command.
- ? The decimal value returned by the last synchronously executed command.
- \$ The process number of this shell.
- ! The process number of the last background command invoked.

The following parameters are used by the shell. The parameters in this section are also referred to as environment variables.

HOME	The default argument (home directory) for the <code>cd</code> command, set to the user's login directory by login(1) from the password file (see passwd(4)).
PATH	The search path for commands (see Execution section below).
CDPATH	The search path for the <code>cd</code> command.
MAIL	If this parameter is set to the name of a mail file <i>and</i> the <code>MAILPATH</code> parameter is not set, the shell informs the user of the arrival of mail in the specified file.
MAILCHECK	This parameter specifies how often (in seconds) the shell checks for the arrival of mail in the files specified by the <code>MAILPATH</code> or <code>MAIL</code> parameters. The default value is <code>600</code> seconds (10 minutes). If set to <code>0</code> , the shell checks before each prompt.
MAILPATH	A colon-separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified files. Each file name can be followed by <code>%</code> and a message that is e printed when the modification time changes. The default message is, you have mail.
PS1	Primary prompt string, by default “ \$ ”.
PS2	Secondary prompt string, by default “ > ”.
IFS	Internal field separators, normally space, tab, and newline (see Blank Interpretation section).

SHACCT If this parameter is set to the name of a file writable by the user, the shell writes an accounting record in the file for each shell procedure executed.

SHELL When the shell is invoked, it scans the environment (see `Environment` section below) for this name.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sh`: `LC_CTYPE` and `LC_MESSAGES`.

The shell gives default values to `PATH`, `PS1`, `PS2`, `MAILCHECK`, and `IFS`. Default values for `HOME` and `MAIL` are set by `login(1)`.

Blank Interpretation After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in `IFS`) and split into distinct arguments where such characters are found. Explicit null arguments (`"` or `'`) are retained. Implicit null arguments (those resulting from *parameters* that have no values) are removed.

Input/Output Redirection A command's input and output can be redirected using a special notation interpreted by the shell. The following can appear anywhere in a *simple-command* or can precede or follow a *command* and are *not* passed on as arguments to the invoked command. *Note*: Parameter and command substitution occurs before *word* or *digit* is used.

`<word` Use file *word* as standard input (file descriptor 0).

`>word` Use file *word* as standard output (file descriptor 1). If the file does not exist, it is created; otherwise, it is truncated to zero length.

`>>word` Use file *word* as standard output. If the file exists, output is appended to it by first seeking to the EOF. Otherwise, the file is created.

`< >word` Open file *word* for reading and writing as standard input.

`<<[-]word` After parameter and command substitution is done on *word*, the shell input is read up to the first line that literally matches the resulting *word*, or to an EOF. If, however, the hyphen (`-`) is appended to `<<`:

1. leading tabs are stripped from *word* before the shell input is read (but after parameter and command substitution is done on *word*);
2. leading tabs are stripped from the shell input as it is read and before each line is compared with *word*; and
3. shell input is read up to the first line that literally matches the resulting *word*, or to an EOF.

If any character of *word* is quoted (see `Quoting` section later), no additional processing is done to the shell input. If no characters of *word* are quoted:

1. parameter and command substitution occurs;
2. (escaped) `\newLines` are removed; and

3. \ must be used to quote the characters \, \$, and '.

The resulting document becomes the standard input.

<&digit Use the file associated with file descriptor *digit* as standard input. Similarly for the standard output using >&digit.

<&- The standard input is closed. Similarly for the standard output using >&-.

If any of the above is preceded by a digit, the file descriptor which is associated with the file is that specified by the digit (instead of the default 0 or 1). For example:

```
... 2>&1
```

associates file descriptor 2 with the file currently associated with file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates redirections left-to-right. For example:

```
... 1>xxx 2>&1
```

first associates file descriptor 1 with file *xxx*. It associates file descriptor 2 with the file associated with file descriptor 1 (that is, *xxx*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and file descriptor 1 would be associated with file *xxx*.

Using the terminology introduced on the first page, under *Commands*, if a *command* is composed of several *simple commands*, redirection is evaluated for the entire *command* before it is evaluated for each *simple command*. That is, the shell evaluates redirection for the entire *list*, then each *pipeline* within the *list*, then each *command* within each *pipeline*, then each *list* within each *command*.

If a command is followed by &, the default standard input for the command is the empty file, /dev/null. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

File Name Generation Before a command is executed, each command *word* is scanned for the characters *, ?, and [. If one of these characters appears the word is regarded as a *pattern*. The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. The character . at the start of a file name or immediately following a /, as well as the character / itself, must be matched explicitly.

* Matches any string, including the null string.

? Matches any single character.

[...] Matches any one of the enclosed characters. A pair of characters separated by - matches any character lexically between the pair, inclusive. If the first character following the opening [is a !, any character not enclosed is matched.

Notice that all quoted characters (see below) must be matched explicitly in a filename.

Quoting The following characters have a special meaning to the shell and cause termination of a word unless quoted:

```
; & ( ) | ^ < > newline space tab
```

A character can be *quoted* (that is, made to stand for itself) by preceding it with a backslash (\) or inserting it between a pair of quote marks (' ' or ""). During processing, the shell can quote certain characters to prevent them from taking on a special meaning. Backslashes used to quote a single character are removed from the word before the command is executed. The pair `\newline` is removed from a word before command and parameter substitution.

All characters enclosed between a pair of single quote marks (' '), except a single quote, are quoted by the shell. Backslash has no special meaning inside a pair of single quotes. A single quote can be quoted inside a pair of double quote marks (for example, " ' "), but a single quote can not be quoted inside a pair of single quotes.

Inside a pair of double quote marks (""), parameter and command substitution occurs and the shell quotes the results to avoid blank interpretation and file name generation. If `$*` is within a pair of double quotes, the positional parameters are substituted and quoted, separated by quoted spaces (`"$1 $2 . . ."`). However, if `$@` is within a pair of double quotes, the positional parameters are substituted and quoted, separated by unquoted spaces (`"$1" "$2" . . .`). \ quotes the characters \, ' , (comma), and \$. The pair `\newline` is removed before parameter and command substitution. If a backslash precedes characters other than \, ' , (comma), \$, and newline, then the backslash itself is quoted by the shell.

Prompting When used interactively, the shell prompts with the value of PS1 before reading a command. If at any time a newline is typed and further input is needed to complete a command, the secondary prompt (that is, the value of PS2) is issued.

Environment The *environment* (see [environ\(5\)](#)) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a parameter for each name found, giving it the corresponding value. If the user modifies the value of any of these parameters or creates new parameters, none of these affects the environment unless the `export` command is used to bind the shell's parameter to the environment (see also `set -a`). A parameter can be removed from the environment with the `unset` command. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by `unset`, plus any modifications or additions, all of which must be noted in `export` commands.

The environment for any *simple-command* can be augmented by prefixing it with one or more assignments to parameters. Thus:

```
TERM=450 command
```

and

```
(export TERM; TERM=450;  command
```

are equivalent as far as the execution of *command* is concerned if *command* is not a Special Command. If *command* is a Special Command, then

```
TERM=450  command
```

modifies the TERM variable in the current shell.

If the -k flag is set, *all* keyword arguments are placed in the environment, even if they occur after the command name. The following example first prints a=b c and c:

```
echo a=b c
```

```
a=b c
```

```
set -k
```

```
echo a=b c
```

```
c
```

Signals The INTERRUPT and QUIT signals for an invoked command are ignored if the command is followed by &. Otherwise, signals have the values inherited by the shell from its parent, with the exception of signal 11 (but see also the trap command below).

Execution Each time a command is executed, the command substitution, parameter substitution, blank interpretation, input/output redirection, and filename generation listed above are carried out. If the command name matches the name of a defined function, the function is executed in the shell process (note how this differs from the execution of shell script files, which require a sub-shell for invocation). If the command name does not match the name of a defined function, but matches one of the Special Commands listed below, it is executed in the shell process.

The positional parameters \$1, \$2, . . . are set to the arguments of the function. If the command name matches neither a Special Command nor the name of a defined function, a new process is created and an attempt is made to execute the command via [exec\(2\)](#).

The shell parameter PATH defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The path to sh is /usr/sunos/bin. The current directory is specified by a null path name, which can appear immediately after the equal sign, between two colon delimiters anywhere in the path list, or at the end of the path list. If the command name contains a / the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an a.out file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. A parenthesized command is also executed in a sub-shell.

The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary *execs* later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the PATH variable is changed or the hash -r command is executed (see below).

Special Commands Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional Special Commands are added to the shell's environment (see Job Control section below).

:	No effect; the command does nothing. A zero exit code is returned.
. <i>filename</i>	Read and execute commands from <i>filename</i> and return. The search path specified by PATH is used to find the directory containing <i>filename</i> .
bg [% <i>jobid</i> . . .]	When Job Control is enabled, the bg command is added to the user's environment to manipulate jobs. Resumes the execution of a stopped job in the background. If % <i>jobid</i> is omitted the current job is assumed. (See Job Control section below for more detail.)
break [<i>n</i>]	Exit from the enclosing for or while loop, if any. If <i>n</i> is specified, break <i>n</i> levels.
cd [<i>argument</i>]	Change the current directory to <i>argument</i> . The shell parameter HOME is the default <i>argument</i> . The shell parameter CDPATH defines the search path for the directory containing <i>argument</i> . Alternative directory names are separated by a colon (:). The default path is <null> (specifying the current directory). <i>Note:</i> The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If <i>argument</i> begins with a / the search

<code>chdir [<i>dir</i>]</code>	<p>path is not used. Otherwise, each directory in the path is searched for <i>argument</i>.</p> <p><code>chdir</code> changes the shell's working directory to directory <i>dir</i>. If no argument is given, change to the home directory of the user. If <i>dir</i> is a relative pathname not found in the current directory, check for it in those directories listed in the CDPATH variable. If <i>dir</i> is the name of a shell variable whose value starts with a /, change to the directory named by that value.</p>
<code>continue [<i>n</i>]</code>	<p>Resume the next iteration of the enclosing <code>for</code> or <code>while</code> loop. If <i>n</i> is specified, resume at the <i>n</i>-th enclosing loop.</p>
<code>echo [<i>arguments</i> ...]</code>	<p>The words in <i>arguments</i> are written to the shell's standard output, separated by space characters. See echo(1) for fuller usage and description.</p>
<code>eval [<i>argument</i> ...]</code>	<p>The arguments are read as input to the shell and the resulting command(s) executed.</p>
<code>exec [<i>argument</i> ...]</code>	<p>The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments can appear and, if no other arguments are given, cause the shell input/output to be modified.</p>
<code>exit [<i>n</i>]</code>	<p>Causes the calling shell or shell script to exit with the exit status specified by <i>n</i>. If <i>n</i> is omitted the exit status is that of the last command executed (an EOF also causes the shell to exit.)</p>
<code>export [<i>name</i> ...]</code>	<p>The given <i>names</i> are marked for automatic export to the <i>environment</i> of subsequently executed commands.</p>

`fg [%jobid...]`

If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. (Variable names exported from a parent shell are listed only if they have been exported again during the current shell's execution.) Function names are *not* exported.

When Job Control is enabled, the `fg` command is added to the user's environment to manipulate jobs. This command resumes the execution of a stopped job in the foreground and also moves an executing background job into the foreground. If `%jobid` is omitted, the current job is assumed. (See `Job Control` section below for more detail.)

`getopts`

Use in shell scripts to support command syntax standards (see [Intro\(1\)](#)). This command parses positional parameters and checks for legal options. See [getoptcvt\(1\)](#) for usage and description.

`hash [-r] [name...]`

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The `-r` option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this are done are indicated

`jobs [-p|-l] [%jobid ...]`
`jobs -x command [arguments]`

by an asterisk (*) adjacent to the *hits* information. *Cost* is incremented when the recalculation is done.

Reports all jobs that are stopped or executing in the background. If *%jobid* is omitted, all jobs that are stopped or running in the background are reported. (See Job Control section below for more detail.)

`kill [-sig] %job ...`
`kill -l`

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in [signal.h\(3HEAD\)](#) stripped of the prefix “SIG” with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process is sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See Job Control section below for a description of the format of *job*. In the second form, `kill -l`, the signal numbers and names are listed. (See [kill\(1\)](#)).

`login [argument ...]`

Equivalent to ‘`exec login argument . . .`’. See [login\(1\)](#) for usage and description.

`newgrp [argument]`

Equivalent to `exec newgrp argument`. See [newgrp\(1\)](#) for usage and description.

`pwd`

Print the current working directory. See [pwd\(1\)](#) for usage and description.

`read name ...`

One line is read from the standard input and, using the internal field separator, IFS (normally space or tab),

readonly [*name* . . .]

return [*n*]

set [-aefhkntuvx [*argument* . . .]]

to delimit word boundaries, the first word is assigned to the first *name*, the second word to the second *name*, and so forth, with leftover words assigned to the last *name*. Lines can be continued using `\newLine`. Characters other than `newLine` can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to *names*, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an EOF is encountered.

The given *names* are marked `readonly` and the values of these *names* can not be changed by subsequent assignment. If no arguments are given, a list of all `readonly` names is printed.

Causes a function to exit with the return value specified by *n*. If *n* is omitted, the return status is that of the last command executed.

- a Mark variables which are modified or created for export.
- e Exit immediately if a command exits with a non-zero exit status.
- f Disable file name generation.
- h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).
- k All keyword arguments are placed in the environment for a

- command, not just those that precede the command name.
- n Read commands but do not execute them.
 - t Exit after reading and executing one command.
 - u Treat unset variables as an error when substituting.
 - v Print shell input lines as they are read.
 - x Print commands and their arguments as they are executed.
 - Do not change any of the flags; useful in setting \$1 to -.

Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags can be found in \$-. The remaining arguments are positional parameters and are assigned, in order, to \$1, \$2, . . . If no arguments are given, the values of all names are printed.

<code>shift [n]</code>	The positional parameters from \$ <i>n</i> +1 . . . are renamed \$1 . . . If <i>n</i> is not given, it is assumed to be 1.
<code>stop pid . . .</code>	Halt execution of the process number <i>pid</i> . (see ps(1)).
<code>suspend</code>	Stops the execution of the current shell (but not if it is the login shell).
<code>test</code>	Evaluate conditional expressions. See test(1) for usage and description.
<code>times</code>	Print the accumulated user and system times for processes run from the shell.

```
trap [ argument n [ n2 . . . ]
```

The command *argument* is to be read and executed when the shell receives numeric or symbolic signal(s) (*n*). (*Note: argument* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If *argument* is absent, all trap(s) *n* are reset to their original values. If *argument* is the null string, this signal is ignored by the shell and by the commands it invokes. If *n* is 0, the command *argument* is executed on exit from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.

```
type [ name . . . ]
```

For each *name*, indicate how it would be interpreted if used as a command name.

```
ulimit [ [-HS] [-a | -cdfnstv] ]
ulimit [ [-HS] [-c | -d | -f | -n | -s | -t | -v] ] limit
```

`ulimit` prints or sets hard or soft resource limits. These limits are described in [getrlimit\(2\)](#).

If *limit* is not present, `ulimit` prints the specified limits. Any number of limits can be printed at one time. The `-a` option prints all limits.

If *limit* is present, `ulimit` sets the specified limit to *limit*. The string `unlimited` requests that the current limit, if any, be removed. Any user can set a soft limit to any value less than or equal to the hard limit. Any user can lower a hard limit. Only a user with

appropriate privileges can raise or remove a hard limit. See [getrlimit\(2\)](#).

The `-H` option specifies a hard limit. The `-S` option specifies a soft limit. If neither option is specified, `ulimit` sets both limits and print the soft limit.

The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.

- `-c` maximum core file size (in 512-byte blocks)
- `-d` maximum size of data segment or heap (in kbytes)
- `-f` maximum file size (in 512-byte blocks)
- `-n` maximum file descriptor plus 1
- `-s` maximum size of stack segment (in kbytes)
- `-t` maximum CPU time (in seconds)
- `-v` maximum size of virtual memory (in kbytes)

Run the [sysdef\(1M\)](#) command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the [bc\(1\)](#) utility. See [swap\(1M\)](#).)

As an example of `ulimit`, to limit the size of a core file dump to 0 Megabytes, type the following:

```
ulimit -c 0
```

<code>umask [<i>nnn</i>]</code>	The user file-creation mask is set to <i>nnn</i> (see <code>umask(1)</code>). If <i>nnn</i> is omitted, the current value of the mask is printed.
<code>unset [<i>name...</i>]</code>	For each <i>name</i> , remove the corresponding variable or function value. The variables <code>PATH</code> , <code>PS1</code> , <code>PS2</code> , <code>MAILCHECK</code> , and <code>IFS</code> cannot be unset.
<code>wait [<i>n</i>]</code>	Wait for your background process whose process id is <i>n</i> and report its termination status. If <i>n</i> is omitted, all your shell's currently active background processes are waited for and the return code is zero.

Invocation If the shell is invoked through `exec(2)` and the first character of argument zero is `-`, commands are initially read from `/etc/profile` and from `$HOME/.profile`, if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as `/usr/sunos/bin/sh`. The flags below are interpreted by the shell on invocation only. *Note:* Unless the `-c` or `-s` flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional parameters to that command file:

- `-c string` If the `-c` flag is present commands are read from *string*.
- `-i` If the `-i` flag is present or if the shell input and output are attached to a terminal, this shell is *interactive*. In this case, `TERMINATE` is ignored (so that `kill 0` does not kill an interactive shell) and `INTERRUPT` is caught and ignored (so that `wait` is interruptible). In all cases, `QUIT` is ignored by the shell.
- `-p` If the `-p` flag is present, the shell does not set the effective user and group IDs to the real user and group IDs.
- `-r` If the `-r` flag is present the shell is a restricted shell (see `rsh(1M)`).
- `-s` If the `-s` flag is present or if no arguments remain, commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output (except for Special Commands) is written to file descriptor 2.

The remaining flags and arguments are described under the `set` command above.

Job Control (jsh) When the shell is invoked as `jsh`, Job Control is enabled in addition to all of the functionality described previously for `sh`. Typically, Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.

With Job Control enabled, every command or pipeline the user enters at the terminal is called a *job*. All jobs exist in one of the following states: foreground, background, or stopped. These terms are defined as follows:

1. A job in the foreground has read and write access to the controlling terminal.
2. A job in the background is denied read access and has conditional write access to the controlling terminal (see [stty\(1\)](#)).
3. A stopped job is a job that has been placed in a suspended state, usually as a result of a SIGTSTP signal (see [signal.h\(3HEAD\)](#)).

Every job that the shell starts is assigned a positive integer, called a *job number* which is tracked by the shell and is used as an identifier to indicate a specific job. Additionally, the shell keeps track of the *current* and *previous* jobs. The *current job* is the most recent job to be started or restarted. The *previous job* is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

`%jobid`

where *jobid* can be specified in any of the following formats:

- | | |
|--------------------|--|
| % or + | For the current job. |
| - | For the previous job. |
| ?< <i>string</i> > | Specify the job for which the command line uniquely contains <i>string</i> . |
| <i>n</i> | For job number <i>n</i> . |
| <i>pref</i> | Where <i>pref</i> is a unique prefix of the command name. For example, if the command <code>ls -l <i>name</i></code> were running in the background, it could be referred to as <code>%<i>ls</i></code> . <i>pref</i> cannot contain blanks unless it is quoted. |

When Job Control is enabled, the following commands are added to the user's environment to manipulate jobs:

- | | |
|--|--|
| <code>bg [<i>jobid</i> . . .]</code> | Resumes the execution of a stopped job in the background. If <i>jobid</i> is omitted the current job is assumed. |
| <code>fg [<i>jobid</i> . . .]</code> | Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If <i>jobid</i> is omitted the current job is assumed. |
| <code>jobs [-p -l] [<i>jobid</i> . . .]</code>
<code>jobs -x <i>command</i></code>
<code>[<i>arguments</i>]</code> | Reports all jobs that are stopped or executing in the background. If <i>jobid</i> is omitted, all jobs that are stopped or running in the background is reported. The following options modify/enhance the output of <code>jobs</code> : |

- l Report the process group ID and working directory of the jobs.
- p Report only the process group ID of the jobs.
- x Replace any *jobid* found in *command* or *arguments* with the corresponding process group ID, and then execute *command* passing it *arguments*.

`kill [-signal] %jobid` Builtin version of `kill` to provide the functionality of the `kill` command for processes identified with a *jobid*.

`stop %jobid . . .` Stops the execution of a background job(s).

`suspend` Stops the execution of the current shell (but not if it is the login shell).

`wait [%jobid . . .]` `wait` builtin accepts a job identifier. If *%jobid* is omitted `wait` behaves as described above under Special Commands.

Large File Behavior See [largefile\(5\)](#) for the description of the behavior of `sh` and `jsh` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above).

jsh Only If the shell is invoked as `jsh` and an attempt is made to exit the shell while there are stopped jobs, the shell issues one warning:

There are stopped jobs.

This is the only message. If another exit attempt is made, and there are still stopped jobs they are sent a `SIGHUP` signal from the kernel and the shell is exited.

Files `$HOME/.profile`

`/dev/null`

`/etc/profile`

`/tmp/sh*`

Warnings The use of setuid shell scripts is *strongly* discouraged.

Notes Words used for filenames in input/output redirection are not interpreted for filename generation (see File Name Generation section above). For example, `cat file1 >a*` creates a file named `a*`.

Because commands in pipelines are run as separate processes, variables set in a pipeline have no effect on the parent shell.

If the input or the output of a `while` or `until` loop is redirected, the commands in the loop are run in a sub-shell, and variables set or changed there have no effect on the parent process:

```
lastline=
while read line
do

    lastline=$line
done < /etc/passwd
echo "lastline=$lastline"      # lastline is empty!
```

In these cases, the input or output can be redirected by using `exec`, as in the following example:

```
# Save standard input (file descriptor 0) as file
# descriptor 3, and redirect standard input from the file
/etc/passwd:

exec 3<&0                # save standard input as fd 3
exec </etc/passwd       # redirect input from file

lastline=
```

```
while read line
do
    lastline=$line
done

exec 0<&3          # restore standard input
exec 3<&-         # close file descriptor 3
echo "$lastline" # lastline
```

If you get the error message, “cannot fork, too many processes”, try using the [wait\(1\)](#) command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.

Only the last process in a pipeline can be waited for.

If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell continues to exec the original command. Use the `hash` command to correct this situation.

The Bourne shell has a limitation on the effective UID for a process. If this UID is less than 100 (and not equal to the real UID of the process), then the UID is reset to the real UID of the process.

Because the shell implements both foreground and background jobs in the same process group, they all receive the same signals, which can lead to unexpected behavior. It is, therefore, recommended that other job control shells be used, especially in an interactive environment.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

Name shcomp – compile a ksh shell script

Synopsis shcomp [-nv] [*infile* [*outfile*]]

shcomp -D [*infile* [*outfile*]]

Description If the -D option is not specified, shcomp takes a shell script, *infile*, and creates a binary format file, *outfile*, that ksh reads and executes with the same effect as the original script.

Aliases are processed as the script is read. Alias definitions whose value requires variable expansion will not work correctly.

Options The following options are supported:

-D

--dictionary Generate a list of strings that need to be placed in a message catalog for internationalization.

With this option, all double quoted strings that are preceded by \$ are printed, one literal per line. A literal "\$foo" prints "foo" in the output. These are the messages that need to be translated to locale specific versions for internationalization.

-n

--noexec Display warning messages for obsolete or non-conforming constructs.

-v

--verbose Display input from *infile* onto standard error as it reads it.

Operands The following operands are supported:

infile Specifies the name of the file that contains the shell script to be used as input.

If *infile* is omitted, the shell script is read from standard input.

outfile Specifies the name of the output file.

If *outfile* is omitted, both modes write their results to standard output.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled
Interface Stability	See below.

The command-line interface and the system variables are Committed. The compiled shell code format is Private. The output of the -D option is Volatile.

See Also [ksh\(1\)](#), [attributes\(5\)](#)

Name shell_builtins, case, for, foreach, function, if, repeat, select, switch, until, while – shell command interpreter built-in commands

Description The shell command interpreters [csh\(1\)](#), [ksh\(1\)](#), [ksh88\(1\)](#), and [sh\(1\)](#) have special built-in commands. The commands `case`, `for`, `foreach`, `function`, `if`, `repeat`, `select`, `switch`, `until`, and `while` are commands in the syntax recognized by the shells. They are described in the `Commands` section of the manual pages of the respective shells. In [ksh\(1\)](#), `fc`, `hash`, `stop`, `suspend`, `times`, and `type` are aliases by default.

The remaining commands listed in the following table are built into the shells for reasons such as efficiency or data sharing between command invocations. They are described on their respective manual pages.

Command	Shell
<code>alarm</code>	<code>ksh</code>
<code>+++alias</code>	<code>csh</code> , <code>ksh88</code> , <code>ksh</code>

Bourne Shell, sh,
Special Commands

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional *Special Commands* are added to the shell's environment.

In addition to these built-in reserved command words, sh also uses:

- : No effect; the command does nothing. A zero exit code is returned.
- .*filename* Read and execute commands from *filename* and return. The search path specified by PATH is used to find the directory containing *filename*.

C shell, csh

Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell. In addition to these built-in reserved command words, csh also uses:

- : Null command. This command is interpreted, but performs no action.

Korn Shell, ksh88,
Special Commands

Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero.

Commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

In addition to these built-in reserved command words, ksh88 also uses:

- * : [*arg* . . .] The command only expands parameters.

* *.file* [*arg* . . .] Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing *file*. If any arguments *arg* are specified, they become the positional parameters. Otherwise, the positional parameters are unchanged. The exit status is the exit status of the last command executed. the loop termination test.

Korn Shell, ksh, Special Commands Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero.

Except for `:`, `true`, `false`, `echo`, `newgrp`, and `login`, all built-in commands accept `--` to indicate end of options. They also interpret the option `--man` as a request to display the manual page onto standard error and `--?` as a help request which prints a usage message on standard error.

Commands that are preceded by one or two `+` are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. They are not valid function names.
5. Words, following a command preceded by `++` that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the `=` sign and field splitting and file name generation are not performed.

In addition to these built-in reserved command words, ksh also uses:

`:` [*arg* . . .] The command only expands parameters.

`.name` [*arg* . . .] If *name* is a function defined with the function *name* reserved word syntax, the function is executed in the current environment (as if it had been defined with the `name()` syntax.) Otherwise if *name* refers to a file, the file is read in its entirety and the commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing the file. If any arguments *arg* are specified, they become the positional parameters while processing the `.` command and the original positional parameters are restored upon completion. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.

Name shift – shell built-in function to traverse either a shell's argument list or a list of field-separated words

Synopsis

sh shift [*n*]

csh shift [*variable*]

ksh88 *shift [*n*]

ksh88 +shift [*n*]

Description

sh The positional parameters from $\$n+1$. . . are renamed $\$1$ If *n* is not specified, it is assumed to be 1.

csh The components of *argv*, or *variable*, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.

ksh88 The positional parameters from $\$n+1$ $\$n+1$. . . are renamed $\$1$. . . , default *n* is 1. The parameter *n* can be any arithmetic expression that evaluates to a non-negative number less than or equal to $\$#$.

On this manual page, [ksh88\(1\)](#) commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ksh shift is a shell special built-in that shifts the positional parameters to the left by the number of places defined by *n*, or 1 if *n* is omitted. The number of positional parameters remaining is reduced by the number of places that are shifted.

If *n* is specified, it is evaluated as an arithmetic expression to determine the number of places to shift. It is an error to shift more than the number of positional parameters or a negative number of places.

The following exit values are returned by shift in ksh:

- 0 Successful completion. The positional parameters were successfully shifted.

>0 An error occurred.

On this manual page, [ksh\(1\)](#) commands that are preceded by one or two + are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. They are not valid function names.
5. Words, following a command preceded by ++ that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and field splitting and file name generation are not performed.

Name shutdown – close down the system at a given time

Synopsis /usr/ucb/shutdown [-fhknr] *time* [*warning-message*]. . .

Description shutdown provides an automated procedure to notify users when the system is to be shut down. *time* specifies when shutdown will bring the system down; it may be the word *now* (indicating an immediate shutdown), or it may specify a future time in one of two formats: *+number* and *hour:min*. The first form brings the system down in *number* minutes, and the second brings the system down at the time of day indicated in 24-hour notation.

At intervals that get closer as the apocalypse approaches, warning messages are displayed at terminals of all logged-in users, and of users who have remote mounts on that machine.

At shutdown time a message is written to the system log daemon, [syslogd\(1M\)](#), containing the time of shutdown, the instigator of the shutdown, and the reason. Then a terminate signal is sent to `init`, which brings the system down to single-user mode.

Options As an alternative to the above procedure, these options can be specified:

- f Arrange, in the manner of [fastboot\(1B\)](#), that when the system is rebooted, the file systems will not be checked.
- h Execute [halt\(1M\)](#).
- k Simulate shutdown of the system. Do not actually shut down the system.
- n Prevent the normal [sync\(2\)](#) before stopping.
- r Execute [reboot\(1M\)](#).

Files /etc/rmtab remote mounted file system table

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

See Also [fastboot\(1B\)](#), [login\(1\)](#), [halt\(1M\)](#), [reboot\(1M\)](#), [syslogd\(1M\)](#), [sync\(2\)](#), [rmtab\(4\)](#), [attributes\(5\)](#)

Notes Only allows you to bring the system down between now and 23:59 if you use the absolute time for shutdown.

Name size – print section sizes in bytes of object files

Synopsis size [-f] [-F] [-n] [-o] [-V] [-x] *filename...*

Description The `size` command produces segment or section size information in bytes for each loaded section in ELF object files. `size` prints out the size of the text, data, and bss (uninitialized data) segments (or sections) and their total.

`size` processes ELF object files entered on the command line. If an archive file is input to the `size` command, the information for each object file in the archive is displayed.

When calculating segment information, the `size` command prints out the total file size of the non-writable segments, the total file size of the writable segments, and the total memory size of the writable segments minus the total file size of the writable segments.

If it cannot calculate segment information, `size` calculates section information. When calculating section information, it prints out the total size of sections that are allocatable, non-writable, and not NOBITS, the total size of the sections that are allocatable, writable, and not NOBITS, and the total size of the writable sections of type NOBITS. NOBITS sections do not actually take up space in the *filename*.

If `size` cannot calculate either segment or section information, it prints an error message and stops processing the file.

Options The following options are supported:

- f Prints out the size of each allocatable section, the name of the section, and the total of the section sizes. If there is no section data, `size` prints out an error message and stops processing the file.
- F Prints out the size of each loadable segment, the permission flags of the segment, then the total of the loadable segment sizes. If there is no segment data, `size` prints an error message and stops processing the file.
- n Prints out non-loadable segment or non-allocatable section sizes. If segment data exists, `size` prints out the memory size of each loadable segment or file size of each non-loadable segment, the permission flags, and the total size of the segments. If there is no segment data, `size` prints out, for each allocatable and non-allocatable section, the memory size, the section name, and the total size of the sections. If there is no segment or section data, `size` prints an error message and stops processing.
- o Prints numbers in octal, not decimal.
- V Prints the version information for the `size` command on the standard error output.
- x Prints numbers in hexadecimal, not decimal.

Examples The examples below are typical `size` output.

EXAMPLE 1 Producing size information

```
example% size filename
2724 + 88 + 0 = 2812
```

EXAMPLE 2 Producing allocatable section size information

```
example% size -f filename
26(.text) + 5(.init) + 5(.fini) = 36
```

EXAMPLE 3 Producing loadable segment size information

```
example% size -F filename
2724(r-x) + 88(rwx) + 0(rwx) = 2812 ... (If statically linked)
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/base-developer-utilities

See Also [as\(1\)](#), [ld\(1\)](#), [ar.h\(3HEAD\)](#), [a.out\(4\)](#), [attributes\(5\)](#)

Notes Since the size of bss sections is not known until link-edit time, the `size` command will not give the true total size of pre-linked objects.

Name sleep – suspend execution for an interval

Synopsis /usr/bin/sleep *interval*[d|h|m|s]...

Description sleep suspends execution for at least the time in seconds specified by *seconds* or until a SIGALRM signal is received. The *seconds* operand can be specified as a floating point number but the actual granularity normally depends on the underlying system.

Operands *interval* A floating-point number specifying the time for which to suspend execution. The floating-point number may be specified in all formats required by C99/XPG6, including constants such as `Inf` or `infinite`. One of four suffixes may optionally be specified, indicating the number specified is days (d), hours (h), minutes (m), or seconds (s). With no suffix, the interval is assumed to be seconds. If multiple intervals are specified they are summed together. Individual intervals may be negative but the sum must be greater than or equal to zero.

Examples EXAMPLE 1 Suspending Command Execution

The following example executes a command after a certain amount of time:

```
example% (sleep 105; command)&
```

EXAMPLE 2 Executing a Command Every So Often

The following example executes a command every so often:

```
example% while true
do
    command
    sleep 37
done
```

EXAMPLE 3 Suspending Command Execution Forever

The following example suspends command execution forever or until a SIGALRM signal is received:

```
example% sleep Inf
```

EXAMPLE 4 Suspending Command Execution for 0.5 Seconds

Suspending command execution for 0.5 seconds using an alternative floating-point representation for the value 0.5:

```
example% printf "%a\n" 0.5
0x1.00000000000000000000000000000000p-01
example% sleep 0x1.00000000000000000000000000000000p-01
```

EXAMPLE 5 Suspending Execution for 23 Hours

The following example suspends execution for twenty three hours using a letter suffixes:

```
example% sleep 1d -1h
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `sleep`: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 The execution was successfully suspended for at least *time* seconds, or a SIGALRM signal was received (see NOTES).
- >0 An error has occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Standard	See standards(5) .

See Also [wait\(1\)](#), [alarm\(2\)](#), [sleep\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes If the `sleep` utility receives a SIGALRM signal, one of the following actions is taken:

- Terminate normally with a zero exit status.
- Effectively ignore the signal.

The `sleep` utility takes the standard action for all other signals.

Name soelim – resolve and eliminate .so requests from nroff or troff input

Synopsis soelim [*filename*]. . .

Description soelim reads the specified files or the standard input and performs the textual inclusion implied by the [nroff\(1\)](#) directives of the form:

```
.so somefile
```

when they appear at the beginning of input lines.

This is useful as programs such as [tbl\(1\)](#) do not normally do this. It allows the placement of individual tables in separate files to be run as a part of a large document.

An argument consisting of – is taken to be a file name corresponding to the standard input.

Inclusion can be suppressed by using a single quote (') instead of a dot (.) that is,

```
' so /usr/share/lib/tmac/tmac.s
```

Examples **EXAMPLE 1** Using the soelim Command

The following is an example of the soelim command:

```
example% soelim exum?.n | tbl | nroff -ms | col | lpr
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools

See Also [more\(1\)](#), [nroff\(1\)](#), [tbl\(1\)](#), [attributes\(5\)](#)

Name sort – sort, merge, or sequence check text files

Synopsis /usr/bin/sort [-bcdfimMnru] [-k *keydef*] [-o *output*]
 [-S *kmem*] [-t *char*] [-T *directory*]
 [+*pos1* [-*pos2*]] [*file*]...

/usr/xpg4/bin/sort [-bcdfimMnru] [-k *keydef*] [-o *output*]
 [-S *kmem*] [-t *char*] [-T *directory*] [-y [*kmem*]]
 [-z *recsz*] [+*pos1* [-*pos2*]] [*file*]...

Description The `sort` command sorts lines of all the named files together and writes the result on the standard output.

Comparisons are based on one or more sort keys extracted from each line of input. By default, there is one sort key, the entire input line. Lines are ordered according to the collating sequence of the current locale.

Options The following options alter the default behavior:

/usr/bin/sort	-c	Checks that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. The exit code is set and no output is produced unless the file is out of sort.
/usr/xpg4/bin/sort	-c	Same as /usr/bin/sort except no output is produced under any circumstances.
	-y <i>kmem</i>	(obsolete). This option was used to specify the amount of main memory initially used by sort. Its functionality is not appropriate for a virtual memory system; memory usage for sort is now specified using the -S option.
	-z <i>recsz</i>	(obsolete). This option was used to prevent abnormal termination when lines longer than the system-dependent default buffer size are encountered. Because sort automatically allocates buffers large enough to hold the longest line, this option has no effect.
/usr/bin/sort and /usr/xpg4/bin/sort	-m	Merges only. The input files are assumed to be already sorted.
	-o <i>output</i>	Specifies the name of an output file to be used instead of the standard output. This file can be the same as one of the input files.
	-S <i>kmem</i>	Specifies the maximum amount of swap-based memory used for sorting, in kilobytes (the default unit). <i>kmem</i> can also be specified directly as a number of bytes (b), kilobytes (k), megabytes (m), gigabytes (g), or terabytes (t); or as a percentage (%) of the installed physical memory.
	-T <i>directory</i>	Specifies the <i>directory</i> in which to place temporary files.
	-u	Unique: suppresses all but one in each set of lines having equal keys. If used with the -c option, checks that there are no lines with duplicate keys in addition to checking that the input file is sorted.

Ordering Options The default sort order depends on the value of `LC_COLLATE`. If `LC_COLLATE` is set to `C`, sorting is in ASCII order. If `LC_COLLATE` is set to `en_US`, sorting is case insensitive except when the two strings are otherwise equal and one has an uppercase letter earlier than the other. Other locales have other sort orders.

The following options override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules are applied globally to all sort keys. When attached to a specific key (see `Sort Key Options`), the specified ordering options override all global ordering options for that key. In the obsolescent forms, if one or more of these options follows a `+pos1` option, it affects only the key field specified by that preceding option.

- d Dictionary order: only letters, digits, and blanks (spaces and tabs) are significant in comparisons.
- f Folds lower-case letters into upper case.
- i Ignores non-printable characters.
- M Compares as months. The first three non-blank characters of the field are folded to upper case and compared. For example, in English the sorting order is "JAN" < "FEB" < . . . < "DEC". Invalid fields compare low to "JAN". The `-M` option implies the `-b` option (see below).
- n Restricts the sort key to an initial numeric string, consisting of optional blank characters, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which is sorted by arithmetic value. An empty digit string is treated as zero. Leading zeros and signs on zeros do not affect ordering.
- r Reverses the sense of comparisons.

Field Separator Options The treatment of field separators can be altered using the following options:

- b Ignores leading blank characters when determining the starting and ending positions of a restricted sort key. If the `-b` option is specified before the first sort key option, it is applied to all sort key options. Otherwise, the `-b` option can be attached independently to each `-k field_start,field_end`, or `+pos1` or `-pos2` option-argument (see below).
- t *char* Use *char* as the field separator character. *char* is not considered to be part of a field (although it can be included in a sort key). Each occurrence of *char* is significant (for example, `<char><char>` delimits an empty field). If `-t` is not specified, blank characters are used as default field separators; each maximal non-empty sequence of blank characters that follows a non-blank character is a field separator.

Sort Key Options Sort keys can be specified using the options:

-k *keydef*

The *keydef* argument is a restricted sort key field definition. The format of this definition is:

```
-k field_start [type] [,field_end [type] ]
```

where:

field_start and *field_end*

define a key field restricted to a portion of the line.

type

is a modifier from the list of characters `bdfiMnr`. The `b` modifier behaves like the `-b` option, but applies only to the *field_start* or *field_end* to which it is attached and characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.) The other modifiers behave like the corresponding options, but apply only to the key field to which they are attached. They have this effect if specified with *field_start*, *field_end* or both. If any modifier is attached to a *field_start* or to a *field_end*, no option applies to either.

When there are multiple key fields, later keys are compared only after all earlier keys compare equal. Except when the `-u` option is specified, lines that otherwise compare equal are ordered as if none of the options `-d`, `-f`, `-i`, `-n` or `-k` were present (but with `-r` still in effect, if it was specified) and with all bytes in the lines significant to the comparison.

The notation:

```
-k field_start[type][,field_end[type]]
```

defines a key field that begins at *field_start* and ends at *field_end* inclusive, unless *field_start* falls beyond the end of the line or after *field_end*, in which case the key field is empty. A missing *field_end* means the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option `-t`, any preceding field separator.

The *field_start* portion of the *keydef* option-argument has the form:

```
field_number[.first_character]
```

Fields and characters within fields are numbered starting with 1. *field_number* and *first_character*, interpreted as positive decimal integers, specify the first character to be used as part of a sort key. If *first_character* is omitted, it refers to the first character of the field.

The *field_end* portion of the *keydef* option-argument has the form:

```
field_number[.last_character]
```

The *field_number* is as described above for *field_start*. *last_character*, interpreted as a non-negative decimal integer, specifies the last character to be used as part of the sort key. If *last_character* evaluates to zero or *.last_character* is omitted, it refers to the last character of the field specified by *field_number*.

If the *-b* option or *b* type modifier is in effect, characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.)

[*+pos1* [*-pos2*]] (obsolete). Provide functionality equivalent to the *-keydef* option.

pos1 and *pos2* each have the form *m.n* optionally followed by one or more of the flags *bdfiMnr*. A starting position specified by *+m.n* is interpreted to mean the *n*+1st character in the *m*+1st field. A missing *.n* means *.0*, indicating the first character of the *m*+1st field. If the *b* flag is in effect *n* is counted from the first non-blank in the *m*+1st field; *+m.0b* refers to the first non-blank character in the *m*+1st field.

A last position specified by *-m.n* is interpreted to mean the *n*th character (including separators) after the last character of the *m*th field. A missing *.n* means *.0*, indicating the last character of the *m*th field. If the *b* flag is in effect *n* is counted from the last leading blank in the *m*+1st field; *-m.1b* refers to the first non-blank in the *m*+1st field.

The fully specified *+pos1 -pos2* form with type modifiers *T* and *U*:

```
+w.xT -y.zU
```

is equivalent to:

```
undefined (z==0 & U contains b & -t is present)
-k w+1.x+1T,y.0U      (z==0 otherwise)
-k w+1.x+1T,y+1.zU   (z > 0)
```

Implementations support at least nine occurrences of the sort keys (the *-k* option and obsolescent *+pos1* and *-pos2*) which are significant in command line order. If no sort key is specified, a default sort key of the entire line is used.

Operands The following operand is supported:

file A path name of a file to be sorted, merged or checked. If no *file* operands are specified, or if a *file* operand is *-*, the standard input is used.

Usage See [largefile\(5\)](#) for the description of the behavior of *sort* when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples In the following examples, first the preferred and then the obsolete way of specifying sort keys are given as an aid to understanding the relationship between the two forms.

EXAMPLE 1 Sorting with the Second Field as a sort Key

Either of the following commands sorts the contents of `infile` with the second field as the sort key:

```
example% sort -k 2,2 infile
example% sort +1 -2 infile
```

EXAMPLE 2 Sorting in Reverse Order

Either of the following commands sorts, in reverse order, the contents of `infile1` and `infile2`, placing the output in `outfile` and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):

```
example% sort -r -o outfile -k 2.2,2.2 infile1 infile2
example% sort -r -o outfile +1.1 -1.2 infile1 infile2
```

EXAMPLE 3 Sorting Using a Specified Character in One of the Files

Either of the following commands sorts the contents of `infile1` and `infile2` using the second non-blank character of the second field as the sort key:

```
example% sort -k 2.2b,2.2b infile1 infile2
example% sort +1.1b -1.2b infile1 infile2
```

EXAMPLE 4 Sorting by Numeric User ID

Either of the following commands prints the `passwd(4)` file (user database) sorted by the numeric user ID (the third colon-separated field):

```
example% sort -t : -k 3,3n /etc/passwd
example% sort -t : +2 -3n /etc/passwd
```

EXAMPLE 5 Printing Sorted Lines Excluding Lines that Duplicate a Field

Either of the following commands prints the lines of the already sorted file `infile`, suppressing all but one occurrence of lines having the same third field:

```
example% sort -um -k 3.1,3.0 infile
example% sort -um +2.0 -3.0 infile
```

EXAMPLE 6 Sorting by Host IP Address

Either of the following commands prints the `hosts(4)` file (IPv4 hosts database), sorted by the numeric IP address (the first four numeric fields):

```
example$ sort -t . -k 1,1n -k 2,2n -k 3,3n -k 4,4n /etc/hosts
example$ sort -t . +0 -1n +1 -2n +2 -3n +3 -4n /etc/hosts
```

EXAMPLE 6 Sorting by Host IP Address (Continued)

Since '.' is both the field delimiter and, in many locales, the decimal separator, failure to specify both ends of the field leads to results where the second field is interpreted as a fractional portion of the first, and so forth.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of sort: LANG, LC_ALL, LC_COLLATE, LC_MESSAGES, and NLSPATH.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single- versus multi-byte characters in arguments and input files) and the behavior of character classification for the -b, -d, -f, -i and -n options.

LC_NUMERIC Determine the locale for the definition of the radix character and thousands separator for the -n option.

Exit Status The following exit values are returned:

- 0 All input files were output successfully, or -c was specified and the input file was correctly sorted.
- 1 Under the -c option, the file was not ordered as specified, or if the -c and -u options were both specified, two input lines were found with equal keys.
- >1 An error occurred.

Files /var/tmp/stm??? Temporary files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/bin/sort	Availability	system/core-os
	CSI	Enabled

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/xpg4/bin/sort	Availability	system/xopen/xcu4
	CSI	Enabled
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [comm\(1\)](#), [join\(1\)](#), [uniq\(1\)](#), [nl_langinfo\(3C\)](#), [strftime\(3C\)](#), [hosts\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Diagnostics Comments and exits with non-zero status for various trouble conditions (for example, when input lines are too long), and for disorders discovered under the `-c` option.

Notes When the last line of an input file is missing a new-line character, `sort` appends one, prints a warning message, and continues.

`sort` does not guarantee preservation of relative line ordering on equal keys.

One can tune `sort` performance for a specific scenario using the `-S` option. However, one should note in particular that `sort` has greater knowledge of how to use a finite amount of memory for sorting than the virtual memory system. Thus, a `sort` invoked to request an extremely large amount of memory via the `-S` option could perform extremely poorly.

As noted, certain of the field modifiers (such as `-M` and `-d`) cause the interpretation of input data to be done with reference to locale-specific settings. The results of this interpretation can be unexpected if one's expectations are not aligned with the conventions established by the locale. In the case of the month keys, `sort` does not attempt to compensate for approximate month abbreviations. The precise month abbreviations from [nl_langinfo\(3C\)](#) or [strftime\(3C\)](#) are the only ones recognized. For printable or dictionary order, if these concepts are not well-defined by the locale, an empty sort key might be the result, leading to the next key being the significant one for determining the appropriate ordering.

Name sortbib – sort a bibliographic database

Synopsis sortbib [-s *KEYS*] *database*...

Description sortbib sorts files of records containing refer key-letters by user-specified keys. Records may be separated by blank lines, or by ‘. [’ and ‘.]’ delimiters, but the two styles may not be mixed together. This program reads through each *database* and pulls out key fields, which are sorted separately. The sorted key fields contain the file pointer, byte offset, and length of corresponding records. These records are delivered using disk seeks and reads, so sortbib may not be used in a pipeline to read standard input.

The most common key-letters and their meanings are given below.

%A	Author's name
%B	Book containing article referenced
%C	City (place of publication)
%D	Date of publication
%E	Editor of book containing article referenced
%F	Footnote number or label (supplied by refer)
%G	Government order number
%H	Header commentary, printed before reference
%I	Issuer (publisher)
%J	Journal containing article
%K	Keywords to use in locating reference
%L	Label field used by -k option of refer
%M	Bell Labs Memorandum (undefined)
%N	Number within volume
%O	Other commentary, printed at end of reference
%P	Page number(s)
%Q	Corporate or Foreign Author (unreversed)
%R	Report, paper, or thesis (unpublished)
%S	Series title
%T	Title of article or book
%V	Volume number
%X	Abstract — used by roffbib, not by refer

`%Y,Z` Ignored by refer

By default, `sortbib` alphabetizes by the first `%A` and the `%D` fields, which contain the senior author and date.

`sortbib` sorts on the last word on the `%A` line, which is assumed to be the author's last name. A word in the final position, such as 'jr.' or 'ed.', will be ignored if the name beforehand ends with a comma. Authors with two-word last names or unusual constructions can be sorted correctly by using the `nroff` convention '\0' in place of a blank. A `%Q` field is considered to be the same as `%A`, except sorting begins with the first, not the last, word. `sortbib` sorts on the last word of the `%D` line, usually the year. It also ignores leading articles (like 'A' or 'The') when sorting by titles in the `%T` or `%J` fields; it will ignore articles of any modern European language. If a sort-significant field is absent from a record, `sortbib` places that record before other records containing that field.

No more than 16 databases may be sorted together at one time. Records longer than 4096 characters will be truncated.

Options `-sKEYS` Specify new *KEYS*. For instance, `-sATD` will sort by author, title, and date, while `-sA+D` will sort by all authors, and date. Sort keys past the fourth are not meaningful.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools

See Also [addbib\(1\)](#), [indxbib\(1\)](#), [lookbib\(1\)](#), [refer\(1\)](#), [roffbib\(1\)](#), [attributes\(5\)](#)

Bugs Records with missing author fields should probably be sorted by title.

Name sotrus – trace shared library procedure calls

Synopsis /usr/bin/sotrus [-f] [-F *bindfromlist*] [-T *bindtolist*]
[-o *outputfile*] executable [*executable arguments...*]

Description sotrus executes the specified command and produces a trace of the library calls that it performs. Each line of the trace output reports what bindings are occurring between dynamic objects as each procedure call is executed. sotrus traces all of the procedure calls that occur between dynamic objects via the *Procedure Linkage Table*, so only those procedure calls which are bound via the *Procedure Linkage Table* will be traced. See [Linker and Libraries Guide](#)

Options

- F *bindfromlist* A colon-separated list of libraries that are to be traced. Only calls from these libraries will be traced. The default is to trace calls from the main executable only.
- T *bindtolist* A colon-separated list of libraries that are to be traced. Only calls to these libraries will be traced. The default is to trace all calls.
- o *outputfile* sotrus output will be directed to the *outputfile*. If this option is combined with the -f option then the *pid* of the executing program will be placed at the end of the filename. By default sotrus output is placed on stderr.
- f Follow all children created by fork() and print truss output on each child process. This option will also cause a *pid* to be output on each truss output line.

Examples EXAMPLE 1 An example of sotrus.

A simple example shows the tracing of a simple ls command:

```
% sotrus ls | more
ls      ->  libc.so.1:*atexit(0xef7d7d1c, 0x23c00, 0x0)
ls      ->  libc.so.1:*atexit(0x1392c, 0xef7d7d1c, 0xef621bb0)
ls      ->  libc.so.1:*setlocale(0x6, 0x1396c, 0xef621ba8)
ls      ->  libc.so.1:*textdomain(0x13970, 0x1396c, 0xef621ba8)
ls      ->  libc.so.1:*time(0x0, 0xef61f6fc, 0xef621ba8)
ls      ->  libc.so.1:*isatty(0x1, 0xef61f6fc, 0x0)
ls      ->  libc.so.1:*getopt(0x1, 0xfffff8fc, 0x13980)
ls      ->  libc.so.1:*malloc(0x100, 0x0, 0x0)
ls      ->  libc.so.1:*malloc(0x9000, 0x0, 0x0)
ls      ->  libc.so.1:*lstat64(0x23ee8, 0xfffff7a0, 0x0)
...
ls      ->  libc.so.1:*printf(0x13a64, 0x26208, 0x23ef0)
ls      ->  libc.so.1:*printf(0x13a64, 0x26448, 0x23ef0)
ls      ->  libc.so.1:*exit(0x0, 0x24220, 0x2421c)
```

Linker and Libraries Guide

Name spell, hashmake, spellin, hashcheck – report spelling errors

Synopsis spell [-bilvx] [+ *local_file*] [*file*] ...

/usr/lib/spell/hashmake

/usr/lib/spell/spellin *n*

/usr/lib/spell/hashcheck *spelling_list*

Description The `spell` command collects words from the named files and looks them up in a spelling list. Words that neither occur among nor are derivable (by applying certain inflections, prefixes, or suffixes) from words in the spelling list are written to the standard output.

If there are no file arguments, words to check are collected from the standard input. `spell` ignores most `troff(1)`, `tbl(1)`, and `eqn(1)` constructs. Copies of all output words are accumulated in the history file (`spellhist`), and a stop list filters out misspellings (for example, `their=thy-y+ier`) that would otherwise pass.

By default, `spell` (like `deroff(1)`) follows chains of included files (`.so` and `.nx troff(1)` requests), unless the names of such included files begin with `/usr/lib`.

The standard spelling list is based on many sources, and while more haphazard than an ordinary dictionary, is also more effective in respect to proper names and popular technical words. Coverage of the specialized vocabularies of biology, medicine and chemistry is light.

Three programs help maintain and check the hash lists used by `spell`:

`hashmake` Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.

`spellin` Reads *n* hash codes from the standard input and writes a compressed spelling list on the standard output.

`hashcheck` Reads a compressed *spelling_list* and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.

Options The following options are supported:

-b Check British spelling. Besides preferring *centre*, *colour*, *programme*, *speciality*, *travelled*, and so forth, this option insists upon *-ise* in words like *standardise*.

-i Cause `deroff(1)` to ignore `.so` and `.nx` commands. If `deroff(1)` is not present on the system, then this option is ignored.

-l Follow the chains of *all* included files.

-v Print all words not literally in the spelling list, as well as plausible derivations from the words in the spelling list.

-x Print every plausible stem, one per line, with = preceding each word.

+local_file Specify a set of words that are correct spellings (in addition to spell's own spelling list) for each job. *local_file* is the name of a user-provided file that contains a sorted list of words, one per line. Words found in *local_file* are removed from spell's output. Use [sort\(1\)](#) to order *local_file* in ASCII collating sequence. If this ordering is not followed, some entries in *local_file* might be ignored.

Operands The following operands are supported:

file A path name of a text file to check for spelling errors. If no files are named, words are collected from the standard input.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of spell: LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files

D_SPELL=/usr/lib/spell/hlist[ab]	hashed spelling lists, American & British
S_SPELL=/usr/lib/spell/hstop	hashed stop list
H_SPELL=\$HOME/.spellhist	history file
/usr/share/lib/dict/words	master dictionary

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/spelling-utilities

See Also [deroff\(1\)](#), [eqn\(1\)](#), [sort\(1\)](#), [tbl\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#)

Notes spell works only on English words defined in the U.S. ASCII codeset.

Bugs The spelling list's coverage is uneven. New installations might wish to monitor the output for several months to gather local additions.

British spelling was done by an American.

Misspelled words can be monitored by default. To do so, set the H_SPELL environment variable to the name of a file which is writable to the spell process. If H_SPELL is not set, \$HOME/.spellhist is used as the history file. If no monitoring is desired, one can create the appropriate spell history file with write permission disabled.

Name split – split a file into pieces

Synopsis split [-linecount | -l *linecount*] [-a *suffixlength*]
[*file* [*name*]]

split [-b *n* | *nk* | *nm*] [-a *suffixlength*] [*file* [*name*]]

Description The `split` utility reads *file* and writes it in *linecount*-line pieces into a set of output-files. The name of the first output-file is *name* with `aa` appended, and so on lexicographically, up to `zz` (a maximum of 676 files). The maximum length of *name* is 2 characters less than the maximum filename length allowed by the filesystem. See [statvfs\(2\)](#). If no output name is given, `x` is used as the default (output-files will be called `xaa`, `xab`, and so forth).

Options The following options are supported:

`-linecount` | `-l linecount` Number of lines in each piece. Defaults to 1000 lines.

`-a suffixlength` Uses *suffixlength* letters to form the suffix portion of the filenames of the split file. If `-a` is not specified, the default suffix length is 2. If the sum of the *name* operand and the *suffixlength* option-argument would create a filename exceeding `NAME_MAX` bytes, an error will result; `split` will exit with a diagnostic message and no files will be created.

`-b n` Splits a file into pieces *n* bytes in size.

`-b nk` Splits a file into pieces $n \cdot 1024$ bytes in size.

`-b nm` Splits a file into pieces $n \cdot 1048576$ bytes in size.

Operands The following operands are supported:

file The path name of the ordinary file to be split. If no input file is given or *file* is `-`, the standard input will be used.

name The prefix to be used for each of the files resulting from the `split` operation. If no *name* argument is given, `x` will be used as the prefix of the output files. The combined length of the basename of *prefix* and *suffixlength* cannot exceed `NAME_MAX` bytes. See [OPTIONS](#).

Usage See [largefile\(5\)](#) for the description of the behavior of `split` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `split`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	Committed
Standard	See standards(5) .

Name srchtxt – display contents of, or search for a text string in, message data bases

Synopsis srchtxt [-s] [-l *locale*] [-m *msgfile* , ...] [*text*]

Description The srchtxt utility is used to display all the text strings in message data bases, or to search for a text string in message data bases (see [mkmsgs\(1\)](#)). These data bases are files in the directory `/usr/lib/locale/locale/LC_MESSAGES` (see [setlocale\(3C\)](#)), unless a file name given with the `-m` option contains a `/`. The directory *locale* can be viewed as the name of the language in which the text strings are written. If the `-l` option is not specified, the files accessed will be determined by the value of the environment variable `LC_MESSAGES`. If `LC_MESSAGES` is not set, the files accessed will be determined by the value of the environment variable `LANG`. If `LANG` is not set, the files accessed will be in the directory `/usr/lib/locale//C/LC_MESSAGES`, which contains default strings.

If no *text* argument is present, then all the text strings in the files accessed will be displayed.

If the `-s` option is not specified, the displayed text is prefixed by message sequence numbers. The message sequence numbers are enclosed in angle brackets: `<msgfile:msgnum>`.

msgfile name of the file where the displayed text occurred

msgnum sequence number in *msgfile* where the displayed text occurred

This display is in the format used by [gettext\(1\)](#) and [gettext\(3C\)](#).

- Options**
- `-s` Suppress printing of the message sequence numbers of the messages being displayed.
 - `-l locale` Access files in the directory `/usr/lib/locale/locale/LC_MESSAGES`. If `-m msgfile` is also supplied, `LOCALE` is ignored for *msgfiles* containing a `/`.
 - `-m msgfile` Access files specified by one or more *msgfiles*. If *msgfile* contains a `/` character, then *msgfile* is interpreted as a pathname; otherwise, it will be assumed to be in the directory determined as described above. To specify more than one *msgfile*, separate the file names using commas.
 - text* Search for the text string specified by *text* and display each one that matches. *text* can take the form of a regular expression; see [regex\(5\)](#).

Examples EXAMPLE 1 Using srchtxt

If message files have been installed in a locale named `french` by using [mkmsgs\(1\)](#), then you could display the entire set of text strings in the `french` locale (`/usr/lib/locale/french/LC_MESSAGES/*`) by typing:

```
example% srchtxt -l french
```

EXAMPLE 2 Using `srchtxt`

If a set of error messages associated with the operating system have been installed in the file `UX` in the french locale (`/usr/lib/locale/french/LC_MESSAGES/UX`), then, using the value of the `LANG` environment variable to determine the locale to be searched, you could search that file in that locale for all error messages dealing with files by typing:

```
example% setenv LANG=french; export LANG
example% srchtxt -m UX "[Ff]ichier"
```

If `/usr/lib/locale/french/LC_MESSAGES/UX` contained the following strings:

```
Erreur E/S\n
Liste d'arguments trop longue\n
Fichier inexistant\n
Argument invalide\n
Trop de fichiers ouverts\n
Fichier trop long\n
Trop de liens\n
Argument hors du domaine\n
Identificateur supprim\n
Etreinte fatale\n
.\n
.\n
.
```

then the following strings would be displayed:

```
<UX:3>Fichier inexistant\n
<UX:5>Trop de fichiers ouverts\n
<UX:6>Fichier trop long\n
```

EXAMPLE 3 Using `srchtxt`

If a set of error messages associated with the operating system have been installed in the file `UX` and a set of error messages associated with the INGRESS data base product have been installed in the file `ingress`, both in the german locale, then you could search for the pattern `[Dd]atei` in both the files `UX` and `ingress` in the german locale by typing:

```
example% srchtxt -l german -m UX,ingress "[Dd]atei"
```

Environment Variables See [envi ron\(5\)](#) for a description of the `LC_CTYPE` environment variable that affects the execution of `srchtxt`.

Files	<code>/usr/lib/locale/C/LC_MESSAGES/*</code>	default files created by mkmsgs(1)
	<code>/usr/lib/locale/locale/LC_MESSAGES/*</code>	message files created by mkmsgs(1)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/locale

See Also [exstr\(1\)](#), [gettxt\(1\)](#), [locale\(1\)](#), [mkmsgs\(1\)](#), [gettxt\(3C\)](#), [setlocale\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [locale\(5\)](#), [regex\(5\)](#)

Diagnostics The error messages produced by `srchtxt` are intended to be self-explanatory. They indicate an error in the command line or errors encountered while searching for a particular locale and/or message file.

Name ssh – secure shell client (remote login program)

Synopsis ssh [-l *login_name*] *hostname* | *user@hostname* [*command*]

```
ssh [-afgknqstvxACNTX1246] [-b bind_address] [-m mac_spec]
    [-c cipher_spec] [-e escape_char] [-i identity_file]
    [-i PKCS#11-URI]
    [-l login_name] [-F configfile] [-o option] [-p port]
    [-L [bind_address:]port:host:hostport]
    [-R [bind_address:]port:host:hostport]
    [-D [bind_address:]port] hostname | user@hostname [command]
```

Description ssh (Secure Shell) is a program for logging into a remote machine and for executing commands on a remote machine. It is intended to replace rlogin and rsh, and to provide secure encrypted communications between two untrusted hosts over an insecure network. X11 connections and arbitrary TCP/IP ports can also be forwarded over the secure channel.

This implementation of ssh supports both SSH protocol versions 1 and 2 simultaneously. Because of security weaknesses in the v1 protocol, only v2 should be run, if possible.

Support for v1 is provided to help sites with existing ssh v1 servers to transition to v2. v1 might not be supported in a future release.

ssh connects and logs into the specified hostname. The user must prove his or her identity to the remote machine using one of several methods depending on the protocol version used:

SSH Protocol Version 1 First, if the machine the user logs in from is listed in /etc/hosts.equiv or /etc/shosts.equiv on the remote machine, and the user names are the same on both sides, the user is immediately permitted to log in. Second, if .rhosts or .shosts exists in the user's home directory on the remote machine and contains a line containing the name of the client machine and the name of the user on that machine, the user is permitted to log in. This form of authentication alone is normally not allowed by the server because it is not secure.

The second (and primary) authentication method is the rhosts or hosts.equiv method combined with RSA-based host authentication. It means that if the login would be permitted by \$HOME/.rhosts, \$HOME/.shosts, /etc/hosts.equiv, or /etc/shosts.equiv, and if additionally the server can verify the client's host key (see /etc/ssh_known_hosts in the FILES section), only then is login permitted. This authentication method closes security holes due to IP spoofing, DNS spoofing, and routing spoofing.

Note to the administrator: /etc/hosts.equiv, \$HOME/.rhosts, and the rlogin/rsh protocol in general, are inherently insecure and should be disabled if security is desired.

As a third authentication method, ssh supports RSA-based authentication. The scheme is based on public-key cryptography. There are cryptosystems where encryption and decryption are done using separate keys, and it is not possible to derive the decryption key from the encryption key. RSA is one such system. The idea is that each user creates a public/private key pair for authentication purposes. The server knows the public key, and only the user knows

the private key. The file `$HOME/.ssh/authorized_keys` lists the public keys that are permitted for logging in. When the user logs in, the `ssh` program tells the server which key pair it would like to use for authentication. The server checks if this key is permitted, and if so, sends the user (actually the `ssh` program running on behalf of the user) a challenge in the form of a random number, encrypted by the user's public key. The challenge can only be decrypted using the proper private key. The user's client then decrypts the challenge using the private key, proving that he or she knows the private key but without disclosing it to the server.

`ssh` implements the RSA authentication protocol automatically. The user creates his or her RSA key pair by running `ssh-keygen(1)`. This stores the private key in `$HOME/.ssh/identity` and the public key in `$HOME/.ssh/identity.pub` in the user's home directory. The user should then copy the `identity.pub` to `$HOME/.ssh/authorized_keys` in his or her home directory on the remote machine (the `authorized_keys` file corresponds to the conventional `$HOME/.rhosts` file, and has one key per line, though the lines can be very long). After this, the user can log in without giving the password. RSA authentication is much more secure than `rhosts` authentication.

The most convenient way to use RSA authentication can be with an authentication agent. See [ssh-agent\(1\)](#) for more information.

If other authentication methods fail, `ssh` prompts the user for a password. The password is sent to the remote host for checking. However, since all communications are encrypted, the password cannot be seen by someone listening on the network.

SSH Protocol Version 2 The SSH version 2 protocol supports multiple user authentication methods, some of which are similar to those available with the SSH protocol version 1. These authentication mechanisms are negotiated by the client and server, with the client trying methods in the order specified in the `PreferredAuthentications` client configuration option. The server decides when enough authentication methods have passed successfully so as to complete the authentication phase of the protocol.

When a user connects by using protocol version 2, similar authentication methods are available. Using the default values for `PreferredAuthentications`, the client tries to authenticate first by using the `hostbased` method. If this method fails, public key authentication is attempted. Finally, if this method fails, `keyboard-interactive` and `password` authentication are tried.

The public key method is similar to RSA authentication described in the previous section and allows the RSA or DSA algorithm to be used: The client uses his or her private key, `$HOME/.ssh/id_dsa` or `$HOME/.ssh/id_rsa`, to sign the session identifier and sends the result to the server. The server checks whether the matching public key is listed in `$HOME/.ssh/authorized_keys` and grants access if both the key is found and the signature is correct. The session identifier is derived from a shared Diffie-Hellman value and is only known to the client and the server.

If public key authentication fails or is not available, a password can be sent encrypted to the remote host for proving the user's identity, or an extended prompt/reply protocol can be engaged.

Additionally, `ssh` supports hostbased or challenge response authentication.

Protocol 2 provides additional mechanisms for confidentiality (the traffic is encrypted using 3DES, Blowfish, CAST128 or Arcfour) and integrity (`hmac-sha2-256`, `hmac-sha2-256-96`, `hmac-sha2-512`, `hmac-sha2-512-96`, `hmac-sha1`, and `hmac-md5`). Protocol 1 lacks a strong mechanism for ensuring the integrity of the connection.

Login Session and Remote Execution

When the user's identity has been accepted by the server, the server either executes the specified command, or logs into the machine and gives the user a normal shell on the remote machine. All communication with the remote command or shell is automatically encrypted.

If a pseudo-terminal has been allocated (normal login session), the user can use the escape characters noted below. If a pseudo-terminal has been allocated (normal login session), the user can disconnect with `~.`, and suspend `ssh` with `~^Z`. All forwarded connections can be listed with `~#`. If the session blocks waiting for forwarded X11 or TCP/IP connections to terminate, `ssh` can be backgrounded with `~&`, although this should not be used while the user shell is active, as it can cause the shell to hang. All available escapes can be listed with `~?`.

A single tilde character can be sent as `~~`, or by following the tilde with a character other than those described above. The escape character must always follow a newline to be interpreted as special. The escape character can be changed in configuration files or on the command line.

If no pseudo tty has been allocated, the session is transparent and can be used to reliably transfer binary data. On most systems, setting the escape character to "none" also makes the session transparent even if a tty is used.

The session terminates when the command or shell on the remote machine exits and all X11 and TCP/IP connections have been closed. The exit status of the remote program is returned as the exit status of `ssh`.

Escape Characters

When a pseudo-terminal has been requested, `ssh` supports a number of functions through the use of an escape character.

A single tilde character can be sent as `~~` or by following the tilde with a character other than those described below. The escape character must always follow a newline to be interpreted as special. The escape character can be changed in configuration files using the `EscapeChar` configuration directive or on the command line by the `-e` option.

The supported escapes, assuming the default `~`, are:

- `~.` Disconnect.
- `~^Z` Background `ssh`.
- `~#` List forwarded connections.

- ~& Background ssh at logout when waiting for forwarded connection / X11 sessions to terminate.
- ~? Display a list of escape characters.
- ~B Send a break to the remote system. Only useful for SSH protocol version 2 and if the peer supports it.
- ~C Open command line. Only useful for adding port forwardings using the -L and -R options).
- ~R Request rekeying of the connection. Only useful for SSH protocol version 2 and if the peer supports it.

X11 and TCP Forwarding

If the `ForwardX11` variable is set to “yes” (or, see the description of the `-X` and `-x` options described later) and the user is using X11 (the `DISPLAY` environment variable is set), the connection to the X11 display is automatically forwarded to the remote side in such a way that any X11 programs started from the shell (or command) goes through the encrypted channel, and the connection to the real X server is made from the local machine. The user should not manually set `DISPLAY`. Forwarding of X11 connections can be configured on the command line or in configuration files.

The `DISPLAY` value set by `ssh` points to the server machine, but with a display number greater than zero. This is normal behavior, because `ssh` creates a “proxy” X11 server on the server machine for forwarding the connections over the encrypted channel.

`ssh` also automatically sets up `Xauthority` data on the server machine. For this purpose, it generates a random authorization cookie, store it in `Xauthority` on the server, and verify that any forwarded connections carry this cookie and replace it by the real cookie when the connection is opened. The real authentication cookie is never sent to the server machine (and no cookies are sent in the plain).

If the `ForwardAgent` variable is set to “yes” (or, see the description of the `-A` and `-a` options described later) and the user is using an authentication agent, the connection to the agent is automatically forwarded to the remote side.

Forwarding of arbitrary TCP/IP connections over the secure channel can be specified either on the command line or in a configuration file. One possible application of TCP/IP forwarding is a secure connection to an electronic purse. Another possible application is firewall traversal.

Server Authentication

`ssh` automatically maintains and checks a database containing identifications for all hosts it has ever been used with. Host keys are stored in `$HOME/.ssh/known_hosts` in the user's home directory. Additionally, the file `/etc/ssh_known_hosts` is automatically checked for known hosts. The behavior of `ssh` with respect to unknown host keys is controlled by the `StrictHostKeyChecking` parameter. If a host's identification ever changes, `ssh` warns about this and disables password authentication to prevent a trojan horse from getting the user's

password. Another purpose of this mechanism is to prevent attacks by intermediaries which could otherwise be used to circumvent the encryption. The `StrictHostKeyChecking` option can be used to prevent logins to machines whose host key is not known or has changed.

However, when using key exchange protected by GSS-API, the server can advertise a host key. The client automatically adds this host key to its known hosts file, `$HOME/.ssh/known_hosts`, regardless of the setting of the `StrictHostKeyChecking` option, unless the advertised host key collides with an existing known hosts entry.

When the user's GSS-API credentials expire, the client continues to be able to rekey the session using the server's public host key to protect the key exchanges.

GSS-API User and Server Authentication

`ssh` uses the user's GSS-API credentials to authenticate the client to the server wherever possible, if `GssKeyEx` and/or `GssAuthentication` are set.

With `GssKeyEx`, one can have an SSHv2 server that has no host public keys, so that only `GssKeyEx` can be used. With such servers, rekeying fails if the client's credentials are expired.

GSS-API user authentication has the disadvantage that it does not obviate the need for SSH host keys, but its failure does not impact rekeying. `ssh` can try other authentication methods (such as public key, password, and so on) if GSS-API authentication fails.

Delegation of GSS-API credentials can be quite useful, but is not without danger. As with passwords, users should not delegate GSS credentials to untrusted servers, since a compromised server can use a user's delegated GSS credentials to impersonate the user.

GSS-API user authorization is covered in [gss_auth_rules\(5\)](#).

Rekeying can be used to redelegate credentials when `GssKeyEx` is “yes”. (See `~R` under `Escape Characters` above.)

Configure `ssh` with:

```
UseFIPS140 yes
```

...to run OpenSSL in FIPS-140 mode. Only SSH Protocol Version 2 is supported. SunSSH may still delegate cryptographic operations for user/host authentication to other parts of Solaris which may or may not be FIPS 140–certified. The default value of `UseOpenSSLEngine` option is `no`, and the setting of `UseOpenSSLEngine` to `yes` does not have an effect in FIPS mode. As a further requirement to run `ssh` in FIPS-140 mode, the client needs to generate the user's private key in PKCS#8 format with the `ssh-keygen -8` command.

For the case of `ssh` with FIPS-140 enabled, when logging into a non-FIPS-140 `sshd`, the supported and approved FIPS ciphers must be explicitly specified in the [sshd_config\(4\)](#), using “Ciphers” for this scenario.

Options The following options are supported:

- 1 Forces ssh to try protocol version 1 only.
- 2 Forces ssh to try protocol version 2 only.
- 4 Forces ssh to use IPv4 addresses only.
- 6 Forces ssh to use IPv6 addresses only.
- a Disables forwarding of the authentication agent connection.
- A Enables forwarding of the authentication agent connection. This can also be specified on a per-host basis in a configuration file.

Agent forwarding should be enabled with caution. Users with the ability to bypass file permissions on the remote host (for the agent's UNIX-domain socket) can access the local agent through the forwarded connection. An attacker cannot obtain key material from the agent. However, the attacker can perform operations on the keys that enable the attacker to authenticate using the identities loaded into the agent.
- b *bind_address* Specifies the interface to transmit from on machines with multiple interfaces or aliased addresses.
- c *cipher_spec* Selects the cipher specification for encrypting the session.

For protocol version 1, *cipher_spec* is a single cipher. See the Cipher option in [ssh_config\(4\)](#) for more information.

For protocol version 2, *cipher_spec* is a comma-separated list of ciphers listed in order of preference. See the Ciphers option in [ssh_config\(4\)](#) for more information.
- C Requests compression of all data (including stdin, stdout, stderr, and data for forwarded X11 and TCP/IP connections). The compression algorithm is the same used by [gzip\(1\)](#). The [gzip](#) man page is available in the [SUNWsfman](#) package. The “level” can be controlled by the `CompressionLevel` option (see [ssh_config\(4\)](#)). Compression is desirable on

-
- modem lines and other slow connections, but only slows down things on fast networks. The default value can be set on a host-by-host basis in the configuration files. See the `Compression` option in `ssh_config(4)`.
- `-D [bind_address:]port`
- Specifies a local dynamic application-level port forwarding. This works by allocating a socket to listen to port on the local side, optionally bound to the specified *bind_address*. Whenever a connection is made to this port, the connection is forwarded over the secure channel. The application protocol is then used to determine where to connect to from the remote machine. Currently, the SOCKS4 and SOCKS5 protocols are supported and `ssh` acts as a SOCKS server. Only a user with enough privileges can forward privileged ports. Dynamic port forwardings can also be specified in the configuration file.
- IPv6 addresses can be specified with an alternative syntax: `[bind_address/]port` or by enclosing the address in square brackets. By default, the local port is bound in accordance with the `GatewayPorts` setting. However, an explicit *bind_address* can be used to bind the connection to a specific address. The *bind_address* of `localhost` indicates that the listening port be bound for local use only, while an empty address or `*` indicates that the port should be available from all interfaces.
- `-e ch | ^ch | none`
- Sets the escape character for sessions with a pty (default: `~`). The escape character is only recognized at the beginning of a line. The escape character followed by a dot (`.`) closes the connection. If followed by `CTRL-z`, the escape character suspends the connection. If followed by itself, the escape character sends itself once. Setting the character to `none` disables any escapes and makes the session fully transparent.
- `-f`
- Requests `ssh` to go to background just before command execution. This is useful if `ssh` is going to ask for passwords or passphrases, but the user wants it in the background. This implies the `-n` option. The

- recommended way to start X11 programs at a remote site is with something like `ssh -f host xterm`.
- `-F configfile` Specifies an alternative per-user configuration file. If a configuration file is specified on the command line, the system-wide configuration file, `/etc/ssh_config`, is ignored. The default for the per-user configuration file is `$HOME/.ssh/config`.
- `-g` Allows remote hosts to connect to local forwarded ports.
- `-i identity_file` Selects a file from which the identity (private key) for RSA or DSA authentication is read. The default is `$HOME/.ssh/identity` for protocol version 1, and `$HOME/.ssh/id_rsa` and `$HOME/.ssh/id_dsa` for protocol version 2. Identity files can also be specified on a per-host basis in the configuration file. It is possible to have multiple `-i` options (and multiple identities specified in configuration files).
- `-I PKCS#11-URI` Works with a certificate and a private key stored in the PKCS#11 token, instead of an identify file. See the Using X.509 Certificates section in the [ssh\(1M\)](#) man page for details.
- `-l login_name` Specifies the user to log in as on the remote machine. This also can be specified on a per-host basis in the configuration file.
- `-L [bind_address:]port:host:hostport` Specifies that the specified port on the local (client) host is to be forwarded to the specified host and port on the remote side. This works by allocating a socket to listen to the port on the local side, optionally bound to the specified `bind_address`. Then, whenever a connection is made to this port, the connection is forwarded over the secure channel and a connection is made to host port `hostport` from the remote machine. Port forwardings can also be specified in the configuration file. Only a user with enough privileges can forward privileged ports. IPv6 addresses can be specified with an alternative syntax: `[bind_address/]port/host/hostport` or by enclosing the address in square brackets.
- By default, the local port is bound in accordance with the `GatewayPorts` setting. However, an explicit

	<p><i>bind_address</i> can be used to bind the connection to a specific address. The <i>bind_address</i> of <code>localhost</code> indicates that the listening port be bound for local use only, while an empty address or <code>*</code> indicates that the port should be available from all interfaces.</p>
<code>-m mac_spec</code>	<p>Additionally, for protocol version 2 a comma-separated list of MAC (message authentication code) algorithms can be specified in order of preference. See the <code>MACs</code> keyword for more information.</p>
<code>-n</code>	<p>Redirects <code>stdin</code> from <code>/dev/null</code> (actually, prevents reading from <code>stdin</code>). This must be used when <code>ssh</code> is run in the background. A common trick is to use this to run X11 programs on a remote machine. For example,</p> <pre>ssh -n shadows.cs.hut.fi emacs &</pre> <p>starts an <code>emacs</code> on <code>shadows.cs.hut.fi</code>, and the X11 connection is automatically forwarded over an encrypted channel. The <code>ssh</code> program is put in the background. This does not work if <code>ssh</code> needs to ask for a password or passphrase. See also the <code>-f</code> option.</p>
<code>-N</code>	<p>Does not execute a remote command. This is useful if you just want to forward ports (protocol version 2 only).</p>
<code>-o option</code>	<p>Can be used to give options in the format used in the configuration file. This is useful for specifying options for which there is no separate command-line flag. The option has the same format as a line in the configuration file.</p>
<code>-p port</code>	<p>Specifies the port to connect to on the remote host. This can be specified on a per-host basis in the configuration file.</p>
<code>-P</code>	<p>Obsoleted option. SSHv1 connections from privileged ports are not supported.</p>
<code>-q</code>	<p>Quiet mode. Causes all warning and diagnostic messages to be suppressed. Only fatal errors are displayed.</p>
<code>-R [bind_address:]port:host:hostport</code>	<p>Specifies that the specified port on the remote (server) host is to be forwarded to the specified host</p>

and port on the local side. This works by allocating a socket to listen to the port on the remote side. Then, whenever a connection is made to this port, the connection is forwarded over the secure channel and a connection is made to host port *hostport* from the local machine. Port forwardings can also be specified in the configuration file. Privileged ports can be forwarded only when logging in on the remote machine as a user with enough privileges.

IPv6 addresses can be specified by enclosing the address in square braces or using an alternative syntax: [*bind_address*/]*host*/*port*/*hostport*.

By default, the listening socket on the server is bound to the loopback interface only. This can be overridden by specifying a *bind_address*. An empty *bind_address*, or the address ***, indicates that the remote socket should listen on all interfaces. Specifying a remote *bind_address* only succeeds if the server's `GatewayPorts` option is enabled. See [sshd_config\(4\)](#).

- s Can be used to request invocation of a subsystem on the remote system. Subsystems are a feature of the SSH2 protocol which facilitate the use of SSH as a secure transport for other applications, for example, `sftp`. The subsystem is specified as the remote command.
- t Forces pseudo-tty allocation. This can be used to execute arbitrary screen-based programs on a remote machine, which can be very useful, for example, when implementing menu services. Multiple `-t` options force allocation, even if `ssh` has no local `tty`.
- T Disables pseudo-tty allocation (protocol version 2 only).
- v Verbose mode. Causes `ssh` to print debugging messages about its progress. This is helpful in debugging connection, authentication, and configuration problems. Multiple `-v` options increase the verbosity. Maximum is 3.
- x Disables X11 forwarding.

-X Enables X11 forwarding. This can also be specified on a per-host basis in a configuration file.

X11 forwarding should be enabled with caution. Users with the ability to bypass file permissions on the remote host (for the user's X authorization database) can access the local X11 display through the forwarded connection. An attacker can then be able to perform activities such as keystroke monitoring.

For this reason, X11 forwarding might be subjected to X11 SECURITY extension restrictions. Refer to the `ForwardX11Trusted` directive in `ssh_config(4)` for more information.

If X11 forwarding is enabled, remote X11 clients is trusted by default. This means that they have full access to the original X11 display.

Environment Variables `ssh` normally sets the following environment variables:

<code>DISPLAY</code>	The <code>DISPLAY</code> variable must be set for X11 display forwarding to work.
<code>SSH_ASKPASS</code>	If <code>ssh</code> needs a passphrase, it reads the passphrase from the current terminal if it was run from a terminal. If <code>ssh</code> does not have a terminal associated with it but <code>DISPLAY</code> and <code>SSH_ASKPASS</code> are set, it executes the program specified by <code>SSH_ASKPASS</code> and opens an X11 window to read the passphrase. This is particularly useful when calling <code>ssh</code> from a <code>.Xsession</code> or related script. On some machines it might be necessary to redirect the input from <code>/dev/null</code> to make this work. The system is shipped with <code>/usr/lib/ssh/ssh-askpass</code> which is the default value for <code>SSH_ASKPASS</code> .
<code>SSH_AUTH_SOCK</code>	Indicates the path of a unix-domain socket used to communicate with the agent.

SSH_LANGS A comma-separated list of IETF language tags (see RFC3066) indicating the languages that the user can read and write. Used for negotiation of the locale on the server.

LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, LC_TIME The values of these environment variables can be set in remote sessions according to the locale settings on the client side and availability of support for those locales on the server side. Environment Variable Passing (see *RFC 4254*) is used for passing them over to the server side.

See the ENVIRONMENT VARIABLES section in the [ssh\(1M\)](#) man page for more information on how locale setting can be further changed depending on server side configuration.

Exit Status The status of the remote program is returned as the exit status of `ssh`. 255 is returned if an error occurred at anytime during the `ssh` connection, including the initial key exchange.

Files `$HOME/.ssh/known_hosts` Records host keys for all hosts the user has logged into that are not in `/etc/ssh/ssh_known_hosts`. See [ssh\(1M\)](#).

`$HOME/.ssh/identity`
`$HOME/.ssh/id_dsa`
`$HOME/.ssh/id_ssa`

Contains the authentication identity of the user. These files are for protocol 1 RSA, protocol 2 DSA, and protocol 2 RSA, respectively. These files contain sensitive data and should be readable by the user but not accessible by others (read/write/execute). `ssh` ignores a private key file if it is accessible by others. It is possible to specify a passphrase when generating the key. The passphrase is used to encrypt the sensitive part of this file using 3DES.

`/etc/ssh/sshrC` Commands in this file are executed by `ssh` when the user logs in just before the user's shell or command is started. See [sshd\(1M\)](#) for more information.

`$HOME/.ssh/rc` Commands in this file are executed by `ssh` when the user logs in just before the user's shell or command is started. See [sshd\(1M\)](#) for more information.

`$HOME/.ssh/environment` Contains additional definitions for environment variables. See ENVIRONMENT VARIABLES.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	See below.

The command line syntax is Committed. The remote locale selection through passing LC_* environment variables is Uncommitted.

See the discussion of the `.k5login` file in [krb5_auth_rules\(5\)](#).

RFC 1928

RFC 4254

Name ssh-add – add RSA or DSA identities to the authentication agent

Synopsis ssh-add [-lLdDxX] [-t *life*] [*file*] . . .

Description The ssh-add utility adds RSA or DSA identities to the authentication agent, [ssh-agent\(1\)](#). When run without arguments, it attempts to add all of the files \$HOME/.ssh/identity (RSA v1), \$HOME/.ssh/id_rsa (RSA v2), and \$HOME/.ssh/id_dsa (DSA v2) that exist. If more than one of the private keys exists, an attempt to decrypt each with the same passphrase is made before reprompting for a different passphrase. The passphrase is read from the user's tty or by running the program defined in SSH_ASKPASS (see below).

The authentication agent must be running.

Options The following options are supported:

- d Instead of adding the identity, this option *removes* the identity from the agent.
- D Deletes all identities from the agent.
- l Lists fingerprints of all identities currently represented by the agent.
- L Lists public key parameters of all identities currently represented by the agent.
- t *life* Sets a maximum lifetime when adding identities to an agent. The lifetime can be specified in seconds or in a time format specified in [sshd\(1M\)](#).
- x Locks the agent with a password.
- X Unlocks the agent.

Environment DISPLAY

Variables SSH_ASKPASS If ssh-add needs a passphrase, it reads the passphrase from the current terminal if it was run from a terminal. If ssh-add does not have a terminal associated with it but DISPLAY and SSH_ASKPASS are set, it executes the program specified by SSH_ASKPASS and open an X11 window to read the passphrase. This is particularly useful when calling ssh-add from a .Xsession or related script. The system is shipped with /usr/lib/ssh/ssh-askpass which is the default value for SSH_ASKPASS.

SSH_AUTH_SOCKET Identifies the path of a unix-domain socket used to communicate with the agent.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Files These files should not be readable by anyone but the user. Notice that ssh-add ignores a file if it is accessible by others. It is possible to specify a passphrase when generating the key; that passphrase is used to encrypt the private part of this file.

If these files are stored on a network file system it is assumed that either the protection provided in the file themselves or the transport layer of the network file system provides sufficient protection for the site policy. If this is not the case, then it is recommended the key files are stored on removable media or locally on the relevant hosts.

Recommended names for the DSA and RSA key files:

<code>\$HOME/.ssh/identity</code>	Contains the RSA authentication identity of the user for protocol version 1.
<code>\$HOME/.ssh/identity.pub</code>	Contains the public part of the RSA authentication identity of the user for protocol version 1.
<code>\$HOME/.ssh/id_dsa</code>	Contains the private DSA authentication identity of the user.
<code>\$HOME/.ssh/id_dsa.pub</code>	Contains the public part of the DSA authentication identity of the user.
<code>\$HOME/.ssh/id_rsa</code>	Contains the private RSA authentication identity of the user.
<code>\$HOME/.ssh/id_rsa.pub</code>	Contains the public part of the RSA authentication identity of the user.
<code>/usr/lib/ssh/ssh-askpass</code>	Contains the default value for <code>SSH_ASKPASS</code> .

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name ssh-agent – authentication agent

Synopsis ssh-agent [-a *bind_address*] [-c | -s] [-d]
 [-t *life*] [*command* [*args*]...]

ssh-agent [-c | -s] -k

Description ssh-agent is a program to hold private keys used for public key authentication (RSA, DSA). ssh-agent is often started at the beginning of a login session. All other windows or programs are started as clients to the ssh-agent program. Through use of environment variables, the agent can be located and automatically used for authentication when logging in to other machines using [ssh\(1\)](#). See the *Oracle Solaris 11.1 Administration: Security Services*.

If a command line is given, this is executed as a subprocess of the agent. When the command dies, so does the agent.

The agent initially does not have any private keys. Keys are added using [ssh-add\(1\)](#), which sends the identity to the agent. Several identities can be stored in the agent; the agent can automatically use any of these identities. Use the -l option in [ssh-add\(1\)](#) to display the identities currently held by the agent.

The agent is run in the user's local host. Authentication data need not be stored on any other machine, and authentication passphrases never go over the network. However, if the connection to the agent is forwarded over SSH remote logins, the user can use the privileges given by the identities anywhere in the network in a secure way.

There are two main ways to get an agent setup. Either you let the agent start a new subcommand into which some environment variables are exported, or you let the agent print the needed shell commands (either [sh\(1\)](#) or [csh\(1\)](#) syntax can be generated) which can be eval'd in the calling shell. Later, use [ssh\(1\)](#) to look at these variables and use them to establish a connection to the agent.

A unix-domain socket is created (/tmp/ssh-XXXXXXX/agent.*pid*) and the name of this socket is stored in the SSH_AUTH_SOCK environment variable. The socket is made accessible only to the current user. This method is easily abused by root or another instance of the same user.

The SSH_AGENT_PID environment variable holds the agent's PID.

The agent exits automatically when the command given on the command line terminates.

Options The following options are supported:

- a *bind_address* Binds the agent to the unix-domain socket *bind_address*. The default is /tmp/ssh-XXXXXXX/agent.*pid*.
- c Generates C-shell commands on stdout. This is the default if SHELL indicates that it is a csh style of shell.
- d Debug mode. When this option is specified, ssh-agent does not fork.

- k Kills the current agent (given by the SSH_AGENT_PID environment variable).
- s Generates Bourne shell commands on stdout. This is the default if SHELL does not indicate that it is a csh style of shell.
- t *life* Set a default value for the maximum lifetime (*life*) of identities added to the agent. *life* can be specified in seconds or in a time format specified in [sshd_config\(4\)](#). *life* specified for an identity with [ssh-add\(1\)](#) overrides this value. Without this option the default maximum *life* is forever.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Files /tmp/ssh-XXXXXXX/agent.*pid* Unix-domain sockets used to contain the connection to the authentication agent. These sockets should only be readable by the owner. The sockets are removed when the agent exits.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	Committed

See Also [ssh\(1\)](#), [ssh-add\(1\)](#), [ssh-keygen\(1\)](#), [sshd\(1M\)](#), [sshd_config\(4\)](#), [attributes\(5\)](#)

Oracle Solaris 11.1 Administration: Security Services

Name ssh-http-proxy-connect – Secure Shell proxy for HTTP

Synopsis /usr/lib/ssh/ssh-http-proxy-connect [-h *http_proxy_host*]
[-p *http_proxy_port*] *connect_host connect_port*

Description A proxy command for [ssh\(1\)](#) that uses HTTP CONNECT. Typical use is where connections external to a network are only allowed via a proxy web server.

Options The following options are supported:

- h *http_proxy_host* Specifies the proxy web server through which to connect. Overrides the HTTPPROXY and http_proxy environment variables if they are set.
- p *http_proxy_port* Specifies the port on which the proxy web server runs. If not specified, port 80 is assumed. Overrides the HTTPPROXYPORT and http_proxy environment variables if they are set.

Operands The following operands are supported:

- http_proxy_host* The host name or IP address (IPv4 or IPv6) of the proxy.
- http_proxy_port* The numeric port number to connect to on *http_proxy_host*.
- connect_host* The name of the remote host to which the proxy web server is to connect you.
- connect_port* The numeric port number of the proxy web server to connect you to on *http_proxy_host*.

Examples The recommended way to use a proxy connection command is to configure the ProxyCommand in [ssh_config\(4\)](#) (see Example 1 and Example 2). Example 3 shows how the proxy command can be specified on the command line when running [ssh\(1\)](#).

EXAMPLE 1 Setting the proxy from the environment

The following example uses ssh-http-proxy-connect in [ssh_config\(4\)](#) when the proxy is set from the environment:

```
Host playtime.foo.com
    ProxyCommand /usr/lib/ssh/ssh-http-proxy-connect \
        playtime.foo.com 22
```

EXAMPLE 2 Overriding proxy environment variables

The following example uses ssh-http-proxy-connect in [ssh_config\(4\)](#) to override (or if not set) proxy environment variables:

```
Host playtime.foo.com
    ProxyCommand /usr/lib/ssh/ssh-http-proxy-connect -h webcache \
        -p 8080 playtime.foo.com 22
```

EXAMPLE 3 Using the command line

The following example uses `ssh-http-proxy-connect` from the `ssh(1)` command line:

```
example$ ssh -o ProxyCommand="/usr/lib/ssh/ssh-http-proxy-connect \  
-h webcache -p 8080 playtime.foo.com 22" playtime.foo.com
```

Environment Variables	HTTPPROXY	Takes the <code>http_proxy_host</code> operand to specify the default proxy host. Overrides <code>http_proxy</code> if both are set.
	HTTPPROXYPORT	Takes the <code>http_proxy_port</code> operand to specify the default proxy port. Ignored if HTTPPROXY is not set.
	<code>http_proxy</code>	URL format for specifying proxy host and port.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	Committed

See Also [ssh\(1\)](#), [ssh-socks5-proxy-connect\(1\)](#), [ssh_config\(4\)](#), [attributes\(5\)](#)

Name ssh-keygen – authentication key generation

Synopsis ssh-keygen [-q] [-b *bits*] -t *type* [-N *new_passphrase*]
[-C *comment*] [-f *output_keyfile*]

ssh-keygen -p [-P *old_passphrase*] [-N *new_passphrase*]
[-f *keyfile*]

ssh-keygen -i [-f *input_keyfile* | *PKCS#11-URI*]

ssh-keygen -e [-f *input_keyfile*]

ssh-keygen -y [-f *input_keyfile*]

ssh-keygen -c [-P *passphrase*] [-C *comment*] [-f *keyfile*]

ssh-keygen -l [-f *input_keyfile* | *PKCS#11-URI*]

ssh-keygen -B [-f *input_keyfile*]

ssh-keygen -F *hostname* [-f *known_hosts_file*]

ssh-keygen -H [-f *known_hosts_file*]

ssh-keygen -R *hostname* [-f *known_hosts_file*]

Description The ssh-keygen utility generates, manages, and converts authentication keys for [ssh\(1\)](#). ssh-keygen can create RSA keys for use by SSH protocol version 1 and RSA or DSA keys for use by SSH protocol version 2. The type of key to be generated is specified with the -t option. ssh-keygen can also generate fingerprints or convert the public keys from the X.509v3 certificates specified as PKCS#11 URIs.

Normally, each user wishing to use SSH with RSA or DSA authentication runs this once to create the authentication key in `$HOME/.ssh/identity`, `$HOME/.ssh/id_dsa`, or `$HOME/.ssh/id_rsa`. The system administrator can also use this to generate host keys..

Ordinarily, this program generates the key and asks for a file in which to store the private key. The public key is stored in a file with the same name but with the “.pub” extension appended. The program also asks for a passphrase. The passphrase can be empty to indicate no passphrase (host keys must have empty passphrases), or it can be a string of arbitrary length. Good passphrases are 10-30 characters long, are not simple sentences or otherwise easy to guess, and contain a mix of uppercase and lowercase letters, numbers, and non-alphanumeric characters. (English prose has only 1-2 bits of entropy per word and provides very poor passphrases.) If a passphrase is set, it must be at least 4 characters long.

The passphrase can be changed later by using the -p option.

There is no way to recover a lost passphrase. If the passphrase is lost or forgotten, you have to generate a new key and copy the corresponding public key to other machines.

For RSA, there is also a comment field in the key file that is only for convenience to the user to help identify the key. The *comment* can tell what the key is for, or whatever is useful. The comment is initialized to “user@host” when the key is created, but can be changed using the -c option.

After a key is generated, instructions below detail where to place the keys to activate them.

Options The following options are supported:

-b *bits*

Specifies the number of bits in the key to create. The minimum number is 512 bits. Generally, 2048 bits is considered sufficient. Key sizes above that no longer improve security but make things slower. The default is 2048 bits.

-B

Shows the bubblebabble digest of the specified private or public key file.

-c

Requests changing the comment in the private and public key files. The program prompts for the file containing the private keys, for the passphrase if the key has one, and for the new comment.

This option only applies to `rsa1` (SSHv1) keys.

-C *comment*

Provides the new comment.

-e

This option reads a private or public OpenSSH key file and prints the key in a “SECSH” Public Key File Format to stdout. This option allows exporting keys for use by several other SSH implementations.

-f

Specifies the filename of the key file.

-F

Search for the specified *hostname* in a `known_hosts` file, listing any occurrences found. This option is useful to find hashed host names or addresses and can also be used in conjunction with the -H option to print found keys in a hashed format.

-H

Hash a `known_hosts` file. This replaces all host names and addresses with hashed representations within the specified file. The original content is moved to a file with a `.old` suffix. These hashes may be used normally by `ssh` and `sshd`, but they do not reveal identifying information should the file's contents be disclosed. This option does not modify existing hashed host names and is therefore safe to use on files that mix hashed and non-hashed names.

- i
This option reads an unencrypted private (or public) key file in SSH2-compatible format and prints an OpenSSH compatible private (or public) key to stdout. `ssh-keygen` also reads the “SECSH” Public Key File Format. This option allows importing keys from several other SSH implementations.
- l
Shows the fingerprint of the specified private or public key file.
- N *new_passphrase*
Provides the new passphrase.
- p
Requests changing the passphrase of a private key file instead of creating a new private key. The program prompts for the file containing the private key, for the old passphrase, and prompts twice for the new passphrase.
- P *passphrase*
Provides the (old) passphrase.
- q
Silences `ssh-keygen`.
- t *type*
Specifies the algorithm used for the key, where *type* is one of `rsa`, `dsa`, and `rsa1`. Type `rsa1` is used only for the SSHv1 protocol.
- R *hostname*
Removes all keys belonging to *hostname* from a `known_hosts` file. This option is useful to delete hashed hosts. See `-H`.
- x
Obsolete. Replaced by the `-e` option.
- X
Obsolete. Replaced by the `-i` option.
- y
This option reads a private OpenSSH format file and prints an OpenSSH public key to stdout.
- B
Specifies that `ssh-keygen` will generate the keys in PKCS#8 format. The supported type of key to be generated is `rsa` or `dsa`.

Exit Status The following exit values are returned:

- 0
Successful completion.

1

An error occurred.

Files `$HOME/.ssh/identity`

This file contains the RSA private key for the SSHv1 protocol. This file should not be readable by anyone but the user. It is possible to specify a passphrase when generating the key; that passphrase is used to encrypt the private part of this file using 128-bit AES. This file is not automatically accessed by `ssh-keygen`, but it is offered as the default file for the private key. `sshd(1M)` reads this file when a login attempt is made.

`$HOME/.ssh/identity.pub`

This file contains the RSA public key for the SSHv1 protocol. The contents of this file should be added to `$HOME/.ssh/authorized_keys` on all machines where you wish to log in using RSA authentication. There is no need to keep the contents of this file secret.

`$HOME/.ssh/id_dsa`

`$HOME/.ssh/id_rsa`

These files contain, respectively, the DSA or RSA private key for the SSHv2 protocol. These files should not be readable by anyone but the user. It is possible to specify a passphrase when generating the key; that passphrase is used to encrypt the private part of the file using 3DES. Neither of these files is automatically accessed by `ssh-keygen` but is offered as the default file for the private key. `sshd(1M)` reads this file when a login attempt is made.

`$HOME/.ssh/id_dsa.pub`

`$HOME/.ssh/id_rsa.pub`

These files contain, respectively, the DSA or RSA public key for the SSHv2 protocol. The contents of these files should be added, respectively, to `$HOME/.ssh/authorized_keys` on all machines where you wish to log in using DSA or RSA authentication. There is no need to keep the contents of these files secret.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	network/ssh/ssh-key
Interface Stability	Committed

See Also [ssh\(1\)](#), [ssh-add\(1\)](#), [ssh-agent\(1\)](#), [sshd\(1M\)](#), [attributes\(5\)](#)

Name ssh-keyscan – gather public ssh host keys of a number of hosts

Synopsis ssh-keyscan [-v46] [-p *port*] [-T *timeout*] [-t *type*]
[-f *file*] [-] [*host...* | *addrlist namelist*] [...]

Description ssh-keyscan is a utility for gathering the public ssh host keys of a number of hosts. It was designed to aid in building and verifying `ssh_known_hosts` files. ssh-keyscan provides a minimal interface suitable for use by shell and perl scripts. The output of ssh-keyscan is directed to standard output.

ssh-keyscan uses non-blocking socket I/O to contact as many hosts as possible in parallel, so it is very efficient. The keys from a domain of 1,000 hosts can be collected in tens of seconds, even when some of those hosts are down or do not run ssh. For scanning, one does not need login access to the machines that are being scanned, nor does the scanning process involve any encryption.

File Format Input format:

`1.2.3.4,1.2.4.4`
`name.my.domain,name,n.my.domain,n,1.2.3.4,1.2.4.4`

Output format for rsa1 keys:

`host-or-namelist bits exponent modulus`

Output format for rsa and dsa keys, where *keytype* is either `ssh-rsa` or `ssh-dsa`:

`host-or-namelist keytype base64-encoded-key`

Options The following options are supported:

-f *filename*

Read hosts or addrlist namelist pairs from this file, one per line. If you specify - instead of a filename, ssh-keyscan reads hosts or addrlist namelist pairs from the standard input.

-p *port*

Port to connect to on the remote host.

-T *timeout*

Set the timeout for connection attempts. If *timeout* seconds have elapsed since a connection was initiated to a host or since the last time anything was read from that host, the connection is closed and the host in question is considered unavailable. The default is for *timeout* is 5 seconds.

-t *type*

Specify the type of the key to fetch from the scanned hosts. The possible values for *type* are `rsa1` for protocol version 1 and `rsa` or `dsa` for protocol version 2. Specify multiple values by separating them with commas. The default is `rsa1`.

-v

Specify verbose mode. Print debugging messages about progress.

-4
Force to use IPv4 addresses only.

-6
Forces to use IPv6 addresses only.

Security If a `ssh_known_hosts` file is constructed using `ssh-keyscan` without verifying the keys, users are vulnerable to man-in-the-middle attacks. If the security model allows such a risk, `ssh-keyscan` can help in the detection of tampered keyfiles or man-in-the-middle attacks which have begun after the `ssh_known_hosts` file was created.

Examples **EXAMPLE 1** Printing the `rsa1` Host Key

The following example prints the `rsa1` host key for machine hostname:

```
$ ssh-keyscan hostname
```

EXAMPLE 2 Finding All Hosts

The following commands finds all hosts from the file `ssh_hosts` which have new or different keys from those in the sorted file `ssh_known_hosts`:

```
$ ssh-keyscan -t rsa,dsa -f ssh_hosts | \
    sort -u - ssh_known_hosts | diff ssh_known_hosts -
```

Files `/etc/ssh_known_hosts`
Contains list of public ssh host keys.

Exit Status The following exit values are returned:

0
No usage errors. `ssh-keyscan` might or might not have succeeded or failed to scan one, more or all of the given hosts.

1
Usage error.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	Committed

See Also [ssh\(1\)](#), [sshd\(1M\)](#), [attributes\(5\)](#)

Authors David Mazieres wrote the initial version, and Wayne Davison added support for protocol version 2.

Bugs ssh-keyscan generates the following messages on the consoles of all machines it scans if the server is older than version 2.9:

```
Connection closed by remote host
```

This is because ssh-keyscan opens a connection to the ssh port, reads the public key, and drops the connection as soon as it gets the key.

Name ssh-socks5-proxy-connect – Secure Shell proxy for SOCKS5

Synopsis `/usr/lib/ssh/ssh-socks5-proxy-connect`
`[-h socks5_proxy_host]`
`[-p socks5_proxy_port] connect_host connect_port`

Description A proxy command for [ssh\(1\)](#) that uses SOCKS5 (RFC 1928). Typical use is where connections external to a network are only allowed via a socks gateway server.

This proxy command does not provide any of the SOCKS5 authentication mechanisms defined in RFC 1928. Only anonymous connections are possible.

Options The following options are supported:

`-h socks5_proxy_host` Specifies the proxy web server through which to connect. Overrides the `SOCKS5_SERVER` environment variable.

`-p socks5_proxy_port` Specifies the port on which the proxy web server runs. If not specified, port 80 is assumed. Overrides the `SOCKS5_PORT` environment variable.

Operands The following operands are supported:

`socks5_proxy_host` The host name or IP address (IPv4 or IPv6) of the proxy.

`socks5_proxy_port` The numeric port number to connect to on `socks5_proxy_host`.

`connect_host` The name of the remote host to which the socks gateway is to connect you.

`connect_port` The numeric port number of the socks gateway to connect you to on `connect_host`.

Examples The recommended way to use a proxy connection command is to configure the ProxyCommand in [ssh_config\(4\)](#) (see Example 1 and Example 2). Example 3 shows how the proxy command can be specified on the command line when running [ssh\(1\)](#).

EXAMPLE 1 Setting the proxy from the environment

The following example uses `ssh-socks5-proxy-connect` in [ssh_config\(4\)](#) when the proxy is set from the environment:

```
Host playtime.foo.com
    ProxyCommand /usr/lib/ssh/ssh-socks5-proxy-connect \
        playtime.foo.com 22
```

EXAMPLE 2 Overriding proxy environment variables

The following example uses `ssh-socks5-proxy-connect` in [ssh_config\(4\)](#) to override (or if not set) proxy environment variables:

EXAMPLE 2 Overriding proxy environment variables (Continued)

```
Host playtime.foo.com
    ProxyCommand /usr/lib/ssh/ssh-socks5-proxy-connect -h socks-gw \
        -p 1080 playtime.foo.com 22
```

EXAMPLE 3 Using the command line

The following example uses `ssh-socks5-proxy-connect` from the `ssh(1)` command line:

```
example$ ssh -o'ProxyCommand=/usr/lib/ssh/ssh-socks5-proxy-connect \
    -h socks-gw -p 1080 playtime.foo.com 22' playtime.foo.com
```

Environment Variables

`SOCKS5_SERVER` Takes `socks5_proxy_host` operand to specify the default proxy host.

`SOCKS5_PORT` Takes `socks5_proxy_port` operand to specify the default proxy port.

Exit Status The following exit values are returned:

0 Successful completion.

1 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	Committed

See Also [ssh\(1\)](#), [ssh-http-proxy-connect\(1\)](#), [ssh_config\(4\)](#), [attributes\(5\)](#)

Name strchg, strconf – change or query stream configuration

Synopsis strchg -h *module1* [, *module2*...]
 strchg -p [-a | -u *module*]
 strchg -f *filename*
 strconf [-m | -t *module*]

Description These commands are used to alter or query the configuration of the stream associated with the user's standard input. The `strchg` command pushes modules on and/or pops modules off the stream. The `strconf` command queries the configuration of the stream. Only the super-user or owner of a STREAMS device can alter the configuration of that stream.

Invoked without any arguments, `strconf` prints a list of all the modules in the stream as well as the topmost driver. The list is printed with one name per line where the first name printed is the topmost module on the stream (if one exists) and the last item printed is the name of the driver.

Options The following options apply to `strchg` and, -h, -f, and -p are mutually exclusive.

- a Pop all the modules above the topmost driver off the stream. This option requires the -p option.
- f *filename* Specify a *filename* that contains a list of modules representing the desired configuration of the stream. Each module name must appear on a separate line where the first name represents the topmost module and the last name represents the module that should be closest to the driver. `strchg` determines the current configuration of the stream and pop and push the necessary modules in order to end up with the desired configuration.
- h *module1* [, *module2*...] Mnemonic for *push*, pushes modules onto a stream. It takes as arguments the names of one or more pushable streams modules. These modules are pushed in order; that is, *module1* is pushed first, *module2* is pushed second, etc.
- p Mnemonic for *pop*, pops modules off the stream. With the -p option alone, `strchg` pops the topmost module from the stream.
- u *module* All modules above, but not including *module* are popped off the stream. This option requires the -p option.

The following options apply to `strconf` and, -m and -t are mutually exclusive.

- m *module* Determine if the named *module* is present on a stream. If it is, `strconf` prints the message `yes` and returns zero. If not, `strconf` prints the message `no` and returns a non-zero value. The `-t` and `-m` options are mutually exclusive.
- t *module* Print only the topmost module (if one exists). The `-t` and `-m` options are mutually exclusive.

Examples EXAMPLE 1 Using the `strchg` Command

The following command pushes the module `ldterm` on the stream associated with the user's standard input:

```
example% strchg -h ldterm
```

The following command pops the topmost module from the stream associated with `/dev/term/24`. The user must be the owner of this device or the super user.

```
example% strchg -p < /dev/term/24
```

If the file `fileconf` contains the following:

```
ttcompat
ldterm
ptem
```

then the command

```
example% strchg -f fileconf
```

configures the user's standard input stream so that the module `ptem` is pushed over the driver, followed by `ldterm` and `ttcompat` closest to the stream head.

The `strconf` command with no arguments lists the modules and topmost driver on the stream; for a stream that has only the module `ldterm` pushed above the `zs` driver, it would produce the following output:

```
ldterm
zs
```

The following command asks if `ldterm` is on the stream:

```
example% strconf -m ldterm
```

and produces the following output while returning an exit status of 0:

```
yes
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
----------------	-----------------

Availability	system/core-os
--------------	----------------

See Also [attributes\(5\)](#), [streamio\(7I\)](#)

Diagnostics `strchg` returns zero on success. It prints an error message and returns non-zero status for various error conditions, including usage error, bad module name, too many modules to push, failure of an `ioctl` on the stream, or failure to open *filename* from the `-f` option.

`strconf` returns zero on success (for the `-m` or `-t` option, "success" means the named or topmost module is present). It returns a non-zero status if invoked with the `-m` or `-t` option and the module is not present. It prints an error message and returns non-zero status for various error conditions, including usage error or failure of an `ioctl` on the stream.

Notes If the user is neither the owner of the stream nor the super-user, the `strchg` command fails. If the user does not have read permissions on the stream and is not the super user, the `strconf` command fails.

If modules are pushed in the wrong order, one could end up with a stream that does not function as expected. For ttys, if the line discipline module is not pushed in the correct place, one could have a terminal that does not respond to any commands.

Name strings – find printable strings in an object or binary file

Synopsis strings [-a | -] [-t *format* | -o] [-n *number* | -number] [-N *name*] [*file*]. . .

Description The `strings` utility looks for ASCII strings in a binary file. A string is any sequence of 4 or more printing characters ending with a NEWLINE or a NULL character.

`strings` is useful for identifying random object files and many other things.

By default, `strings` looks at program sections that are loaded in memory. Program sections are identified by the section type `SHT_PROGBITS`. Sections that are loaded in memory are identified by the section flag `SHF_ALLOC`. Use [elfdump\(1\)](#) to display complete section information for a file.

All sections can be inspected with the `-a` option. Individual sections can be inspected with the `-N` option.

Options The following options are supported:

<code>-a -</code>	Look everywhere in the file for strings.
<code>-n <i>number</i> -<i>number</i></code>	Use a <i>number</i> as the minimum string length rather than the default, which is 4. An invalid number results in the default string length being used.
<code>-N <i>name</i></code>	Look only in ELF section name. See elfdump(1) . Multiple <code>-N</code> options can be specified to inspect multiple sections. If the <code>-a</code> or <code>-o</code> option is specified, all <code>-N</code> options are ignored.
<code>-o</code>	Equivalent to <code>-t d</code> option.
<code>-t <i>format</i></code>	Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the <i>format</i> option-argument: d The offset is written in decimal. o The offset is written in octal. x The offset is written in hexadecimal.

Operands The following operand is supported:

file A path name of a regular file to be used as input. If no *file* operand is specified, the `strings` utility reads from the standard input.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `strings`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	See below.

The `strings` utility, including all options except `-N`, are specified by standards. See [standards\(5\)](#). The `-N` option is not currently specified by any standard.

See Also [elfdump\(1\)](#), [od\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes The algorithm for identifying strings is extremely primitive.

For backwards compatibility, the options `-a` and `-` are interchangeable.

Name strip – strip symbol table, debugging and line number information from an object file

Synopsis strip [-lVx] *file*...

Description The `strip` command removes the symbol table `SHT_SYMTAB` and its associated string table, debugging information, and line number information from ELF object files. That is, besides the symbol table and associated string table, the following sections are removed:

```
.line
.debug*
.stab*
```

Once this stripping process has been done, limited symbolic debugging access is available for that file. Therefore, this command is normally run only on production modules that have been debugged and tested.

If `strip` is executed on a common archive file (see [ar.h\(3HEAD\)](#)) in addition to processing the members, `strip` removes the archive symbol table. The archive symbol table must be restored by executing the [ar\(1\)](#) command with the `-s` option before the archive can be linked by the [ld\(1\)](#) command. `strip` produces appropriate warning messages when this situation arises.

`strip` is used to reduce the file storage overhead taken by the object file.

Options The amount of information stripped from the ELF object file can be controlled by using any of the following options. The following options are supported:

- l Strip line number information only. Does not strip the symbol table or debugging information.
- V Prints, on standard error, the version number of `strip`.
- x Does not strip the symbol table. Debugging and line number information might be stripped.

Operands The following operand is supported:

file A path name referring to an executable file.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `strip`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /tmp/strip* Temporary files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/base-developer-utilities
Interface Stability	Committed
Standard	See standards(5) .

See Also [ar\(1\)](#), [as\(1\)](#), [ld\(1\)](#), [mcs\(1\)](#), [elf\(3ELF\)](#), [tmpnam\(3C\)](#), [a.out\(4\)](#), [ar.h\(3HEAD\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes The symbol table section is not removed if it is contained within a segment or if the file is a relocatable object.

The line number and debugging sections are not removed if they are contained within a segment or if their associated relocation section is contained within a segment.

The `strip` command is used to remove a standard predefined set of sections from an ELF object file. To remove a user specified section by name, see [mcs\(1\)](#).

Name stty – set the options for a terminal

Synopsis /usr/bin/stty [-a] [-g]
 /usr/bin/stty [*modes*]
 /usr/xpg4/bin/stty [-a | -g]
 /usr/xpg4/bin/stty [*modes*]
 /usr/xpg6/bin/stty [-a | -g]
 /usr/xpg6/bin/stty [*modes*]

Description The stty utility sets certain terminal I/O options for the device that is the current standard input. Without arguments, stty reports the settings of certain options.

In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding control character (for example, ^h is CTRL-h. In this case, recall that CTRL-h is the same as the BACKSPACE key). The sequence ^@ means that an option has a null value.

See [termio\(7I\)](#) for detailed information about the modes listed from Control Modes through Local Modes. For detailed information about the modes listed under Hardware Flow Control Modes and Clock Modes, see [termiox\(7I\)](#).

Operands described in the Combination Modes section are implemented using options in the earlier sections. Notice that many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options might not be supported by all hardware interfaces.

Options The following options are supported:

- a Writes to standard output all of the option settings for the terminal.
- g Reports current settings in a form that can be used as an argument to another stty command. Emits termios-type output if the underlying driver supports it. Otherwise, it emits termio-type output.

Operands The following *mode* operands are supported:

Control Modes	parenb (-parenb)	Enable (disable) parity generation and detection.
	parext (-parext)	Enable (disable) extended parity generation and detection for mark and space parity.
	parodd (-parodd)	Select odd (even) parity, or mark (space) parity if parext is enabled.
	cs5 cs6 cs7 cs8	Select character size (see termio(7I)).
	0	Hang up line immediately.
	hupcl (-hupcl)	Hang up (do not hang up) connection on last close.

	<code>hup (-hup)</code>	Same as <code>hupcl(-hupcl)</code> .
	<code>cstopb (-cstopb)</code>	Use two (one) stop bits per character.
	<code>cread (-cread)</code>	Enable (disable) the receiver.
	<code>crtcts (-crtcts)</code>	Enable output hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.
	<code>crtxoff (-crtxoff)</code>	Enable input hardware flow control. Raise the RTS (Request to Send) modem control line to receive data. Suspends input when RTS is low.
	<code>cllocal (-cllocal)</code>	Assume a line without (with) modem control.
	<code>defeucw</code>	Set the widths of multibyte characters to the values defined in the current locale specified by <code>LC_CTYPE</code> . Internally, width is expressed in terms of bytes per character, and screen or display columns per character.
	110 300 600 1200 1800 2400 4800 9600 19200 38400 357600 76800 115200 153600 230400 307200 460800	Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)
	<code>ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800</code>	Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to 0, the input baud rate is specified by the value of the output baud rate.
	<code>ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400 57600 76800 115200 153600 230400 307200 460800</code>	Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the output baud rate is set to 0, the line is hung up immediately.
Input Modes	<code>ignbrk (-ignbrk)</code>	Ignore (do not ignore) break on input.
	<code>brkint (-brkint)</code>	Signal (do not signal) INTR on break.
	<code>ignpar (-ignpar)</code>	Ignore (do not ignore) parity errors.
	<code>parmrk (-parmrk)</code>	Mark (do not mark) parity errors (see termio(7I)).

	<code>inpck (-inpck)</code>	Enable (disable) input parity checking.
	<code>istrip (-istrip)</code>	Strip (do not strip) input characters to seven bits.
	<code>inlcr (-inlcr)</code>	Map (do not map) NL to CR on input.
	<code>igncr (-igncr)</code>	Ignore (do not ignore) CR on input.
	<code>icrnl (-icrnl)</code>	Map (do not map) CR to NL on input.
	<code>iuclc (-iuclc)</code>	Map (do not map) upper-case alphabets to lower case on input.
	<code>ixon (-ixon)</code>	Enable (disable) START/STOP output control. Output is stopped by sending STOP control character and started by sending the START control character.
	<code>ixany (-ixany)</code>	Allow any character (only DC1) to restart output.
	<code>ixoff (-ixoff)</code>	Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.
	<code>imaxbel (-imaxbel)</code>	Echo (do not echo) BEL when the input line is too long. If <code>imaxbel</code> is set, the ASCII BEL character (07 hex) is echoed if the input stream overflows. Further input is not stored, but any input already present is not disturbed. If <code>-imaxbel</code> is set, no BEL character is echoed, and all unread input present in the input queue is discarded if the input stream overflows.
Output Modes	<code>opost (-opost)</code>	Post-process output (do not post-process output; ignore all other output modes).
	<code>olcuc (-olcuc)</code>	Map (do not map) lower-case alphabets to upper case on output.
	<code>onlcr (-onlcr)</code>	Map (do not map) NL to CR-NL on output.
	<code>ocrnl (-ocrnl)</code>	Map (do not map) CR to NL on output.
	<code>onocr (-onocr)</code>	Do not (do) output CRs at column zero.
	<code>onlret (-onlret)</code>	On the terminal NL performs (does not perform) the CR function.
	<code>ofill (-ofill)</code>	Use fill characters (use timing) for delays.
	<code>ofdel (-ofdel)</code>	Fill characters are DELs (NULs).
	<code>cr0 cr1 cr2 cr3</code>	Select style of delay for carriage returns (see termio(7I)).
	<code>nl0 nl1</code>	Select style of delay for line-feeds (see termio(7I)).
	<code>tab0 tab1 tab2 tab3</code>	Select style of delay for horizontal tabs (see termio(7I)).
	<code>bs0 bs1</code>	Select style of delay for backspaces (see termio(7I)).
	<code>ff0 ff1</code>	Select style of delay for form-feeds (see termio(7I)).

	<code>vt0 vt1</code>	Select style of delay for vertical tabs (see termio(7I)).
Local Modes	<code>isig(-isig)</code>	Enable (disable) the checking of characters against the special control characters INTR, QUIT, SWTCH, and SUSP. For information on SWTCH, see NOTES.
	<code>icanon(-icanon)</code>	Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.
	<code>xcase(-xcase)</code>	Canonical (unprocessed) upper/lower-case presentation.
	<code>echo(-echo)</code>	Echo back (do not echo back) every character typed.
	<code>echoe(-echoe)</code>	Echo (do not echo) ERASE character as a backspace-space-backspace string. This mode erases the ERASEed character on many CRT terminals; however, it does not keep track of column position and, as a result, it might be confusing for escaped characters, tabs, and backspaces.
	<code>echok(-echok)</code>	Echo (do not echo) NL after KILL character.
	<code>lfkc(-lfkc)</code>	The same as <code>echok(-echok)</code> ; obsolete.
	<code>echonl(-echonl)</code>	Echo (do not echo) NL.
	<code>noflsh(-noflsh)</code>	Disable (enable) flush after INTR, QUIT, or SUSP.
	<code>stwrap(-stwrap)</code>	Disable (enable) truncation of lines longer than 79 characters on a synchronous line.
	<code>tostop(-tostop)</code>	Send (do not send) SIGTTOU when background processes write to the terminal.
	<code>echoctl(-echoctl)</code>	Echo (do not echo) control characters as <code>^char</code> , delete as <code>^?</code> .
	<code>echoprnt(-echoprnt)</code>	Echo (do not echo) erase character as character is "erased".
	<code>echoke(-echoke)</code>	BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
	<code>flusho(-flusho)</code>	Output is (is not) being flushed.
	<code>pendin(-pendin)</code>	Retype (do not retype) pending input at next read or input character.
	<code>iexten(-iexten)</code>	Enable (disable) special control characters not currently controlled by <code>icanon</code> , <code>isig</code> , <code>ixon</code> , or <code>ixoff</code> : VEOL, VSWTCH, VREPRINT, VDISCARD, VDSUSP, VWERASE, and VLNEXT.
	<code>stflush(-stflush)</code>	Enable (disable) flush on a synchronous line after every write(2) .
	<code>stappl(-stappl)</code>	Use application mode (use line mode) on a synchronous line.

Hardware Flow Control Modes	<code>rtsxoff (- rtsxoff)</code>	Enable (disable) RTS hardware flow control on input.
	<code>ctsxon (- ctsxon)</code>	Enable (disable) CTS hardware flow control on output.
	<code>dtrxoff (- dtrxoff)</code>	Enable (disable) DTR hardware flow control on input.
	<code>cdxon (- cdxon)</code>	Enable (disable) CD hardware flow control on output.
	<code>isxoff (- isxoff)</code>	Enable (disable) isochronous hardware flow control on input.
Clock Modes	<code>xcibrng</code>	Get transmit clock from internal baud rate generator.
	<code>xctset</code>	Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	<code>xcrset</code>	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	<code>rcibrng</code>	Get receive clock from internal baud rate generator.
	<code>rctset</code>	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	<code>rcrset</code>	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	<code>tsetcoff</code>	Transmitter signal element timing clock not provided.
	<code>tsetcrbrng</code>	Output receive baud rate generator on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>tsetctbrng</code>	Output transmit baud rate generator on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>tsetctset</code>	Output transmitter signal element timing (DCE source) on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>tsetcrset</code>	Output receiver signal element timing (DCE source) on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	<code>rsetcoff</code>	Receiver signal element timing clock not provided.
	<code>rsetcrbrng</code>	Output receive baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
	<code>rsetctbrng</code>	Output transmit baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
	<code>rsetctset</code>	Output transmitter signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.
	<code>rsetcrset</code>	Output receiver signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

Control Assignments *control-character c*

Set *control-character* to *c*, where:

control-character is *ctab*, *discard*, *dsusp*, *eof*, *eol*, *eol2*, *erase*, *intr*, *kill*, *lnext*, *quit*, *reprint*, *start*, *stop*, *susp*, *swtch*, or *werase* (*ctab* is used with *-stappl*, see [termio\(7I\)](#)). For information on *swtch*, see NOTES.

c If *c* is a single character, the control character is set to that character.

In the POSIX locale, if *c* is preceded by a caret (^) indicating an escape from the shell and is one of those listed in the ^*c* column of the following table, then its value used (in the Value column) is the corresponding control character (for example, “^d” is a CTRL-d). “^?” is interpreted as DEL and “^–” is interpreted as undefined.

<i>^c</i>	Value	<i>^c</i>	Value	<i>^c</i>	Value
a, A	<SOH>	l, L	<FF>	w, W	<ETB>
b, B	<STX>	m, M	<CR>	x, X	<CAN>
c, C	<ETX>	n, N	<SO>	y, Y	
d, D	<EOT>	o, O	<SI>	z, Z	<SUB>
e, E	<ENQ>	p, P	<DLE>	[<ESC>
f, F	<ACK>	q, Q	<DC1>	\	<FS>
g, G	<BEL>	r, R	<DC2>]	<GS>
h, H	<BS>	s, S	<DC3>	^	<RS>
i, I	<HT>	t, T	<DC4>	_	<US>
j, J	<LF>	u, U	<NAK>	?	
k, K	<VT>	v, V	<SYN>		

min number

time number Set the value of *min* or *time* to *number*. MIN and TIME are used in Non-Canonical mode input processing (*-icanon*).

line i Set line discipline to *i* ($0 < i < 127$).

Combination Modes *saved settings* Set the current terminal characteristics to the saved settings produced by the *-g* option.

evenp or parity Enable *parenb* and *cs7*, or disable *parodd*.

	oddp	Enable parenb, cs7, and parodd.
	spacep	Enable parenb, cs7, and parext.
	markp	Enable parenb, cs7, parodd, and parext.
	-parity, or -evenp	Disable parenb, and set cs8.
	-oddp	Disable parenb and parodd, and set cs8.
	-spacep	Disable parenb and parext, and set cs8.
	-markp	Disable parenb, parodd, and parext, and set cs8.
	raw (-raw or cooked)	Enable (disable) raw input and output. Raw mode is equivalent to setting: <pre>stty cs8 -icanon min 1 time 0 -isig -xcase \ -inpck -opost</pre>
/usr/bin/stty, /usr/xpg6/bin/stty	nl (-nl)	Unset (set) icrnl, onlcr. In addition -nl unsets inlcr, igncr, ocrnl, and onlret.
/usr/xpg4/bin/stty	nl (-nl)	Set (unset) icrnl. In addition, -nl unsets inlcr, igncr, ocrnl, and onlret; -nl sets onlcr, and nl unsets onlcr.
	lcase (-lcase)	Set (unset) xcase, iuclc, and olcuc.
	LCASE (-LCASE)	Same as lcase (-lcase).
	tabs (-tabs or tab3)	Preserve (expand to spaces) tabs when printing.
	ek	Reset ERASE and KILL characters back to normal DEL and CTRL-u, respectively.
	sane	Reset all modes to some reasonable values.
	term	Set all modes suitable for the terminal type <i>term</i> , where <i>term</i> is one of tty33, tty37, vt05, tn300, ti700, or tek.
	async	Set normal asynchronous communications where clock settings are xcibrg, rcibrg, tsetcoff and rsetcoff.
Window Size	rows <i>n</i>	Set window size to <i>n</i> rows.
	columns <i>n</i>	Set window size to <i>n</i> columns.
	cols <i>n</i>	Set window size to <i>n</i> columns. cols is a shorthand alias for columns.
	ypixels <i>n</i>	Set vertical window size to <i>n</i> pixels.
	xpixels <i>n</i>	Set horizontal window size to <i>n</i> pixels.

Usage The `-g` flag is designed to facilitate the saving and restoring of terminal state from the shell level. For example, a program can:

```
saveterm="$(stty -g)"      # save terminal state
stty (new settings)      # set new state
...                      # ...
stty $saveterm           # restore terminal state
```

Since the `-a` format is so loosely specified, scripts that save and restore terminal settings should use the `-g` option.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `stty`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

```
0      Successful completion.
>0    An error occurred.
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/bin/stty	Availability	system/core-os

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/xpg4/bin/stty	Availability	system/xopen/xcu4
	Interface Stability	Committed
	Standard	See standards(5) .

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
/usr/xpg6/bin/stty	Availability	system/xopen/xcu6
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [tabs\(1\)](#), [ioctl\(2\)](#), [write\(2\)](#), [getwidth\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#), [ldterm\(7M\)](#), [termio\(7I\)](#), [termiox\(7I\)](#)

Notes Solaris does not support any of the actions implied by `swtch`, which was used by the `sxt` driver on System V release 4. Solaris allows the `swtch` value to be set, and prints it out if set, but it does not perform the `swtch` action.

The job switch functionality on Solaris is actually handled by job control. `susp` is the correct setting for this.

Name stty – set the options for a terminal

Synopsis /usr/ucb/stty [-a] [-g] [-h] [*modes*]

Description stty sets certain terminal I/O options for the device that is the current standard output. Without arguments, stty reports the settings of certain options.

Options In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding CTRL character (for example, ^h is CTRL-h. In this case, recall that CTRL-h is the same as the BACKSPACE key.) The sequence ^@ means that an option has a null value.

- a Reports all of the option settings.
- g Reports current settings in a form that can be used as an argument to another stty command.
- h Reports all the option settings with the control characters in an easy to read column format.

Options in the last group are implemented using options in the previous groups. Many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options might not be supported by all hardware interfaces. The options are selected from the following:

Special Requests	all	Reports the same option settings as stty without arguments, but with the control characters in column format.
	everything	Everything stty knows about is printed. Same as -h option.
	speed	The terminal speed alone is reported on the standard output.
	size	The terminal (window) sizes are printed on the standard output, first rows and then columns. This option is only appropriate if currently running a window system.
		size and speed always report on the settings of /dev/tty, and always report the settings to the standard output.

Control Modes	parenb (-parenb)	Enable (disable) parity generation and detection.
	parext (-parext)	Enable (disable) extended parity generation and detection for mark and space parity.
	parodd (-parodd)	Select odd (even) parity, or mark (space) parity if parext is enabled.
	cs5 cs6 cs7 cs8	Select character size (see termio(7I)).
	0	Hang up line immediately.

`110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb`

Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)

`ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb`

Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to zero, the input baud rate is specified by the value of the output baud rate.

`ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 exta 38400 extb`

Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the baud rate is set to zero, the line is hung up immediately.

`hupcl (-hupcl)`

Hang up (do not hang up) connection on last close.

`hup (-hup)`

Same as `hupcl (-hupcl)`.

`cstopb (-cstopb)`

Use two (one) stop bits per character.

`cread (-cread)`

Enable (disable) the receiver.

`clocal (-clocal)`

Assume a line without (with) modem control.

`crtsets (-crtsets)`

Enable hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.

`loblk (-loblk)`

Block (do not block) output from a non-current layer.

Input Modes	<code>ignbrk (-ignbrk)</code>	Ignore (do not ignore) break on input.
	<code>brkint (-brkint)</code>	Signal (do not signal) INTR on break.
	<code>ignpar (-ignpar)</code>	Ignore (do not ignore) parity errors.
	<code>parmrk (-parmrk)</code>	Mark (do not mark) parity errors (see termio(7I)).
	<code>inpck (-inpck)</code>	Enable (disable) input parity checking.
	<code>istrip (-istrip)</code>	Strip (do not strip) input characters to seven bits.
	<code>inlcr (-inlcr)</code>	Map (do not map) NL to CR on input.
	<code>igncr (-igncr)</code>	Ignore (do not ignore) CR on input.
	<code>icrnl (-icrnl)</code>	Map (do not map) CR to NL on input.
	<code>iuclc (-iuclc)</code>	Map (do not map) upper-case alphabetic to lower case on input.

	<code>ixon (-ixon)</code>	Enable (disable) START/STOP output control. Output is stopped by sending a STOP and started by sending a START.
	<code>ixany (-ixany)</code>	Allow any character (only START) to restart output.
	<code>decctlq (-decctlq)</code>	Same as <code>-ixany</code> .
	<code>ixoff (-ixoff)</code>	Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.
	<code>tandem (-tandem)</code>	Same as <code>ixoff</code> .
	<code>imaxbel (-imaxbel)</code>	Echo (do not echo) BEL when the input line is too long.
	<code>iexten (-iexten)</code>	Enable (disable) extended (implementation-defined) functions for input data.
Output Modes	<code>opost (-opost)</code>	Post-process output (do not post-process output; ignore all other output modes).
	<code>olcuc (-olcuc)</code>	Map (do not map) lower-case alphabetic to upper case on output.
	<code>onlcr (-onlcr)</code>	Map (do not map) NL to CR-NL on output.
	<code>ocrnl (-ocrnl)</code>	Map (do not map) CR to NL on output.
	<code>onocr (-onocr)</code>	Do not (do) output CRs at column zero.
	<code>onlret (-onlret)</code>	On the terminal NL performs (does not perform) the CR function.
	<code>ofill (-ofill)</code>	Use fill characters (use timing) for delays.
	<code>ofdel (-ofdel)</code>	Fill characters are DELs (NULs).
	<code>cr0 cr1 cr2 cr3</code>	Select style of delay for carriage returns (see termio(7I)).
	<code>nl0 nl1</code>	Select style of delay for line-feeds (see termio(7I)).
	<code>tab0 tab1 tab2 tab3</code>	Select style of delay for horizontal tabs (see termio(7I)).
	<code>bs0 bs1</code>	Select style of delay for backspaces (see termio(7I)).
	<code>ff0 ff1</code>	Select style of delay for form-feeds (see termio(7I)).
	<code>vt0 vt1</code>	Select style of delay for vertical tabs (see termio(7I)).
Local Modes	<code>isig (-isig)</code>	Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SWTCH. For information on SWTCH, see NOTES.
	<code>icanon (-icanon)</code>	Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.
	<code>cbreak (-cbreak)</code>	Equivalent to <code>-icanon min 1 time 0</code> .

	<code>xcase (-xcase)</code>	Canonical (unprocessed) upper/lower-case presentation.
	<code>echo (-echo)</code>	Echo back (do not echo back) every character typed.
	<code>echoe (-echoe)</code>	Echo (do not echo) ERASE character as a backspace-space-backspace string. Note: This mode erases the ERASEed character on many CRT terminals; however, it does <i>not</i> keep track of column position and, as a result, can be confusing on escaped characters, tabs, and backspaces.
	<code>crterase (-crterase)</code>	Same as <code>echoe</code> .
	<code>echok (-echok)</code>	Echo (do not echo) NL after KILL character.
	<code>lfkc (-lfkc)</code>	The same as <code>echok (-echok)</code> ; obsolete.
	<code>echonl (-echonl)</code>	Echo (do not echo) NL.
	<code>noflsh (-noflsh)</code>	Disable (enable) flush after INTR, QUIT, or SWTCH. For information on SWTCH, see NOTES.
	<code>stwrap (-stwrap)</code>	Disable (enable) truncation of lines longer than 79 characters on a synchronous line. (Does not apply to the 3B2.)
	<code>tostop (-tostop)</code>	Send (do not send) SIGTTOU for background processes.
	<code>echoctl (-echoctl)</code>	Echo (do not echo) control characters as <i>^char</i> , delete as <i>^?</i>
	<code>ctlecho (-ctlecho)</code>	Same as <code>echoctl</code> .
	<code>echoprt (-echoprt)</code>	Echo (do not echo) erase character as character is “erased”.
	<code>prterase (-prterase)</code>	Same as <code>echoprt</code> .
	<code>echoke (-echoke)</code>	BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
	<code>crtkill (-crtkill)</code>	Same as <code>echoke</code> .
	<code>flusho (-flusho)</code>	Output is (is not) being flushed.
	<code>pendin (-pendin)</code>	Retype (do not retype) pending input at next read or input character.
	<code>stflush (-stflush)</code>	Enable (disable) flush on a synchronous line after every <code>write(2)</code> . (Does not apply to the 3B2.)
	<code>stappl (-stappl)</code>	Use application mode (use line mode) on a synchronous line. (Does not apply to the 3B2.)
Hardware Flow Control Modes	<code>rtsxoff (-rtsxoff)</code>	Enable (disable) RTS hardware flow control on input.
	<code>ctson (-ctson)</code>	Enable (disable) CTS hardware flow control on output.
	<code>dterxoff (-dterxoff)</code>	Enable (disable) DTER hardware flow control on input.

	<code>r_lsdxon (-r_lsdxon)</code>	Enable (disable) RLS _D hardware flow control on output.
	<code>isxoff (-isxoff)</code>	Enable (disable) isochronous hardware flow control on input.
Clock Modes	<code>xcibrg</code>	Get transmit clock from internal baud rate generator.
	<code>xctset</code>	Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	<code>xcrset</code>	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	<code>rcibrg</code>	Get receive clock from internal baud rate generator.
	<code>rctset</code>	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	<code>rcrset</code>	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	<code>tsetcoff</code>	Transmitter signal element timing clock not provided.
	<code>tsetcrc</code>	Output receive clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	<code>tsetcxc</code>	Output transmit clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	<code>rsetcoff</code>	Receiver signal element timing clock not provided.
	<code>rsetcrc</code>	Output receive clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.
	<code>rsetcxc</code>	Output transmit clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.
	Control Assignments	<code>control-character c</code>
<code>line i</code>		Set line discipline to <i>i</i> ($0 < i < 127$).
Combination Modes	<code>evenp or parity</code>	Enable <code>parenb</code> and <code>cs7</code> .
	<code>-evenp, or -parity</code>	Disable <code>parenb</code> , and set <code>cs8</code> .
	<code>even (-even)</code>	Same as <code>evenp (-evenp)</code> .

	oddp	Enable parenb, cs7, and parodd.
	-oddp	Disable parenb and parodd, and set cs8.
	odd (-odd)	Same as oddp (-oddp).
	spacep	Enable parenb, cs7, and parext.
	-spacep	Disable parenb and parext, and set cs8.
	markp	Enable parenb, cs7, parodd, and parext.
	-markp	Disable parenb, parodd, and parext, and set cs8.
	raw (-raw or cooked)	Enable (disable) raw input and output (no ERASE, KILL, INTR, QUIT, SWTCH, EOT, or output post processing). For information on SWTCH, see NOTES.
	nI (-nI)	Unset (set) icrnl, onlcr. In addition -nI unsets inlcr, igncr, ocrnl, and onlret.
	lcase (-lcase)	Set (unset) xcase, iuclc, and olcuc.
	LCASE (-LCASE)	Same as lcase (-lcase).
	tabs (-tabs or tab3)	Preserve (expand to spaces) tabs when printing.
	ek	Reset ERASE and KILL characters back to normal DEL and CTRL-u, respectively.
	sane	Reset all modes to some reasonable values.
	term	Set all modes suitable for the terminal type <i>term</i> , where <i>term</i> is one of tty33, tty37, vt05, tn300, ti700, or tek.
	async	Set normal asynchronous communications where clock settings are xcibrg, rcibrg, tsetcoff and rsetcoff.
	litout (-litout)	Disable (enable) parenb, istrip, and opost, and set cs8 (cs7).
	pass8 (-pass8)	Disable (enable) parenb and istrip, and set cs8 (cs7).
	crt	Set options for a CRT (echoe, echoctl, and, if >= 1200 baud, echoke.)
	dec	Set all modes suitable for Digital Equipment Corp. operating systems users ERASE, KILL, and INTR characters to ^?, ^U, and ^C, decctlq, and crt.)
Window Size	rows <i>n</i>	Set window size to <i>n</i> rows.
	columns <i>n</i>	Set window size to <i>n</i> columns.
	cols <i>n</i>	An alias for columns <i>n</i> .

`ypixels`*n* Set vertical window size to *n pixels*.

`xpixels`*n* Set horizontal window size to *n pixels*.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

See Also [tabs\(1\)](#), [ioctl\(2\)](#), [attributes\(5\)](#), [termio\(7I\)](#), [termiox\(7I\)](#)

Notes Solaris does not support any of the actions implied by `swt ch`, which was used by the `sxt` driver on System V release 4. Solaris allows the `swt ch` value to be set, and prints it out if set, but it does not perform the `swt ch` action.

The job switch functionality on Solaris is actually handled by job control. `susp` is the correct setting for this.

Name sum – print checksum and block count for a file

Synopsis /usr/bin/sum [-r] [*file*...]

Description The sum lists the checksum for each of its file arguments. The standard input is read if there are no file arguments.

Options The following option is supported:

-r Use an alternate (machine-dependent) algorithm in computing the checksum.

Operands The following operands are supported:

file A path name of a file. If no files are named, the standard input is used.

Usage See [largefile\(5\)](#) for the description of the behavior of sum when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of sum: LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned.

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled

See Also [cksum\(1\)](#), [getconf\(1\)](#), [sum\(1B\)](#), [wc\(1\)](#), [libmd\(3LIB\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#)

Diagnostics Read error is indistinguishable from end of file on most devices. Check the block count.

Notes Portable applications should use [cksum\(1\)](#). The default algorithm for this command is defined in the POSIX standard and is identical across platforms.

sum and usr/ucb/sum (see [sum\(1B\)](#)) return different checksums.

Name sum – calculate a checksum for a file

Synopsis /usr/ucb/sum *file...*

Description sum calculates and displays a 16-bit checksum for the named file and displays the size of the file in kilobytes. It is typically used to look for bad spots, or to validate a file communicated over some transmission line. The checksum is calculated by an algorithm which may yield different results on machines with 16-bit ints and machines with 32-bit ints, so it cannot always be used to validate that a file has been transferred between machines with different-sized ints.

Usage See [largefile\(5\)](#) for the description of the behavior of sum when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

See Also [sum\(1\)](#), [wc\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Diagnostics Read error is indistinguishable from EOF on most devices; check the block count.

Notes sum and /usr/bin/sum (see [sum\(1\)](#)) return different checksums.

This utility is obsolete.

Name suspend – shell built-in function to halt the current shell

Synopsis

sh suspend

csh suspend

ksh suspend

Description

sh Stops the execution of the current shell (but not if it is the login shell).

csh Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z. This is most often used to stop shells started by su.

ksh Stops the execution of the current shell (but not if it is the login shell).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [csh\(1\)](#), [kill\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [su\(1M\)](#), [attributes\(5\)](#)

- Name** `svccprop` – retrieve values of service configuration properties
- Synopsis** `svccprop [-afqtv] [-C | -c | -s snapshot] [-p [name/name]... [-g pgtype]... -l layer[,...] {FMRI | pattern}...]`
`svccprop -w [-fqtv] [-p [name/name] {FMRI | pattern}]`
- Description** The `svccprop` utility prints values of properties in the service configuration repository. Properties are selected by `-p` options and the operands. If `-p` is not used to specifically select a property or property group, `svccprop` will not print SMF template definition properties. More SMF infrastructure properties may be hidden from the default output in future releases. If `-a` is used, all properties, including SMF template definition properties, will be displayed.
- Without the `-C`, `-c`, or `-s` options, `svccprop` accesses effective properties. The effective properties of a service are its directly attached properties. The effective properties of a service instance are the union of properties in the composed view of its *running* snapshot and the properties in non-persistent property groups in the composed view of the instance's directly attached properties. See [smf\(5\)](#) for an explanation of property composition. If the *running* snapshot does not exist then the instance's directly attached properties are used instead.
- Output Format** By default, when a single property is selected, the values for each are printed on separate lines. Empty ASCII string values are represented by a pair of double quotes (`""`). Bourne shell metacharacters (`'`; `'&`; `'('`; `'`; `'|'`; `'^'`; `'<`; `'>`; newline, space, tab, backslash, `''`, single-quote, `"`) in ASCII string values are quoted by backslashes (`\`).
- When multiple properties are selected, a single line is printed for each. Each line comprises a property designator, a property type, and the values (as described above), separated by spaces. By default, if a single *FMRI* operand has been supplied, the property designator consists of the property group name and the property name joined by a slash (`/`). If multiple *FMRI* operands are supplied, the designator is the canonical *FMRI* for the property.
- If access controls prohibit reading the value of a property, and no property or property group is specified explicitly by a `-p` option, the property is displayed as if it had no values. If one or more property or property group names is specified by a `-p` option, and any property value cannot be read due to access controls, an error results.
- Error messages are printed to the standard error stream.
- Options** The following options are supported:
- a
Display all properties, including those in SMF template definition property groups.
 - C
Uses the directly attached properties, without composition.
 - c
For service instances, uses the composed view of their directly attached properties.

- f
Selects the multi-property output format, with full FMRI as designators.
- g *pgtype*
Display only the selected properties belonging to property groups of type *pgtype*. Multiple -g options will display properties from multiple properties group types. This option implies multi-property output format (-t).
- l *layer[,...]*
Display only the properties defined at the selected layers. Available layers are *manifest*, *system-profile*, *site-profile*, and *admin*. The alias *all* is available to select all layers. Properties that belong to non-persistent property groups will not be displayed when this option is used.
- p *name*
For each service or service instance specified by the operands, selects all properties in the *name* property group. For property groups specified by the operands, selects the *name* property. If used with -g, selects the *name* property for all matching property group types.
- p *pg/prop*
Selects property *prop* in property group *pg* for each of the services or service instances specified by the operands.
- q
Quiet. Produces no output.
- s *name*
Uses the composed view of the *name* snapshot for service instances.
- t
Selects the multi-property output format.
- v
Verbose. Prints error messages for nonexistent properties, even if option -q is also used.
- w
Waits until the specified property group or the property group containing the specified property changes before printing.

This option is only valid when a single entity is specified. If more than one operand is specified, or an operand matches more than one instance, an error message is printed and no action is taken. The -C option is implied.

Operands The following operands are supported:

FMRI

The FMRI of a service, a service instance, a property group, or a property.

Instances and services can be abbreviated by specifying the instance name, or the trailing portion of the service name. Properties and property groups must be specified by a full FMRI. For example, given the FMRI:

```
svc:/network/smtp:sendmail
```

The following are valid abbreviations:

```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```

The following are invalid abbreviations:

```
mailnetwork
network/smt
```

Abbreviated forms of FMRIs are Uncommitted and should not be used in scripts or other permanent tools. If an abbreviation matches multiple instances, `svccprop` acts on each instance.

pattern

A glob pattern which is matched against the FMRIs of services and instances in the repository. See [fnmatch\(5\)](#). If a pattern matches multiple services or instances, `svccprop` acts on each service or instance.

Examples

EXAMPLE 1 Displaying the Value of a Single Property

The following example displays the value of the state property in the restarter property group of instance default of service system/cron.

```
example% svccprop -p restarter/state system/cron:default
online
```

EXAMPLE 2 Retrieving Whether a Service is Enabled

Whether a service is enabled is determined by its `-general/enabled` property. This property takes immediate effect, so the `-c` option must be used:

```
example% svccprop -c -p general/enabled system/cron:default
true
```

EXAMPLE 3 Displaying All Properties in a Property Group

On a default installation of Solaris, the following example displays all properties in the general property group of each instance of the network/ntp service:

```
example% svccprop -p general ntp
general/package astring SUNWntpr
general/enabled boolean true
general/entity_stability astring Uncommitted
```

EXAMPLE 3 Displaying All Properties in a Property Group *(Continued)*

```
general/single_instance boolean true
```

EXAMPLE 4 Testing the Existence of a Property

The following example tests the existence of the `general/enabled` property for all instances of service identity:

```
example% svccprop -q -p general/enabled identity:
example% echo $?
0
```

EXAMPLE 5 Waiting for Property Change

The following example waits for the `sendmail` instance to change state.

```
example% svccprop -w -p restarter/state sendmail
```

EXAMPLE 6 Retrieving the Value of a Boolean Property in a Script

The following example retrieves the value of a boolean property in a script:

```
set -- 'svccprop -c -t -p general/enabled service'
code=$?
if [ $code -ne 0 ]; then
    echo "svccprop failed with exit code $code"
    return 1
fi
if [ $2 != boolean ]; then
    echo "general/enabled has unexpected type $2"
    return 2
fi
if [ $# -ne 3 ]; then
    echo "general/enabled has wrong number of values"
    return 3
fi
value=$3
...
```

EXAMPLE 7 Using svccprop in a Script

The following example gets the value of a service property and uses it in a script (`/usr/bin/Xserver`):

```
fmri=$1
prop=$2
if svccprop -q -p ${prop} ${fmri} ; then
    propval=$(svccprop -p ${prop} "${fmri}")
    if [[ "${propval}" == "\"\"" ]] ; then
        propval=""
    fi
fi
```

EXAMPLE 7 Using svccprop in a Script *(Continued)*

```

    fi
fi

```

EXAMPLE 8 Filtering Output by Property Group Type

The following example gets the methods for `svc:/network/ssh:default`

```

example% svccprop -p exec -g method svc:/network/ssh:default
start/exec astring /lib/svc/method/sshd\ start
stop/exec astring :kill
refresh/exec astring /lib/svc/method/sshd\ restart
unconfigure/exec astring /lib/svc/method/sshd\ -u

```

EXAMPLE 9 Displaying Administratively Customized Properties

The following command uses SMF layers to display administratively customized properties.

```

example% svccprop -p config -l admin svc:/network/dns/client
config/domain      astring      admin        my.domain.com
config/nameserver  net_address  admin        10.22.33.44  10.44.33.11

```

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1
An error occurred.
- 2
Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [svcs\(1\)](#), [inetd\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [svc.startd\(1M\)](#), [service_bundle\(4\)](#), [attributes\(5\)](#), [fnmatch\(5\)](#), [smf\(5\)](#), [smf_method\(5\)](#), [smf_security\(5\)](#)

Name svcs – report service status

Synopsis svcs [-aHpv?] [-o col[,col]]... [-R *FMRI-instance*]...
[-sS col]... [*FMRI* | *pattern*]...
svcs {-d | -D} [-Hpv?] [-o col[,col]]... [-sS col]...
[*FMRI* | *pattern*] ...
svcs -n [*FMRI*] ...
svcs -l [-v] [*FMRI* | *pattern*]...
svcs -x [-v] [*FMRI*]...

Description The `svcs` command displays information about service instances as recorded in the service configuration repository.

The first form of this command prints one-line status listings for service instances specified by the arguments. Each instance is listed only once. With no arguments, all enabled service instances, even if temporarily disabled, are listed with the columns indicated below.

The second form prints one-line status listings for the dependencies or dependents of the service instances specified by the arguments.

The third form prints detailed information about specific services and instances.

The fourth form explains the states of service instances. For each argument, a block of human-readable text is displayed which explains what state the service is in, and why it is in that state. With no arguments, problematic services are described.

Error messages are printed to the standard error stream.

The output of this command can be used appropriately as input to the `svcadm(1M)` command.

Options The following options are supported:

-?

Displays an extended usage message, including column specifiers.

-a

Show all services, even disabled ones and incomplete ones. Incomplete services can be further explained using `svcs -x<service>`.

This option has no effect if services are selected.

-d

Lists the services or service instances upon which the given service instances depend.

-D

Lists the service instances that depend on the given services or service instances.

-H

Omits the column headers.

-l

(The letter ell.) Displays all available information about the selected services and service instances, with one service attribute displayed for each line. Information for different instances are separated by blank lines.

The following specific attributes require further explanation:

dependency

Information about a dependency. The grouping and `restart_on` properties are displayed first and are separated by a forward slash (/). Next, each entity and its state is listed. See [smf\(5\)](#) for information about states. In addition to the standard states, each service dependency can have the following state descriptions:

absent

No such service is defined on the system.

invalid

The fault management resource identifier (FMRI) is invalid (see [smf\(5\)](#)).

multiple

The entity is a service with multiple instances.

File dependencies can only have one of the following state descriptions:

absent

No such file on the system.

online

The file exists.

If the file did not exist the last time that `svc.startd` evaluated the service's dependencies, it can consider the dependency to be unsatisfied. `svcadm refresh` forces dependency re-evaluation.

unknown

`stat(2)` failed for a reason other than `ENOENT`.

See [smf\(5\)](#) for additional details about dependencies, grouping, and `restart_on` values.

enabled

Whether the service is enabled or not, and whether it is enabled or disabled temporarily (until the next system reboot). The former is specified as either `true` or `false`, and the latter is designated by the presence of `(temporary)`.

A service might be temporarily disabled because an administrator has run `svcadm disable -t`, used `svcadm milestone`, or booted the system to a specific milestone. See [svcadm\(1M\)](#) for details.

- n
Prints notification parameters. See [smf\(5\)](#). It always prints the FMA events notification parameters and the system-wide SMF state transition notification parameters, regardless of the FMRI or pattern selected.
- o *col[,col]...*
Prints the specified columns. Each *col* should be a column name. See COLUMNS below for available columns.
- p
Lists processes associated with each service instance. A service instance can have no associated processes. The process ID, start time, and command name (PID, STIME, and CMD fields from [ps\(1\)](#)) are displayed for each process.
- R *FMRI-instance*
Selects service instances that have the given service instance as their restarter.
- s *col*
Sorts output by column. *col* should be a column name. See COLUMNS below for available columns. Multiple -s options behave additively.
- S *col*
Sorts by *col* in the opposite order as option -s.
- v
Without -x or -l, displays verbose columns: STATE, NSTATE, STIME, CTID, and FMRI.

With -x, displays extra information for each explanation.

With -l, displays user-visible properties in property groups of type application and their description.
- x
Displays explanations for service states.

Without arguments, the -x option explains the states of services which:
 - are enabled, but are not running.
 - are preventing another enabled service from running.

Operands The following operands are supported:

FMRI

A fault management resource identifier (FMRI) that specifies one or more instances (see [smf\(5\)](#)). FMRI's can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the FMRI:

```
svc:/network/smtp:sendmail
```

The following are valid abbreviations:

```

sendmail
:sendmail
smtp
smtp:sendmail
network/smtp

```

The following are invalid abbreviations:

```

mail
network
network/smt

```

If the FMRI specifies a service, then the command applies to all instances of that service, except when used with the `-D` option.

Abbreviated forms of FMRI are unstable, and should not be used in scripts or other permanent tools.

pattern

A pattern that is matched against the *FMRI*s of service instances according to the globbing rules described by `fnmatch(5)`. If the pattern does not begin with `svc:`, then `svc:/` is prepended. The following is a typical example of a glob pattern:

```

qexample% svcs \*key serv\*
STATE      STIME      FMRI
disabled   Aug_02     svc:/network/rpc/key serv:default

```

FMRI-instance

An FMRI that specifies an instance.

Columns Column names are case insensitive. The default output format is equivalent to “`-o state,stime,fmri`”. The default sorting columns are STATE, STIME, FMRI.

CTID

The primary contract ID for the service instance. Not all instances have valid primary contract IDs.

DESC

A brief description of the service, from its template element. A service might not have a description available, in which case a hyphen (-) is used to denote an empty value.

FMRI

The *FMRI* of the service instance.

INST

The instance name of the service instance.

NSTA

The abbreviated next state of the service instance, as given in the STA column description. A hyphen denotes that the instance is not transitioning. Same as STA otherwise.

NSTATE

The next state of the service. A hyphen is used to denote that the instance is not transitioning. Same as STATE otherwise.

SCOPE

The scope name of the service instance.

SVC

The service name of the service instance.

STA

The abbreviated state of the service instance (see [smf\(5\)](#)):

DGD

degraded

DIS

disabled

LRC

legacy rc*.d script-initiated instance

MNT

maintenance

OFF

offline

ON

online

UN

uninitialized

Absent or unrecognized states are denoted by a question mark (?) character. An asterisk (*) is appended for instances in transition, unless the NSTA or NSTATE column is also being displayed.

See [smf\(5\)](#) for an explanation of service states.

STATE

The state of the service instance. An asterisk is appended for instances in transition, unless the NSTA or NSTATE column is also being displayed.

See [smf\(5\)](#) for an explanation of service states.

STIME

If the service instance entered the current state within the last 24 hours, this column indicates the time that it did so. Otherwise, this column indicates the date on which it did so, printed with underscores (_) in place of blanks.

Examples EXAMPLE 1 Displaying the Default Output

This example displays default output:

```
example% svcs
STATE          STIME      FMRI
...
legacy_run    13:25:04  lrc:/etc/rc3_d/S42myscript
...
online        13:21:50  svc:/system/svc/restarter:default
...
online        13:25:03  svc:/milestone/multi-user:default
...
online        13:25:07  svc:/milestone/multi-user-server:default
...
```

EXAMPLE 2 Listing All Local Instances

This example lists all local instances of the service1 service.

```
example% svcs -o state,nstate,fmri service1
STATE          NSTATE      FMRI
online         -           svc:/service1:instance1
disabled      -           svc:/service1:instance2
```

EXAMPLE 3 Listing Verbose Information

This example lists verbose information.

```
example% svcs -v network/rpc/rstat:udp
STATE          NSTATE      STIME      CTID      FMRI
online         -           Aug_09     -         svc:/network/rpc/rstat:udp
```

EXAMPLE 4 Listing Detailed Information

This example lists detailed information about all instances of system/service3. Additional fields can be displayed, as appropriate to the managing restarter.

```
example% svcs -l network/rpc/rstat:udp

fmri           svc:/network/rpc/rstat:udp
enabled        true
state          online
next_state     none
restarter      svc:/network/inetd:default
contract_id
dependency     require_all/error svc:/network/rpc/bind (online)
```

EXAMPLE 5 Listing Processes

```
example% svcs -p sendmail
STATE          STIME      FMRI
```

EXAMPLE 5 Listing Processes (Continued)

```

online          13:25:13 svc:/network/smtp:sendmail
                13:25:15 100939 sendmail
13:25:15       100940 sendmail

```

EXAMPLE 6 Explaining Service States Using `svcs -x`

(a) In this example, `svcs -x` has identified that the `print/server` service being disabled is the root cause of two services which are enabled but not online. `svcs -xv` shows that those services are `print/rfc1179` and `print/ipp-listener`. This situation can be rectified by either enabling `print/server` or disabling `rfc1179` and `ipp-listener`.

```

example% svcs -x
svc:/application/print/server:default (LP print server)
  State: disabled since Mon Feb 13 17:56:21 2006
Reason: Disabled by an administrator.
  See: http://support.oracle.com/msg/SMF-8000-05
  See: lpsched(1M)
Impact: 2 dependent services are not running. (Use -v for list.)

```

(b) In this example, NFS is not working:

```

example$ svcs nfs/client
STATE      STIME      FMRI
offline    16:03:23  svc:/network/nfs/client:default

```

(c) The following example shows that the problem is `nfs/status`. `nfs/client` is waiting because it depends on `nfs/nlockmgr`, which depends on `nfs/status`:

```

example$ svcs -xv nfs/client
svc:/network/nfs/client:default (NFS client)
  State: offline since Mon Feb 27 16:03:23 2006
Reason: Service svc:/network/nfs/status:default
        is not running because a method failed repeatedly.
  See: http://support.oracle.com/msg/SMF-8000-GE
Path:  svc:/network/nfs/client:default
        svc:/network/nfs/nlockmgr:default
        svc:/network/nfs/status:default
  See: man -M /usr/share/man -s 1M mount_nfs
  See: /var/svc/log/network-nfs-client:default.log
Impact: This service is not running.

```

Exit Status The following exit values are returned:

- 0
Successful command invocation.
- 1
Fatal error.

2

Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

Screen output is Uncommitted. The invocation is Committed.

See Also [ps\(1\)](#), [svccprop\(1\)](#), [svccadm\(1M\)](#), [svccfg\(1M\)](#), [svc.startd\(1M\)](#), [stat\(2\)](#), [libscf\(3LIB\)](#), [attributes\(5\)](#), [fnmatch\(5\)](#), [smf\(5\)](#)

Name symorder – rearrange a list of symbols

Synopsis symorder [-s] *objectfile symbolfile*

Description symorder was used in SunOS 4.x specifically to cut down on the overhead of getting symbols from `vmunix`. This is no longer applicable as kernel symbol entries are dynamically obtained through `/dev/ksyms`.

This script is provided as a convenience for software developers who need to maintain scripts that are portable across a variety of operating systems.

Exit Status symorder has exit status 0.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/base-developer-utilities

See Also [nlist\(3ELF\)](#), [attributes\(5\)](#), [ksyms\(7D\)](#).

Name sys-suspend – suspend or shutdown the system and power off

Synopsis /usr/bin/sys-suspend [-fnxh][-d *displayname*]

Description sys-suspend provides options to suspend or shutdown the whole system.

A system can be suspended to conserve power or to prepare the system for transport. The suspend should not be used when performing any hardware reconfiguration or replacement.

In case of suspend, the current system state is preserved either by keeping memory powered (Suspend to RAM), or by saving the state to non-volatile storage (Suspend to Disk) until a resume operation is performed by power on or a wake-up event.

On a resume in the windows environment, the system brings up lockscreen to ensure that only the authorized person has access to the system. In a non-windows environment, the user is prompted for password.

It is possible that when devices or processes are performing critical or time sensitive operations (such as real time operations) the system fails to suspend. When this occurs, the system remains in its current running state. Messages reporting the failure are displayed on the console or system log. Once the system is successfully suspended, the resume operation always succeed barring external influences such as hardware reconfiguration or the like.

In case of shutdown, the system responds as if [poweroff\(1M\)](#) was performed.

This command enforces the `solaris.system.power.suspend` authorizations. On a default install these are associated with the console user. Other users need to include these authorizations or include the Suspend profile.

Options The following operands are supported:

- d *displayname* Connect to the X server specified by *displayname*.
- f Force suspend. Causes a [poweroff\(1M\)](#) to occur if the suspend fails. System state are not be saved, and a normal boot follows.
- h Change the default from suspend to shutdown.
- n Do not display messages or request user intervention.
- x Disable lockscreen. This flag disables the execution of lockscreen at resume time.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/kernel/power
Interface Stability	Committed

See Also [halt\(1M\)](#), [poweroff\(1M\)](#), [shutdown\(1M\)](#), [attributes\(5\)](#), [cpr\(7\)](#)

Name sysV-make – maintain, update, and regenerate groups of programs

Synopsis /usr/lib/svr4.make [-f *makefile*] [-eiknpqrst] [*names*]

Description This is the *vanilla* System V version of make. If the environment variable USE_SVR4_MAKE is set, then the command make will invoke this version of make. (See also the ENVIRONMENT section.)

make allows the programmer to maintain, update, and regenerate groups of computer programs. make executes commands in *makefile* to update one or more target *names* (*names* are typically programs). If the -f option is not present, then *makefile*, *Makefile*, and the Source Code Control System (SCCS) files *s.makefile* and *s.Makefile* are tried in order. If *makefile* is '-' the standard input is taken. More than one -f *makefile* argument pair may appear.

make updates a target only if its dependents are newer than the target. All prerequisite files of a target are added recursively to the list of targets. Missing files are deemed to be outdated.

The following list of four directives can be included in *makefile* to extend the options provided by make. They are used in *makefile* as if they were targets:

- .DEFAULT: If a file must be made but there are no explicit commands or relevant built-in rules, the commands associated with the name .DEFAULT are used if it exists.
- .IGNORE: Same effect as the -i option.
- .PRECIOUS: Dependents of the .PRECIOUS entry will not be removed when quit or interrupt are hit.
- .SILENT: Same effect as the -s option.

Options The options for make are listed below:

- e Environment variables override assignments within makefiles.
- f *makefile* Description filename (*makefile* is assumed to be the name of a description file).
- i Ignore error codes returned by invoked commands.
- k Abandon work on the current entry if it fails, but continue on other branches that do not depend on that entry.
- n No execute mode. Print commands, but do not execute them. Even command lines beginning with an '@' are printed.
- p Print out the complete set of macro definitions and target descriptions.
- q Question. make returns a zero or non-zero status code depending on whether or not the target file has been updated.
- r Do not use the built-in rules.
- s Silent mode. Do not print command lines before executing.

-t Touch the target files (causing them to be updated) rather than issue the usual commands.

Creating the makefile The makefile invoked with the `-f` option is a carefully structured file of explicit instructions for updating and regenerating programs, and contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, then a `:'`, then a (possibly null) list of prerequisite files or dependencies. Text following a `;` and all following lines that begin with a tab are shell commands to be executed to update the target. The first non-empty line that does not begin with a tab or `#` begins a new dependency or macro definition. Shell commands may be continued across lines with a backslash-new-line (`\-NEWLINE`) sequence. Everything printed by make (except the initial TAB) is passed directly to the shell as is. Thus,

```
echo a\  
b
```

will produce

```
ab
```

exactly the same as the shell would.

Number-sign (`#`) and `NEWLINE` surround comments including contained `\-NEWLINE` sequences.

The following makefile says that `pgm` depends on two files `a.o` and `b.o`, and that they in turn depend on their corresponding source files (`a.c` and `b.c`) and a common file `incl.h`:

```
pgm: a.o b.o  
    cc a.o b.o -o pgm  
a.o: incl.h a.c  
    cc -c a.c  
b.o: incl.h b.c  
    cc -c b.c
```

Command lines are executed one at a time, each by its own shell. The `SHELL` environment variable can be used to specify which shell make should use to execute commands. The default is `/usr/bin/sh`. The first one or two characters in a command can be the following: `@`, `-`, `^@-`, or `^-@`. If `@` is present, printing of the command is suppressed. If `-` is present, make ignores an error. A line is printed when it is executed unless the `-s` option is present, or the entry `.SILENT:` is included in *makefile*, or unless the initial character sequence contains a `@`. The `-n` option specifies printing without execution; however, if the command line has the string `$(MAKE)` in it, the line is always executed (see the discussion of the `MAKEFLAGS` macro in the `make Environment` sub-section below). The `-t` (touch) option updates the modified date of a file without executing any commands.

Commands returning non-zero status normally terminate `make`. If the `-i` option is present, if the entry `.IGNORE:` is included in *makefile*, or if the initial character sequence of the command contains `'-`', the error is ignored. If the `-k` option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.

Interrupt and quit cause the target to be deleted unless the target is a dependent of the directive `.PRECIOUS`.

make Environment The environment is read by `make`. All variables are assumed to be macro definitions and are processed as such. The environment variables are processed before any *makefile* and after the internal rules; thus, macro assignments in a *makefile* override environment variables. The `-e` option causes the environment to override the macro assignments in a *makefile*. Suffixes and their associated rules in the *makefile* will override any identical suffixes in the built-in rules.

The `MAKEFLAGS` environment variable is processed by `make` as containing any legal input option (except `-f` and `-p`) defined for the command line. Further, upon invocation, `make` “invents” the variable if it is not in the environment, puts the current options into it, and passes it on to invocations of commands. Thus, `MAKEFLAGS` always contains the current input options. This feature proves very useful for “super-makes”. In fact, as noted above, when the `-n` option is used, the command `$(MAKE)` is executed anyway; hence, one can perform a `make -n` recursively on a whole software system to see what would have been executed. This result is possible because the `-n` is put in `MAKEFLAGS` and passed to further invocations of `$(MAKE)`. This usage is one way of debugging all of the *makefiles* for a software project without actually doing anything.

Include Files If the string *include* appears as the first seven letters of a line in a *makefile*, and is followed by a blank or a tab, the rest of the line is assumed to be a filename and will be read by the current invocation, after substituting for any macros.

Macros Entries of the form *string1 = string2* are macro definitions. *string2* is defined as all characters up to a comment character or an unescaped NEWLINE. Subsequent appearances of `$(string1[:subst1=[subst2]])` are replaced by *string2*. The parentheses are optional if a single-character macro name is used and there is no substitute sequence. The optional `:subst1=subst2` is a substitute sequence. If it is specified, all non-overlapping occurrences of *subst1* in the named macro are replaced by *subst2*. Strings (for the purposes of this type of substitution) are delimited by BLANKs, TABs, NEWLINE characters, and beginnings of lines. An example of the use of the substitute sequence is shown in the `Libraries` sub-section below.

Internal Macros There are five internally maintained macros that are useful for writing rules for building targets.

`$(*)` The macro `$(*)` stands for the filename part of the current dependent with the suffix deleted. It is evaluated only for inference rules.

- `$$` The `$$` macro stands for the full target name of the current target. It is evaluated only for explicitly named dependencies.
- `$$<` The `$$<` macro is only evaluated for inference rules or the `$.DEFAULT` rule. It is the module that is outdated with respect to the target (the “manufactured” dependent file name). Thus, in the `$.c.o` rule, the `$$<` macro would evaluate to the `$.c` file. An example for making optimized `$.o` files from `$.c` files is:
- ```
$.c.o:
 cc c O $*.c

or:

$.c.o:
 cc c O $$<
```
- `$$?` The `$$?` macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are outdated with respect to the target, and essentially those modules that must be rebuilt.
- `$$%` The `$$%` macro is only evaluated when the target is an archive library member of the form `lib(file.o)`. In this case, `$$` evaluates to `lib` and `$$%` evaluates to the library member, `file.o`.

Four of the five macros can have alternative forms. When an upper case D or F is appended to any of the four macros, the meaning is changed to “directory part” for D and “file part” for F. Thus, `$$(@D)` refers to the directory part of the string `$$`. If there is no directory part, `./` is generated. The only macro excluded from this alternative form is `$$?`.

**Suffixes** Certain names (for instance, those ending with `$.o`) have inferable prerequisites such as `$.c`, `$.s`, etc. If no update commands for such a file appear in *makefile*, and if an inferable prerequisite exists, that prerequisite is compiled to make the target. In this case, `make` has inference rules that allow building files from other files by examining the suffixes and determining an appropriate inference rule to use. The current default inference rules are:

---

|                      |                        |                      |                      |                      |                      |                      |                      |                      |                      |
|----------------------|------------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| <code>\$.c</code>    | <code>\$.c~</code>     | <code>\$.f</code>    | <code>\$.f~</code>   | <code>\$.s</code>    | <code>\$.s~</code>   | <code>\$.sh</code>   | <code>\$.sh~</code>  | <code>\$.C</code>    | <code>\$.C~</code>   |
| <code>\$.c.a</code>  | <code>\$.c.o</code>    | <code>\$.c~.a</code> | <code>\$.c~.c</code> | <code>\$.c~.o</code> | <code>\$.f.a</code>  | <code>\$.f.o</code>  | <code>\$.f~.a</code> | <code>\$.f~.f</code> | <code>\$.f~.o</code> |

---

The internal rules for `make` are contained in the source file `make.rules` for the `make` program. These rules can be locally modified. To print out the rules compiled into the `make` on any machine in a form suitable for re-compilation, the following command is used:

```
make -pf -2>/dev/null < /dev/null
```

A tilde in the above rules refers to an SCCS file (see [sccsfile\(4\)](#)). Thus, the rule `.c~.o` would transform an SCCS C source file into an object file (`.o`). Because the `s.` of the SCCS files is a prefix, it is incompatible with the `make` suffix point of view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (for example, `.c:`) is the definition of how to build `x` from `x.c`. In effect, the other suffix is null. This feature is useful for building targets from only one source file, for example, shell procedures and simple C programs.

Additional suffixes are given as the dependency list for `.SUFFIXES`. Order is significant: the first possible name for which both a file and a rule exist is inferred as a prerequisite. The default list is:

```
.SUFFIXES: .o .c .c~ .y .y~ .l .l~ .s .s~ .sh .sh~ .h .h~ .f .f~ .C .C~ .Y .Y~ .L
.L~
```

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; `.SUFFIXES:` with no dependencies clears the list of suffixes.

**Inference Rules** The first example can be done more briefly.

```
pgm: a.o b.o
 cc a.o b.o o pgm
a.o b.o: incl.h
```

This abbreviation is possible because `make` has a set of internal rules for building files. The user may add rules to this list by simply putting them in the *makefile*.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix `.o` from a file with suffix `.c` is specified as an entry with `.c.o:` as the target and no dependents. Shell commands associated with the target define the rule for making a `.o` file from a `.c` file. Any target that has no slashes in it and starts with a dot is identified as a rule and not a true target.

**Libraries** If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus, `lib(file.o)` and `$(LIB)(file.o)` both refer to an archive library that contains `file.o`. (This example assumes the `LIB` macro has been previously defined.) The expression `$(LIB)(file1.o file2.o)` is not

legal. Rules pertaining to archive libraries have the form `.XX.a` where the `XX` is the suffix from which the archive member is to be made. An unfortunate by-product of the current implementation requires the `XX` to be different from the suffix of the archive member. Thus, one cannot have `lib(file.o)` depend upon `file.o` explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
 @echo lib is now up-to-date
.c.a:
 $(CC) -c $(CFLAGS) $<
 $(AR) $(ARFLAGS) $@ $*.o
 rm -f $*.o
```

In fact, the `.c.a` rule listed above is built into `make` and is unnecessary in this example. A more interesting, but more limited example of an archive library maintenance construction follows:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
 $(CC) -c $(CFLAGS) $(?:.o=.c)
 $(AR) $(ARFLAGS) lib $?
 rm $?
 @echo lib is now up-to-date
.c.a:;
```

Here the substitution mode of the macro expansions is used. The `?$` list is defined to be the set of object filenames (inside `lib`) whose C source files are outdated. The substitution mode translates the `.o` to `.c`. (Unfortunately, one cannot as yet transform to `.c~`; however, this transformation may become possible in the future.) Also note the disabling of the `.c.a` rule, which would have created each object file, one by one. This particular construct speeds up archive library maintenance considerably. This type of construct becomes very cumbersome if the archive library contains a mix of assembly programs and C programs.

|                              |                            |                                                                                                                                                                                                                             |
|------------------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Environment Variables</b> | <code>USE_SVR4_MAKE</code> | If this environment variable is set, then the <code>make</code> command will invoke this System V version of <code>make</code> . If this variable is not set, then the default version of <code>make(1S)</code> is invoked. |
|------------------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`USE_SVR4_MAKE` can be set as follows (Bourne shell):

```
$ USE_SVR4_MAKE="" ; export USE_SVR4_MAKE
```

or (C shell):

```
% setenv USE_SVR4_MAKE
```

|              |                                             |                        |
|--------------|---------------------------------------------|------------------------|
| <b>Files</b> | <code>[Mm]akefile</code>                    |                        |
|              | <code>s.[Mm]akefile</code>                  | default makefiles      |
|              | <code>/usr/bin/sh</code>                    | default shell for make |
|              | <code>/usr/share/lib/make/make.rules</code> | default rules for make |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE      |
|----------------|----------------------|
| Availability   | developer/build/make |

**See Also** [cd\(1\)](#), [make\(1S\)](#), [sh\(1\)](#), [printf\(3C\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

**Notes** Some commands return non-zero status inappropriately; use `-i` or the `'-'` command line prefix to overcome the difficulty.

Filenames containing the characters `=`, `:`, and `@` do not work. Commands that are directly executed by the shell, notably [cd\(1\)](#), are ineffectual across NEWLINES in `make`. The syntax `lib(file1.o file2.o file3.o)` is illegal. You cannot build `lib(file.o)` from `file.o`.

**Name** tabs – set tabs on a terminal

**Synopsis** tabs [-n | *—file*  
 [[-code] | -a | -a2 | -c | -c2 | -c3 | -f | -p | -s | -u]]  
 q!! [+m [n]] [-T type]  
 tabs [-T type] [+ m [n]] n1 [, n2 , ...]

**Description** The tabs utility sets the tab stops on the user's terminal according to a tab specification, after clearing any previous settings. The user's terminal must have remotely settable hardware tabs.

**Options** The following options are supported. If a given flag occurs more than once, the last value given takes effect:

-T *type* tabs needs to know the type of terminal in order to set tabs and margins. *type* is a name listed in [term\(5\)](#). If no -T flag is supplied, tabs uses the value of the environment variable TERM. If the value of TERM is NULL or TERM is not defined in the environment (see [environ\(5\)](#)), tabs uses ansi+tabs as the terminal type to provide a sequence that will work for many terminals.

+m [n] The margin argument may be used for some terminals. It causes all tabs to be moved over *n* columns by making column *n*+1 the left margin. If +m is given without a value of *n*, the value assumed is 10. For a TerminoNet, the first value in the tab list should be 1, or the margin will move even further to the right. The normal (leftmost) margin on most terminals is obtained by +m0. The margin for most terminals is reset only when the +m flag is given explicitly.

**Tab Specification** Four types of tab specification are accepted. They are described below: canned, repetitive (-n), arbitrary (n1,n2,...), and file (-file).

If no tab specification is given, the default value is -8, that is, UNIX system "standard" tabs. The lowest column number is 1. Note: For tabs, column 1 always refers to the leftmost column on a terminal, even one whose column markers begin at 0, for example, the DASI 300, DASI 300s, and DASI 450.

**Canned -code** Use one of the codes listed below to select a canned set of tabs. If more than one code is specified, the last code option will be used. The legal codes and their meanings are as follows:

-a 1, 10, 16, 36, 72 Assembler, IBM S/370, first format

-a2 1, 10, 16, 40, 72

Assembler, IBM S/370, second format

-c 1, 8, 12, 16, 20, 55

COBOL, normal format

-c2 1, 6, 10, 14, 49

COBOL compact format (columns 1-6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a format specification as follows (see [fspec\(4\)](#)):

```
<:t-c2 m6 s66 d:>
```

-c3 1, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62, 67

COBOL compact format (columns 1-6 omitted), with more tabs than -c2. This is the recommended format for COBOL. The appropriate format specification is (see [fspec\(4\)](#)):

```
<:t-c3 m6 s66 d:>
```

-f 1, 7, 11, 15, 19, 23

FORTRAN

-p 1, 5, 9, 13, 17, 21, 25, 29, 33, 37, 41, 45, 49, 53, 57, 61

PL/I

-s 1, 10, 55

SNOBOL

-u 1, 12, 20, 44

UNIVAC 1100 Assembler

*Repetitive* -n A *repetitive* specification requests tabs at columns  $1+n$ ,  $1+2^*n$ , etc., where  $n$  is a single-digit decimal number. Of particular importance is the value 8: this represents the UNIX system “standard” tab setting, and is the most likely tab setting to be found at a terminal. When  $-0$  is used, the tab stops are cleared and no new ones are set.

*Arbitrary* See OPERANDS.

*File* -file If the name of a *file* is given, tabs reads the first line of the file, searching for a format specification (see [fspec\(4\)](#)). If it finds one there, it sets the tab stops according to it, otherwise it sets them as  $-8$ . This type of specification may be used to make sure that a tabbed file is printed with correct tab settings, and would be used with the `pr` command:

```
example% tabs -file; pr file
```

Tab and margin setting is performed via the standard output.

**Operands** The following operand is supported:

*n1*[,*n2*, . . .] The *arbitrary* format consists of tab-stop values separated by commas or spaces. The tab-stop values must be positive decimal integers in ascending order. Up to 40 numbers are allowed. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. Thus, the formats **1,10,20,30**, and **1,10,+10,+10** are considered identical.

**Examples** EXAMPLE 1 Using the tabs command

The following command is an example using *-code* (*canned* specification) to set tabs to the settings required by the IBM assembler: columns 1, 10, 16, 36, 72:

```
example% tabs -a
```

The next command is an example of using *-n* (*repetitive* specification), where *n* is 8, causes tabs to be set every eighth position: 1+(1\*8), 1+(2\*8), . . . which evaluate to columns 9, 17, . . . :

```
example% tabs -8
```

This command uses *n1,n2,. . .* (*arbitrary* specification) to set tabs at columns 1, 8, and 36:

```
example% tabs 1,8,36
```

The last command is an example of using *-file* (*file* specification) to indicate that tabs should be set according to the first line of \$HOME/fspec.list/att4425 (see [fspec\(4\)](#)).

```
example% tabs -$HOME/fspec.list/att4425
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of tabs: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**TERM** Determine the terminal type. If this variable is unset or null, and if the *-T* option is not specified, terminal type `ansi+tabs` will be used.

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | system/core-os  |
| CSI                 | Enabled         |
| Interface Stability | Committed       |

---

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                    |
|----------------|------------------------------------|
| Standard       | See <a href="#">standards(5)</a> . |

**See Also** [expand\(1\)](#), [newform\(1\)](#), [pr\(1\)](#), [stty\(1\)](#), [tput\(1\)](#), [fspec\(4\)](#), [terminfo\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [term\(5\)](#), [standards\(5\)](#)

**Notes** There is no consistency among different terminals regarding ways of clearing tabs and setting the left margin.

tabs clears only 20 tabs (on terminals requiring a long sequence), but is willing to set 64.

The *tabspec* used with the tabs command is different from the one used with the newform command. For example, tabs -8 sets every eighth position; whereas newform -i-8 indicates that tabs are set every eighth position.

**Name** tail – deliver the last part of a file

**Synopsis** /usr/bin/tail [ $\pm$ s *number* [*lbcrl*]] [*file*]  
/usr/bin/tail [-*lbcrl*] [*file*]  
/usr/bin/tail [ $\pm$  *number* [*lbcfl*]] [*file*]  
/usr/bin/tail [-*lbcfl*] [*file*]  
/usr/xpg4/bin/tail [-*f* | -*r*] [-*c number* | -*n number*] [*file*]  
/usr/xpg4/bin/tail [ $\pm$  *number* [*l* | *b* | *c*] [*f*]] [*file*]  
/usr/xpg4/bin/tail [ $\pm$  *number* [*l*] [*f* | *r*]] [*file*]

**Description** The tail utility copies the named file to the standard output beginning at a designated place. If no file is named, the standard input is used.

Copying begins at a point in the file indicated by the *-c number*, *-n number*, or  $\pm$  *number* options (if  $\pm$  *number* is specified, begins at distance *number* from the beginning; if *- number* is specified, from the end of the input; if *number* is NULL, the value 10 is assumed). *number* is counted in units of lines or byte according to the *-c* or *-n* options, or lines, blocks, or bytes, according to the appended option *l*, *b*, or *c*. When no units are specified, counting is by lines.

**Options** The following options are supported for both /usr/bin/tail and /usr/xpg4/bin/tail. The *-r* and *-f* options are mutually exclusive. If both are specified on the command line, the *-f* option is ignored.

-b Units of blocks.

-c Units of bytes.

-f Follow. If the input-file is not a pipe, the program does not terminate after the line of the input-file has been copied, but enters an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input-file. Thus it can be used to monitor the growth of a file that is being written by some other process.

-l Units of lines.

-r Reverse. Copies lines from the specified starting point in the file in reverse order. The default for *r* is to print the entire file in reverse order.

/usr/xpg4/bin/tail The following options are supported for /usr/xpg4/bin/tail only:

-c *number* The *number* option-argument must be a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying:

+ Copying starts relative to the beginning of the file.

- Copying starts relative to the end of the file.

none Copying starts relative to the end of the file.

The origin for counting is 1; that is, `-c +1` represents the first byte of the file, `-c -1` the last.

`-n number` Equivalent to `-c number`, except the starting location in the file is measured in lines instead of bytes. The origin for counting is 1. That is, `-n +1` represents the first line of the file, `-n -1` the last.

**Operands** The following operand is supported:

*file* A path name of an input file. If no *file* operands are specified, the standard input is used.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `tail` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Using the tail Command

The following command prints the last ten lines of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed.

```
example% tail -f fred
```

The next command prints the last 15 bytes of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed:

```
example% tail -15cf fred
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `tail`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

|               | ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|---------------|----------------|
| /usr/bin/tail | Availability  | system/core-os |
|               | CSI           | Enabled        |

|                    | ATTRIBUTETYPE | ATTRIBUTEVALUE    |
|--------------------|---------------|-------------------|
| /usr/xpg4/bin/tail | Availability  | system/xopen/xcu4 |
|                    | CSI           | Enabled           |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [cat\(1\)](#), [head\(1\)](#), [more\(1\)](#), [pg\(1\)](#), [dd\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** Piped tails relative to the end of the file are stored in a buffer, and thus are limited in length. Various kinds of anomalous behavior can happen with character special files.

**Name** talk – talk to another user

**Synopsis** talk *address* [*terminal*]

**Description** The talk utility is a two-way, screen-oriented communication program.

When first invoked, talk sends a message similar to:

```
Message from TalkDaemon@ her_machine at time...
talk: connection requested by your_address
talk: respond with: talk your_address
```

to the specified *address*. At this point, the recipient of the message can reply by typing:

```
talk your_address
```

Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters are processed as follows:

- Typing the alert character will alert the recipient's terminal.
- Typing Control-L will cause the sender's screen regions to be refreshed.
- Typing the erase and kill characters will affect the sender's terminal in the manner described by the [termios\(3C\)](#) interface.
- Typing the interrupt or end-of-file (EOF) characters will terminate the local talk utility. Once the talk session has been terminated on one side, the other side of the talk session will be notified that the talk session has been terminated and will be able to do nothing except exit.
- Typing characters from LC\_CTYPE classifications print or space will cause those characters to be sent to the recipient's terminal.
- When and only when the stty iexten local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.
- Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a caret ( ^ ) followed by the appropriate ASCII character, and characters with the high-order bit set will appear in “meta” notation. For example, ‘\003’ is displayed as ‘^C’ and ‘\372’ as ‘M-z’.

Permission to be a recipient of a talk message can be denied or granted by use of the [mesg\(1\)](#) utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. Certain commands, such as [pr\(1\)](#), disallow messages in order to prevent interference with their output. talk will fail when the user lacks the appropriate privileges to perform the requested action.

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for talk. When this type of exchange cannot be

supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.

**Operands** The following operands are supported:

*address* The recipient of the talk session. One form of *address* is the *username*, as returned by the [who\(1\)](#) utility. If you wish to talk to someone on your own machine, then *username* is just the person's login name. If you wish to talk to a user on another host, then *username* is one of the following forms:

*host!user*  
*host.user*  
*host:user*  
*user@host*

although *user@host* is perhaps preferred.

*terminal* If the recipient is logged in more than once, *terminal* can be used to indicate the appropriate terminal name. If *terminal* is not specified, the talk message will be displayed on one or more accessible terminals in use by the recipient. The format of *terminal* will be the same as that returned by [who](#).

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of talk: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

TERM Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified terminal type will be used.

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred, or talk was invoked on a terminal incapable of supporting it.

**Files** /etc/hosts host name database  
 /var/adm/utmpx user and accounting information for talk

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |

| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [mail\(1\)](#), [mesg\(1\)](#), [pr\(1\)](#), [stty\(1\)](#), [who\(1\)](#), [write\(1\)](#), [talkd\(1M\)](#), [termios\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes** Typing Control-L redraws the screen, while the erase, kill, and word kill characters will work in `talk` as normal. To exit, type an interrupt character. `talk` then moves the cursor to the bottom of the screen and restores the terminal to its previous state.

**Name** tar – create tape archives and add or extract files

**Synopsis** tar c[BDFHijlnopTVwzZ@[0-7]][bf][X...] [*blocksize*]  
           [*tarfile*] [*size*] [*exclude-file*]...  
           {*file* | -I *include-file* | -C *directory file*}...  
 tar r[BDFHijlnTVwzZ@[0-7]][bf] [*blocksize*] [*tarfile*]  
           [*size*]  
           {*file* | -I *include-file* | -C *directory file*}...  
 tar t[BFHijlnTvzZ[0-7]][f][X...] [*tarfile*] [*size*]  
           [*exclude-file*]... {*file* | -I *include-file*}...  
 tar u[BDFHijlnTVwzZ@[0-7]][bf] [*blocksize*] [*tarfile*]  
           [*size*] *file*...  
 tar x[BFHilmnjopTVwzZ@[0-7]][f][X...] [*tarfile*] [*size*]  
           [*exclude-file*]... [*file*]...

**Description** The tar command archives and extracts files to and from a single file called a *tarfile*. A tarfile is usually a magnetic tape, but it can be any file. tar's actions are controlled by the *key* argument. The *key* is a string of characters containing exactly one function letter (c, r, t, u, or x) and zero or more function modifiers (letters or digits), depending on the function letter used. The *key* string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the *key* string.

The -I *include-file*, -C *directory file*, and *file* arguments specify which files or directories are to be archived or extracted. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory. Arguments appearing within braces ( { } ) indicate that one of the arguments must be specified.

**Operands** The following operands are supported:

-C *directory file*

Performs a `chdir` (see [cd\(1\)](#)) operation on *directory* and performs the c (create) or r (replace) operation on *file*. Use short relative path names for *file*. If *file* is ".", archive all files in *directory*. This operand enables archiving files from multiple directories not related by a close common parent.

-I *include-file*

Opens *include-file* containing a list of files, one per line, and treats it as if each file appeared separately on the command line. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the included file, the entire line (apart from the newline) is used to match against the initial string of files to include. In the case where excluded files (see X function modifier) are also specified, they take precedence over all included files. If a file is specified in both the *exclude-file* and the *include-file* (or on the command line), it is excluded.

*file*

A path name of a regular file or directory to be archived (when the *c*, *r* or *u* functions are specified), extracted (*x*) or listed (*t*). When *file* is the path name of a directory, the action applies to all of the files and (recursively) subdirectories of that directory.

When a file is archived, and the *E* flag (see *Function Modifiers*) is not specified, the filename cannot exceed 256 characters. In addition, it must be possible to split the name between parent directory names so that the prefix is no longer than 155 characters and the name is no longer than 100 characters. If *E* is specified, a name of up to *PATH\_MAX* characters can be specified.

For example, a file whose basename is longer than 100 characters could not be archived without using the *E* flag. A file whose directory portion is 200 characters and whose basename is 50 characters could be archived (without using *E*) if a slash appears in the directory name somewhere in character positions 151-156.

Function Letters The function portion of the key is specified by one of the following letters:

*c*

Create. Writing begins at the beginning of the tarfile, instead of at the end.

*r*

Replace. The named *files* are written at the end of the tarfile. A file created with extended headers must be updated with extended headers (see *E* flag under *Function Modifiers*). A file created without extended headers cannot be modified with extended headers.

*t*

Table of Contents. The names of the specified files are listed each time they occur in the tarfile. If no *file* argument is specified, the names of all files and any associated extended attributes in the tarfile are listed. With the *v* function modifier, additional information for the specified files is displayed.

*u*

Update. The named *files* are written at the end of the tarfile if they are not already in the tarfile, or if they have been modified since last written to that tarfile. An update can be rather slow. A tarfile created on a 5.x system cannot be updated on a 4.x system. A file created with extended headers must be updated with extended headers (see *E* flag under *Function Modifiers*). A file created without extended headers cannot be modified with extended headers.

*x*

Extract or restore. The named *files* are extracted from the tarfile and written to the directory specified in the tarfile, relative to the current directory. Use the relative path names of files and directories to be extracted.

Absolute path names contained in the tar archive are unpacked using the absolute path names, that is, the leading forward slash (*/*) is *not* stripped off.

By default, absolute pathnames (those that begin with a / character) have the leading slash removed, therefore extracting those files and directories relative to the current directory.

If a named file matches a directory whose contents has been written to the tarfile, this directory is recursively extracted. The owner, modification time, and mode are restored, if possible. Otherwise, to restore owner, you must be the super-user. Character-special and block-special devices (created by `mknod(1M)`) can only be extracted by the super-user. If no *file* argument is specified, the entire content of the tarfile is extracted. If the tarfile contains several files with the same name, each file is written to the appropriate directory, overwriting the previous one. Filename substitution wildcards cannot be used for extracting files from the archive. Rather, use a command of the form:

```
tar xvf ... /dev/rmt/0` tar tf ... /dev/rmt/0 | \
 grep 'pattern'`
```

When extracting tapes created with the `r` or `u` functions, directory modification times can not be set correctly. These same functions cannot be used with many tape drives due to tape drive limitations such as the absence of backspace or append capabilities.

When using the `r`, `u`, or `x` functions or the `X` function modifier, the named files must match exactly the corresponding files in the *tarfile*. For example, to extract `./thisfile`, you must specify `./thisfile`, and not `thisfile`. The `t` function displays how each file was archived.

Function Modifiers The characters below can be used in conjunction with the letter that selects the desired function.

#### **b** *blocksize*

Blocking Factor. Use when reading or writing to raw magnetic archives (see `f` below). The *blocksize* argument specifies the number of 512-byte tape blocks to be included in each read or write operation performed on the tarfile. The minimum is 1, the default is 20. The maximum value is a function of the amount of memory available and the blocking requirements of the specific tape device involved (see `mtio(7I)` for details.) The maximum cannot exceed `INT_MAX/512` (4194303).

When a tape archive is being read, its actual blocking factor is automatically detected, provided that it is less than or equal to the nominal blocking factor (the value of the *blocksize* argument, or the default value if the `b` modifier is not specified). If the actual blocking factor is greater than the nominal blocking factor, a read error results. See Example 5 in EXAMPLES.

#### **B**

Block. Force `tar` to perform multiple reads (if necessary) to read exactly enough bytes to fill a block. This function modifier enables `tar` to work across the Ethernet, since pipes and sockets return partial blocks even when more data is coming. When reading from standard input, “-”, this function modifier is selected by default to ensure that `tar` can recover from short reads.

## D

Data change warnings. Used with *c*, *r*, or *u* function letters. Ignored with *t* or *x* function letters. If the size of a file changes while the file is being archived, treat this condition as a warning instead of as an error. A warning message is still written, but the exit status is not affected.

## E

Write a tarfile with extended headers. (Used with *c*, *r*, or *u* function letters. Ignored with *t* or *x* function letters.) When a tarfile is written with extended headers, the modification time is maintained with a granularity of microseconds rather than seconds. In addition, filenames no longer than `PATH_MAX` characters that could not be archived without *E*, and file sizes greater than 8GB, are supported. The *E* flag is required whenever the larger files and/or files with longer names, or whose UID/GID exceed 2097151, are to be archived, or if time granularity of microseconds is desired.

## f

File. Use the *tarfile* argument as the name of the tarfile. If *f* is specified, `/etc/default/tar` is not searched. If *f* is omitted, *tar* uses the device indicated by the `TAPE` environment variable, if set. Otherwise, *tar* uses the default values defined in `/etc/default/tar`. The number matching the `archiveN` string is used as the output device with the blocking and size specifications from the file. For example,

```
tar -c 2/tmp/*
```

writes the output to the device specified as `archive2` in `/etc/default/tar`.

If the name of the tarfile is “-”, *tar* writes to the standard output or reads from the standard input, whichever is appropriate. *tar* can be used as the head or tail of a pipeline. *tar* can also be used to move hierarchies with the command:

```
example% cd fromdir; tar cf - . | (cd todir; tar xfbp -)
```

## F

With one *F* argument, *tar* excludes all directories named `SCCS` and `RCS` from the tarfile. With two arguments, *FF*, *tar* excludes all directories named `SCCS` and `RCS`, all files with `.o` as their suffix, and all files named `errs`, `core`, and `a.out`.

## h

Follow symbolic links as if they were normal files or directories. Normally, *tar* does not follow symbolic links.

## i

Ignore directory checksum errors.

## j

*c* mode only. Compress the resulting archive with `bzip2`. In extract or list modes, this option is ignored. The implementation recognizes `bzip2` compression type automatically when reading archives. Upgrade/replace first decompresses and then applies the same mechanism to compress the archive automatically.

- l**  
Link. Output error message if unable to resolve all links to the files being archived. If **l** is not specified, no error messages are printed.
- m**  
Modify. The modification time of the file is the time of extraction. This function modifier is valid only with the **x** function.
- n**  
The file being read is a non-tape device. Reading of the archive is faster since **tar** can randomly seek around the archive.
- o**  
Ownership. Assign to extracted files the user and group identifiers of the user running the program, rather than those on tarfile. This is the default behavior for users other than root. If the **o** function modifier is not set and the user is root, the extracted files takes on the group and user identifiers of the files on tarfile (see [chown\(1\)](#) for more information). The **o** function modifier is only valid with the **x** function.
- p**  
Restore the named files to their original modes, and ACLs if applicable, ignoring the present [umask\(1\)](#). This is the default behavior if invoked as super-user with the **x** function letter specified. If super-user, SETUID, and sticky information are also extracted, and files are restored with their original owners and permissions, rather than owned by root. When this function modifier is used with the **c** function, ACLs are created in the tarfile along with other information. Errors occur when a tarfile with ACLs is extracted by previous versions of **tar**.
- P**  
For archive creation, suppress the addition of a trailing **/** on directory entries in the archive.  
  
For archive extraction, preserve pathnames. By default, absolute pathnames (those that begin with a **/** character) have the leading slash removed when extracting archives. Also, **tar** refuses to extract archive entries whose pathnames contain a dot-dot (**..**).  
  
This option suppresses these behaviors.
- T**  
This modifier is only available if the system is configured with Trusted Extensions.  
  
When this modifier is used with the function letter **c**, **r**, or **u** for creating, replacing or updating a tarfile, the sensitivity label associated with each archived file and directory is stored in the tarfile.  
  
Specifying **T** implies the function modifier **p**.  
  
When used with the function letter **x** for extracting a tarfile, the **tar** program verifies that the file's sensitivity label specified in the archive equals the sensitivity label of the destination directory. If not, the file is not restored. This operation must be invoked from

the global zone. If the archived file has a relative pathname, it is restored to the corresponding directory with the same label, if available. This is done by prepending to the current destination directory the root pathname of the zone whose label equals the file. If no such zone exists, the file is not restored.

Limited support is provided for extracting labeled archives from Trusted Solaris 8. Only sensitivity labels, and multi-level directory specifications are interpreted. Privilege specifications and audit attribute flags are silently ignored. Multilevel directory specifications including symbolic links to single level directories are mapped into zone-relative pathnames if a zone with the same label is available. This support is intended to facilitate migration of home directories. Architectural differences preclude the extraction of arbitrarily labeled files from Trusted Solaris 8 into identical pathnames in Trusted Extensions. Files cannot be extracted unless their archived label matches the destination label.

v

Verbose. Output the name of each file preceded by the function letter. With the `t` function, `v` provides additional information about the tarfile entries. The listing is similar to the format produced by the `-l` option of the `ls(1)` command.

w

What. Output the action to be taken and the name of the file, then await the user's confirmation. If the response is affirmative, the action is performed; otherwise, the action is not performed. This function modifier cannot be used with the `t` function.

X

Exclude. Use the *exclude-file* argument as a file containing a list of relative path names for files (or directories) to be excluded from the tarfile when using the functions `c`, `x`, or `t`. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the excluded file, the entire line (apart from the newline) is used to match against the initial string of files to exclude. Lines in the exclude file are matched exactly, so an entry like `/var` does *not* exclude the `/var` directory if `tar` is backing up relative pathnames. The entry should read `./var` under these circumstances. The `tar` command does not expand shell metacharacters in the exclude file, so specifying entries like `*.o` does not have the effect of excluding all files with names suffixed with `.o`. If a complex list of files is to be excluded, the exclude file should be generated by some means such as the `find(1)` command with appropriate conditions.

Multiple `X` arguments can be used, with one *exclude-file* per argument. In the case where included files (see `-I include-file` operand) are also specified, the excluded files take precedence over all included files. If a file is specified in both the *exclude-file* and the *include-file* (or on the command line), it is excluded.

z

`c` mode only. Compress the resulting archive with `gzip`. In extract or list mode, this option is ignored. The implementation recognizes `gzip` compression type automatically when

reading archives. Upgrade/replace first decompresses and then applies the same mechanism to compress the archive automatically.

Z

c mode only. Compress the resulting archive with `compress`. See [compress\(1\)](#). In extract or list modes, this option is ignored. The implementation recognizes `compress` compression type automatically when reading archives. Upgrade/replace first decompresses and then applies the same mechanism to compress the archive automatically.

@

Include extended attributes in archive. By default, `tar` does not place extended attributes in the archive. With this flag, `tar` looks for extended attributes on the files to be placed in the archive and add them to the archive. Extended attributes go in the archive as special files with a special type label. When this modifier is used with the `x` function, extended attributes are extracted from the tape along with the normal file data. Extended attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.

/

Include extended system attributes in archive. By default, `tar` does not place extended system attributes in the archive. With this flag, `tar` looks for extended system attributes on the files to be placed in the archive and adds them to the archive. Extended system attributes go in the archive as special files with a special type label. When this modifier is used with the `x` function, extended system attributes are extracted from the tape along with the normal file data. Extended system attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.

[0-7]

Select an alternative drive on which the tape is mounted. The default entries are specified in `/etc/default/tar`. If no digit or `f` function modifier is specified, the entry in `/etc/default/tar` with digit “0” is the default.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `tar` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

The automatic determination of the actual blocking factor can be fooled when reading from a pipe or a socket (see the `B` function modifier below).

1/4” streaming tape has an inherent blocking factor of one 512-byte block. It can be read or written using any blocking factor.

This function modifier works for archives on disk files and block special devices, among others, but is intended principally for tape devices.

For information on `tar` header format, see [archives.h\(3HEAD\)](#).

**Examples** EXAMPLE 1 Creating an Archive of Your Home Directory

The following is an example using `tar` to create an archive of your home directory on a tape mounted on drive `/dev/rmt/0`:

```
example% cd
example% tar cvf /dev/rmt/0 .
messages from tar
```

The `c` function letter means create the archive. The `v` function modifier outputs messages explaining what `tar` is doing. The `f` function modifier indicates that the tarfile is being specified (`/dev/rmt/0` in this example). The dot (`.`) at the end of the command line indicates the current directory and is the argument of the `f` function modifier.

Display the table of contents of the tarfile with the following command:

```
example% tar tvf /dev/rmt/0
```

The output is similar to the following for the POSIX locale:

```
rw-r--r-- 1677/40 2123 Nov 7 18:15 1985 ./test.c
...
example%
```

The columns have the following meanings:

- column 1 is the access permissions to `./test.c`
- column 2 is the *user-id/group-id* of `./test.c`
- column 3 is the size of `./test.c` in bytes
- column 4 is the modification date of `./test.c`. When the `LC_TIME` category is not set to the POSIX locale, a different format and date order field can be used.
- column 5 is the name of `./test.c`

To extract files from the archive:

```
example% tar xvf /dev/rmt/0
messages from tar
example%
```

If there are multiple archive files on a tape, each is separated from the following one by an EOF marker. To have `tar` read the first and second archives from a tape with multiple archives on it, the *non-rewinding* version of the tape device name must be used with the `f` function modifier, as follows:

```
example% tar xvfp /dev/rmt/0n read first archive from tape
messages from tar
example% tar xvfp /dev/rmt/0n read second archive from tape
messages from tar
example%
```

**EXAMPLE 1** Creating an Archive of Your Home Directory (Continued)

Notice that in some earlier releases, the above scenario did not work correctly, and intervention with `mt(1)` between `tar` invocations was necessary. To emulate the old behavior, use the non-rewind device name containing the letter `b` for BSD behavior. See the `Close Operations` section of the `mtio(7I)` manual page.

**EXAMPLE 2** Archiving Files from `/usr/include` and from `/etc` to Default Tape Drive 0

To archive files from `/usr/include` and from `/etc` to default tape drive 0:

```
example% tar c -C /usr include -C /etc .
```

The table of contents from the resulting tarfile would produce output like the following:

```
include/
include/a.out.h
and all the other files in /usr/include ...
./chown and all the other files in /etc
```

To extract all files in the `include` directory:

```
example% tar xv include
x include/, 0 bytes, 0 tape blocks \
 and all files under include ...
```

**EXAMPLE 3** Transferring Files Across the Network

The following is an example using `tar` to transfer files across the network. First, here is how to archive files from the local machine (`example`) to a tape on a remote system (`host`):

```
example% tar cvfb - 20 files | \
 ssh host dd of=/dev/rmt/0 obs=20b
messages from tar
example%
```

In the example above, we are *creating a tarfile* with the `c` key letter, asking for *verbose* output from `tar` with the `v` function modifier, specifying the name of the output *tarfile* using the `f` function modifier (the standard output is where the *tarfile* appears, as indicated by the `'-'` sign), and specifying the blocksize (`20`) with the `b` function modifier. If you want to change the blocksize, you must change the blocksize arguments both on the `tar` command *and* on the `dd` command.

**EXAMPLE 4** Retrieving Files from a Tape on the Remote System Back to the Local System

The following is an example that uses `tar` to retrieve files from a tape on the remote system back to the local system:

```
example% ssh -n host dd if=/dev/rmt/0 bs=20b | \
 tar xvBfb - 20 files
```

**EXAMPLE 4** Retrieving Files from a Tape on the Remote System Back to the Local System  
(Continued)

```
messages from tar
example%
```

In the example above, we are *extracting* from the *tarfile* with the *x* key letter, asking for *verbose output from tar* with the *v* function modifier, telling *tar* it is reading from a pipe with the *B* function modifier, specifying the name of the input *tarfile* using the *f* function modifier (the standard input is where the *tarfile* appears, as indicated by the “-” sign), and specifying the blocksize (20) with the *b* function modifier.

**EXAMPLE 5** Creating an Archive of the Home Directory

The following example creates an archive of the home directory on `/dev/rmt/0` with an actual blocking factor of 19:

```
example% tar cvfb /dev/rmt/0 19 $HOME
```

To recognize this archive's actual blocking factor without using the *b* function modifier:

```
example% tar tvf /dev/rmt/0
tar: blocksize = 19
...
```

To recognize this archive's actual blocking factor using a larger nominal blocking factor:

```
example% tar tvf /dev/rmt/0 30
tar: blocksize = 19
...
```

Attempt to recognize this archive's actual blocking factor using a nominal blocking factor that is too small:

```
example% tar tvf /dev/rmt/0 10
tar: tape read error
```

**EXAMPLE 6** Creating Compressed Archives

The following example creates a compressed archive using *bzip*:

```
example% tar cjf tarfile /tmp/*
```

The compressed file name is `tarfile.bz2`

The same compressed archive would be created in this case if the following sequence of commands had been used instead:

```
example% tar cf tarfile /tmp/*
example% bzip2 tarfile
```

however, the creation and removal of the intermediate file is eliminated. The function modifiers *z* and *Z* behave similarly, but use *gzip* and *compress*, respectively.

**EXAMPLE 6** Creating Compressed Archives *(Continued)*

The following example creates a compressed archive using `compress`:

```
example% tar czf tarfile /tmp/*
```

The compressed file name is `tarfile.Z`.

The following example creates a compressed archive using `gzip`:

```
example% tar czf tarfile /tmp/*
```

The compressed file name is `tarfile.gz`.

**EXAMPLE 7** Extracting Files from a Compressed Archive

The following examples extract files from a compressed archive: For archives compressed using `bzip2` compression mode:

```
example% tar xvf tarfile.bz2
example% tar xvfj tarfile.bz2
example% bzcata tarfile.bz2 | tar xvf -
```

For archives compressed using `compress` compression mode:

```
example% tar xvf tarfile.Z
example% tar xvfZ tarfile.Z
example% zcat tarfile.Z | tar xvf -
```

For archives compressed using `gzip` compression mode:

```
example% tar xvf tarfile.gz
example% tar xvfz tarfile.gz
example% gzcat tarfile.gz | tar xvf -
```

**Environment** **TMPDIR****Variables**

Creates a temporary file in `/tmp` by default. Otherwise, `tar` uses the directory specified by `TMPDIR`.

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `tar`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

Affirmative responses are processed using the extended regular expression defined for the `yesexpr` keyword in the `LC_MESSAGES` category of the user's locale. The locale specified in the `LC_COLLATE` category defines the behavior of ranges, equivalence classes, and multi-character collating elements used in the expression defined for `yesexpr`. The locale specified in `LC_CTYPE` determines the locale for interpretation of sequences of bytes of text data a characters, the behavior of character classes used in the expression defined for the `yesexpr`. See [locale\(5\)](#).

**Exit Status** The following exit values are returned:

0  
Successful completion.

>0  
An error occurred.

- Files**
- /dev/rmt/[0-7][b][n]
  - /dev/rmt/[0-7]l[b][n]
  - /dev/rmt/[0-7]m[b][n]
  - /dev/rmt/[0-7]h[b][n]
  - /dev/rmt/[0-7]u[b][n]
  - /dev/rmt/[0-7]c[b][n]
  - /etc/default/tar

Setting for /etc/default/tar might look like the following:

```
archive0=/dev/rmt/0
archive1=/dev/rmt/0n
archive2=/dev/rmt/1
archive3=/dev/rmt/1n
archive4=/dev/rmt/0
archive5=/dev/rmt/0n
archive6=/dev/rmt/1
archive7=/dev/rmt/1n
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | system/core-os |
| CSI                 | Enabled        |
| Interface Stability | Committed      |

**See Also** [ar\(1\)](#), [basename\(1\)](#), [cd\(1\)](#), [chown\(1\)](#), [compress\(1\)](#), [cpio\(1\)](#), [csh\(1\)](#), [dirname\(1\)](#), [find\(1\)](#), [ls\(1\)](#), [mt\(1\)](#), [pax\(1\)](#), [setfacl\(1\)](#), [umask\(1\)](#), [mknod\(1M\)](#), [archives.h\(3HEAD\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [mtio\(7I\)](#)

**Diagnostics** Diagnostic messages are output for bad key characters and tape read/write errors, and for insufficient memory to hold the link tables.

**Notes** There is no way to access the *n*-th occurrence of a file.

Tape errors are handled ungracefully.

The tar archive format allows UIDs and GIDs up to 2097151 to be stored in the archive header. Files with UIDs and GIDs greater than this value is archived with the UID and GID of 60001.

If an archive is created that contains files whose names were created by processes running in multiple locales, a single locale that uses a full 8-bit codeset (for example, the en\_US locale) should be used both to create the archive and to extract files from the archive.

Neither the r function letter nor the u function letter can be used with quarter-inch archive tapes, since these tape drives cannot backspace.

Since tar has no options, the standard “—” argument that is normally used in other utilities to terminate recognition of options is not needed. If used, it is recognized only as the first argument and is ignored.

Since `-C directory file` and `-I include-file` are multi-argument operands, any of the following methods can be used to archive or extract a file named `-C` or `-I`:

1. Specify them using file operands containing a / character on the command line (such as `/home/joe/-C` or `./-I`).
2. Include them in an include file with `-I include-file`.
3. Specify the directory in which the file resides:  
`-C directory -C`  
or  
`-C directory -I`
4. Specify the entire directory in which the file resides:  
`-C directory .`

**Name** tbl – format tables for nroff or troff

**Synopsis** tbl [-me] [-mm] [-ms] [*filename*]...

**Description** tbl is a preprocessor for formatting tables for **nroff(1)** or **troff(1)**. The input *filenames* are copied to the standard output, except that lines between .TS and .TE command lines are assumed to describe tables and are reformatted.

If no arguments are given, tbl reads the standard input, so tbl may be used as a filter. When tbl is used with **eqn(1)** or **neqn**, the tbl command should be first, to minimize the volume of data passed through pipes.

**Options**

- me Copy the -me macro package to the front of the output file.
- mm Copy the -mm macro package to the front of the output file.
- ms Copy the -ms macro package to the front of the output file.

**Examples** EXAMPLE 1 Using tbl

As an example, letting '@' (at-sign) represent a TAB, which should be typed as an actual TAB character in the input file

```
.TS
c s s
c c s
c c c
l n n.
Household Population
Town@Households
@Number@Size
Bedminster@789@3.26
Bernards Twp.@3087@3.74
Bernardsville@2018@3.30
Bound Brook@3425@3.04
Branchburg@1644@3.49

| Availability   | text/doctools   |

**See Also** [eqn\(1\)](#), [nroff\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#)

**Name** tcopy – copy a magnetic tape

**Synopsis** tcopy *source* [*destination*]

**Description** The tcopy utility copies the magnetic tape mounted on the tape drive specified by the *source* argument. The only assumption made about the contents of a tape is that there are two tape marks at the end.

When only a source drive is specified, tcopy scans the tape, and displays information about the sizes of records and tape files. If a destination is specified, tcopy makes a copies the source tape onto the *destination* tape, with blocking preserved. As it copies, tcopy produces the same output as it does when only scanning a tape.

The tcopy utility requires the use of Berkeley-compatible device names. For example,

```
example% tcopy /dev/rmt/1b /dev/rmt/2b
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [mt\(1\)](#), [ioctl\(2\)](#), [attributes\(5\)](#)

**Notes** tcopy will only run on systems supporting an associated set of [ioctl\(2\)](#) requests.

**Name** tee – replicate the standard output

**Synopsis** /usr/bin/tee [-ai] [*file*...]

**Description** tee copies standard input to standard output and to zero or more files. The options determine whether the specified files are overwritten or appended to. The tee utility does not buffer output. If a write to a file fails, tee continues to write to other files although it exits with a non-zero exit status.

The number of *file* operands that can be specified is limited by the underlying operating system.

**Options** The following options are supported:

- a Appends the output to the files rather than overwriting them.
- i Ignores interrupts.

**Operands** The following operands are supported:

*file* A path name of an output file.

**Usage** See [largefile\(5\)](#) for the description of the behavior of tee when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of tee: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 Successful completion. The standard input was successfully copied to all output files.
- >0 An error occurred. The number of files that could not be opened or whose status could not be obtained.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |

**Name** telnet – user interface to a remote system using the TELNET protocol

**Synopsis** telnet [-8EFKLacdfrx] [-X *atype*] [-e *escape\_char*]  
 [-k *realm*] [-l *user*] [-n *file*]  
 [ [ [!] @hop1 [@hop2... ] @] *host* [*port*]]

**Description** The telnet utility communicates with another host using the TELNET protocol. If telnet is invoked without arguments, it enters command mode, indicated by its prompt, telnet>. In this mode, it accepts and executes its associated commands. See USAGE. If it is invoked with arguments, it performs an open command with those arguments.

If, for example, a *host* is specified as *@hop1@hop2@host*, the connection goes through hosts *hop1* and *hop2*, using loose source routing to end at *host*. If a leading ! is used, the connection follows strict source routing. Notice that when telnet uses IPv6, it can only use loose source routing, and the connection ignores the !.

Once a connection has been opened, telnet enters input mode. In this mode, text typed is sent to the remote host. The input mode entered will be either “line mode”, “character at a time”, or “old line by line”, depending upon what the remote system supports.

In “line mode”, character processing is done on the local system, under the control of the remote system. When input editing or character echoing is to be disabled, the remote system will relay that information. The remote system will also relay changes to any special characters that happen on the remote system, so that they can take effect on the local system.

In “character at a time” mode, most text typed is immediately sent to the remote host for processing.

In “old line by line” mode, all text is echoed locally, and (normally) only completed lines are sent to the remote host. The “local echo character” (initially ^E) may be used to turn off and on the local echo. (Use this mostly to enter passwords without the password being echoed.)

If the “line mode” option is enabled, or if the `localchars` toggle is TRUE (the default in “old line by line” mode), the user's `quit`, `intr`, and `flush` characters are trapped locally, and sent as TELNET protocol sequences to the remote side. If “line mode” has ever been enabled, then the user's `susp` and `eof` are also sent as TELNET protocol sequences. `quit` is then sent as a TELNET ABORT instead of BREAK. The options `toggle autoflush` and `toggle autosynch` cause this action to flush subsequent output to the terminal (until the remote host acknowledges the TELNET sequence); and to flush previous terminal input, in the case of `quit` and `intr`.

While connected to a remote host, the user can enter telnet command mode by typing the telnet escape character (initially ^]). When in command mode, the normal terminal editing conventions are available. Pressing RETURN at the telnet command prompt causes telnet to exit command mode.

**Options** The following options are supported:

- 8  
Specifies an 8-bit data path. Negotiating the TELNET BINARY option is attempted for both input and output.
- a  
Attempts automatic login. This sends the user name by means of the USER variable of the ENVIRON option, if supported by the remote system. The name used is that of the current user as returned by `getlogin(3C)` if it agrees with the current user ID. Otherwise, it is the name associated with the user ID.
- c  
Disables the reading of the user's `telnetrc` file. (See the `toggle skiprc` command on this reference page.)
- d  
Sets the initial value of the debug toggle to TRUE.
- e *escape\_char*  
Sets the initial escape character to *escape\_char*. *escape\_char* may also be a two character sequence consisting of ^ (Control key) followed by one character. If the second character is ?, the DEL character is selected. Otherwise, the second character is converted to a control character and used as the escape character. If *escape\_char* is defined as the null string (that is, -e ''), this is equivalent to -e '^@' (Control-@). To specify that no character can be the escape character, use the -E option.
- E  
Stops any character from being recognized as an escape character.
- f  
Forwards a copy of the local credentials to the remote system.
- F  
Forwards a forwardable copy of the local credentials to the remote system.
- k *realm*  
If Kerberos authentication is being used, requests that `telnet` obtain tickets for the remote host in *realm* instead of the remote host's default realm as determined in `krb5.conf(4)`.
- K  
Specifies no automatic login to the remote system.
- l *user*  
When connecting to a remote system that understands the ENVIRON option, then *user* will be sent to the remote system as the value for the ENVIRON variable USER.
- L  
Specifies an 8-bit data path on output. This causes the BINARY option to be negotiated on output.

- n *tracefile*  
Opens *tracefile* for recording trace information. See the set *tracefile* command below.
- r  
Specifies a user interface similar to `rlogin`. In this mode, the escape character is set to the tilde (~) character, unless modified by the -e option. The `rlogin` escape character is only recognized when it is preceded by a carriage return. In this mode, the telnet escape character, normally '^\_]', must still precede a telnet command. The `rlogin` escape character can also be followed by '\r' or '^Z', and, like `rlogin(1)`, closes or suspends the connection, respectively. This option is an uncommitted interface and may change in the future.
- x  
Turns on encryption of the data stream. When this option is turned on, telnet will exit with an error if authentication cannot be negotiated or if encryption cannot be turned on.
- X *atype*  
Disables the *atype* type of authentication.

## Usage

telnet Commands The commands described in this section are available with telnet. It is necessary to type only enough of each command to uniquely identify it. (This is also true for arguments to the mode, set, toggle, unset, environ, and display commands.)

auth *argument* ...

The auth command manipulates the information sent through the TELNET AUTHENTICATE option. Valid arguments for the auth command are as follows:

disable *type*

Disables the specified type of authentication. To obtain a list of available types, use the auth disable ? command.

enable *type*

Enables the specified type of authentication. To obtain a list of available types, use the auth enable ? command.

status

Lists the current status of the various types of authentication.

open [-l *user*] [[!] @*hop1* [@*hop2* ...]@*host* [*port* ]

Open a connection to the named host. If no port number is specified, telnet will attempt to contact a TELNET server at the default port. The host specification may be either a host name (see `hosts(4)`) or an Internet address specified in the “dot notation” (see `inet(7P)` or `inet6(7P)`). If the *host* is specified as @*hop1*@*hop2*@*host*, the connection goes through hosts *hop1* and *hop2*, using loose source routing to end at *host*. The @ symbol is required as a separator between the hosts specified. If a leading ! is used with IPv4, the connection follows strict source routing.

The `-l` option passes the *user* as the value of the ENVIRON variable `USER` to the remote system.

#### `close`

Close any open TELNET session. An EOF (in command mode) will also close a session and exit.

#### `encrypt`

The `encrypt` command manipulates the information sent through the TELNET ENCRYPT option.

Valid arguments for the `encrypt` command are as follows:

##### `disable type [input|output]`

Disables the specified type of encryption. If you omit the input and output, both input and output are disabled. To obtain a list of available types, use the `encrypt disable ?` command.

##### `enable type [input|output]`

Enables the specified type of encryption. If you omit input and output, both input and output are enabled. To obtain a list of available types, use the `encrypt enable ?` command.

##### `input`

This is the same as the `encrypt start input` command.

##### `-input`

This is the same as the `encrypt stop input` command.

##### `output`

This is the same as the `encrypt start output` command.

##### `-output`

This is the same as the `encrypt stop output` command.

##### `start [input|output]`

Attempts to start encryption. If you omit input and output, both input and output are enabled. To obtain a list of available types, use the `encrypt enable ?` command.

##### `status`

Lists the current status of encryption.

##### `stop [input|output]`

Stops encryption. If you omit input and output, encryption is on both input and output.

##### `type type`

Sets the default type of encryption to be used with later `encrypt start` or `encrypt stop` commands.

#### `quit`

Same as `close`.

z

Suspend `telnet`. This command only works when the user is using a shell that supports job control, such as `sh(1)`.

*mode type*

The remote host is asked for permission to go into the requested mode. If the remote host is capable of entering that mode, the requested mode will be entered. The argument *type* is one of the following:

*character*

Disable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then enter “character at a time” mode.

*line*

Enable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then attempt to enter “old-line-by-line” mode.

*isig (-isig)*

Attempt to enable (disable) the TRAPSIG mode of the LINEMODE option. This requires that the LINEMODE option be enabled.

*edit (-edit)*

Attempt to enable (disable) the EDIT mode of the LINEMODE option. This requires that the LINEMODE option be enabled.

*softtabs (-softtabs)*

Attempt to enable (disable) the SOFT\_TAB mode of the LINEMODE option. This requires that the LINEMODE option be enabled.

*litecho (-litecho)*

Attempt to enable (disable) the LIT\_ECHO mode of the LINEMODE option. This requires that the LINEMODE option be enabled.

*?*

Prints out help information for the mode command.

*status*

Show the current status of `telnet`. This includes the peer one is connected to, as well as the current mode.

*display*

[*argument . . .*] Display all, or some, of the set and toggle values (see `toggle argument. . .`).

*?*

[*command*] Get help. With no arguments, `telnet` prints a help summary. If a command is specified, `telnet` will print the help information for just that command.

*send argument . . .*

Send one or more special character sequences to the remote host. The following are the arguments that can be specified (more than one argument may be specified at a time):

**escape**

Send the current telnet escape character (initially ^]).

**synch**

Send the TELNET SYNCH sequence. This sequence discards all previously typed, but not yet read, input on the remote system. This sequence is sent as TCP urgent data and may not work if the remote system is a 4.2 BSD system. If it does not work, a lowercase "r" may be echoed on the terminal.

**brk or break**

Send the TELNET BRK (Break) sequence, which may have significance to the remote system.

**ip**

Send the TELNET IP (Interrupt Process) sequence, which aborts the currently running process on the remote system.

**abort**

Send the TELNET ABORT (Abort Process) sequence.

**ao**

Send the TELNET AO (Abort Output) sequence, which flushes all output from the remote system to the user's terminal.

**ayt**

Send the TELNET AYT (Are You There) sequence, to which the remote system may or may not respond.

**ec**

Send the TELNET EC (Erase Character) sequence, which erases the last character entered.

**el**

Send the TELNET EL (Erase Line) sequence, which should cause the remote system to erase the line currently being entered.

**eof**

Send the TELNET EOF (End Of File) sequence.

**eor**

Send the TELNET EOR (End Of Record) sequence.

**ga**

Send the TELNET GA (Go Ahead) sequence, which probably has no significance for the remote system.

**getstatus**

If the remote side supports the TELNET STATUS command, `getstatus` will send the subnegotiation to request that the server send its current option status.

**nop**

Send the TELNET NOP (No Operation) sequence.

`susp`

Send the TELNET SUSP (Suspend Process) sequence.

`do option`

`dont option`

`will option`

`wont option`

Send the TELNET protocol option negotiation indicated. Option may be the text name of the protocol option, or the number corresponding to the option. The command will be silently ignored if the option negotiation indicated is not valid in the current state. If the *option* is given as `help` or `?`, the list of option names known is listed. This command is mostly useful for unusual debugging situations.

`?`

Print out help information for the send command.

`set argument [value]`

`unset argument`

Set any one of a number of `telnet` variables to a specific value. The special value `off` turns off the function associated with the variable. The values of variables may be interrogated with the `display` command. If *value* is omitted, the value is taken to be true, or “on”. If the `unset` form is used, the value is taken to be false, or `off`. The variables that may be specified are:

`echo`

This is the value (initially `^E`) that, when in “line by line” mode, toggles between local echoing of entered characters for normal processing, and suppressing echoing of entered characters, for example, entering a password.

`escape`

This is the `telnet` escape character (initially `^J`) that enters `telnet` command mode when connected to a remote system.

`interrupt`

If `telnet` is in `localchars` mode (see `toggle`, `localchars`) and the `interrupt` character is typed, a TELNET IP sequence (see `send` and `ip`) is sent to the remote host. The initial value for the `interrupt` character is taken to be the terminal's `intr` character.

`quit`

If `telnet` is in `localchars` mode and the `quit` character is typed, a TELNET BRK sequence (see `send`, `brk`) is sent to the remote host. The initial value for the `quit` character is taken to be the terminal's `quit` character.

`flushoutput`

If `telnet` is in `localchars` mode and the `flushoutput` character is typed, a TELNET AO sequence (see `send`, `ao`) is sent to the remote host. The initial value for the `flush` character is taken to be the terminal's `flush` character.

**erase**

If telnet is in localchars mode *and* operating in “character at a time” mode, then when the erase character is typed, a TELNET EC sequence (see send, ec) is sent to the remote system. The initial value for the erase character is taken to be the terminal's erase character.

**kill**

If telnet is in localchars mode *and* operating in “character at a time” mode, then when the kill character is typed, a TELNET EL sequence (see send, el) is sent to the remote system. The initial value for the kill character is taken to be the terminal's kill character.

**eof**

If telnet is operating in “line by line”/ mode, entering the eof character as the first character on a line sends this character to the remote system. The initial value of eof is taken to be the terminal's eof character.

**ayt**

If telnet is in localchars mode, or LINEMODE is enabled, and the status character is typed, a TELNET AYT (“Are You There”) sequence is sent to the remote host. (See send, ayt above.) The initial value for ayt is the terminal's status character.

**forw1****forw2**

If telnet is operating in LINEMODE, and the forw1 or forw2 characters are typed, this causes the forwarding of partial lines to the remote system. The initial values for the forwarding characters come from the terminal's eol and eol2 characters.

**lnext**

If telnet is operating in LINEMODE or “old line by line” mode, then the lnext character is assumed to be the terminal's lnext character. The initial value for the lnext character is taken to be the terminal's lnext character.

**reprint**

If telnet is operating in LINEMODE or “old line by line” mode, then the reprint character is assumed to be the terminal's reprint character. The initial value for reprint is taken to be the terminal's reprint character.

**rlogin**

This is the rlogin escape character. If set, the normal telnet escape character is ignored, unless it is preceded by this character at the beginning of a line. The rlogin character, at the beginning of a line followed by a “.” closes the connection. When followed by a ^Z, the rlogin command suspends the telnet command. The initial state is to disable the rlogin escape character.

**start**

If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the start character is taken to be the terminal's start character. The initial value for the kill character is taken to be the terminal's start character.

**stop**

If the TELNET TOGGLE-*FLOW-CONTROL* option has been enabled, then the *stop* character is taken to be the terminal's *stop* character. The initial value for the *kill* character is taken to be the terminal's *stop* character.

**susp**

If *telnet* is in *localchars* mode, or *LINEMODE* is enabled, and the suspend character is typed, a TELNET SUSP sequence (see *send*, *susp* above) is sent to the remote host. The initial value for the suspend character is taken to be the terminal's suspend character.

**tracefile**

This is the file to which the output, generated when the *netdata* or the *debug* option is *TRUE*, will be written. If *tracefile* is set to “-”, then tracing information will be written to standard output (the default).

**worderase**

If *telnet* is operating in *LINEMODE* or “old line by line” mode, then this character is taken to be the terminal's *worderase* character. The initial value for the *worderase* character is taken to be the terminal's *worderase* character.

**?**

Displays the legal set and unset commands.

***s\c state***

The *s\c* (Set Local Characters) command is used to set or change the state of special characters when the TELNET *LINEMODE* option has been enabled. Special characters are characters that get mapped to TELNET commands sequences (like *ip* or *quit*) or line editing characters (like *erase* and *kill*). By default, the local special characters are exported. The following values for *state* are valid:

**check**

Verifies the settings for the current special characters. The remote side is requested to send all the current special character settings. If there are any discrepancies with the local side, the local settings will switch to the remote values.

**export**

Switches to the local defaults for the special characters. The local default characters are those of the local terminal at the time when *telnet* was started.

**import**

Switches to the remote defaults for the special characters. The remote default characters are those of the remote system at the time when the TELNET connection was established.

**?**

Prints out help information for the *s\c* command.

***toggle argument...***

Toggle between *TRUE* and *FALSE* the various flags that control how *telnet* responds to events. More than one argument may be specified. The state of these flags may be interrogated with the *display* command. Valid arguments are:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| authdebug   | Turns on debugging information for the authentication code.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| autodecrypt | When the TELNET ENCRYPT option is negotiated, by default the actual encryption (decryption) of the data stream does not start automatically. The autoencrypt (autodecrypt) command states that encryption of the output (input) stream should be enabled as soon as possible.                                                                                                                                                                                                                                   |
| autologin   | If the remote side supports the TELNET AUTHENTICATION option, telnet attempts to use it to perform automatic authentication. If the AUTHENTICATION option is not supported, the user's login name is propagated through the TELNET ENVIRON option. This command is the same as specifying the -a option on the open command.                                                                                                                                                                                    |
| autoflush   | If autoflush and localchars are both TRUE, then when the ao, intr, or quit characters are recognized (and transformed into TELNET sequences; see set for details), telnet refuses to display any data on the user's terminal until the remote system acknowledges (using a TELNET Timing Mark option) that it has processed those TELNET sequences. The initial value for this toggle is TRUE if the terminal user has not done an "stty noflsh". Otherwise, the value is FALSE (see <a href="#">stty(1)</a> ). |
| autosynch   | If autosynch and localchars are both TRUE, then when either the interrupt or quit characters are typed (see set for descriptions of interrupt and quit), the resulting TELNET sequence sent is followed by the TELNET SYNCH sequence. This procedure <i>should</i> cause the remote system to begin throwing away all previously typed input until both of the TELNET sequences have been read and acted upon. The initial value of this toggle is FALSE.                                                       |
| binary      | Enable or disable the TELNET BINARY option on both input and output.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| inbinary    | Enable or disable the TELNET BINARY option on input.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| outbinary   | Enable or disable the TELNET BINARY option on output.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| crlf        | Determines how carriage returns are sent. If the value is TRUE, then carriage returns will be sent as <CR><LF>. If the value is FALSE, then carriage returns will be sent as <CR><NUL>. The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                             |
| crmod       | Toggle RETURN mode. When this mode is enabled, most RETURN characters received from the remote host will be mapped into a RETURN followed by a line feed. This mode does not affect those characters typed by the user, only those received from the remote                                                                                                                                                                                                                                                     |

---

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | host. This mode is useful only for remote hosts that send RETURN but never send LINEFEED. The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| debug           | Toggle socket level debugging (only available to the super-user). The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| encdebug        | Turns on debugging information for the encryption code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| localchars      | If this toggle is TRUE, then the flush, interrupt, quit, erase, and kill characters (see set) are recognized locally, and transformed into appropriate TELNET control sequences, respectively ao, ip, brk, ec, and eI (see send). The initial value for this toggle is TRUE in “line by line” mode, and FALSE in “character at a time” mode. When the LINEMODE option is enabled, the value of localchars is ignored, and assumed always to be TRUE. If LINEMODE has ever been enabled, then quit is sent as abort, and eof and suspend are sent as eof and susp (see send above). |
| netdata         | Toggle the display of all network data (in hexadecimal format). The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| options         | Toggle the display of some internal TELNET protocol processing (having to do with telnet options). The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| prettydump      | When the netdata toggle is enabled, if prettydump is enabled, the output from the netdata command will be formatted in a more user readable format. Spaces are put between each character in the output. The beginning of any TELNET escape sequence is preceded by an asterisk (*) to aid in locating them.                                                                                                                                                                                                                                                                       |
| skiprc          | When the skiprc toggle is TRUE, TELNET skips the reading of the .telnetrc file in the user's home directory when connections are opened. The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                               |
| termdata        | Toggles the display of all terminal data (in hexadecimal format). The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| verbose_encrypt | When the verbose_encrypt flag is TRUE, TELNET prints out a message each time encryption is enabled or disabled. The initial value for this toggle is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ?               | Display the legal toggle commands.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

#### *environ argument . . .*

The `environ` command is used to manipulate variables that may be sent through the TELNET ENVIRON option. The initial set of variables is taken from the users environment. Only the DISPLAY and PRINTER variables are exported by default. Valid arguments for the `environ` command are:

**define *variable value***

Define *variable* to have a value of *value*. Any variables defined by this command are automatically exported. The *value* may be enclosed in single or double quotes, so that tabs and spaces may be included.

**undefine *variable***

Remove *variable* from the list of environment variables.

**export *variable***

Mark the *variable* to be exported to the remote side.

**unexport *variable***

Mark the *variable* to not be exported unless explicitly requested by the remote side.

**list**

List the current set of environment variables. Those marked with an asterisk (\*) will be sent automatically. Other variables will be sent only if explicitly requested.

**?**

Prints out help information for the `envi ron` command.

**logout**

Sends the telnet logout option to the remote side. This command is similar to a `close` command. However, if the remote side does not support the `logout` option, nothing happens. If, however, the remote side does support the `logout` option, this command should cause the remote side to close the TELNET connection. If the remote side also supports the concept of suspending a user's session for later reattachment, the `logout` argument indicates that the remote side should terminate the session immediately.

**Files** `$HOME/.telnetrc` file that contains commands to be executed before initiating a telnet session

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | network/telnet  |

**See Also** [rlogin\(1\)](#), [sh\(1\)](#), [stty\(1\)](#), [getlogin\(3C\)](#), [hosts\(4\)](#), [krb5.conf\(4\)](#), [nologin\(4\)](#), [telnetrc\(4\)](#), [attributes\(5\)](#), [inet\(7P\)](#), [inet6\(7P\)](#)

**Diagnostics** NO LOGINS: System going down in *N* minutes  
The machine is in the process of being shut down and logins have been disabled.

**Notes** On some remote systems, `echo` has to be turned off manually when in “line by line” mode.

In “old line by line” mode, or LINEMODE, the terminal's EOF character is only recognized (and sent to the remote system) when it is the first character on a line.

The telnet protocol only uses single DES for session protection—clients request service tickets with single DES session keys. The KDC must know that host service principals that offer the telnet service support single DES, which, in practice, means that such principals must have single DES keys in the KDC database.

**Name** test – evaluate condition(s)

**Synopsis** /usr/bin/test [*condition*]

[ [*condition*] ]

sh test [*condition*]

[ [*condition*] ]

csh test [*condition*]

[ [*condition*] ]

ksh88 test [*condition*]

[ [*condition*] ]

ksh test [*condition*]

[ [*condition*] ]

**Description** The test utility evaluates the *condition* and indicates the result of the evaluation by its exit status. An exit status of zero indicates that the condition evaluated as true and an exit status of 1 indicates that the condition evaluated as false.

In the first form of the utility shown using the SYNOPSIS:

```
test [condition]
```

the square brackets denote that *condition* is an optional operand and are not to be entered on the command line.

In the second form of the utility shown using the SYNOPSIS:

```
[[condition]]
```

the first open square bracket, [, is the required utility name. *condition* is optional, as denoted by the inner pair of square brackets. The final close square bracket, ], is a required operand.

See [largefile\(5\)](#) for the description of the behavior of test when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

The test and [ utilities evaluate the condition *condition* and, if its value is true, set exit status to 0. Otherwise, a non-zero (false) exit status is set. test and [ also set a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.

All operators, flags, and brackets (brackets used as shown in the last SYNOPSIS line) must be separate arguments to these commands. Normally these arguments are separated by spaces.

**Operands** The primaries listed below with two elements of the form:

*-primary\_operator primary\_operand*

are known as *unary primaries*. The primaries with three elements in either of the two forms:

*primary\_operand -primary\_operator primary\_operand*

*primary\_operand primary\_operator primary\_operand*

are known as *binary primaries*.

If any file operands except for `-h` and `-L` primaries refer to symbolic links, the symbolic link is expanded and the test is performed on the resulting file.

If you test a file you own (the `-r` `-w` or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status is returned even though the file can have the group or other bit set for that permission.

The `=` and `!=` primaries have a higher precedence than the unary primaries. The `=` and `!=` primaries always expect arguments; therefore, `=` and `!=` cannot be used as an argument to the unary primaries.

The following primaries can be used to construct *condition*:

- `-a file` True if *file* exists. (Not available in sh.)
- `-b file` True if *file* exists and is a block special file.
- `-c file` True if *file* exists and is a character special file.
- `-d file` True if *file* exists and is a directory.
- `-e file` True if *file* exists. (Not available in sh.)
- `-f file` True if *file* exists and is a regular file. Alternatively, if `/usr/bin/sh` users specify `/usr/ucb` before `/usr/bin` in their `PATH` environment variable, then test returns true if *file* exists and is (not-a-directory). The `csh` test and `[` built-ins always use this alternative behavior.
- `-g file` True if *file* exists and its set group ID flag is set.
- `-G file` True if *file* exists and its group matches the effective group ID of this process. (Not available in sh.)
- `-h file` True if *file* exists and is a symbolic link.
- `-k file` True if *file* exists and has its sticky bit set.
- `-L file` True if *file* exists and is a symbolic link.
- `-n string` True if the length of *string* is non-zero.

|                                   |                                                                                                                                                                                                                                           |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-o option</code>            | True if option named <i>option</i> is on. This option is not available in <code>csh</code> or <code>sh</code> .                                                                                                                           |
| <code>-O file</code>              | True if <i>file</i> exists and is owned by the effective user ID of this process. This option is not available in <code>sh</code> .                                                                                                       |
| <code>-p file</code>              | True if <i>file</i> is a named pipe (FIFO).                                                                                                                                                                                               |
| <code>-r file</code>              | True if <i>file</i> exists and is readable.                                                                                                                                                                                               |
| <code>-s file</code>              | True if <i>file</i> exists and has a size greater than zero.                                                                                                                                                                              |
| <code>-S file</code>              | True if <i>file</i> exists and is a socket. This option is not available in <code>sh</code> .                                                                                                                                             |
| <code>-t [file_descriptor]</code> | True if the file whose file descriptor number is <i>file_descriptor</i> is open and is associated with a terminal. If <i>file_descriptor</i> is not specified, 1 is used as a default value.                                              |
| <code>-u file</code>              | True if <i>file</i> exists and its set-user-ID flag is set.                                                                                                                                                                               |
| <code>-w file</code>              | True if <i>file</i> exists and is writable. True indicates only that the write flag is on. The <i>file</i> is not writable on a read-only file system even if this test indicates true.                                                   |
| <code>-x file</code>              | True if <i>file</i> exists and is executable. True indicates only that the execute flag is on. If <i>file</i> is a directory, true indicates that <i>file</i> can be searched.                                                            |
| <code>-z string</code>            | True if the length of string <i>string</i> is zero.                                                                                                                                                                                       |
| <code>file1 -nt file2</code>      | True if <i>file1</i> exists and is newer than <i>file2</i> . This option is not available in <code>sh</code> .                                                                                                                            |
| <code>file1 -ot file2</code>      | True if <i>file1</i> exists and is older than <i>file2</i> . This option is not available in <code>sh</code> .                                                                                                                            |
| <code>file1 -ef file2</code>      | True if <i>file1</i> and <i>file2</i> exist and refer to the same file. This option is not available in <code>sh</code> .                                                                                                                 |
| <code>string</code>               | True if the string <i>string</i> is not the null string.                                                                                                                                                                                  |
| <code>string1 = string2</code>    | True if the strings <i>string1</i> and <i>string2</i> are identical.                                                                                                                                                                      |
| <code>string1 != string2</code>   | True if the strings <i>string1</i> and <i>string2</i> are not identical.                                                                                                                                                                  |
| <code>n1 -eq n2</code>            | True if the numbers <i>n1</i> and <i>n2</i> are algebraically equal. A number may be integer, floating point or floating-point constant (such as <code>[+/-]Inf</code> , <code>[+/-]NaN</code> ) in any format specified by C99/XPG6/SUS. |

---

|                                        |                                                                                                                                                                                                                                        |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n1</i> -ne <i>n2</i>                | True if the numbers <i>n1</i> and <i>n2</i> are not algebraically equal. A number may be integer, floating point or floating-point constant (such as [+/-]Inf, [+/-]NaN) in any format specified by C99/XPG6/SUS.                      |
| <i>n1</i> -gt <i>n2</i>                | True if the number <i>n1</i> is algebraically greater than the number <i>n2</i> . A number may be integer, floating point or floating-point constant (such as [+/-]Inf, [+/-]NaN) in any format specified by C99/XPG6/SUS.             |
| <i>n1</i> -ge <i>n2</i>                | True if the number <i>n1</i> is algebraically greater than or equal to the number <i>n2</i> . A number may be integer, floating point or floating-point constant (such as [+/-]Inf, [+/-]NaN) in any format specified by C99/XPG6/SUS. |
| <i>n1</i> -lt <i>n2</i>                | True if the number <i>n1</i> is algebraically less than the number <i>n2</i> . A number may be integer, floating point or floating-point constant (such as [+/-]Inf, [+/-]NaN) in any format specified by C99/XPG6/SUS.                |
| <i>n1</i> -le <i>n2</i>                | True if the number <i>n1</i> is algebraically less than or equal to the number <i>n2</i> . A number may be integer, floating point or floating-point constant (such as [+/-]Inf, [+/-]NaN) in any format specified by C99/XPG6/SUS.    |
| <i>condition1</i> -a <i>condition2</i> | True if both <i>condition1</i> and <i>condition2</i> are true. The -a binary primary is left associative and has higher precedence than the -o binary primary.                                                                         |
| <i>condition1</i> -o <i>condition2</i> | True if either <i>condition1</i> or <i>condition2</i> is true. The -o binary primary is left associative.                                                                                                                              |

These primaries can be combined with the following operators:

|                      |                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ! <i>condition</i>   | True if <i>condition</i> is false.                                                                                                                                                              |
| ( <i>condition</i> ) | True if <i>condition</i> is true. The parentheses ( ) can be used to alter the normal precedence and associativity. The parentheses are meaningful to the shell and, therefore, must be quoted. |

The algorithm for determining the precedence of the operators and the return value that is generated is based on the number of arguments presented to `test`. (However, when using the `[...]` form, the right-bracket final argument is not counted in this algorithm.)

In the following list, \$1, \$2, \$3 and \$4 represent the arguments presented to `test` as a *condition*, *condition1*, or *condition2*.

0 arguments:     Exit false (1).

*1 argument:* Exit true (0) if \$1 is not null. Otherwise, exit false.

*2 arguments:*

- If \$1 is !, exit true if \$2 is null, false if \$2 is not null.
- If \$1 is a unary primary, exit true if the unary test is true, false if the unary test is false.
- Otherwise, produce unspecified results.

*3 arguments:*

- If \$2 is a binary primary, perform the binary test of \$1 and \$3.
- If \$1 is !, negate the two-argument test of \$2 and \$3.
- Otherwise, produce unspecified results.

*4 arguments:*

- If \$1 is !, negate the three-argument test of \$2, \$3, and \$4.
- Otherwise, the results are unspecified.

**Usage** Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like `test "$1" -a "$2"` should be written as `test "$1" && test "$2"` to avoid problems if a user supplied values such as \$1 set to ! and \$2 set to the null string. That is, in cases where maximal portability is of concern, replace `test expr1 -a expr2` with `test expr1 && test expr2`, and replace `test expr1 -o expr2` with `test expr1 || test expr2`. But notice that, in `test`, `-a` has *higher* precedence than `-o`, while `&&` and `||` have *equal* precedence in the shell.

Parentheses or braces can be used in the shell command language to effect grouping.

Parentheses must be escaped when using `sh`. For example:

```
test \(expr1 -a expr2 \) -o expr3
```

This command is not always portable outside XSI-conformant systems. The following form can be used instead:

```
(test expr1 && test expr2) || test expr3
```

The two commands:

```
test "$1"
test ! "$1"
```

could not be used reliably on some historical systems. Unexpected results would occur if such a *string* condition were used and \$1 expanded to !, (, or a known unary primary. Better constructs are, respectively,

```
test -n "$1"
test -z "$1"
```

Historical systems have also been unreliable given the common construct:

```
test "$response" = "expected string"
```

One of the following is a more reliable form:

```
test "X$response" = "Xexpected string"
test "expected string" = "$response"
```

The second form assumes that `expected string` could not be confused with any unary primary. If `expected string` starts with `-`, `(`, `!` or even `=`, the first form should be used instead. Using the preceding rules without the marked extensions, any of the three comparison forms is reliable, given any input. (However, observe that the strings are quoted in all cases.)

Because the string comparison binary primaries, `=` and `!=`, have a higher precedence than any unary primary in the `>4` argument case, unexpected results can occur if arguments are not properly prepared. For example, in

```
test -d $1 -o -d $2
```

If `$1` evaluates to a possible directory name of `=`, the first three arguments are considered a string comparison, which causes a syntax error when the second `-d` is encountered. is encountered. One of the following forms prevents this; the second is preferred:

```
test \(-d "$1" \) -o \(-d "$2" \)
test -d "$1" || test -d "$2"
```

Also in the `>4` argument case:

```
test "$1" = "bat" -a "$2" = "ball"
```

Syntax errors occur if `$1` evaluates to `(` or `!`. One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" -a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

**Examples** In the `if` command examples, three conditions are tested, and if all three evaluate as true or successful, then their validities are written to the screen. The three tests are:

- if a variable set to 1 is greater than 0,
- if a variable set to 2 is equal to 2, and
- if the word `root` is included in the text file `/etc/passwd`.

`/usr/bin/test` **EXAMPLE 1** Using `/usr/bin/test`

Perform a `mkdir` if a directory does not exist:

```
test ! -d tempdir && mkdir tempdir
```

Wait for a file to become non-readable:

```
while test -r thefile
do
 sleep 30
done
echo "thefile" is no longer readable'
```

Perform a command if the argument is one of three strings (two variations), using the open bracket version `[` of the `test` command:

```
if ["$1" = "pear"] || ["$1" = "grape"] || ["$1" = "apple"]
then
 command
fi
case "$1" in
 pear|grape|apple) command;;
esac
```

**EXAMPLE 2** Using `/usr/bin/test` for the `-e` option

If one really wants to use the `-e` option in `sh`, use `/usr/bin/test`, as in the following:

```
if [! -h $PKG_INSTALL_ROOT$rLink] && /usr/bin/test -e
$PKG_INSTALL_ROOT/usr/bin/$rFile ; then
 ln -s $rFile $PKG_INSTALL_ROOT$rLink
fi
```

The test built-in The two forms of the `test` built-in follow the Bourne shell's `if` example.

**EXAMPLE 3** Using the `sh` built-in

```
ZERO=0 ONE=1 TWO=2 ROOT=root
```

```
if [$ONE -gt $ZERO]
```

```
[$TWO -eq 2]
```

```
grep $ROOT /etc/passwd >&1 > /dev/null # discard output
```

```
then
```

```
 echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
 "a user-name in the password file"
```

**EXAMPLE 3** Using the sh built-in *(Continued)*

```

else

 echo "At least one of the three test conditions is false"
fi

```

**EXAMPLE 4** Using the test built-in

Examples of the test built-in:

```
test `grep $ROOT /etc/passwd >&1 /dev/nul`l # discard output
```

```
echo $? # test for success
[`grep nosuchname /etc/passwd >&1 /dev/nul`l]
```

```
echo $? # test for failure
```

**cs** **EXAMPLE 5** Using the csh built-in

```

@ ZERO = 0; @ ONE = 1; @ TWO = 2; set ROOT = root
grep $ROOT /etc/passwd >&1 /dev/null # discard output
$status must be tested for immediately following grep
if ("$status" == "0" && $ONE > $ZERO && $TWO == 2) then
 echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
 "a user-name in the password file"
endif

```

**ksh88** **EXAMPLE 6** Using the ksh88/ksh built-in

```

ZERO=0 ONE=1 TWO=$((ONE+ONE)) ROOT=root
if ((ONE > ZERO)) # arithmetical comparison
[[$TWO = 2]] # string comparison
[`grep $ROOT /etc/passwd >&1 /dev/nul`l] # discard output
then
 echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
 "a user-name in the password file"

else
 echo "At least one of the three test conditions is false"
fi

```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of test: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 *condition* evaluated to true.
- 1 *condition* evaluated to false or *condition* was missing.

>1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| /usr/bin/test, csh,<br>ksh88, sh | ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|----------------------------------|---------------------|------------------------------------|
|                                  | Availability        | system/core-os                     |
|                                  | Interface Stability | Committed                          |
|                                  | Standard            | See <a href="#">standards(5)</a> . |

| ksh | ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|-----|---------------------|-----------------|
|     | Availability        | system/core-os  |
|     | Interface Stability | Uncommitted     |

**See Also** [csh\(1\)](#), [ksh\(1\)](#), [ksh88\(1\)](#), [sh\(1\)](#), [test\(1B\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** The `not-a-directory` alternative to the `-f` option is a transition aid for BSD applications and may not be supported in future releases.

XPG4 sh, ksh88, ksh Use arithmetic expressions such as

```
$((x > 3.1)) #
```

instead of

```
$ /usr/bin/test "$x" -gt 3.1 #)
```

when comparing two floating-point variables or a constant and a floating-point variable to prevent rounding errors (caused by the base16 to base10 transformation) to affect the result. Additionally the built-in arithmetic support in XPG4 sh, ksh88 and ksh is significantly faster because it does not require the explicit transformation to strings for each comparison.

**Name** test – condition evaluation command

**Synopsis** /usr/ucb/test *expression*  
*expression*

**Description** test evaluates the expression *expression* and, if its value is true, sets 0 (true) exit status; otherwise, a non-zero (false) exit status is set. test also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.

All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to the test command; normally these items are separated by spaces.

### Usage

**Primitives** The following primitives are used to construct *expression*:

- r *filename* True if *filename* exists and is readable.
- w *filename* True if *filename* exists and is writable.
- x *filename* True if *filename* exists and is executable.
- f *filename* True if *filename* exists and is a regular file. Alternatively, if /usr/bin/sh users specify /usr/ucb before /usr/bin in their PATH environment variable, then test will return true if *filename* exists and is (not-a-directory). This is also the default for /usr/bin/csh users.
- d *filename* True if *filename* exists and is a directory.
- c *filename* True if *filename* exists and is a character special file.
- b *filename* True if *filename* exists and is a block special file.
- p *filename* True if *filename* exists and is a named pipe (fifo).
- u *filename* True if *filename* exists and its set-user-ID bit is set.
- g *filename* True if *filename* exists and its set-group-ID bit is set.
- k *filename* True if *filename* exists and its sticky bit is set.
- s *filename* True if *filename* exists and has a size greater than zero.
- t[ *fdes* ] True if the open file whose file descriptor number is *fdes* (1 by default) is associated with a terminal device.
- z *s1* True if the length of string *s1* is zero.
- n *s1* True if the length of the string *s1* is non-zero.
- s1* = *s2* True if strings *s1* and *s2* are identical.
- s1* != *s2* True if strings *s1* and *s2* are *not* identical.

*s1* True if *s1* is *not* the null string.

*n1* `-eq` *n2* True if the integers *n1* and *n2* are algebraically equal. Any of the comparisons `-ne`, `-gt`, `-ge`, `-lt`, and `-le` may be used in place of `-eq`.

**Operators** These primaries may be combined with the following operators:

`!` Unary negation operator.

`-a` Binary *and* operator.

`-o` Binary *or* operator (`-a` has higher precedence than `-o`).

*(expression)* Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | compatibility/ucb |

**See Also** [find\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#)

**Notes** The `not-a-directory` alternative to the `-f` option is a transition aid for BSD applications and may not be supported in future releases.

If you test a file you own (the `-r`, `-w`, or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The `=` and `!=` operators have a higher precedence than the `-r` through `-n` operators, and `=` and `!=` always expect arguments; therefore, `=` and `!=` cannot be used with the `-r` through `-n` operators.

If more than one argument follows the `-r` through `-n` operators, only the first argument is examined; the others are ignored, unless a `-a` or a `-o` is the second argument.

- Name** tftp – trivial file transfer program
- Synopsis** tftp [*host* [*port*]]
- Description** tftp is the user interface to the Internet TFTP (Trivial File Transfer Protocol), which allows users to transfer files to and from a remote machine. The remote *host* and optional *port* may be specified on the command line, in which case tftp uses *host* as the default host, and if specified, *port* as the default port, for future transfers. See the connect command below.
- Usage** Once tftp is running, it issues the prompt tftp> and recognizes the following commands:
- Commands** connect *host-name* [*port*]  
 Set the *host*, and optionally *port*, for transfers. The TFTP protocol, unlike the FTP protocol, does not maintain connections between transfers; thus, the connect command does not actually create a connection, but merely remembers what host is to be used for transfers. You do not have to use the connect command; the remote host can be specified as part of the get or put commands.
- mode *transfer-mode*  
 Set the mode for transfers; *transfer-mode* may be one of *ascii* or *binary*. The default is *ascii*.
- put *filename*  
 put *localfile remotefile*  
 put *filename1 filename2 . . . filenameN remote-directory*  
 Transfer a file, or a set of files, to the specified remote file or directory. The destination can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:  
*host:filename*  
 to specify both a *host* and *filename* at the same time. If the latter form is used, the specified host becomes the default for future transfers. If the remote-directory form is used, the remote host is assumed to be running the UNIX system.
- The *host* can be a host name (see [hosts\(4\)](#)) or an IPv4 or IPv6 address string (see [inet\(7P\)](#) or [inet6\(7P\)](#)). Since IPv6 addresses already contain “:”s, the *host* should be enclosed in square brackets when an IPv6 address is used. Otherwise, the first occurrence of a colon will be interpreted as the separator between the *host* and the *filename*. For example,  
 [1080::8:800:200c:417A]:myfile  
 Files may be written only if they already exist and are publicly writable. See [in.tftpd\(1M\)](#).
- get *filename*  
 get *remotename localname*  
 get *filename1 filename2 filename3 . . . filenameN*  
 Get a file or set of files (three or more) from the specified remote *sources*. *source* can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:

*host:filename*

to specify both a host and filename at the same time. If the latter form is used, the last host specified becomes the default for future transfers. See the `put` command regarding specifying a *host*.

`quit`

Exit `tftp`. An EOF also exits.

`verbose`

Toggle verbose mode.

`trace`

Toggle packet tracing.

`status`

Show current status.

`rext` *retransmission-timeout*

Set the per-packet retransmission timeout, in seconds.

`timeout` *total-transmission-timeout*

Set the total transmission timeout, in seconds.

`ascii`

Shorthand for mode `ascii`.

`binary`

Shorthand for mode `binary`.

`blksize` *transfer-blocksize*

The value of the transfer blocksize option to negotiate with the server. A value of 0 disables the negotiation of this option.

`srext` *server-retransmission-timeout*

The value of the retransmission timeout option to request that the server uses. A value of 0 disables the negotiation of this option.

`tsize`

A toggle that sends the transfer size option to the server. By default, the option is not sent. The transfer size option is not sent with a `write` request when the *transfer-mode* is `ascii`.

? [ *command-name . . .* ]

Print help information.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE      |
|----------------|----------------------|
| Availability   | service/network/tftp |

---

**See Also** `in.tftpd(1M)`, `hosts(4)`, `attributes(5)`, `inet(7P)`, `inet6(7P)`

Malkin, G. and Harkin, A. *RFC 2347, TFTP Option Extension*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2348, TFTP Blocksize Option*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2349, TFTP Timeout Interval and Transfer Size Options*. The Internet Society. May 1998

Sollins, K.R. *RFC 1350, The TFTP Protocol (Revision 2)*. Network Working Group. July 1992.

**Notes** The default *transfer-mode* is `ascii`. This differs from pre-SunOS 4.0 and pre-4.3BSD systems, so explicit action must be taken when transferring non-ASCII binary files such as executable commands.

Because there is no user-login or validation within the TFTP protocol, many remote sites restrict file access in various ways. Approved methods for file access are specific to each site, and therefore cannot be documented here.

When using the `get` command to transfer multiple files from a remote host, three or more files must be specified. If two files are specified, the second file is used as a local file.

With the default block size of 512 octets and a 16-bit block counter, some TFTP implementations might have problems with files over 33,553,919 octets (513 octets short of 32MB) in size. The Solaris implementation can transfer files up to 4GB in size.

By default, the Solaris TFTP client does not enable the `blocksize` or `transfer size` options. Setting the `blocksize` option to a higher value is sometimes useful as a workaround when dealing with peers that have a 32MB limit.

**Name** time – time a simple command

**Synopsis** time [-p] *utility* [*argument*]...

**Description** The `time` utility invokes *utility* operand with *argument*, and writes a message to standard error that lists timing statistics for *utility*. The message includes the following information:

- The elapsed (real) time between invocation of *utility* and its termination.
- The User CPU time, equivalent to the sum of the `tms_utime` and `tms_cutime` fields returned by the `times(2)` function for the process in which *utility* is executed.
- The System CPU time, equivalent to the sum of the `tms_stime` and `tms_cstime` fields returned by the `times()` function for the process in which *utility* is executed.

When `time` is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities `a` and `c`, respectively:

```
time a | b | c { time a } | b | c
a | b | time c a | b | (time c)
```

**Options** The following option is supported:

-p     Writes the timing output to standard error in the following format:

```
real %f\nuser %f\nsys %f\n < real seconds>, <user seconds>,
<system seconds>
```

**Operands** The following operands are supported:

*utility*        The name of the utility that is to be invoked.

*argument*      Any string to be supplied as an argument when invoking *utility*.

**Usage** The `time` utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings. Most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.

**Examples** EXAMPLE 1 Using the `time` command

It is frequently desirable to apply `time` to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file. This single file can then be invoked as a utility, and the `time` applies to everything in the file.

Alternatively, the following command can be used to apply `time` to a complex command:

```
example% time sh -c 'complex-command-line'
```

**EXAMPLE 2** Using time in the csh shell

The following two examples show the differences between the csh version of `time` and the version in `/usr/bin/time`. These examples assume that csh is the shell in use.

```
example% time find / -name csh.1 -print
/usr/share/man/man1/csh.1
95.0u 692.0s 1:17:52 16% 0+0k 0+0io 0pf+0w
```

See [csh\(1\)](#) for an explanation of the format of `time` output.

```
example% /usr/bin/time find / -name csh.1 -print
/usr/share/man/man1/csh.1
real 1:23:31.5
user 1:33.2
sys 11:28.2
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `time`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, `NLSPATH`, and `PATH`.

**Exit Status** If *utility* is invoked, the exit status of `time` will be the exit status of *utility*. Otherwise, the `time` utility will exit with one of the following values:

1–125     An error occurred in the `time` utility.  
 126       *utility* was found but could not be invoked.  
 127       *utility* could not be found.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [csh\(1\)](#), [shell\\_builtins\(1\)](#), [timex\(1\)](#), [times\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes** When the `time` command is run on a multiprocessor machine, the total of the values printed for `user` and `sys` can exceed `real`. This is because on a multiprocessor machine it is possible to divide the task between the various processors.

When the command being timed is interrupted, the timing values displayed may not always be accurate.

**Bugs** Elapsed time is accurate to the second, while the CPU times are measured to the 100th second. Thus the sum of the CPU times can be up to a second larger than the elapsed time.

**Name** times – shell built-in function to report time usages of the current shell

### Synopsis

sh times

ksh times

### Description

sh Print the accumulated user and system times for processes run from the shell.

ksh Print the accumulated user and system times for the shell and for processes run from the shell.

On this man page, [ksh\(1\)](#) commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [ksh\(1\)](#), [sh\(1\)](#), [time\(1\)](#), [attributes\(5\)](#)

**Name** timex – time a command; report process data and system activity

**Synopsis** timex [-o] [-p [-fhkmrt]] [-s] *command*

**Description** The given *command* is executed; the elapsed time, user time and system time spent in execution are reported in seconds. Optionally, process accounting data for the *command* and all its children can be listed or summarized, and total system activity during the execution interval can be reported.

The output of `timex` is written on standard error.

**Options** The following options are supported:

- o Report the total number of blocks read or written and total characters transferred by *command* and all its children. This option works only if the process accounting software is installed.
- p List process accounting records for *command* and all its children. This option works only if the process accounting software is installed. Suboptions `f`, `h`, `k`, `m`, `r`, and `t` modify the data items reported. The options are as follows:
  - f Print the `fork(2)`/`exec(2)` flag and system exit status columns in the output.
  - h Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This “hog factor” is computed as (total CPU time)/(elapsed time).
  - k Instead of memory size, show total kcore-minutes.
  - m Show mean core size (the default).
  - r Show CPU factor (user time/(system-time + user-time)).
  - t Show separate system and user CPU times. The number of blocks read or written and the number of characters transferred are always reported.
- s Report total system activity (not just that due to *command*) that occurred during the execution interval of *command*. All the data items listed in `sar(1)` are reported.

**Examples** EXAMPLE 1 Examples of `timex`.

A simple example:

```
example% timex -ops sleep 60
```

A terminal session of arbitrary complexity can be measured by timing a sub-shell:

```
example% timex -opskmt sh
 session commands
```

```
EOT
```

---

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                     |
|----------------|-------------------------------------|
| Availability   | system/accounting/legacy-accounting |

**See Also** [sar\(1\)](#), [time\(1\)](#), [exec\(2\)](#), [fork\(2\)](#), [times\(2\)](#), [attributes\(5\)](#)

**Notes** Process records associated with command are selected from the accounting file `/var/adm/pacct` by inference, since process genealogy is not available. Background processes having the same user ID, terminal ID, and execution time window will be spuriously included.

**Name** tip – connect to remote system

**Synopsis** tip [-v] [-speed-entry] {hostname | phone-number | device}

**Description** The `tip` utility establishes a full-duplex terminal connection to a remote host. Once the connection is established, a remote session using `tip` behaves like an interactive session on a local terminal.

The remote file contains entries describing remote systems and line speeds used by `tip`.

Each host has a default baud rate for the connection, or you can specify a speed with the `-speed-entry` command line argument.

When `phone-number` is specified, `tip` looks for an entry in the remote file of the form:

```
tip -speed-entry
```

When `tip` finds such an entry, it sets the connection speed accordingly. If it finds no such entry, `tip` interprets `-speed-entry` as if it were a system name, resulting in an error message.

If you omit `-speed-entry`, `tip` uses the `tip0` entry to set a speed for the connection.

When `device` is specified, `tip` attempts to open that device, but will do so using the access privileges of the user, rather than `tip`'s usual access privileges (`setuid uucp`). The user must have read/write access to the device. The `tip` utility interprets any character string beginning with the slash character ( / ) as a device name.

When establishing the connection, `tip` sends a connection message to the remote system. The default value for this message can be found in the remote file.

When `tip` attempts to connect to a remote system, it opens the associated device with an exclusive-open `ioctl(2)` call. Thus, only one user at a time may access a device. This is to prevent multiple processes from sampling the terminal line. In addition, `tip` honors the locking protocol used by `uucp(1C)`.

When `tip` starts up, it reads commands from the file `.tiprc` in your home directory.

**Options** -v Display commands from the `.tiprc` file as they are executed.

**Usage** Typed characters are normally transmitted directly to the remote machine, which does the echoing as well.

At any time that `tip` prompts for an argument (for example, during setup of a file transfer), the line typed may be edited with the standard erase and kill characters. A null line in response to a prompt, or an interrupt, aborts the dialogue and returns you to the remote machine.

**Commands** A tilde (~) appearing as the first character of a line is an escape signal which directs `tip` to perform some special action. `tip` recognizes the following escape sequences:

---

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ~^D                          |                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ~.                           | Drop the connection and exit (you may still be logged in on the remote machine). <i>Note:</i> If you rlogin and then run <code>tip</code> on the remote host, you must type <code>~~.</code> (tilde tilde dot) to end the <code>tip</code> session. If you type <code>~.</code> (tilde dot), it terminates the rlogin.                                                                                            |
| ~c [ <i>name</i> ]           | Change directory to <i>name</i> . No argument implies change to your home directory.                                                                                                                                                                                                                                                                                                                              |
| ~!                           | Escape to an interactive shell on the local machine. Exiting the shell returns you to <code>tip</code> .                                                                                                                                                                                                                                                                                                          |
| ~>                           | Copy file from local to remote.                                                                                                                                                                                                                                                                                                                                                                                   |
| ~<                           | Copy file from remote to local.                                                                                                                                                                                                                                                                                                                                                                                   |
| ~p <i>from</i> [ <i>to</i> ] | Send a file to a remote host running the UNIX system. When you use the <code>put</code> command, the remote system runs the command string<br><br><code>cat &gt; to</code><br><br>while <code>tip</code> sends it the <i>from</i> file. If the <i>to</i> file is not specified, the <i>from</i> file name is used. This command is actually a UNIX-system-specific version of the ' <code>~&gt;</code> ' command. |
| ~t <i>from</i> [ <i>to</i> ] | Take a file from a remote host running the UNIX system. As in the <code>put</code> command the <i>to</i> file defaults to the <i>from</i> file name if it is not specified. The remote host executes the command string<br><br><code>cat from ; echo ^A</code><br><br>to send the file to <code>tip</code> .                                                                                                      |
| ~                            | Pipe the output from a remote command to a local process. The command string sent to the local system is processed by the shell.                                                                                                                                                                                                                                                                                  |
| ~C                           | Connect a program to the remote machine. The command string sent to the program is processed by the shell. The program inherits file descriptors 0 as remote line input, 1 as remote line output, and 2 as tty standard error.                                                                                                                                                                                    |
| ~\$                          | Pipe the output from a local process to the remote host. The command string sent to the local system is processed by the shell.                                                                                                                                                                                                                                                                                   |
| ~#                           | Send a BREAK to the remote system.                                                                                                                                                                                                                                                                                                                                                                                |
| ~s                           | Set a variable (see the discussion below).                                                                                                                                                                                                                                                                                                                                                                        |
| ~^Z                          | Stop <code>tip</code> . Only available when run under a shell that supports job control, such as the C shell.                                                                                                                                                                                                                                                                                                     |

`~^Y` Stop only the “local side” of `tip`. Only available when run under a shell that supports job control, such as the C shell. The “remote side” of `tip`, that is, the side that displays output from the remote host, is left running.

`~?` Get a summary of the tilde escapes.

Copying files requires some cooperation on the part of the remote host. When a `~>` or `~<` escape is used to send a file, `tip` prompts for a file name (to be transmitted or received) and a command to be sent to the remote system, in case the file is being transferred from the remote system. While `tip` is transferring a file, the number of lines transferred will be continuously displayed on the screen. A file transfer may be aborted with an interrupt.

**Auto-call Units** `tip` may be used to dial up remote systems using a number of auto-call unit's (ACUs). When the remote system description contains the `du` capability, `tip` uses the call-unit (`cu`), ACU type (`at`), and phone numbers (`pn`) supplied. Normally, `tip` displays verbose messages as it dials.

Depending on the type of auto-dialer being used to establish a connection, the remote host may have garbage characters sent to it upon connection. The user should never assume that the first characters typed to the foreign host are the first ones presented to it. The recommended practice is to immediately type a `kill` character upon establishing a connection (most UNIX systems either support `@` or Control-U as the initial kill character).

`tip` currently supports the Ventel MD-212+ modem and DC Hayes-compatible modems.

When `tip` initializes a Hayes-compatible modem for dialing, it sets up the modem to auto-answer. Normally, after the conversation is complete, `tip` drops DTR, which causes the modem to “hang up.”

Most modems can be configured so that when DTR drops, they re-initialize themselves to a preprogrammed state. This can be used to reset the modem and disable auto-answer, if desired.

Additionally, it is possible to start the phone number with a Hayes `S` command so that you can configure the modem before dialing. For example, to disable auto-answer, set up all the phone numbers in `/etc/remote` using something like `pn=S0=0DT5551212`. The `S0=0` disables auto-answer.

**Remote Host Description** Descriptions of remote hosts are normally located in the system-wide file `/etc/remote`. However, a user may maintain personal description files (and phone numbers) by defining and exporting the `REMOTE` shell variable. The `remote` file must be readable by `tip`, but a secondary file describing phone numbers may be maintained readable only by the user. This secondary phone number file is `/etc/phones`, unless the shell variable `PHONES` is defined and exported. The phone number file contains lines of the form:

*system-name phone-number*

Each phone number found for a system is tried until either a connection is established, or an end of file is reached. Phone numbers are constructed from `'0123456789-=*'`, where the `'='` and `'*'` are used to indicate a second dial tone should be waited for (ACU dependent).

**tip Internal Variables** `tip` maintains a set of variables which are used in normal operation. Some of these variables are read-only to normal users (root is allowed to change anything of interest). Variables may be displayed and set through the `~s` escape. The syntax for variables is patterned after `vi(1)` and `mail(1)`. Supplying `all` as an argument to the `~s` escape displays all variables that the user can read. Alternatively, the user may request display of a particular variable by attaching a `?` to the end. For example, `'~s escape?'` displays the current escape character.

Variables are numeric (num), string (str), character (char), or Boolean (bool) values. Boolean variables are set merely by specifying their name. They may be reset by prepending a `!` to the name. Other variable types are set by appending an `=` and the value. The entire assignment must not have any blanks in it. A single set command may be used to interrogate as well as set a number of variables.

Variables may be initialized at run time by placing set commands (without the `~s` prefix) in a `.tiprc` file in one's home directory. The `-v` option makes `tip` display the sets as they are made. Comments preceded by a `#` sign can appear in the `.tiprc` file.

Finally, the variable names must either be completely specified or an abbreviation may be given. The following list details those variables known to `tip`.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>beautify</code>    | (bool) Discard unprintable characters when a session is being scripted; abbreviated <code>be</code> . If the <code>nb</code> capability is present, <code>beautify</code> is initially set to <code>off</code> . Otherwise, <code>beautify</code> is initially set to <code>on</code> .                                                                                                                                                                                                         |
| <code>baudrate</code>    | (num) The baud rate at which the connection was established; abbreviated <code>ba</code> . If a baud rate was specified on the command line, <code>baudrate</code> is initially set to the specified value. Or, if the <code>br</code> capability is present, <code>baudrate</code> is initially set to the value of that capability. Otherwise, <code>baudrate</code> is set to 300 baud. Once <code>tip</code> has been started, <code>baudrate</code> can only be changed by the super-user. |
| <code>dialtimeout</code> | (num) When dialing a phone number, the time (in seconds) to wait for a connection to be established; abbreviated <code>dial</code> . <code>dialtimeout</code> is initially set to 60 seconds, and can only be changed by the super-user.                                                                                                                                                                                                                                                        |
| <code>disconnect</code>  | (str) The string to send to the remote host to disconnect from it; abbreviated <code>di</code> . If the <code>di</code> capability is present, <code>disconnect</code> is initially set to the value of that capability. Otherwise, <code>disconnect</code> is set to a null string ( <code>""</code> ).                                                                                                                                                                                        |

|                         |                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>echocheck</code>  | (bool) Synchronize with the remote host during file transfer by waiting for the echo of the last character transmitted; abbreviated <code>ec</code> . If the <code>ec</code> capability is present, <code>echocheck</code> is initially set to <code>on</code> . Otherwise, <code>echocheck</code> is initially set to <code>off</code> .             |
| <code>eofread</code>    | (str) The set of characters which signify an end-of-transmission during a <code>~&lt;</code> file transfer command; abbreviated <code>eofr</code> . If the <code>ie</code> capability is present, <code>eofread</code> is initially set to the value of that capability. Otherwise, <code>eofread</code> is set to a null string ( <code>""</code> ). |
| <code>eofwrite</code>   | (str) The string sent to indicate end-of-transmission during a <code>~&gt;</code> file transfer command; abbreviated <code>eofw</code> . If the <code>oe</code> capability is present, <code>eofread</code> is initially set to the value of that capability. Otherwise, <code>eofread</code> is set to a null string ( <code>""</code> ).            |
| <code>eo1</code>        | (str) The set of characters which indicate an end-of-line. <code>tip</code> will recognize escape characters only after an end-of-line. If the <code>e1</code> capability is present, <code>eo1</code> is initially set to the value of that capability. Otherwise, <code>eo1</code> is set to a null string ( <code>""</code> ).                     |
| <code>escape</code>     | (char) The command prefix (escape) character; abbreviated <code>es</code> . If the <code>es</code> capability is present, <code>escape</code> is initially set to the value of that capability. Otherwise, <code>escape</code> is set to <code>' ~ '</code> .                                                                                         |
| <code>etimeout</code>   | (num) The amount of time, in seconds, that <code>tip</code> should wait for the echo-check response when <code>echocheck</code> is set; abbreviated <code>et</code> . If the <code>et</code> capability is present, <code>etimeout</code> is initially set to the value of that capability. Otherwise, <code>etimeout</code> is set to 10 seconds.    |
| <code>exceptions</code> | (str) The set of characters which should not be discarded due to the beautification switch; abbreviated <code>ex</code> . If the <code>ex</code> capability is present, <code>exceptions</code> is initially set to the value of that capability. Otherwise, <code>exceptions</code> is set to <code>'\t\n\f\b'</code> .                              |
| <code>force</code>      | (char) The character used to force literal data transmission; abbreviated <code>fo</code> . If the <code>fo</code> capability is present, <code>force</code> is initially set to the value of that capability. Otherwise, <code>force</code> is set to <code>\377</code> (which disables it).                                                         |
| <code>framesize</code>  | (num) The amount of data (in bytes) to buffer between file system writes when receiving files; abbreviated <code>fr</code> . If the <code>fs</code> capability is present, <code>framesize</code> is initially set to the value of that capability. Otherwise, <code>framesize</code> is set to 1024.                                                 |
| <code>halfduplex</code> | (bool) Do local echoing because the host is half-duplex; abbreviated <code>hdx</code> . If the <code>hd</code> capability is present, <code>halfduplex</code> is initially set to <code>on</code> . Otherwise, <code>halfduplex</code> is initially set to <code>off</code> .                                                                         |

---

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>hardwareflow</code> | (bool) Do hardware flow control; abbreviated <code>hf</code> . If the <code>hf</code> capability is present, <code>hardwareflow</code> is initially set to <code>on</code> . Otherwise, <code>hardwareflowcontrol</code> is initially set to <code>off</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>host</code>         | (str) The name of the host to which you are connected; abbreviated <code>ho</code> . <code>host</code> is permanently set to the name given on the command line or in the <code>HOST</code> environment variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>localecho</code>    | (bool) A synonym for <code>halfduplex</code> ; abbreviated <code>le</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>log</code>          | (str) The name of the file to which to log information about outgoing phone calls. <code>log</code> is initially set to <code>/var/adm/acu</code> <code>log</code> , and can only be inspected or changed by the super-user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>parity</code>       | (str) The parity to be generated and checked when talking to the remote host; abbreviated <code>par</code> . The possible values are:<br><br><code>none</code> ><br><code>zero</code> Parity is not checked on input, and the parity bit is set to zero on output.<br><br><code>one</code> Parity is not checked on input, and the parity bit is set to one on output.<br><br><code>even</code> Even parity is checked for on input and generated on output.<br><br><code>odd</code> Odd parity is checked for on input and generated on output.<br><br>If the <code>pa</code> capability is present, <code>parity</code> is initially set to the value of that capability; otherwise, <code>parity</code> is set to <code>none</code> . |
| <code>phones</code>       | The file in which to find hidden phone numbers. If the environment variable <code>PHONES</code> is set, <code>phones</code> is set to the value of <code>PHONES</code> . Otherwise, <code>phones</code> is set to <code>/etc/phones</code> . The value of <code>phones</code> cannot be changed from within <code>tip</code> .                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>prompt</code>       | (char) The character which indicates an end-of-line on the remote host; abbreviated <code>pr</code> . This value is used to synchronize during data transfers. The count of lines transferred during a file transfer command is based on receipt of this character. If the <code>pr</code> capability is present, <code>prompt</code> is initially set to the value of that capability. Otherwise, <code>prompt</code> is set to <code>\n</code> .                                                                                                                                                                                                                                                                                       |
| <code>raise</code>        | (bool) Upper case mapping mode; abbreviated <code>ra</code> . When this mode is enabled, all lower case letters will be mapped to upper case by <code>tip</code> for transmission to the remote machine. If the <code>ra</code> capability is present, <code>raise</code> is initially set to <code>on</code> . Otherwise, <code>raise</code> is initially set to <code>off</code> .                                                                                                                                                                                                                                                                                                                                                     |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>raisechar</code> | (char) The input character used to toggle upper case mapping mode; abbreviated <code>rc</code> . If the <code>rc</code> capability is present, <code>raisechar</code> is initially set to the value of that capability. Otherwise, <code>raisechar</code> is set to <code>\377</code> (which disables it).                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>rawftp</code>    | (bool) Send all characters during file transfers; do not filter non-printable characters, and do not do translations like <code>\n</code> to <code>\r</code> . Abbreviated <code>raw</code> . If the <code>rw</code> capability is present, <code>rawftp</code> is initially set to <code>on</code> . Otherwise, <code>rawftp</code> is initially set to <code>off</code> .                                                                                                                                                                                                                                                                                                                              |
| <code>record</code>    | (str) The name of the file in which a session script is recorded; abbreviated <code>rec</code> . If the <code>re</code> capability is present, <code>record</code> is initially set to the value of that capability. Otherwise, <code>record</code> is set to <code>tip.record</code> .                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>remote</code>    | The file in which to find descriptions of remote systems. If the environment variable <code>REMOTE</code> is set, <code>remote</code> is set to the value of <code>REMOTE</code> . Otherwise, <code>remote</code> is set to <code>/etc/remote</code> . The value of <code>remote</code> cannot be changed from within <code>tip</code> .                                                                                                                                                                                                                                                                                                                                                                 |
| <code>script</code>    | (bool) Session scripting mode; abbreviated <code>sc</code> . When <code>script</code> is on, <code>tip</code> will record everything transmitted by the remote machine in the script record file specified in <code>record</code> . If the <code>beautify</code> switch is on, only printable ASCII characters will be included in the script file (those characters between 040 and 0177). The variable <code>exceptions</code> is used to indicate characters which are an exception to the normal beautification rules. If the <code>sc</code> capability is present, <code>script</code> is initially set to <code>on</code> . Otherwise, <code>script</code> is initially set to <code>off</code> . |
| <code>tabexpand</code> | (bool) Expand TAB characters to SPACE characters during file transfers; abbreviated <code>tab</code> . When <code>tabexpand</code> is on, each tab is expanded to eight SPACE characters. If the <code>tb</code> capability is present, <code>tabexpand</code> is initially set to <code>on</code> . Otherwise, <code>tabexpand</code> is initially set to <code>off</code> .                                                                                                                                                                                                                                                                                                                            |
| <code>tandem</code>    | (bool) Use XON/XOFF flow control to limit the rate that data is sent by the remote host; abbreviated <code>ta</code> . If the <code>nt</code> capability is present, <code>tandem</code> is initially set to <code>off</code> . Otherwise, <code>tandem</code> is initially set to <code>on</code> .                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>verbose</code>   | (bool) Verbose mode; abbreviated <code>verb</code> ; When verbose mode is enabled, <code>tip</code> prints messages while dialing, shows the current number of lines transferred during a file transfer operations, and more. If the <code>nv</code> capability is present, <code>verbose</code> is initially set to <code>off</code> . Otherwise, <code>verbose</code> is initially set to <code>on</code> .                                                                                                                                                                                                                                                                                            |
| <code>SHELL</code>     | (str) The name of the shell to use for the <code>~!</code> command; default value is <code>/bin/sh</code> , or taken from the environment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>HOME</code>      | (str) The home directory to use for the <code>~c</code> command. Default value is taken from the environment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Examples** EXAMPLE 1 Using the tip command

An example of the dialog used to transfer files is given below.

```
arpa% tip monet
[connected]
...(assume we are talking to a UNIX system)...
ucbmonet login: sam
Password:
monet% cat sylvester.c
~> Filename: sylvester.c
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~< Filename: reply.c
List command for remote host: cat reply.c
65 lines transferred in 2 minutes
monet%
...(or, equivalently)...
monet% ~p sylvester.c
...(actually echoes as ~[put] sylvester.c)...
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~t reply.c
...(actually echoes as ~[take] reply.c)...
65 lines transferred in 2 minutes
monet%
...(to print a file locally)...
monet% ~|Local command: pr h sylvester.c | lpr
List command for remote host: cat sylvester.c
monet% ~^D
[EOT]
...(back on the local system)...
```

**Environment Variables** The following environment variables are read by tip.

|        |                                                            |
|--------|------------------------------------------------------------|
| REMOTE | The location of the remote file.                           |
| PHONES | The location of the file containing private phone numbers. |
| HOST   | A default host to connect to.                              |
| HOME   | One's log-in directory (for chdirs).                       |
| SHELL  | The shell to fork on a '~!' escape.                        |

|              |                        |                                         |
|--------------|------------------------|-----------------------------------------|
| <b>Files</b> | /etc/phones            |                                         |
|              | /etc/remote            |                                         |
|              | /var/spool/locks/LCK.* | lock file to avoid conflicts with UUCP  |
|              | /var/adm/acu log       | file in which outgoing calls are logged |

~/.tiprc initialization file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [cu\(1C\)](#), [mail\(1\)](#), [uucp\(1C\)](#), [vi\(1\)](#), [ioctl\(2\)](#), [attributes\(5\)](#)

**Bugs** There are two additional variables, `chardelay` and `linedelay`, that are currently not implemented.

- Name** touch, settime – change file access and modification times
- Synopsis** touch [-acm] [-r *ref\_file* | -t *time* | -d *date\_time*] *file* . . .  
 touch [-acm] [*time\_spec*] *file* . . .  
 settime [-f *ref\_file*] [*time\_spec*] *file* . . .
- Description** The touch utility sets the access and modification times of each file. The *file* operand is created if it does not already exist.
- The time used can be specified by -t *time*, by -d *date\_time*, by the corresponding time fields of the file referenced by -r *ref\_file*, or by the *time\_spec* operand. If none of these are specified, touch uses the current time.
- If neither the -a nor -m options are specified, touch updates both the modification and access times.
- A user with write access to a file, but who is not the owner of the file or a super-user, can change the modification and access times of that file only to the current time. Attempts to set a specific time with touch results in an error.

The settime utility is equivalent to touch -c [*time\_spec*] *file*.

- Options** The following options are supported in the touch and settime utilities:

touch The following options are supported for the touch utility:

-a

Changes the access time of *file*. Does not change the modification time unless -m is also specified.

-c

Does not create a specified *file* if it does not exist. Does not write any diagnostic messages concerning this condition.

-d *date\_time*

Uses the specified *date\_time* instead of the current time. The option-argument must be a string of the form:

YYYY-MM-DDThh:mm:ss[.*frac*][*tz*]

or

YYYY-MM-DDThh:mm:ss[,*frac*][*tz*]

where

- YYYY is at least four decimal digits giving the year
- MM, DD, hh, mm, and SS are as with -t *time*
- T is either the letter T or a single SPACE character

- [*frac*] and [*frac*] are either empty, or a period (.) or a comma (,) respectively, followed by one or more decimal digits, specifying a fractional second
- [*tz*] is either empty, signifying local time, or the letter Z, signifying UTC. If [*tz*] is empty, the resulting time is affected by the value of the TZ environment variable

-m

Changes the modification time of *file*. Does not change the access time unless -a is also specified.

-r *ref\_file*

Uses the corresponding times of the file named by *ref\_file* instead of the current time.

-t *time*

Uses the specified *time* instead of the current time. *time* is a decimal number of the form:

[ [CC]YY]MMDDhhmm[.SS]

where each two digits represent the following:

*MM*

The month of the year [01-12].

*DD*

The day of the month [01-31].

*hh*

The hour of the day [00-23].

*mm*

The minute of the hour [00-59].

*CC*

The first two digits of the year.

*YY*

The second two digits of the year.

*SS*

The second of the minute [00-61].

Both *CC* and *YY* are optional. If neither is given, the current year is assumed. If *YY* is specified, but *CC* is not, *CC* is derived as follows:

| If YY is: | CC becomes: |
|-----------|-------------|
| 69-99     | 19          |
| 00-38     | 20          |
| 39-68     | ERROR       |

The resulting time is affected by the value of the TZ environment variable. The range of valid times is the Epoch to January 18, 2038.

The range for SS is [00-61] rather than [00-59] because of leap seconds. If SS is 60 or 61, and the resulting time, as affected by the TZ environment variable, does not refer to a leap second, the resulting time is one or two seconds after a time where SS is 59. If SS is not given, it is assumed to be 0.

**settime** The following option is supported for the `settime` utility:

`-f ref_file`

Uses the corresponding times of the file named by `ref_file` instead of the current time.

**Operands** The following operands are supported for the `touch` and `settime` utilities:

*file*

A path name of a file whose times are to be modified.

*time\_spec*

Uses the specified *time\_spec* instead of the current time. This operand is a decimal number of the form:

*MMDDhhmm* [YY]

where each two digits represent the following:

*MM*

The month of the year [01-12].

*DD*

The day of the month [01-31].

*hh*

The hour of the day [00-23].

*mm*

The minute of the hour [00-59].

*YY*

The second two digits of the year.

*YY* is optional. If it is omitted, the current year is assumed. If *YY* is specified, the year is derived as follows:

| YY    | Corresponding Year |
|-------|--------------------|
| 69-99 | 1969-1999          |
| 00-38 | 2000-2038          |
| 39-68 | ERROR              |

If no `-d`, `-r`, or `-t` option is specified, at least two operands are specified, and the first operand is an eight- or ten-digit decimal integer, the first operand is assumed to be a *time\_spec* operand. Otherwise, the first operand is assumed to be a *file* operand.

**Usage** See [largefile\(5\)](#) for the description of the behavior of touch when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of touch: LANG, LC\_ALL, LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

TZ

Determine the timezone to be used for interpreting the *time* or *date\_time* option-argument or the *time\_spec* operand.

**Exit Status** The following exit values are returned:

0

The touch utility executed successfully and all requested changes were made.

>0

An error occurred. The touch utility returned the number of files for which the times could not be successfully modified.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| CSI                 | Enabled                            |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [futimens\(2\)](#), [stat\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** Users familiar with the BSD environment find that for the touch utility, the `-f` option is accepted but ignored. The `-f` option is unnecessary because touch succeeds for all files owned by the user regardless of the permissions on the files.

**Name** touch – change file access and modification times

**Synopsis** /usr/ucb/touch [-acfm] file...

**Description** touch sets the access and modification times of each file to the current time. file is created if it does not already exist.

**Options**

- a Change the access time of file. Do not change the modification time unless -m is also specified.
- c Do not create file if it does not exist.
- f Attempt to force the touch in spite of read and write permissions on file.
- m Change the modification time of file. Do not change the access time unless -a is also specified.

**Usage** See [largefile\(5\)](#) for the description of the behavior of touch when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Exit Status** The following exit values are returned:

- 0 touch executed successfully and all requested changes were made.
- >0 An error occurred. touch returns the number of files for which the times could not be successfully modified.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTE VALUE   |
|---------------|-------------------|
| Availability  | compatibility/ucb |

**See Also** [touch\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Name** tplot, t300, t300s, t4014, t450, tek, ver – graphics filters for various plotters

**Synopsis** /usr/bin/tplot [-T *terminal*]

**Description** tplot reads plotting instructions from the standard input and produces plotting instructions suitable for a particular *terminal* on the standard output.

If no *terminal* is specified, the environment variable TERM is used. The default *terminal* is tek.

**Files** /usr/lib/t300

/usr/lib/t300s

/usr/lib/t4014

/usr/lib/t450

/usr/lib/tek

/usr/lib/vplot

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [vi\(1\)](#), [attributes\(5\)](#)

**Name** tput – initialize a terminal or query terminfo database

**Synopsis** tput [-T *type*] *capname* [*parm*]. . .

tput -S <<

**Description** The tput utility uses the terminfo database to make the values of terminal-dependent capabilities and information available to the shell (see [sh\(1\)](#)); to clear, initialize or reset the terminal; or to return the long name of the requested terminal type. tput outputs a string if the capability attribute (*capname*) is of type string, or an integer if the attribute is of type integer. If the attribute is of type boolean, tput simply sets the exit status (0 for TRUE if the terminal has the capability, 1 for FALSE if it does not), and produces no output. Before using a value returned on standard output, the user should test the exit status (\$?, see [sh\(1\)](#)) to be sure it is 0. See the EXIT STATUS section.

**Options** The following options are supported:

- T*type* Indicates the *type* of terminal. Normally this option is unnecessary, because the default is taken from the environment variable TERM. If -T is specified, then the shell variables LINES and COLUMNS and the layer size will not be referenced.
- S Allows more than one capability per invocation of tput. The capabilities must be passed to tput from the standard input instead of from the command line (see the example in the EXAMPLES section). Only one *capname* is allowed per line. The -S option changes the meaning of the 0 and 1 boolean and string exit statuses (see the EXAMPLES section).

**Operands** The following operands are supported:

*capname* Indicates the capability attribute from the terminfo database. See [terminfo\(4\)](#) for a complete list of capabilities and the *capname* associated with each.

The following strings will be supported as operands by the implementation in the "C" locale:

- |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clear | Display the clear-screen sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| init  | If the terminfo database is present and an entry for the user's terminal exists (see -T <i>type</i> , above), the following will occur: <ol style="list-style-type: none"> <li>1. if present, the terminal's initialization strings will be output (<i>is1</i>, <i>is2</i>, <i>is3</i>, <i>if</i>, <i>iprog</i>),</li> <li>2. any delays (for instance, newline) specified in the entry will be set in the tty driver,</li> <li>3. tabs expansion will be turned on or off according to the specification in the entry, and</li> </ol> |

- if tabs are not expanded, standard tabs will be set (every 8 spaces). If an entry does not contain the information needed for any of the four above activities, that activity will silently be skipped.

**reset** Instead of putting out initialization strings, the terminal's reset strings will be output if present (*rs1*, *rs2*, *rs3*, *rf*). If the reset strings are not present, but initialization strings are, the initialization strings will be output. Otherwise, reset acts identically to *init*.

**longname** If the *terminfo* database is present and an entry for the user's terminal exists (see *-Ttype* above), then the long name of the terminal will be put out. The long name is the last name in the first line of the terminal's description in the *terminfo* database (see [term\(5\)](#)).

*parm* If the attribute is a string that takes parameters, the argument *parm* will be instantiated into the string. An all numeric argument will be passed to the attribute as a number.

#### Examples **EXAMPLE 1** Initializing the terminal according to TERM

This example initializes the terminal according to the type of terminal in the environment variable *TERM*. This command should be included in everyone's *.profile* after the environment variable *TERM* has been exported, as illustrated on the [profile\(4\)](#) manual page.

```
example% tput init
```

#### **EXAMPLE 2** Resetting a terminal

This example resets an AT&T 5620 terminal, overriding the type of terminal in the environment variable *TERM*:

```
example% tput -T5620 reset
```

#### **EXAMPLE 3** Moving the cursor

The following example sends the sequence to move the cursor to row 0, column 0 (the upper left corner of the screen, usually known as the "home" cursor position).

```
example% tput cup 0 0
```

This next example sends the sequence to move the cursor to row 23, column 4.

```
example% tput cup 23 4
```

**EXAMPLE 4** Echoing the clear-screen sequence

This example echos the clear-screen sequence for the current terminal.

```
example% tput clear
```

**EXAMPLE 5** Printing the number of columns

This command prints the number of columns for the current terminal.

```
example% tput cols
```

The following command prints the number of columns for the 450 terminal.

```
example% tput -T450 cols
```

**EXAMPLE 6** Setting shell variables

This example sets the shell variables `bold`, to begin stand-out mode sequence, and `offbold`, to end standout mode sequence, for the current terminal. This might be followed by a prompt:

```
echo "${bold}Please type in your name: ${offbold}\c"
```

```
example% bold='tput smso'
```

```
example% offbold='tput rmso'
```

**EXAMPLE 7** Setting the exit status

This example sets the exit status to indicate if the current terminal is a hardcopy terminal.

```
example% tput hc
```

**EXAMPLE 8** Printing the long name from terminfo

This command prints the long name from the `terminfo` database for the type of terminal specified in the environment variable `TERM`.

```
example% tput longname
```

**EXAMPLE 9** Processing several capabilities with one invocation

This example shows `tput` processing several capabilities in one invocation. This example clears the screen, moves the cursor to position `10, 10` and turns on `bold` (extra bright) mode. The list is terminated by an exclamation mark (!) on a line by itself.

```
example% tput -S <<!
```

```
> clear
```

```
> cup 10 10
```

```
> bold
```

```
> !
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `tput`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**TERM** Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, an unspecified default terminal type will be used.

**Exit Status** The following exit values are returned:

0

- If *capname* is of type boolean and `-S` is not specified, indicates TRUE.
- If *capname* is of type string and `-S` is not specified, indicates *capname* is defined for this terminal type.
- If *capname* is of type boolean or string and `-S` is specified, indicates that all lines were successful.
- *capname* is of type integer.
- The requested string was written successfully.

1

- If *capname* is of type boolean and `-S` is not specified, indicates FALSE.
- If *capname* is of type string and `-S` is not specified, indicates that *capname* is not defined for this terminal type.

2 Usage error.

3 No information is available about the specified terminal type.

4 The specified operand is invalid.

>4 An error occurred.

-1 *capname* is a numeric variable that is not specified in the terminfo database. For instance, `tput -T450 lines` and `tput -T2621 xmc`.

**Files**

**Name** tr – translate characters

**Synopsis** /usr/bin/tr [-cds] [*string1* [*string2*]]  
/usr/xpg4/bin/tr [-cs] *string1 string2*  
/usr/xpg4/bin/tr -s | -d [-c] *string1*  
/usr/xpg4/bin/tr -ds [-c] *string1 string2*  
/usr/xpg6/bin/tr [-c | -C] [-s] *string1 string2*  
/usr/xpg6/bin/tr -s [-c | -C] *string1*  
/usr/xpg6/bin/tr -d [-c | -C] *string1*  
/usr/xpg6/bin/tr -ds [-c | -C] *string1 string2*

**Description** The `tr` utility copies the standard input to the standard output with substitution or deletion of selected characters. The options specified and the *string1* and *string2* operands control translations that occur while copying characters and single-character collating elements.

**Options** The following options are supported:

- c   Complements the set of values specified by *string1*.
- C   Complements the set of characters specified by *string1*.
- d   Deletes all occurrences of input characters that are specified by *string1*.
- s   Replaces instances of repeated characters with a single character.

When the `-d` option is not specified:

- Each input character found in the array specified by *string1* is replaced by the character in the same relative position in the array specified by *string2*. When the array specified by *string2* is shorter than the one specified by *string1*, the results are unspecified.
- If the `-c` option is specified, the complements of the values specified by *string1* are placed in the array in ascending order by binary value.
- If the `-C` option is specified, the complements of the characters specified by *string1* (the set of all characters in the current character set, as defined by the current setting of `LC_CTYPE`, except for those actually specified in the *string1* operand) are placed in the array in ascending collation sequence, as defined by the current setting of `LC_COLLATE`.
- Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.

When the `-d` option is specified:

- Input characters found in the array specified by *string1* are deleted.

- When the `-C` option is specified with `-d`, all values except those specified by *string1* are deleted. The contents of *string2* are ignored, unless the `-s` option is also specified.
- If the `-c` option is specified, the complements of the values specified by *string1* are placed in the array in ascending order by binary value.
- The same string cannot be used for both the `-d` and the `-s` option. When both options are specified, both *string1* (used for deletion) and *string2* (used for squeezing) are required.

When the `-s` option is specified, after any deletions or translations have taken place, repeated sequences of the same character is replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

```
tr -s '[:space:]'
```

the last operand's array contains all of the characters in that character class. However, in a case conversion, as described previously, such as

```
tr -s '[:upper:]' '[:lower:]'
```

the last operand's array contains only those characters defined as the second characters in each of the `toupper` or `tolower` character pairs, as appropriate. (See [toupper\(3C\)](#) and [tolower\(3C\)](#)).

An empty string used for *string1* or *string2* produces undefined results.

**Operands** The following operands are supported:

*string1*

*string2* Translation control strings. Each string represents a set of characters to be converted into an array of characters used for the translation.

The operands *string1* and *string2* (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, `tr` excludes, without a diagnostic, those multi-character elements from the resulting array.

*character* Any character not described by one of the conventions below represents itself.

*\octal* Octal sequences can be used to represent characters with specific coded values. An octal sequence consists of a backslash followed by the longest sequence of one-, two-, or three-octal-digit characters (01234567). The sequence causes the character whose encoding is represented by the one-, two- or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading `\` for each byte.

`\character` The backslash-escape sequences `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, and `\v` are supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.

`/usr/xpg4/bin/tr c-c`

`/usr/bin/tr [c-c]`

In the POSIX locale, this construct represents the range of collating elements between the range endpoints (as long as neither endpoint is an octal sequence of the form `\octal`), inclusively, as defined by the collation sequence. The characters or collating elements in the range are placed in the array in ascending collation sequence. If the second endpoint precedes the starting endpoint in the collation sequence, it is unspecified whether the range of collating elements is empty, or this construct is treated as invalid. In locales other than the POSIX locale, this construct has unspecified behavior.

If either or both of the range endpoints are octal sequences of the form `\octal`, represents the range of specific coded binary values between two range endpoints, inclusively.

`[ :class: ]` Represents all characters belonging to the defined character class, as defined by the current setting of the LC\_CTYPE locale category. The following character class names are accepted when specified in *string1*:

```
alnum blank digit lower punct upper
alpha cntrl graph print space xdigit
```

In addition, character class expressions of the form `[ :name: ]` are recognized in those locales where the *name* keyword has been given a `charClass` definition in the LC\_CTYPE category.

When both the `-d` and `-s` options are specified, any of the character class names are accepted in *string2*. Otherwise, only character class names `lower` or `upper` are valid in *string2* and then only if the corresponding character class `upper` and `lower`, respectively, is specified in the same relative position in *string1*. Such a specification is interpreted as a request for case conversion. When `[ :lower: ]` appears in *string1* and `[ :upper: ]` appears in *string2*, the arrays contain the characters from the `toupper` mapping in the LC\_CTYPE category of the current locale. When `[ :upper: ]` appears in *string1* and `[ :lower: ]` appears in *string2*, the arrays contain the characters from the `tolower` mapping in the LC\_CTYPE category of the current locale. The first character from each mapping pair is in the array for *string1* and the second character from each mapping pair is in the array for *string2* in the same relative position.

Except for case conversion, the characters specified by a character class expression are placed in the array in an unspecified order.

If the name specified for *class* does not define a valid character class in the current locale, the behavior is undefined.

[*=equiv=*] Represents all characters or collating elements belonging to the same equivalence class as *equiv*, as defined by the current setting of the LC\_COLLATE locale category. An equivalence class expression is allowed only in *string1*, or in *string2* when it is being used by the combined -d and -s options. The characters belonging to the equivalence class are placed in the array in an unspecified order.

[*x\*n*] Represents *n* repeated occurrences of the character *x*. Because this expression is used to map multiple characters to one, it is only valid when it occurs in *string2*. If *n* has a leading 0, it is interpreted as an octal value. Otherwise, it is interpreted as a decimal value.

If *n* is omitted or is 0, /usr/bin/tr interprets this as huge; /usr/xpg4/bin/tr and /usr/xpg6/bin/tr interprets this as large enough to extend the *string2*-based sequence to the length of the *string1*-based sequence.

**Usage** See [largefile\(5\)](#) for the description of the behavior of tr when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

**Examples** EXAMPLE 1 Creating a list of words

The following example creates a list of all words in *file1*, one per line in *file2*, where a word is taken to be a maximal string of letters.

```
tr -cs "[:alpha:]" "[\n*]" <file1 >file2
```

EXAMPLE 2 Translating characters

This example translates all lower-case characters in *file1* to upper-case and writes the results to standard output.

```
tr "[:lower:]" "[:upper:]" <file1
```

Notice that the caveat expressed in the corresponding example in XPG3 is no longer in effect. This case conversion is now a special case that employs the *tolower* and *toupper* classifications, ensuring that proper mapping is accomplished (when the locale is correctly defined).

EXAMPLE 3 Identifying equivalent characters

This example uses an equivalence class to identify accented variants of the base character *e* in *file1*, which are stripped of diacritical marks and written to *file2*.

```
tr "[=e=]" e <file1 >file2
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `tr`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- `0` All input was processed successfully.
- `>0` An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

|                  | Standard            | See <a href="#">standards(5)</a> . |

**See Also** [ed\(1\)](#), [sed\(1\)](#), [sh\(1\)](#), [tolower\(3C\)](#), [toupper\(3C\)](#), [ascii\(5\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#), [standards\(5\)](#)

**Notes** Unlike some previous versions, `/usr/xpg4/bin/tr` correctly processes NUL characters in its input stream. NUL characters can be stripped by using `tr -d '\000'`.

**Name** tr – translate characters

**Synopsis** /usr/ucb/tr [-cds] [*string1* [*string2*]]

**Description** The `tr` utility copies the standard input to the standard output with substitution or deletion of selected characters. The arguments *string1* and *string2* are considered sets of characters. Any input character found in *string1* is mapped into the character in the corresponding position within *string2*. When *string2* is short, it is padded to the length of *string1* by duplicating its last character.

In either string the notation:

*a–b*

denotes a range of characters from *a* to *b* in increasing ASCII order. The character `\`, followed by 1, 2 or 3 octal digits stands for the character whose ASCII code is given by those digits. As with the shell, the escape character `\`, followed by any other character, escapes any special meaning for that character.

**Options** Any combination of the options `-c`, `-d`, or `-s` may be used:

- `-c` Complement the set of characters in *string1* with respect to the universe of characters whose ASCII codes are 01 through 0377 octal.
- `-d` Delete all input characters in *string1*.
- `-s` Squeeze all strings of repeated output characters that are in *string2* to single characters.

**Examples** **EXAMPLE 1** Creating a list of all the words in a filename

The following example creates a list of all the words in *filename1*, one per line, in *filename2*, where a word is taken to be a maximal string of alphabetic. The second string is quoted to protect `\` from the shell. 012 is the ASCII code for NEWLINE.

```
example% tr -cs A-Za-z '\012' < filename1 > filename2
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | compatibility/ucb |

**See Also** [ed\(1\)](#), [ascii\(5\)](#), [attributes\(5\)](#)

**Notes** Will not handle ASCII NUL in *string1* or *string2*. `tr` always deletes NUL from input.

**Name** trap, onintr – shell built-in functions to respond to (hardware) signals

## Synopsis

```
sh trap [argument n [n2]...]
csh onintr [-| label]
ksh88 *trap [arg sig [sig2...]]
ksh +trap [-p] [action condition...]
```

## Description

- sh The `trap` command *argument* is to be read and executed when the shell receives numeric or symbolic signal(s) (*n*). (Note: *argument* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If *argument* is absent all trap(s) *n* are reset to their original values. If *argument* is the null string this signal is ignored by the shell and by the commands it invokes. If *n* is 0 the command *argument* is executed on exit from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.
- csh `onintr` controls the action of the shell on interrupts. With no arguments, `onintr` restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the `-` argument, the shell ignores all interrupts. With a *label* argument, the shell executes a `goto label` when an interrupt is received or a child process terminates because it was interrupted.
- ksh88 `trap` uses *arg* as a command to be read and executed when the shell receives signal(s) *sig*. *arg* is scanned once when the trap is set and once when the trap is taken. Each *sig* can be specified as a number or as the name of the signal. `trap` commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If *arg* is omitted or is `-`, then the trap(s) for each *sig* are reset to their original values. If *arg* is the null (the empty string, for example, `""`) string then this signal is ignored by the shell and by the commands it invokes. If *sig* is ERR then *arg* are executed whenever a command has a non-zero exit status. If *sig* is DEBUG then *arg* are executed after each command. If *sig* is 0 or EXIT for a `trap` set outside any function then the command *arg* is executed on exit from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.

On this manual page, [ksh88\(1\)](#) commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.

3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by **\*\*** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**ksh** `trap` is a special built-in that defines actions to be taken when conditions such as receiving a signal occur. `trap` can also be used to display the current trap settings on standard output.

If *action* is `-`, `trap` resets each condition to the default value. If *action* is an empty string, the shell ignores each of the conditions if they arise. Otherwise, the argument *action* is read and executed by the shell as if it were processed by `eval` when one of the corresponding conditions arise. The action of the trap overrides any previous action associated with each specified condition. The value of  `$?`  is not altered by the trap execution.

*condition* can be the name or number of a signal, or one of the following:

|                    |                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>EXIT</code>  | Execute this trap when the shell exits. If defined within a function with the <code>function</code> reserved word, executes the trap in the caller's environment when the function returns. The trap action is restored to the value it had when it called the function. |
| <code>0</code>     | Same as <code>EXIT</code> .                                                                                                                                                                                                                                              |
| <code>DEBUG</code> | Execute before each simple command is executed but after the arguments are expanded.                                                                                                                                                                                     |
| <code>ERR</code>   | Execute whenever <code>set -e</code> would cause the shell to exit.                                                                                                                                                                                                      |
| <code>KEYBD</code> | Execute when a key is entered from a terminal device.                                                                                                                                                                                                                    |

Signal names are case insensitive and the `sig` prefix is optional. Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset although doing so does not report an error. The use of signal numbers other than 1, 2, 3, 6, 9, 14, and 15 are not portable.

Although `trap` is a special built-in, specifying a condition that the shell does not know about causes `trap` to exit with a non-zero exit status, but does not terminate the invoking shell.

If no action or conditions are specified then all the current trap settings are written to standard output.

The following options are supported by the `trap` built-in command in `ksh`:

`-p` Causes the current traps to be output in a format that can be processed as input to the shell to recreate the current traps.

The trap built-in in `ksh` exits with one of the following values:

`0` Successful completion.

>0 An error occurred.

On this manual page, [ksh\(1\)](#) commands that are preceded by one or two + (plus signs) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. They are not valid function names.
5. Words, following a command preceded by ++ that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [csh\(1\)](#), [eval\(1\)](#), [exit\(1\)](#), [ksh\(1\)](#), [ksh88\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#)

**Name** troff – typeset or format documents

**Synopsis** troff [-a] [-f] [-Fdir] [-i] [-mname] [-nN] [-olist] [-raN]  
[-sN] [-uN] [-z] [filename]...

**Description** troff formats text in the *filenames* for typesetting or laser printing. Input to troff is expected to consist of text interspersed with formatting requests and macros. If no *filename* argument is present, troff reads standard input. A minus sign (–) as a *filename* indicates that standard input should be read at that point in the list of input files.

**Options** The following options are supported. They may appear in any order, but all must appear before the first *filename*.

- a Send an ASCII approximation of formatted output to standard output. (Note: a rough ASCII version can also be printed out on ordinary terminals with an old and rarely used command, /usr/bin/ta.)
- f Do not print a trailer after the final page of output or cause the postprocessor to relinquish control of the device.
- Fdir Search directory *dir* for font width or terminal tables instead of the system default directory.
- i Read standard input after all input files are exhausted.
- mname Prepend the macro file /usr/share/lib/tmac/*name* to the input *filenames*. Note: most references to macro packages include the leading *m* as part of the name; for example, the [man\(5\)](#) macros reside in /usr/share/lib/tmac/an. The macro directory can be changed by setting the TROFFMACS environment variable to a specific path. Be certain to include the trailing ' / ' (slash) at the end of the path.
- nN Number the first generated page *N*.
- olist Print only pages whose page numbers appear in the comma-separated *list* of numbers and ranges. A range *N–M* means pages *N* through *M*; an initial *–N* means from the beginning to page *N*; and a final *N–* means from *N* to the end.
- q Quiet mode in nroff; ignored in troff.
- raN Set register *a* (one-character names only) to *N*.
- sN Stop the phototypesetter every *N* pages. On some devices, troff produces a trailer so you can change cassettes; resume by pressing the typesetter's start button.
- uN Set the emboldening factor for the font mounted in position 3 to *N*. If *N* is missing, then set the emboldening factor to 0.
- z Suppress formatted output. Only diagnostic messages and messages output using the .tm request are output.

**Operands** The following operand is supported:

*filename* The file containing text to be processed by `troff`.

**Files**

|                                     |                                                                  |
|-------------------------------------|------------------------------------------------------------------|
| <code>/tmp/trtmp</code>             | temporary file                                                   |
| <code>/usr/share/lib/tmac/*</code>  | standard macro files                                             |
| <code>/usr/lib/font/*</code>        | font width tables for alternate mounted <code>troff</code> fonts |
| <code>/usr/share/lib/nterm/*</code> | terminal driving tables for <code>nroff</code>                   |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | text/doctools   |

**See Also** [checknr\(1\)](#), [col\(1\)](#), [eqn\(1\)](#), [man\(1\)](#), [nroff\(1\)](#), [tbl\(1\)](#), [attributes\(5\)](#), [man\(5\)](#), [me\(5\)](#), [ms\(5\)](#)

**Notes** `troff` is not 8-bit clean because it is by design based on 7-bit ASCII.

Previous documentation incorrectly described the numeric register `yr` as being the Last two digits of current year. `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` may be included in a document and subsequently used to display a two-digit year. Note that any other available one- or two-character register name may be substituted for `yy`.

```
.\" definition of new string register yy--last two digits of year
.\" use yr (# of years since 1900) if it is < 100
.ie \n(yr<100 .ds yy \n(yr
.el \{
 .\" else, subtract 100 from yr, store in ny
.nr ny \n(yr-100
.ie \n(ny>9 \{
 .\" use ny if it is two digits
.ds yy \n(ny
.\" remove temporary number register ny
.rr ny \}
.el \{.ds yy 0
.\" if ny is one digit, append it to 0
.as yy \n(ny
.rr ny \} \}
```

**Name** true, false – provide truth values

**Synopsis** true

false

**Description** The `true` utility does nothing, successfully. The `false` utility does nothing, unsuccessfully. They are typically used in a shell script `sh` as:

```
while true
do
 command
done
```

which executes *command* forever.

**Exit Status** `true` has exit status 0.

`false` always will exit with a non-zero value.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|

| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [sh\(1\)](#), [attributes\(5\)](#), [standards\(5\)](#)

**Name** truss – trace system calls and signals

**Synopsis** truss [-fcaeildDE] [- [tTvX] [!] *syscall* , ...]  
 [- [sS] [!] *signal* , ...] [- [mM] [!] *fault* , ...]  
 [- [rw] [!] *fd* , ...]  
 [- [uU] [!] *lib* , ... : [:] [!] *func* , ...]  
 [-o *outfile*] *command* | -p *pid*[/lwps]...

**Description** The `truss` utility executes the specified command and produces a trace of the system calls it performs, the signals it receives, and the machine faults it incurs. Each line of the trace output reports either the fault or signal name or the system call name with its arguments and return value(s). System call arguments are displayed symbolically when possible using defines from relevant system headers. For any path name pointer argument, the pointed-to string is displayed. Error returns are reported using the error code names described in [Intro\(3\)](#). If, in the case of an error, the kernel reports a missing privilege, a privilege name as described in [privileges\(5\)](#) is reported in square brackets ([ ]) after the error code name. See NOTES for more information on error reporting.

Optionally (see the `-u` option), `truss` also produce an entry/exit trace of user-level function calls executed by the traced process, indented to indicate nesting.

**Options** For those options that take a list argument, the name `all` can be used as a shorthand to specify all possible members of the list. If the list begins with a `!`, the meaning of the option is negated (for example, exclude rather than trace). Multiple occurrences of the same option can be specified. For the same name in a list, subsequent options (those to the right) override previous ones (those to the left).

The following options are supported:

- a Shows the argument strings that are passed in each `exec()` system call.
- c Counts traced system calls, faults, and signals rather than displaying the trace line-by-line. A summary report is produced after the traced command terminates or when `truss` is interrupted. If `-f` is also specified, the counts include all traced system calls, faults, and signals for child processes.
- d Includes a time stamp on each line of trace output. The time stamp appears as a field containing *seconds . fraction* at the start of the line. This represents a time in seconds relative to the beginning of the trace. The first line of the trace output shows the base time from which the individual time stamps are measured, both as seconds since the epoch (see [time\(2\)](#)) and as a date string (see [ctime\(3C\)](#) and [date\(1\)](#)). The times that are reported are the times that the event in question occurred. For all system calls, the event is the completion of the system call, not the start of the system call.

- 
- D Includes a time delta on each line of trace output. The value appears as a field containing *seconds . fraction* and represents the elapsed time for the LWP that incurred the event since the last reported event incurred by that LWP. Specifically, for system calls, this is not the time spent within the system call.
- e Shows the environment strings that are passed in each `exec()` system call.
- E Includes a time delta on each line of trace output. The value appears as a field containing *seconds . fraction* and represents the difference in time elapsed between the beginning and end of a system call.
- In contrast to the -D option, this is the amount of time spent within the system call.
- f Follows all children created by `fork()` or `vfork()` and includes their signals, faults, and system calls in the trace output. Normally, only the first-level command or process is traced. When -f is specified, the process-id is included with each line of trace output to indicate which process executed the system call or received the signal.
- i Does not display interruptible sleeping system calls. Certain system calls, such as `open()` and `read()` on terminal devices or pipes, can sleep for indefinite periods and are interruptible. Normally, `truss` reports such sleeping system calls if they remain asleep for more than one second. The system call is reported again a second time when it completes. The -i option causes such system calls to be reported only once, when they complete.
- l Includes the id of the responsible lightweight process (LWP) with each line of trace output. If -f is also specified, both the process-id and the LWP-id are included.
- m [!]*fault*,... Machine faults to trace or exclude. Those faults specified in the comma-separated list are traced. Faults can be specified by name or number (see `<sys/fault.h>`). If the list begins with a !, the specified faults are excluded from the trace output. Default is `-mall -m !fltpage`.
- M [!]*fault*,... Machine faults that stop the process. The specified faults are added to the set specified by -m. If one of the specified faults is incurred, `truss` leaves the process stopped and abandoned (see the -T option). Default is `-M!all`.

- `-o outfile` File to be used for the trace output. By default, the output goes to standard error.
- `-p` Interprets the *command* arguments to `truss` as a list of process-ids for existing processes (see `ps(1)`) rather than as a command to be executed. `truss` takes control of each process and begins tracing it provided that the `userid` and `groupid` of the process match those of the user or that the user is a privileged user. Users can trace only selected threads by appending */thread-id* to the process-id. Multiple threads can be selected using the `-` and `,` delimiters. For example `/1,2,7-9` traces threads 1, 2, 7, 8, and 9. Processes can also be specified by their names in the `/proc` directory, for example, `/proc/12345`.
- `-r [!]fd,...` Shows the full contents of the I/O buffer for each `read()` on any of the specified file descriptors. The output is formatted 32 bytes per line and shows each byte as an ASCII character (preceded by one blank) or as a 2-character C language escape sequence for control characters such as horizontal tab (`\t`) and newline (`\n`). If ASCII interpretation is not possible, the byte is shown in 2-character hexadecimal representation. (The first 12 bytes of the I/O buffer for each traced `print >read()` are shown even in the absence of `-r`.) Default is `-r!all`.
- `-s [!]signal,...` Signals to trace or exclude. Those signals specified in the comma-separated list are traced. The trace output reports the receipt of each specified signal, even if the signal is being ignored (not blocked). (Blocked signals are not received until they are unblocked.) Signals can be specified by name or number (see `<sys/signal.h>`). If the list begins with a `!`, the specified signals are excluded from the trace output. Default is `-sall`.
- `-S [!]signal,...` Signals that stop the process. The specified signals are added to the set specified by `-s`. If one of the specified signals is received, `truss` leaves the process stopped and abandoned (see the `-T` option). Default is `-S!all`.
- `-t [!]syscall,...` System calls to trace or exclude. Those system calls specified in the comma-separated list are traced. If the list begins with a `!`, the specified system calls are excluded from the trace output. Default is `-tall`.

-T [!]*syscall*,...

Specifies system calls that stop the process. The specified system calls are added to the set specified by -t. If one of the specified system calls is encountered, `truss` leaves the process stopped and abandoned. That is, `truss` releases the process and exits but leaves the process in the stopped state at completion of the system call in question. A debugger or other process inspection tool (see [proc\(1\)](#)) can then be applied to the stopped process. `truss` can be reapplied to the stopped process with the same or different options to continue tracing. Default is `-T!all`.

A process left stopped in this manner cannot be restarted by the application of `kill -CONT` because it is stopped on an event of interest via `/proc`, not by the default action of a stopping signal (see [signal.h\(3HEAD\)](#)). The [prun\(1\)](#) command described in [proc\(1\)](#) can be used to set the stopped process running again.

-u [!]*lib*,...:[:]*func*,...

User-level function call tracing. *lib*,... is a comma-separated list of dynamic library names, excluding the “.so.n” suffix. *func*,... is a comma-separated list of function names. In both cases the names can include name-matching metacharacters \*,?,[,] with the same meanings as those of [sh\(1\)](#) but as applied to the library/function name spaces, not to files. An empty library or function list defaults to \*, trace all libraries or functions in a library. A leading ! on either list specifies an exclusion list, names of libraries or functions not to be traced. Excluding a library excludes all functions in that library; any function list following a library exclusion list is ignored.

A single : separating the library list from the function list means to trace calls into the libraries from outside the libraries, but omit calls made to functions in a library from other functions in the same library. A double : : means to trace all calls, regardless of origin.

Library patterns do not match either the executable file or the dynamic linker unless there is an exact match (l\* does not match ld.so.1). To trace functions in either of these objects, the names must be specified exactly, as in:

```
truss -u a.out -u ld ...
```

`a.out` is the literal name to be used for this purpose; it does not stand for the name of the executable file. Tracing `a.out` function calls implies all calls (default is `:.:`).

Multiple `-u` options can be specified and they are honored left-to-right. The id of the lightweight process and id of the thread that performed the function call is included in the trace output for the call, separated by a slash (/) and an at-sign (@) character, respectively.

- U [!]lib, . . . :[:][!]func, . . .
User-level function calls that stop the process. The specified functions are added to the set specified by `-u`. If one of the specified functions is called, `truss` leaves the process stopped and abandoned (see the `-T` option).
- v [!]syscall,...
Verbose. Displays the contents of any structures passed by address to the specified system calls (if traced by `-t`). Input values as well as values returned by the operating system are shown. For any field used as both input and output, only the output value is shown. Default is `-v!all`.
- w [!]fd,...
Shows the contents of the I/O buffer for each `write()` on any of the specified file descriptors (see the `-r` option). Default is `-w!all`.
- x [!]syscall,...
Displays the arguments to the specified system calls (if traced by `-t`) in raw form, usually hexadecimal, rather than symbolically. This is for unredeemed hackers who must see the raw bits to be happy. Default is `-x!all`.

See *man pages section 2: System Calls* for system call names accepted by the `-t`, `-T`, `-v`, and `-x` options. System call numbers are also accepted.

If `truss` is used to initiate and trace a specified command and if the `-o` option is used or if standard error is redirected to a non-terminal file, then `truss` runs with `hangup`, `interrupt`, and `quit` signals ignored. This facilitates tracing of interactive programs that catch `interrupt` and `quit` signals from the terminal.

If the trace output remains directed to the terminal, or if existing processes are traced (the `-p` option), then `truss` responds to `hangup`, `interrupt`, and `quit` signals by releasing all traced processes and exiting. This enables the user to terminate excessive trace output and to release previously-existing processes. Released processes continue normally, as though they had never been touched.

When tracing existing processes, `truss` releases processes and sets them running when `truss` exits. This includes exiting due to signals, such as `SIGINT`, `SIGHUP`, or `SIGQUIT`. This enables

the user to terminate excessive trace output and to release previously-existing processes. Released processes continue normally, as though they had never been touched.

**Examples** EXAMPLE 1 Tracing a Command

The following example produces a trace of the `find(1)` command on the terminal:

```
example$ truss find . -print >find.out
```

EXAMPLE 2 Tracing Common System Calls

The following example shows only a trace of the open, close, read, and write system calls:

```
example$ truss -t open,close,read,write find . -print >find.out
```

EXAMPLE 3 Tracing a Shell Script

The following example produces a trace of the `spell(1)` command on the file `truss.out`:

```
example$ truss -f -o truss.out spell document
```

`spell` is a shell script, so the `-f` flag is needed to trace not only the shell but also the processes created by the shell. (The spell script runs a pipeline of eight processes.)

EXAMPLE 4 Abbreviating Output

The following example abbreviates output:

```
example$ truss nroff -mm document >nroff.out
```

because 97% of the output reports `lseek()`, `read()`, and `write()` system calls. To abbreviate it:

```
example$ truss -t !lseek,read,write nroff -mm document >nroff.out
```

EXAMPLE 5 Tracing Library Calls From Outside the C Library

The following example traces all user-level calls made to any function in the C library from outside the C library:

```
example$ truss -u libc ...
```

EXAMPLE 6 Tracing library calls from within the C library

The following example includes calls made to functions in the C library from within the C library itself:

```
example$ truss -u libc:: ...
```

**EXAMPLE 7** Tracing Library Calls Other Than the C Library

The following example traces all user-level calls made to any library other than the C library:

```
example$ truss -u '*' -u !libc ...
```

**EXAMPLE 8** Tracing printf and scanf Function Calls

The following example traces all user-level calls to functions in the printf and scanf family contained in the C library:

```
example$ truss -u 'libc:*printf,*scanf' ...
```

**EXAMPLE 9** Tracing Every User-level Function Call

The following example traces every user-level function call from anywhere to anywhere:

```
example$ truss -u a.out -u ld:: -u :: ...
```

**EXAMPLE 10** Tracing a System Call Verbosely

The following example verbosely traces the system call activity of process #1, `init(1M)` (if you are a privileged user):

```
example# truss -p -v all 1
```

Interrupting `truss` returns `init` to normal operation.

**Files** /proc/\* Process files

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [date\(1\)](#), [find\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [sh\(1\)](#), [spell\(1\)](#), [init\(1M\)](#), [Intro\(3\)](#), [exec\(2\)](#), [fork\(2\)](#), [lseek\(2\)](#), [open\(2\)](#), [read\(2\)](#), [time\(2\)](#), [vfork\(2\)](#), [write\(2\)](#), [ctime\(3C\)](#), [signal.h\(3HEAD\)](#), [proc\(4\)](#), [attributes\(5\)](#), [mwac\(5\)](#), [privileges\(5\)](#), [threads\(5\)](#)

*man pages section 2: System Calls*

**Notes** Some of the system calls described in *man pages section 2: System Calls* differ from the actual operating system interfaces. Do not be surprised by minor deviations of the trace output from the descriptions in that document.

Every machine fault (except a page fault) results in the posting of a signal to the LWP that incurred the fault. A report of a received signal immediately follows each report of a machine fault (except a page fault) unless that signal is being blocked.

The operating system enforces certain security restrictions on the tracing of processes. In particular, any command whose object file (`a.out`) cannot be read by a user cannot be traced by that user; `setuid` and `setgid` commands can be traced only by a privileged user. Unless it is run by a privileged user, `truss` loses control of any process that performs an `exec()` of a set-id or unreadable object file; such processes continue normally, though independently of `truss`, from the point of the `exec()`.

To avoid collisions with other controlling processes, `truss` does not trace a process that it detects is being controlled by another process via the `/proc` interface. This allows `truss` to be applied to [proc\(4\)](#)-based debuggers as well as to another instance of itself.

The trace output contains tab characters under the assumption that standard tab stops are set (every eight positions).

The trace output for multiple processes or for a multithreaded process (one that contains more than one LWP) is not produced in strict time order. For example, a `read()` on a pipe can be reported before the corresponding `write()`. For any one LWP (a traditional process contains only one), the output is strictly time-ordered.

When tracing more than one process, `truss` runs as one controlling process for each process being traced. For the example of the `spell` command shown above, `spell` itself uses 9 process slots, one for the shell and 8 for the 8-member pipeline, while `truss` adds another 9 processes, for a total of 18.

Not all possible structures passed in all possible system calls are displayed under the `-v` option.

When `truss` reports on errors returned by system calls that are caused by missing privilege, `truss` displays either the simple privilege name after the error-code or a complex privilege description. See [privileges\(5\)](#). This complex description can consist of:

- [ALL]           The process needs all privileges for the requested operation.
- [MULTIPLE]     The process lacks multiple privileges.
- [ZONE]          The process lacks one of the available privileges in the zone (zone-local variant of ALL).
- [GLOBAL]        The requested operation requires that the process is running in the global zone.
- [MWAC]          The requested operation violates a [mwac\(5\)](#) policy that is in place for the process.

**Name** tset, reset – establish or restore terminal characteristics

**Synopsis** tset [-InQrs] [-ec] [-kc]  
           [-m [*port-ID* [*baudrate*] : *type*]...] [*type*]  
 reset [-] [-ec] [-I] [-kc]  
       [-n] [-Q] [-r] [-s]  
       [-m [*indent*] [*test baudrate*] : *type*]... [*type*]

**Description** The tset utility sets up your terminal, typically when you first log in. It does terminal dependent processing such as setting erase and kill characters, setting or resetting delays, sending any sequences needed to properly initialize the terminal, and the like. tset first determines the type of terminal involved, and then does necessary initializations and mode settings. If a port is not wired permanently to a specific terminal (not hardwired) it is given an appropriate generic identifier such as dialup.

reset clears the terminal settings by turning off CBREAK and RAW modes, output delays and parity checking, turns on NEWLINE translation, echo and TAB expansion, and restores undefined special characters to their default state. It then sets the modes as usual, based on the terminal type (which will probably override some of the above). See [stty\(1\)](#) for more information. All arguments to tset may be used with reset. reset also uses rs= and rf= to reset the initialization string and file. This is useful after a program dies and leaves the terminal in a funny state. Often in this situation, characters will not echo as you type them. You may have to type LINEFEED reset LINEFEED since RETURN may not work.

When no arguments are specified, tset reads the terminal type from the TERM environment variable and re-initializes the terminal, and performs initialization of mode, environment and other options at login time to determine the terminal type and set up terminal modes.

When used in a startup script (.profile for [sh\(1\)](#) users or .login for [csh\(1\)](#) users) it is desirable to give information about the type of terminal you will usually use on ports that are not hardwired. Any of the alternate generic names given in the file /etc/termcap are possible identifiers. Refer to the -m option below for more information. If no mapping applies and a final type option, not preceded by a -m, is given on the command line then that type is used.

It is usually desirable to return the terminal type, as finally determined by tset, and information about the terminal's capabilities, to a shell's environment. This can be done using the -, -s, or -S options.

For the Bourne shell, put this command in your .profile file:

```
eval 'tset -s options...'
```

or using the C shell, put these commands in your .login file:

```
set noglob
eval 'tset -s options...'unset noglob
```

With the C shell, it is also convenient to make an alias in your `.cshrc` file:

```
alias ts 'eval `tset -s \!*`'
```

This also allows the command:

```
ts 2621
```

to be invoked at any time to set the terminal and environment. It is not possible to get this aliasing effect with a Bourne shell script, because shell scripts cannot set the environment of their parent. If a process could set its parent's environment, none of this nonsense would be necessary in the first place.

Once the terminal type is known, `tset` sets the terminal driver mode. This normally involves sending an initialization sequence to the terminal, setting the single character erase (and optionally the line-kill (full line erase)) characters, and setting special character delays. TAB and NEWLINE expansion are turned off during transmission of the terminal initialization sequence.

On terminals that can backspace but not overstrike (such as a CRT), and when the erase character is `#`, the erase character is changed as if `-e` had been used.

- Options**
- The name of the terminal finally decided upon is output on the standard output. This is intended to be captured by the shell and placed in the `TERM` environment variable.
  - ec Set the erase character to be the named character *c* on all terminals. Default is the BACKSPACE key on the keyboard, usually `^H` (CTRL-H). The character *c* can either be typed directly, or entered using the circumflex-character notation used here.
  - ic Set the interrupt character to be the named character *c* on all terminals. Default is `^C` (CTRL-C). The character *c* can either be typed directly, or entered using the circumflex-character notation used here.
  - I Suppress transmitting terminal-initialization strings.
  - kc Set the line kill character to be the named character *c* on all terminals. Default is `^U` (CTRL-U). The kill character is left alone if `-k` is not specified. Control characters can be specified by prefixing the alphabetical character with a circumflex (as in CTRL-U) instead of entering the actual control key itself. This allows you to specify control keys that are currently assigned.
  - n Specify that the new tty driver modes should be initialized for this terminal. Probably useless since `stty new` is the default.
  - Q Suppress printing the 'Erase set to' and 'Kill set to' messages.
  - r In addition to other actions, reports the terminal type.
  - s Output commands to set and export `TERM`. This can be used with

```
set noglob
eval 'tset -s ...'
unset noglob
```

to bring the terminal information into the environment. Doing so makes programs such as `vi(1)` start up faster. If the SHELL environment variable ends with `csh`, C shell commands are output, otherwise Bourne shell commands are output.

`-m [port-ID [baudrate] : type] ...` Specify (map) a terminal type when connected to a generic port (such as *dialup* or *plugboard*) identified by *port-ID*. The *baudrate* argument can be used to check the baudrate of the port and set the terminal type accordingly. The target rate is prefixed by any combination of the following operators to specify the conditions under which the mapping is made:

- > Greater than
- @ Equals or “at”
- < Less than
- ! It is not the case that (negates the above operators)
- ? Prompt for the terminal type. If no response is given, then *type* is selected by default.

In the following example, the terminal type is set to `adm3a` if the port is a dialup with a speed of greater than 300 or to `dw2` if the port is a dialup at 300 baud or less. In the third case, the question mark preceding the terminal type indicates that the user is to verify the type desired. A NULL response indicates that the named type is correct. Otherwise, the user's response is taken to be the type desired.

```
tset -m 'dialup>300:adm3a' -m 'dialup:dw2' -m 'plugboard:?adm3a'
```

To prevent interpretation as metacharacters, the entire argument to `-m` should be enclosed in single quotes. When using the C shell, exclamation points should be preceded by a backslash (`\`).

**Examples** These examples all use the `-'` option. A typical use of `tset` in a `.profile` or `.login` will also use the `-e` and `-k` options, and often the `-n` or `-Q` options as well. These options have been omitted here to keep the examples short.

**EXAMPLE 1** Selecting a terminal

To select a 2621, you might put the following sequence of commands in your `.login` file (or `.profile` for Bourne shell users).

```
set noglob
eval 'tset -s 2621'
unset noglob
```

If you want to make the selection based only on the baud rate, you might use the following:

```
set noglob
eval 'tset -s -m '>1200:wy' 2621'
unset noglob
```

**EXAMPLE 2** Selecting terminals according to speed or baud rate

If you have a switch which connects to various ports (making it impractical to identify which port you may be connected to), and use various terminals from time to time, you can select from among those terminals according to the *speed* or baud rate. In the example below, `tset` will prompt you for a terminal type if the baud rate is greater than 1200 (say, 9600 for a terminal connected by an RS-232 line), and use a Wyse® 50 by default. If the baud rate is less than or equal to 1200, it will select a 2621. Note the placement of the question mark, and the quotes to protect the `>` and `?` from interpretation by the shell.

```
set noglob
eval 'tset -s -m 'switch>1200:?wy' -m 'switch<=1200:2621''
unset noglob
```

**EXAMPLE 3** Selecting the terminal used most often

The following entry is appropriate if you always dial up, always at the same baud rate, on many different kinds of terminals, and the terminal you use most often is an `adm3a`.

```
set noglob
eval 'tset -s ?adm3a'
unset noglob
```

**EXAMPLE 4** Selecting a terminal with specific settings

The following example quietly sets the erase character to `BACKSPACE`, and kill to `CTRL-U`. If the port is switched, it selects a Concept™ 100 for speeds less than or equal to 1200, and asks for the terminal type otherwise (the default in this case is a Wyse 50). If the port is a direct dialup, it selects Concept 100 as the terminal type. If logging in over the ARPANET, the terminal type selected is a Datamedia® 2500 terminal or emulator. Note the backslash escaping the `NEWLINE` at the end of the first line in the example.

```
set noglob
eval 'tset -e -k^U -Q -s -m 'switch<=1200:concept100' -m\
'switch:?wy' -m dialup:concept100 -m arpanet:dm2500'
```

EXAMPLE 4 Selecting a terminal with specific settings (Continued)

```
unset noglob
```

**Files** .login

```
.profile
```

```
/etc/termcap
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | compatibility/ucb |

**See Also** [csh\(1\)](#), [sh\(1\)](#), [stty\(1\)](#), [vi\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** The `tset` command is one of the first commands a user must master when getting started on a UNIX system. Unfortunately, it is one of the most complex, largely because of the extra effort the user must go through to get the environment of the login shell set. Something needs to be done to make all this simpler, either the `login` program should do this stuff, or a default shell alias should be made, or a way to set the environment of the parent should exist.

This program cannot intuit personal choices for erase, interrupt and line kill characters, so it leaves these set to the local system standards.

It could well be argued that the shell should be responsible for ensuring that the terminal remains in a sane state; this would eliminate the need for the `reset` program.

**Name** tsort – topological sort

**Synopsis** tsort [*file*]

**Description** The tsort command produces on the standard output a totally ordered list of items consistent with a partial ordering of items mentioned in the input *file*.

The input consists of pairs of items (non-empty strings) separated by blanks. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.

**Operands** The following operand is supported:

*file* A path name of a text file to order. If no *file* operand is given, the standard input is used.

**Examples** EXAMPLE 1 An example of the tsort command

The command:

```
example% tsort <<EOF
a b c c d e
g g
f g e f
EOF
```

produces the output:

```
a
b
c
d
e
f
g
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of tsort: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [lorder\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Diagnostics** Odd data: there are an odd number of fields in the input file.

**Name** `tty` – return user's terminal name

**Synopsis** `/usr/bin/tty [-l] [-s]`

**Description** The `tty` utility writes to the standard output the name of the terminal that is open as standard input. The name that is used is equivalent to the string that would be returned by the [ttyname\(3C\)](#) function.

**Options** The following options are supported:

- l Prints the synchronous line number to which the user's terminal is connected, if it is on an active synchronous line.
- s Inhibits printing of the terminal path name, allowing one to test just the exit status.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `tty`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 Standard input is a terminal.
- 1 Standard input is not a terminal.
- >1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                |
|---------------------|--------------------------------|
| Availability        | system/core-os                 |
| CSI                 | Enabled                        |
| Interface Stability | Committed                      |
| Standard            | <a href="#">standards(5)</a> . |

**See Also** [isatty\(3C\)](#), [ttyname\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Diagnostics** `not on an active synchronous line` The standard input is not a synchronous terminal and `-l` is specified.

`not a tty` The standard input is not a terminal and `-s` is not specified.

**Notes** The `-s` option is useful only if the exit status is wanted. It does not rely on the ability to form a valid path name. Portable applications should use `test -t`.

**Name** type – write a description of command type

**Synopsis** type *name*...

**Description** The type utility indicates how each *name* operand would be interpreted if used as a command. type displays information about each operand identifying the operand as a shell built-in, function, alias, hashed command, or keyword, and where applicable, may display the operand's path name.

There is also a shell built-in version of type that is similar to the type utility.

**Operands** The following operand is supported:

*name*     A name to be interpreted.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of type: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

PATH     Determine the location of *name*.

**Exit Status** The following exit values are returned:

0        Successful completion.

>0      An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [typeset\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** typeset, whence – shell built-in functions to set/get attributes and values for shell variables and functions

**Synopsis** typeset [ -CDHLRZfilrtux [*n*] [*name*[=*value*]]...

whence [ -pv] *name*...

**Description** typeset sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables *name* is created. The variables *value* and type are restored when the function completes. The following list of attributes is supported:

- C Compound variable. Each name is a compound variable. If *value* names a compound variable it is copied to *name*. Otherwise if the variable already exists, it is first to be unset
- D Reserved for future use.
- H Provide UNIX to hostname file mapping on non-UNIX machines.
- L Left justify and remove leading blanks from value. If *n* is non-zero it defines the width of the field. Otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the -Z flag is also set. The -R flag is turned off.
- R Right justify and fill with leading blanks. If *n* is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The -L flag is turned off.
- Z Right justify and fill with leading zeros if the first non-blank character is a digit and the -L flag has not been set. If *n* is non-zero it defines the width of the field. Otherwise, it is determined by the width of the value of first assignment.
- f All uppercase characters are converted to lowercase. The uppercase flag, -u is turned off.  
  
The FPATH variable is searched to find the function definition when the function is referenced. The flag -x allows the function definition to remain in effect across shell procedures invoked by name.
- i Parameter is an integer. This makes arithmetic faster. If *n* is non-zero it defines the output arithmetic base. Otherwise, the first assignment determines the output base.
- l All uppercase characters are converted to lowercase. The uppercase flag, -u is turned off.
- m Move. The value is the name of a variable whose value is moved to name. The original variable is unset. Cannot be used with any other options.

- r The specified names are marked read-only and these names cannot be changed by subsequent assignment.
- t Tags the variables. Tags are user definable and have no special meaning to the shell.
- u All lowercase characters are converted to uppercase characters. The lowercase flag, -l is turned off.
- x The specified names are marked for automatic export to the environment of subsequently-executed commands.

The *i* attribute can not be specified along with -R, -L, -Z, or -f.

Using + rather than - causes these flags to be turned off. If no name arguments are specified but flags are specified, a list of names (and optionally the values) of the variables which have these flags set is printed. Using + rather than - keeps the values from being printed. If no names and flags are specified, the names and attributes of all variables are printed.

For each name, whence indicates how it would be interpreted if used as a command name.

The -v flag produces a more verbose report.

The -p flag does a path search for *name* even if *name* is an alias, a function, or a reserved word.

On this manual page, [ksh\(1\)](#) commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [ksh\(1\)](#), [ksh88\(1\)](#), [set\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#)

**Name** ul – do underlining

**Synopsis** ul [-i] [-t *terminal*] [*filename*]...

**Description** ul reads the named *filenames* (or the standard input if none are given) and translates occurrences of underscores to the sequence which indicates underlining for the terminal in use, as specified by the environment variable TERM. ul uses the /usr/share/lib/terminfo entry to determine the appropriate sequences for underlining. If the terminal is incapable of underlining, but is capable of a standout mode then that is used instead. If the terminal can overstrike, or handles underlining automatically, ul degenerates to [cat\(1\)](#). If the terminal cannot underline, underlining is ignored.

**Options**

- t *terminal*      Override the terminal kind specified in the environment. If the terminal cannot underline, underlining is ignored. If the terminal name is not found, no underlining is attempted.
- i                    Indicate underlining by a separate line containing appropriate dashes ‘-’; this is useful when you want to look at the underlining which is present in an [nroff\(1\)](#) output stream on a CRT-terminal.

**Return Values** ul returns exit code 1 if the file specified is not found.

**Files** /usr/share/lib/terminfo/\*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | text/doctools   |

**See Also** [cat\(1\)](#), [man\(1\)](#), [nroff\(1\)](#), [attributes\(5\)](#)

**Bugs** nroff usually generates a series of backspaces and underlines intermixed with the text to indicate underlining. ul makes attempt to optimize the backward motion.

**Name** umask – get or set the file mode creation mask

**Synopsis** /usr/bin/umask [-S] [*mask*]

sh umask [*ooo*]

csh umask [*ooo*]

ksh88 umask [-S] [*mask*]

ksh umask [-S] [*mask*]

**Description** The umask utility sets the file mode creation mask of the current shell execution environment to the value specified by the *mask* operand. This mask affects the initial value of the file permission bits of subsequently created files. If umask is called in a subshell or separate utility execution environment, such as one of the following:

```
(umask 002)
nohup umask ...
find . -exec umask ...
```

it does not affect the file mode creation mask of the caller's environment. For this reason, the /usr/bin/umask utility cannot be used to change the umask in an ongoing session. Its usefulness is limited to checking the caller's umask. To change the umask of an ongoing session you must use one of the shell builtins.

If the *mask* operand is not specified, the umask utility writes the value of the invoking process's file mode creation mask to standard output.

sh The user file-creation mode mask is set to *ooo*. The three octal digits refer to read/write/execute permissions for owner, group, and other, respectively (see [chmod\(1\)](#), [chmod\(2\)](#), and [umask\(2\)](#)). The value of each specified digit is subtracted from the corresponding "digit" specified by the system for the creation of a file (see [creat\(2\)](#)). For example, umask 022 removes write permission for group and other. Files (and directories) normally created with mode 777 become mode 755. Files (and directories) created with mode 666 become mode 644).

- If *ooo* is omitted, the current value of the mask is printed.
- umask is recognized and executed by the shell.
- umask can be included in the user's .profile (see [profile\(4\)](#)) and invoked at login to automatically set the user's permissions on files or directories created.

csh See the description above for the Bourne shell (sh)umask built-in.

ksh88 The user file-creation mask is set to *mask*. *mask* can either be an octal number or a symbolic value as described in [chmod\(1\)](#). If a symbolic value is given, the new umask value is the complement of the result of applying *mask* to the complement of the previous umask value. If *mask* is omitted, the current value of the mask is printed.

**ksh** `umask` sets the file creation mask of the current shell execution environment to the value specified by the *mask* operand. This mask affects the file permission bits of subsequently created files. *mask* can either be an octal number or a symbolic value as described in `chmod(1)`. If a symbolic value is specified, the new file creation mask is the complement of the result of applying *mask* to the complement of the current file creation mask. If *mask* is not specified, `umask` writes the value of the file creation mask for the current process to standard output.

## Options

**ksh88** The following option is supported for `/usr/bin/umask` and `umask` in `ksh88`:

**-S** Produces symbolic output.

The default output style is unspecified, but will be recognized on a subsequent invocation of `umask` on the same system as a *mask* operand to restore the previous file mode creation mask.

**ksh** The following option is supported in `ksh`:

**-S** Causes the file creation mask to be written or treated as a symbolic value rather than an octal number.

**Operands** The following operand is supported:

***mask*** A string specifying the new file mode creation mask. The string is treated in the same way as the *mode* operand described in the `chmod(1)` manual page.

For a *symbolic\_mode* value, the new value of the file mode creation mask is the logical complement of the file permission bits portion of the file mode specified by the *symbolic\_mode* string.

In a *symbolic\_mode* value, the permissions *op* characters `+` and `-` are interpreted relative to the current file mode creation mask. `+` causes the bits for the indicated permissions to be cleared in the mask. `-` causes the bits of the indicated permissions to be set in the mask.

The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

The file mode creation mask is set to the resulting numeric value.

The default output of a prior invocation of `umask` on the same system with no operand will also be recognized as a *mask* operand. The use of an operand obtained in this way is not obsolescent, even if it is an octal number.

**Output** When the *mask* operand is not specified, the `umask` utility will write a message to standard output that can later be used as a `umask mask` operand.

If `-S` is specified, the message will be in the following format:

```
"u=%s,g=%s,o=%s\n", owner permissions, group permissions, \
other permissions
```

where the three values will be combinations of letters from the set {`r`, `w`, `x`}. The presence of a letter will indicate that the corresponding bit is clear in the file mode creation mask.

If a *mask* operand is specified, there will be no output written to standard output.

### Examples EXAMPLE 1 Using the umask Command

The examples in this section refer to the `/usr/bin/umask` utility and the `ksh88 umask` builtin.

Either of the commands:

```
umask a=rx,ug+w
umask 002
```

sets the mode mask so that subsequently created files have their `S_IWOTH` bit cleared.

After setting the mode mask with either of the above commands, the `umask` command can be used to write the current value of the mode mask:

```
example$ umask
0002
```

The output format is unspecified, but historical implementations use the obsolescent octal integer mode format.

```
example$ umask -S
u=rwx,g=rwx,o=rx
```

Either of these outputs can be used as the *mask* operand to a subsequent invocation of the `umask` utility.

Assuming the mode mask is set as above, the command:

```
umask g-w
```

sets the mode mask so that subsequently created files have their `S_IWGRP` and `S_IWOTH` bits cleared.

The command:

```
umask --w
```

sets the mode mask so that subsequently created files have all their write bits cleared. Notice that *mask* operands `r`, `w`, `x`, or anything beginning with a hyphen (`-`), must be preceded by `-` to keep it from being interpreted as an option.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `umask`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 The file mode creation mask was successfully changed, or no *mask* operand was supplied.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

`/usr/bin/umask`, `csh`,

**See Also** [chmod\(1\)](#), [csh\(1\)](#), [ksh\(1\)](#), [ksh88\(1\)](#), [sh\(1\)](#), [chmod\(2\)](#), [creat\(2\)](#), [umask\(2\)](#), [profile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** `uname` – print name of current system

**Synopsis** `uname [-aimnprsvX]`  
`uname [-S system_name]`

**Description** The `uname` utility prints information about the current system on the standard output. When options are specified, symbols representing one or more system characteristics will be written to the standard output. If no options are specified, `uname` prints the current operating system's name. The options print selected information returned by [uname\(2\)](#), [sysinfo\(2\)](#), or both.

**Options** The following options are supported:

- a  
Prints basic information currently available from the system.
- i  
Prints the name of the platform. For machines of the sun4v architecture, the `-i` option returns: sun4v. Use [prtconf\(1M\)](#) with the `-b` option to obtain the platform name for a sun4v machine.
- m  
Prints the machine hardware name (class). Use of this option is discouraged. Use `uname -p` instead. See NOTES section below.
- n  
Prints the nodename (the nodename is the name by which the system is known to a communications network).
- p  
Prints the current host's ISA or processor type.
- r  
Prints the operating system release level.
- s  
Prints the name of the operating system. This is the default.
- S *system\_name*  
The nodename may be changed by specifying a system name argument. The system name argument is restricted to `SYS_NMLN` characters. `SYS_NMLN` is an implementation specific value defined in `<sys/utsname.h>`. Only the super-user is allowed this capability. This change does not persist across reboots of the system.
- v  
Prints the operating system version.
- X  
Prints expanded system information, one information element per line, as expected by SCO UNIX. The displayed information includes:
  - system name, node, release, version, machine, and number of CPUs.

- BusType, Serial, and Users (set to unknown in Solaris)
- OEM# and Origin# (set to 0 and 1, respectively)

**Examples** EXAMPLE 1 Printing the OS Name and Release Level

The following command prints the operating system name and release level, separated by one SPACE character:

```
example% uname -sr
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `uname`: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

0  
Successful completion.

>0  
An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE                     |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [arch\(1\)](#), [isalist\(1\)](#), [prtconf\(1M\)](#), [sysinfo\(2\)](#), [uname\(2\)](#), [nodename\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes** Independent software vendors (ISVs) and others who need to determine detailed characteristics of the platform on which their software is either being installed or executed should use the `uname` command.

To determine the operating system name and release level, use `uname -sr`. To determine only the operating system release level, use `uname -r`. Notice that operating system release levels are not guaranteed to be in *x.y* format (such as 5.3, 5.4, 5.5, and so forth); future releases could be in the *x.y.z* format (such as 5.3.1, 5.3.2, 5.4.1, and so forth).

In SunOS 4.x releases, the [arch\(1\)](#) command was often used to obtain information similar to that obtained by using the `uname` command. The [arch\(1\)](#) command output `sun4` was often incorrectly interpreted to signify a SunOS SPARC system. If hardware platform information is desired, use `uname -sp`.

The `arch -k` and `uname -m` commands return equivalent values; however, the use of either of these commands by third party programs is discouraged, as is the use of the `arch` command in general. To determine the machine's Instruction Set Architecture (ISA or processor type), use `uname` with the `-p` option.

**Name** unifdef – resolve and remove `ifdef`ed lines from C program source

**Synopsis** `unifdef [-c] [-Dname] [-Uname] [-iDname] [-iUname] ...`  
`[filename]`

**Description** `unifdef` removes `ifdef`ed lines from a file while otherwise leaving the file alone. It is smart enough to deal with the nested `ifdef`s, comments, single and double quotes of C syntax, but it does not do any including or interpretation of macros. Neither does it strip out comments, though it recognizes and ignores them. You specify which symbols you want defined with `-D` options, and which you want undefined with `-U` options. Lines within those `ifdef`s will be copied to the output, or removed, as appropriate. Any `ifdef`, `ifndef`, `else`, and `endif` lines associated with *filename* will also be removed.

`ifdef`s involving symbols you do not specify are untouched and copied out along with their associated `ifdef`, `else`, and `endif` lines.

If an `ifdefX` occurs nested inside another `ifdefX`, then the inside `ifdef` is treated as if it were an unrecognized symbol. If the same symbol appears in more than one argument, only the first occurrence is significant.

`unifdef` copies its output to the standard output and will take its input from the standard input if no *filename* argument is given.

**Options** The following options are supported:

- `-c` Complement the normal operation. Lines that would have been removed or blanked are retained, and vice versa.
- `-l` Replace “lines removed” lines with blank lines.
- `-t` Plain text option. `unifdef` refrains from attempting to recognize comments and single and double quotes.
- `-Dname` Lines associated with the defined symbol *name*.
- `-Uname` Lines associated with the undefined symbol *name*.
- `-iDname` Ignore, but print out, lines associated with the defined symbol *name*. If you use `ifdef`s to delimit non-C lines, such as comments or code which is under construction, then you must tell `unifdef` which symbols are used for that purpose so that it will not try to parse for quotes and comments within them.
- `-iUname` Ignore, but print out, lines associated with the undefined symbol *name*.

**Exit Status** The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                    |
|----------------|------------------------------------|
| Availability   | developer/base-developer-utilities |

**See Also** [diff\(1\)](#), [attributes\(5\)](#)

**Diagnostics** Premature EOF    Inappropriate else or endif.

**Name** `uniq` – report or filter out repeated lines in a file

**Synopsis** `/usr/bin/uniq [-c | -d | -u ] [ -f fields ] [-s char ]  
           [input_file [output_file]]`  
`/usr/bin/uniq [-c | -d | -u ] [-n ] [ +m ]  
           [input_file [output_file]]`

**Description** `uniq` reads an input, comparing adjacent lines, and writing one copy of each input line on the output. The second and succeeding copies of the repeated adjacent lines are not written.

If the output file, *output\_file*, is not specified, `uniq` writes to standard output. If no *input\_file* is given, or if the *input\_file* is `-`, `uniq` reads from standard input with the start of the file is defined as the current offset.

**Options** The following options are supported:

- c Precedes each output line with a count of the number of times the line occurred in the input.
- d Suppresses the writing of lines that are not repeated in the input.
- f Ignores the first *fields* *fields* on each input line when doing comparisons, where *fields* is a positive decimal integer. A *field* is the maximal string matched by the basic regular expression:  
`[[:blank:]]*^[[:blank:]]*`  
 If *fields* specifies more *fields* than appear on an input line, a null string are used for comparison.
- s Ignores the first *chars* characters when doing comparisons, where *chars* is a positive decimal integer. If specified in conjunction with the `-f` option, the first *chars* characters after the first *fields* *fields* are ignored. If *chars* specifies more characters than remain on an input line, a null string are used for comparison.
- u Suppresses the writing of lines that are repeated in the input.
- n Equivalent to `-f fields` with *fields* set to *n*.
- +*m* Equivalent to `-s chars` with *chars* set to *m*.

**Operands** The following operands are supported:

- input\_file* A path name of the input file. If *input\_file* is not specified, or if the *input\_file* is `-`, the standard input is used.
- output\_file* A path name of the output file. If *output\_file* is not specified, the standard output is used. The results are unspecified if the file named by *output\_file* is the file named by *input\_file*.

**Examples** EXAMPLE 1 Using the `uniq` Command

The following example lists the contents of the `uniq.test` file and outputs a copy of the repeated lines.

```
example% cat uniq.test
This is a test.
This is a test.
TEST.
Computer.
TEST.
TEST.
Software.
```

```
example% uniq -d uniq.test
This is a test.
TEST.
example%
```

The next example outputs just those lines that are not repeated in the `uniq.test` file.

```
example% uniq -u uniq.test
TEST.
Computer.
Software.
example%
```

The last example outputs a report with each line preceded by a count of the number of times each line occurred in the file:

```
example% uniq -c uniq.test
 2 This is a test.
 1 TEST.
 1 Computer.
 2 TEST.
 1 Software.
example%
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `uniq`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| CSI                 | Enabled                            |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [comm\(1\)](#), [pack\(1\)](#), [pcat\(1\)](#), [sort\(1\)](#), [uncompress\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** units – converts quantities expressed in standard scales to other scales

**Synopsis** units

**Description** units converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:

```
You have:~~inch
You want:~~cm
 * 2.540000e+00
/ 3.937008e-01
```

A quantity is specified as a multiplicative combination of units optionally preceded by a numeric multiplier. Powers are indicated by suffixed positive integers, division by the usual sign:

```
You have:~~15 lbs force/in2
You want:~~atm
 * 1.020689e+00
 / 9.797299e-01
```

units only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Celsius to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, together with a generous leavening of exotica and a few constants of nature including:

pi        ratio of circumference to diameter,  
c        speed of light,  
e        charge on an electron,  
g        acceleration of gravity,  
force    same as g,  
mole     Avogadro's number,  
water    pressure head per unit height of water,  
au       astronomical unit.

Pound is not recognized as a unit of mass; lb is. Compound names are run together, (for example, lightyear). British units that differ from their U.S. counterparts are prefixed thus: brgallon. For a complete list of units, type:

```
cat /usr/share/lib/unittab
```

**Files** /usr/share/lib/unittab

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTE VALUE |
|---------------|-----------------|
| Availability  | system/core-os  |

**See Also** [attributes\(5\)](#)

**Name** unix2dos – convert text file from ISO format to DOS format

**Synopsis** `unix2dos [-ascii] [-iso] [-7]  
[-437 | -850 | -860 | -863 | -865] originalfile convertedfile`

**Description** The `unix2dos` utility converts ISO standard characters to the corresponding characters in the DOS extended character set.

This command may be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.

If the original file and the converted file are the same, `unix2dos` will rewrite the original file after converting it.

**Options** The following options are supported:

- `-ascii` Adds carriage returns and converts end of file characters in SunOS format text files to conform to DOS requirements.
- `-iso` This is the default. Converts ISO standard characters to the corresponding character in the DOS extended character set.
- `-7` Converts 8 bit SunOS characters to 7 bit DOS characters.

On non-i386 systems, `unix2dos` will attempt to obtain the keyboard type to determine which code page to use. Otherwise, the default is US. The user may override the code page with one of the following options:

- `-437` Use US code page
- `-850` Use multilingual code page
- `-860` Use Portuguese code page
- `-863` Use French Canadian code page
- `-865` Use Danish code page

**Operands** The following operands are required:

- originalfile* The original file in ISO format that is being converted to DOS format.
- convertedfile* The new file in DOS format that has been converted from the original ISO file format.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [dos2unix\(1\)](#), [ls\(1\)](#), [attributes\(5\)](#)

**Diagnostics** File *filename* not found, or no read permission

The input file you specified does not exist, or you do not have read permission. Check with the SunOS command, `ls -l` (see [ls\(1\)](#)).

Bad output filename *filename*, or no write permission

The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive is not write-protected.

Error while writing to temporary file

An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the `DIR` command. Also be certain that the default drive is write-enabled (not write-protected). When this error occurs, the original file remains intact.

Translated tmpfile name = *filename*.

Could not rename tmpfile to *filename*.

The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this message.

**Name** updatehome – update the home directory copy and link files for the current label

**Synopsis** /usr/bin/updatehome [-cirs]

**Description** updatehome reads the user's minimum-label copy and link-control files (`.copy_files` and `.link_files`). These files contain a list of files to be copied and symbolically linked from the user's minimum-label home directory to the user's home directory at the current label.

By default, the minimum user label is specified in `label_encodings(4)`, and can be explicitly specified in `user_attr(4)`. When created using `txzonemgr(1M)`, the public zone is assigned the default minimum label, and is configured as a multilevel NFS server. An authorized administrator in the public zone can use the `share(1M)` command to export home directories, so that they can be mounted in read-only mode by higher-level zones. Additional zones created by means of `txzonemgr(1M)` are configured with an `automount(1M)` entry that mounts the public zone's home directories at `/zone/public/home`.

If the user's minimum home directory has been shared in this fashion, a user can run the `updatehome` command in higher-level zones, either manually or by executing it in a startup file. For example, the user probably wants a symbolic link to such files as `.profile`, `.login`, `.cshrc`, `.exrc`, `.mailrc`, and `~/bin`. The `updatehome` command provides a convenient mechanism for accomplishing this symlink. The user can add files to those to be copied (`.copy_files`) and to those to be symbolically linked (`.link_files`).

**Options**

- c Replace existing home-directory copies at the current label. The default is to skip over existing copies.
- i Ignore errors encountered. The default aborts on error.
- r Replace existing home-directory copies or symbolic links at the current label. This option implies options -c and -s. The default is to skip over existing copies or symbolic links.
- s Replace existing home-directory symbolic links at the current label. The default is to skip over existing symbolic links.

**Exit Status** Upon success, `updatehome` returns 0. Upon failure, `updatehome` returns 1 and writes diagnostic messages to standard error.

**Examples** EXAMPLE 1 A Sample `.copy_files` File

The files that are listed in `.copy_files` can be modified at every user's label.

```
.cshrc
.mailrc
.mozilla/bookmarks.html
```

EXAMPLE 2 A Sample `.link_files` File

The files that are listed in `.link_files` can be modified at the lowest label. The changes propagate to the other labels that are available to the user.

**EXAMPLE 2** A Sample `.link_files` File (Continued)

```
~/bin
.mozilla/preferences
.xrc
.rhosts
```

**EXAMPLE 3** Updating the Linked and Copied Files

The `.copy_files` and `.link_files` were updated by the user at the minimum label. At a higher label, the user refreshes the copies and the links. No privileges are required to run the command.

```
% updatehome -r
```

**Files** `$HOME/.copy_files` List of files to be copied  
`$HOME/.link_files` List of files to be symbolically linked

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | system/trusted |
| Interface Stability | Committed      |

**See Also** [automount\(1M\)](#), [share\(1M\)](#), [txzonemgr\(1M\)](#), [label\\_encodings\(4\)](#), [user\\_attr\(4\)](#), [attributes\(5\)](#)

“`.copy_files` and `.link_files` Files” in *Trusted Extensions Configuration and Administration*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

**Name** uptime – show how long the system has been up

**Synopsis** uptime

**Description** The uptime command prints the current time, the length of time the system has been up, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. It is, essentially, the first line of a [w\(1\)](#) command.

**Examples** Below is an example of the output uptime provides:

```
example% uptime
10:47am up 27 day(s), 50 mins, 1 user, load average: 0.18, 0.26, 0.20
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [w\(1\)](#), [who\(1\)](#), [whodo\(1M\)](#), [attributes\(5\)](#)

**Notes** who -b gives the time the system was last booted.

**Name** userattr – print attribute value granted to a user or role

**Synopsis** userattr [-v] *attribute\_name* [*user*]

**Description** The `userattr` command prints on standard output the first value found for the attribute `attribute_name`. If `user` is not specified, the user is taken from the real user ID of the process. Attribute names are those found defined in [user\\_attr\(4\)](#) and [prof\\_attr\(4\)](#). Use the [profiles\(1\)](#) command for the profiles assigned to a user. Use the [auths\(1\)](#) command for the authorizations assigned to a user. The order of search is the user's `user_attr` entry followed by the user's profiles.

If the attribute, *attribute\_name*, is not assigned to the user, and for any errors, `userattr` returns a non-zero exit code. Otherwise, `userattr` returns a zero exit code.

The `-v` option additionally prints where the attribute was found.

**Examples** EXAMPLE 1 Using `userattr`

```
example% userattr lock_after_retries root
no
```

**Files** /etc/user\_attr

/etc/security/policy.conf

/etc/security/prof\_attr

**Exit Status** The following exit values are returned:

0 Successful completion.

1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | See below.      |

The exit code is Committed. The output for the `-v` option is Not-an-Interface.

**See Also** [auths\(1\)](#), [profiles\(1\)](#), [policy.conf\(4\)](#), [prof\\_attr\(4\)](#), [user\\_attr\(4\)](#), [attributes\(5\)](#)

**Name** users – display a compact list of users logged in

**Synopsis** /usr/ucb/users [*filename*]

**Description** The users utility lists the login names of the users currently on the system in a compact, one-line format.

Specifying *filename* tells users where to find its information; by default it checks /var/adm/utmpx.

Typing users is equivalent to typing who -q.

**Examples** EXAMPLE 1 Listing current users

```
example% users
paul george ringoexample%
```

**Files** /var/adm/utmpx

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | compatibility/ucb |

**See Also** [who\(1\)](#), [attributes\(5\)](#)

**Name** uucp, uulog, uuname – UNIX-to-UNIX system copy

**Synopsis** uucp [-c | -C] [-d | -f] [-ggrade] [-jmr] [-nuser] [-sfile]  
 [-xdebug\_level] source-file destination-file

uulog [-ssys] [-fsystem] [-x] [-number] system

uuname [-c | -l]

## Description

**uucp** The uucp utility copies files named by the *source-file* arguments to the *destination-file* argument.

**uulog** The uulog utility queries a log file of uucp or uuxqt transactions in file */var/uucp/.Log/uucico/system* or */var/uucp/.Log/uuxqt/system*.

**uuname** The uuname utility lists the names of systems known to uucp.

## Options

**uucp** The following options are supported by uucp:

- c Does not copy local file to the spool directory for transfer to the remote machine (default).
- C Forces the copy of local files to the spool directory for transfer.
- d Makes all necessary directories for the file copy (default).
- f Does not make intermediate directories for the file copy.
- g *grade* *grade* can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The `uuglist` command can determine whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the `uuglist` command is a list of service grades that are available, or a message that says to use a single letter or number as a grade of service.
- j Prints the uucp job identification string on standard output. This job identification can be used by `uustat` to obtain the status of a uucp job or to terminate a uucp job. The uucp job is valid as long as the job remains queued on the local system.
- m Sends mail to the requester when the copy is complete.
- n *user* Notifies *user* on the remote system that a file was sent.  
 When multiple -n options are passed in, uucp only retains the value specified for the last -n option. This is the only user notified.
- r Does not start the file transfer, just queue the job.

- s *file* Reports status of the transfer to *file*. This option is accepted for compatibility, but it is ignored because it is insecure.
- x *debug\_level* Produce debugging output on standard output. *debug\_level* is a number between 0 and 9. As *debug\_level* increases to 9, more detailed debugging information is given. This option may not be available on all systems.

uulog The following options cause uulog to print logging information:

- s *sys* Prints information about file transfer work involving system *sys*.
- f *system* Executes a `tail -f` command of the file transfer log for *system*. You must press BREAK to exit this function.

Other options used in conjunction with the above options are:

- x Looks in the uuxqt log file for the given system.
- number* Executes a `tail` command of *number* lines.

uuname The following options are supported by uuname:

- c Displays the names of systems known to cu. The two lists are the same, unless your machine is using different `Systems` files for cu and uucp. See the `Sysfiles` file.
- l Displays the local system name.

**Operands** The source file name may be a path name on your machine, or may have the form:

*system-name!pathname*

where *system-name* is taken from a list of system names that uucp knows about. *source\_file* is restricted to no more than one *system-name*. The destination *system-name* may also include a list of system names such as

*system-name!system-name!...!system-name!pathname*

In this case, an attempt is made to send the file, using the specified route, to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information. See NOTES for restrictions.

For C-Shell users, the exclamation point (!) character must be surrounded by single quotes ('), or preceded by a backslash (\).

The shell metacharacters ?, \* and [...] appearing in *pathname* are expanded on the appropriate system.

Pathnames may be one of the following:

1. An absolute pathname.

2. A pathname preceded by *~user* where *user* is a login name on the specified system and is replaced by that user's login directory.
3. A pathname preceded by *~/destination* where *destination* is appended to `/var/spool/uucppublic`. This destination is treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that the destination is a directory, follow it with a forward slash (/). For example, `~/dan/` as the destination creates the directory `/var/spool/uucppublic/dan` if it does not exist and put the requested file(s) in that directory.

Anything else is prefixed by the current directory.

If the result is an erroneous path name for the remote system, the copy fails. If the *destination-file* is a directory, the last part of the *source-file* name is used.

Invoking `uucp` with shell wildcard characters as the remote *source-file* invokes the `uux(1C)` command to execute the `uucp` command on the remote machine. The remote `uucp` command spools the files on the remote machine. After the first session terminates, if the remote machine is configured to transfer the spooled files to the local machine, the remote machine initiates a call and send the files; otherwise, the user must "call" the remote machine to transfer the files from the spool directory to the local machine. This call can be done manually using `Uutry(1M)`, or as a side effect of another `uux(1C)` or `uucp` call.

Notice that the local machine must have permission to execute the `uucp` command on the remote machine in order for the remote machine to send the spooled files.

`uucp` removes execute permissions across the transmission and gives `0666` read and write permissions (see `chmod(2)`).

**Environment Variables** See `environ(5)` for descriptions of the following environment variables that affect the execution of `uucp`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `NLSPATH`, and `TZ`.

**Exit Status** The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

|              |                                      |                                            |
|--------------|--------------------------------------|--------------------------------------------|
| <b>Files</b> | <code>/etc/uucp/*</code>             | other data files                           |
|              | <code>/var/spool/uucp</code>         | spool directories                          |
|              | <code>/usr/lib/uucp/*</code>         | other program files                        |
|              | <code>/var/spool/uucppublic/*</code> | public directory for receiving and sending |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | service/network/uucp               |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [mail\(1\)](#), [uuglist\(1C\)](#), [uustat\(1C\)](#), [uux\(1C\)](#), [Uutry\(1M\)](#), [uuxqt\(1M\)](#), [chmod\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes** For security reasons, the domain of remotely accessible files may be severely restricted. You probably are not able to access files by path name. Ask a responsible person on the remote system to send them to you. For the same reasons you are probably not able to send files to arbitrary path names. As distributed, the remotely accessible files are those whose names begin `/var/spool/uucppublic` (equivalent to `~/`).

All files received by uucp are owned by uucp.

The `-m` option only works when sending files or receiving a single file. Receiving multiple files specified by special shell characters `?`, `&`, and `[ . . . ]` does not activate the `-m` option.

The forwarding of files through other systems may not be compatible with the previous version of uucp. If forwarding is used, all systems in the route must have compatible versions of uucp.

Protected files and files that are in protected directories that are owned by the requester can be sent by uucp. However, if the requester is root, and the directory is not searchable by "other" or the file is not readable by "other", the request fails.

Strings that are passed to remote systems may not be evaluated in the same locale as the one in use by the process that invoked uucp on the local system.

Configuration files must be treated as C (or POSIX) locale text files.

**Name** uuencode, uudecode – encode a binary file, or decode its encoded representation

**Synopsis** uuencode [*source-file*] *decode\_pathname*  
 uuencode [-m] [*source-file*] *decode\_pathname*  
 uudecode [-p] [*encoded-file*]  
 uudecode [-o *outfile*] [*encoded-file*]

**Description** These commands encode and decode files as follows:

**uuencode** The uuencode utility converts a binary file into an encoded representation that can be sent using [mail\(1\)](#). It encodes the contents of *source-file*, or the standard input if no *source-file* argument is given. The *decode\_pathname* argument is required. The *decode\_pathname* is included in the encoded file's header as the name of the file into which uudecode is to place the binary (decoded) data. uuencode also includes the permission modes of *source-file* (except `setuid`, `setgid`, and sticky-bits), so that *decode\_pathname* is recreated with those same permission modes.

**uudecode** The uudecode utility reads an *encoded-file*, strips off any leading and trailing lines added by mailer programs, and recreates the original binary data with the filename and the mode specified in the header.

The encoded file is an ordinary portable character set text file; it can be edited by any text editor. It is best only to change the mode or *decode\_pathname* in the header to avoid corrupting the decoded binary.

**Options** The following options are supported:

**uuencode** -m Encodes *source-file* using Base64 encoding and sends it to standard output.

**uudecode** -o *outfile* Specifies a file pathname that should be used instead of any pathname contained in the input data. Specifying an *outfile* option-argument of `/dev/stdout` indicates standard output. This allows uudecode to be used in a pipeline.

-p Decodes *encoded-file* and sends it to standard output. This allows uudecode to be used in a pipeline.

**Operands** The following operands are supported by uuencode and uudecode:

**uuencode** *decode\_pathname* The pathname of the file into which the uudecode utility will place the decoded file. If there are characters in *decode\_pathname* that are not in the portable filename character set, the results are unspecified.

*source-file* A pathname of the file to be encoded.

**uudecode** *encoded-file* The pathname of a file containing the output of uuencode.

**Usage** See [largefile\(5\)](#) for the description of the behavior of uuencode and uudecode when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of uuencode and uudecode: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Output** stdout

uuencode Base64 Algorithm The standard output is a text file, encoded in the character set of the current locale, that begins with the line:

```
begin-base64 %s %s\n, mode, decode_pathname
```

and ends with the line:

```
====\n
```

In both cases, the lines have no preceding or trailing blank characters.

The encoding process represents 24-bit groups of input bits as output strings of four encoded characters. Proceeding from left to right, a 24-bit input group is formed by concatenating three 8-bit input groups. Each 24-bit input group is then treated as four concatenated 6-bit groups, each of which is translated into a single digit in the Base64 alphabet. When encoding a bit stream by means of the Base64 encoding, the bit stream is presumed to be ordered with the most-significant bit first. That is, the first bit in the stream is the high-order bit in the first byte, and the eighth bit is the low-order bit in the first byte, and so on. Each 6-bit group is used as an index into an array of 64 printable characters, as shown in the following table.

| Value | Encoding | Value | Encoding | Value | Encoding | Value | Encoding |
|-------|----------|-------|----------|-------|----------|-------|----------|
| 0     | A        | 17    | R        | 34    | i        | 51    | z        |
| 1     | B        | 18    | S        | 35    | j        | 52    | 0        |
| 2     | C        | 19    | T        | 36    | k        | 53    | 1        |
| 3     | D        | 20    | U        | 37    | l        | 54    | 2        |
| 4     | E        | 21    | V        | 38    | m        | 55    | 3        |
| 5     | F        | 22    | W        | 39    | n        | 56    | 4        |
| 6     | G        | 23    | X        | 40    | o        | 57    | 5        |
| 7     | H        | 24    | Y        | 41    | p        | 58    | 6        |
| 8     | I        | 25    | Z        | 42    | q        | 59    | 7        |
| 9     | J        | 26    | a        | 43    | r        | 60    | 8        |
| 10    | K        | 27    | b        | 44    | s        | 61    | 9        |
| 11    | L        | 28    | c        | 45    | t        | 62    | +        |
| 12    | M        | 29    | d        | 46    | u        | 63    | /        |
| 13    | N        | 30    | e        | 47    | v        |       |          |
| 14    | O        | 31    | f        | 48    | w        | (pad) | =        |
| 15    | P        | 32    | g        | 49    | x        |       |          |
| 16    | Q        | 33    | h        | 50    | y        |       |          |

The character referenced by the index is placed in the output string.

The output stream (encoded bytes) is represented in lines of no more than 76 characters each. All line breaks or other characters not found in the table are ignored by decoding software (see `uudecode`).

Special processing is performed if fewer than 24 bits are available at the end of a message or encapsulated part of a message. A full encoding quantum is always completed at the end of a message. When fewer than 24 input bits are available in an input group, zero bits are added on the right to form an integral number of 6-bit groups. Output character positions that are not required to represent actual input data are set to the equals (=) character. Since all Base64 input is an integral number of octets, only the following cases can arise:

1. The final quantum of encoding input is an integral multiple of 24 bits. Here, the final unit of encoded output is an integral multiple of four characters with no '=' padding.
2. The final quantum of encoding input is exactly 16 bits. Here, the final unit of encoded output is three characters followed by one '=' padding character.
3. The final quantum of encoding input is exactly 8 bits. Here, the final unit of encoded output is two characters followed by two '=' padding characters.

A terminating "====" evaluates to nothing and denotes the end of the encoded data.

#### uuencode Historical Algorithm

The standard output is a text file (encoded in the character set of the current locale) that begins with the line:

```
begin %s %s\n, mode, decode_pathname
```

and ends with the line:

```
end\n
```

In both cases, the lines have no preceding or trailing blank characters.

The algorithm that is used for lines between `begin` and `end` takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets are converted to characters by adding a value of `0x20` to each octet, so that each octet is in the range `0x20–0x5f`, and each octet is assumed to represent a printable character. Each octet is then translated into the corresponding character codes for the codeset in use in the current locale. For example, the octet `0x41`, representing 'A', would be translated to 'A' in the current codeset, such as `0xc1` if the codeset were EBCDIC.

Where the bits of two octets are combined, the least significant bits of the first octet are shifted left and combined with the most significant bits of the second octet shifted right. Thus, the three octets A, B, C are converted into the four octets:

$$0x20 + ((A \gg 2) \ll 4) \& 0x3F)$$

$$0x20 + (((A \ll 4) \& 0xF) \ll 2) \& 0x3F)$$

$$0x20 + (((B \ll 2) \& 0x3) \ll 6) \& 0x3F)$$

$0x20 + ((C \quad ) \& 0x3F)$

These octets are then translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded plus  $0x20$  translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line is 45.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | system/core-os                     |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [mail\(1\)](#), [mailx\(1\)](#), [uucp\(1C\)](#), [uux\(1C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** The size of the encoded file is expanded by 35% (3 bytes become 4, plus control information), causing it to take longer to transmit than the equivalent binary.

The user on the remote system who is invoking `uudecode` (typically `uucp`) must have write permission on the file specified in the *decode\_pathname*.

If you invoke `uuencode` and then execute `uudecode` on a file in the same directory, you will overwrite the original file.

**Name** uuglist – print the list of service grades that are available on this UNIX system

**Synopsis** uuglist [-u]

**Description** uuglist prints the list of service grades that are available on the system to use with the -g option of [uucp\(1C\)](#) and [uux\(1C\)](#).

**Options** -u List the names of the service grades that the user is allowed to use with the -g option of the uucp and uux commands.

**Files** /etc/uucp/Grades contains the list of service grades

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE      |
|----------------|----------------------|
| Availability   | service/network/uucp |

**See Also** [uucp\(1C\)](#), [uux\(1C\)](#), [attributes\(5\)](#)

**Name** uustat – uucp status inquiry and job control

**Synopsis** uustat  
 [ [-m] | [-p] | [-q] | [-k *jobid* [-n]] | [-r *jobid* [-n]] ]  
 uustat [-a] [-s *system* [-j]] [-u *user*] [-S *qric*]  
 uustat -t *system* [-c] [-d *number*]

**Description** The uustat utility functions in the following three areas:

1. Displays the general status of, or cancels, previously specified uucp commands.
2. Provides remote system performance information, in terms of average transfer rates or average queue times.
3. Provides general remote system-specific and user-specific status of uucp connections to other systems.

**Options** The following options are supported:

**General Status** These options obtain general status of, or cancel, previously specified uucp commands:

- a Lists all jobs in queue.
- j Lists the total number of jobs displayed. The -j option can be used in conjunction with the -a or the -s option.
- k*jobid* Kills the uucp request whose job identification is *jobid*. The killed uucp request must belong to the user issuing the uustat command unless the user is the super-user or uucp administrator. If the job is killed by the super-user or uucp administrator, electronic mail is sent to the user.
- m Reports the status of accessibility of all machines.
- n Suppresses all standard output, but not standard error. The -n option is used in conjunction with the -k and -r options.
- p Executes the command `ps -flp` for all the process-ids that are in the lock files.
- q Lists the jobs queued for each machine. If a status file exists for the machine, its date, time and status information are reported. In addition, if a number appears in parentheses next to the number of C or X files, it is the age in days of the oldest C./X. file for that system. The Retry field represents the number of hours until the next possible call. The Count is the number of failure attempts. *Note:* For systems with a moderate number of outstanding jobs, this could take 30 seconds or more of real-time to execute. An example of the output produced by the -q option is:

```
eagle 3C 04/07-11:07 NO DEVICES AVAILABLE
mh3bs3 2C 07/07-10:42 SUCCESSFUL
```

This indicates the number of command files that are waiting for each system. Each command file may have zero or more files to be sent (zero means to call the system

and see if work is to be done). The date and time refer to the previous interaction with the system followed by the status of the interaction.

**-rjobid** Rejuvenates *jobid*. The files associated with *jobid* are touched so that their modification time is set to the current time. This prevents the cleanup daemon from deleting the job until the jobs' modification time reaches the limit imposed by the daemon.

**Remote System Status** These options provide remote system performance information, in terms of average transfer rates or average queue times. The **-c** and **-d** options can only be used in conjunction with the **-t** option:

**-t<sub>system</sub>** Reports the average transfer rate or average queue time for the past 60 minutes for the remote *system*. The following parameters can only be used with this option:

**-c** Average queue time is calculated when the **-c** parameter is specified and average transfer rate when **-c** is not specified. For example, the command:

```
example% uustat -teagle -d50 -c
```

produces output in the following format:

```
average queue time to eagle for last 50 minutes:
 5 seconds
```

The same command without the **-c** parameter produces output in the following format:

```
average transfer rate with eagle for last 50 minutes:
 2000.88 bytes/sec
```

**-d<sub>number</sub>** *number* is specified in minutes. Used to override the 60 minute default used for calculations. These calculations are based on information contained in the optional performance log and therefore may not be available. Calculations can only be made from the time that the performance log was last cleaned up.

**User- or System-Specific Status** These options provide general remote system-specific and user-specific status of uucp connections to other systems. Either or both of the following options can be specified with `uustat`. The **-j** option can be used in conjunction with the **-s** option to list the total number of jobs displayed:

**-ssystem** Reports the status of all uucp requests for remote system *system*.

**-uuser** Reports the status of all uucp requests issued by *user*.

Output for both the **-s** and **-u** options has the following format:

```
eagleN1bd7 4/07-11:07 S eagle dan 522 /home/dan/A
eagleC1bd8 4/07-11:07 S eagle dan 59 D.3b2a12ce4924
4/07-11:07 S eagle dan rmail mike
```

With the above two options, the first field is the *jobid* of the job. This is followed by the date/time. The next field is an S if the job is sending a file or an R if the job is requesting a file. The next field is the machine where the file is to be transferred. This is followed by the user-id of the user who queued the job. The next field contains the size of the file, or in the case of a remote execution (`rmail` is the command used for remote mail), the name of the command. When the size appears in this field, the file name is also given. This can either be the name given by the user or an internal name (for example, `D.3b2a1ce4924`) that is created for data files associated with remote executions (`rmail` in this example).

`-Sqric` Reports the job state:

- q for queued jobs
- r for running jobs
- i for interrupted jobs
- c for completed jobs

A job is queued if the transfer has not started. A job is running when the transfer has begun. A job is interrupted if the transfer began but was terminated before the file was completely transferred. A completed job is a job that successfully transferred. The completed state information is maintained in the accounting log, which is optional and therefore may be unavailable. The parameters can be used in any combination, but at least one parameter must be specified. The `-S` option can also be used with `-s` and `-u` options. The output for this option is exactly like the output for `-s` and `-u` except that the job states are appended as the last output word. Output for a completed job has the following format:

```
eagleC1bd3 completed
```

When no options are given, `uustat` writes to standard output the status of all `uucp` requests issued by the current user.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `uustat`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `NLSPATH`, and `TZ`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Files**

|                                        |                   |
|----------------------------------------|-------------------|
| <code>/var/spool/uucp/*</code>         | spool directories |
| <code>/var/uucp/.Admin/account</code>  | accounting log    |
| <code>/var/uucp/.Admin/perfllog</code> | performance log   |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | service/network/uucp               |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [uucp\(1C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Diagnostics** The -t option produces no message when the data needed for the calculations is not being recorded.

**Notes** After the user has issued the uucp request, if the file to be transferred is moved, deleted or was not copied to the spool directory (-C option) when the uucp request was made, uustat reports a file size of -99999. This job will eventually fail because the file(s) to be transferred can not be found.

**Name** uuto, uupick – public UNIX-to-UNIX system file copy

**Synopsis** uuto [-mp] *source-file*... *destination*

uupick [-s *system*]

## Description

**uuto** uuto sends *source-file* to *destination*. uuto uses the **uucp(1C)** facility to send files, while it allows the local system to control the file access. A source-file name is a path name on your machine. Destination has the form:

*system*[!*system*]...!*user*

where *system* is taken from a list of system names that uucp knows about. *User* is the login name of someone on the specified system.

The files (or sub-trees if directories are specified) are sent to PUBDIR on *system*, where PUBDIR is a public directory defined in the uucp source. By default, this directory is `/var/spool/uucppublic`. Specifically the files are sent to

`PUBDIR/receive/user/mysystem/files`.

The recipient is notified by **mail(1)** of the arrival of files.

**uupick** uupick accepts or rejects the files transmitted to the user. Specifically, uupick searches PUBDIR for files destined for the user. For each entry (file or directory) found, the following message is printed on standard output:

from *system sysname*: [file *file-name*] [dir *dirname*] ?

uupick then reads a line from standard input to determine the disposition of the file:

<new-line>           Go to next entry.

d                     Delete the entry.

m [*dir*]             Move the entry to named directory *dir*. If *dir* is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.

a [*dir*]             Same as m above, except it moves all the files sent from *system*.

p                     Print the content of the file.

q                     Stop.

EOT (control-d)     Same as q.

!command            Escape to the shell to do command.

\* Print a command summary.

### Options

**uuto** The following options are supported by **uuto**:

- m Send mail to the sender when the copy is complete.
- p Copy the source file into the spool directory before transmission.

**uupick** The following option is supported by **uupick**:

- s *system* Search only the PUBDIR for files sent from *system*.

**Operands** The following operands are supported for **uuto**:

*destination* A string of the form:

*system-name ! user*

where *system-name* is taken from a list of system names that **uucp** knows about; see **uname**. The argument *user* is the login name of someone on the specified system. The destination *system-name* can also be a list of names such as

*system-name ! system-name ! . . . ! system-name ! user*

in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.

*source-file* A pathname of a file on the local system to be copied to *destination*.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of **uuto** and **uupick**: `LC_TYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Files** `PUBDIR` /var/spool/uucppublic public directory

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE       |
|---------------|----------------------|
| Availability  | service/network/uucp |

**See Also** [mail\(1\)](#), [uucp\(1C\)](#), [uustat\(1C\)](#), [uux\(1C\)](#), [uucleanup\(1M\)](#), [attributes\(5\)](#)

**Notes** In order to send files that begin with a dot (for instance, `.profile`), the files must be qualified with a dot. For example, the following files are correct:

```
.profile .prof* .profil?
```

The following files are incorrect:

```
prof ?profile
```

**Name** uux – UNIX-to-UNIX system command execution

**Synopsis** uux [-] [-bcCjnprz] [-a *name*] [-g *grade*]  
 [-s *filename*] [-x *debug\_level*] *command-string*

**Description** The uux utility will gather zero or more files from various systems, execute a command on a specified system and then send standard output to a file on a specified system.

*Note:* For security reasons, most installations limit the list of commands executable on behalf of an incoming request from uux, permitting only the receipt of mail (see [mail\(1\)](#)). (Remote execution permissions are defined in `/etc/uucp/Permissions`.)

The *command-string* is made up of one or more arguments that look like a shell command line, except that the command and file names may be prefixed by *system-name!*. A null *system-name* is interpreted as the local system.

File names may be one of the following:

- An absolute path name.
- A path name preceded by `~xxx`, where `xxx` is a login name on the specified system and is replaced by that user's login directory.

Anything else is prefixed by the current directory.

As an example, the command:

```
example% uux "!"diff sys1!/home/dan/filename1 \

 sys2!/a4/dan/filename2 > !~/dan/filename.diff"
```

will get the `filename1` and `filename2` files from the `sys1` and `sys2` machines, execute a [diff\(1\)](#) command and put the results in `filename.diff` in the local `PUBDIR/dan/` directory. `PUBDIR` is a public directory defined in the uucp source. By default, this directory is `/var/spool/uucppublic`.

Any special shell characters (such as `<` `>` `;` `|`) should be quoted either by quoting the entire *command-string*, or quoting the special characters as individual arguments. The redirection operators `>>`, `<<`, `>|`, and `>&` cannot be used.

uux will attempt to get all appropriate files to the specified system where they will be processed. For files that are output files, the file name must be escaped using parentheses. For example, the command:

```
example% uux "a!cut -f1 b!/usr/filename > c!/usr/filename"
```

gets `/usr/filename` from system `b` and sends it to system `a`, performs a `cut` command on that file and sends the result of the `cut` command to system `c`.

uux will notify you if the requested command on the remote system was disallowed. This notification can be turned off by the `-n` option. The response comes by remote mail from the remote machine.

**Options** The following options are supported:

- The standard input to uux is made the standard input to the *command-string*.
- a *name* Uses *name* as the user job identification replacing the initiator user-id. (Notification will be returned to user-id *name*.)
- b Returns whatever standard input was provided to the uux command if the exit status is non-zero.
- c Does not copy local file to the spool directory for transfer to the remote machine (default).
- C Forces the copy of local files to the spool directory for transfer.
- g *grade* *grade* can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The `uuglist(1C)` command determines whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the `uuglist` command will be a list of service grades that are available or a message that says to use a single letter or number as a grade of service.
- j Outputs the jobid string on the standard output which is the job identification. This job identification can be used by `uustat(1C)` to obtain the status or terminate a job.
- n Does not notify the user if the command fails.
- p Same as –. The standard input to uux is made the standard input to the *command-string*.
- r Does not start the file transfer, but just queues the job.
- s *filename* Reports status of the transfer in *filename*. This option is accepted for compatibility, but it is ignored because it is insecure.
- x *debug\_level* Produces debugging output on the standard output. *debug\_level* is a number between 0 and 9. As *debug\_level* increases to 9, more detailed debugging information is given.
- z Sends success notification to the user.

**Environment Variables** See `environ(5)` for descriptions of the following environment variables that affect the execution of uux: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

|              |                       |                              |
|--------------|-----------------------|------------------------------|
| <b>Files</b> | /etc/uucp/*           | other data and programs      |
|              | /etc/uucp/Permissions | remote execution permissions |
|              | /usr/lib/uucp/*       | other programs               |
|              | /var/spool/uucp       | spool directories            |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | service/network/uucp               |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [cut\(1\)](#), [mail\(1\)](#), [uucp\(1C\)](#), [uuglist\(1C\)](#), [uustat\(1C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes** The execution of commands on remote systems takes place in an execution directory known to the uucp system.

All files required for the execution will be put into this directory unless they already reside on that machine. Therefore, the simple file name (without path or machine reference) must be unique within the uux request. The following command will NOT work:

```
example% uux "a!diff b!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

But the command:

```
example% uux "a!diff a!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

will work (if `diff` is a permitted command.)

Protected files and files that are in protected directories that are owned by the requester can be sent in commands using uux. However, if the requester is root, and the directory is not searchable by "other", the request will fail.

The following restrictions apply to the shell pipeline processed by uux:

- In gathering files from different systems, pathname expansion is not performed by uux. Thus, a request such as
 

```
uux "c89 remsys!~/*.c"
```

 would attempt to copy the file named literally `*.c` to the local system.
- Only the first command of a shell pipeline may have a *system-name!*. All other commands are executed on the system of the first command.
- The use of the shell metacharacter `*` will probably not do what you want it to do.

- The shell tokens << and >> are not implemented.
- The redirection operators >>, <<, >|, and >& cannot be used.
- The reserved word ! cannot be used at the head of the pipeline to modify the exit status.
- Alias substitution is not performed.

- Name** vacation – reply to mail automatically
- Synopsis** vacation [-I]  
 vacation [-a *alias*] [-e *filter\_file*] [-f *database\_file*]  
           [-j] [-m *message\_file*] [-s *sender*] [-tN] *username*  
 vacation [-f *database\_file*] -l
- Description** The vacation utility automatically replies to incoming mail.
- Installation** The installation consists of an interactive program which sets up vacation's basic configuration.
- To install vacation, type it with no arguments on the command line. The program creates a .vacation.msg file, which contains the message that is automatically sent to all senders when vacation is enabled, and starts an editor for you to modify the message. (See USAGE section.) Which editor is invoked is determined by the VISUAL or EDITOR environment variable, or vi(1) if neither of those environment variables are set.
- A .forward file is also created if one does not exist in your home directory. Once created, the .forward file will contain a line of the form:
- One copy of an incoming message is sent to the *username* and another copy is piped into vacation:
- ```
username, "|/usr/bin/vacation username"
```
- If a .forward file is present in your home directory, it will ask whether you want to remove it, which disables vacation and ends the installation.
- The program automatically creates .vacation.pag and .vacation.dir, which contain a list of senders when vacation is enabled.
- Activation and Deactivation** The presence of the .forward file determines whether or not vacation is disabled or enabled. To disable vacation, remove the .forward file, or move it to a new name.
- Initialization** The -I option clears the vacation log files, .vacation.pag and .vacation.dir, erasing the list of senders from a previous vacation session. (See OPTIONS section.)
- Additional Configuration** vacation provides configuration options that are not part of the installation, these being -a, -e, -f, -j, -m, -s, and -t. (See OPTIONS section.)
- Reporting** vacation provides a reporting option, -l. See OPTIONS.
- Options** The following options are supported:
- I Initializes the .vacation.pag and .vacation.dir files and enables vacation. If the -I flag is not specified, and a *user* argument is given, vacation reads the first line from the standard input (for a From: line, no colon). If absent, it produces an error message.

Options `-a`, `-e`, `-f`, `-j`, `-m`, `-s`, and `-t` are configuration options to be used in conjunction with `vacation` in the `.forward` file, not on the command line. For example,

```
\username, "|/usr/bin/vacation -t1m username"
```

repeats replies to the sender every minute.

- `-a alias` Indicates that *alias* is one of the valid aliases for the user running `vacation`, so that mail addressed to that alias generates a reply.
- `-e filter_file` Uses *filter_file* instead of `.vacation.filter` as the source of the domain and email address filters.
- `-f database_file` Uses *database_file* instead of `.vacation` as the base name for the database file.
- `-j` Does not check whether the recipient appears in the `To:` or the `Cc:` line. Warning: use of this option can result in `vacation` replies being sent to mailing lists and other inappropriate places; its use is therefore strongly discouraged.
- `-m message_file` Uses `~/message_file` as the message to send for the reply instead of `~/vacation.msg`. *message_file* is a relative path to the desired vacation message file. To prevent directory/file “not found” errors, *message_file* should be on the same disk partition as `~/forward`.
- `-s sender` Replies to *sender* instead of the value read from the UNIX `From` line of the incoming message.
- `-tN` Changes the interval between repeat replies to the same sender. The default is 1 week. A trailing `s`, `m`, `h`, `d`, or `w` scales *N* to seconds, minutes, hours, days, or weeks, respectively.

The `-l` option is neither for initialization nor configuration., but for reporting. The `-f` option can also be used in conjunction with the `-l`.

- `-l` Lists the addresses to which a reply has been sent since the last invocation of `vacation` `-I`, along with a date and time stamp.

Usage `.vacation.msg` should include a header with at least a `Subject:` line (it should not include a `To:` line). For example:

```
Subject: I am on vacation  
I am on vacation until July 22. If you have something urgent,  
please contact Joe Jones (jones@fB0).  
--John
```

If the string `$SUBJECT` appears in the `.vacation.msg` file, it is replaced with the subject of the original message when the reply is sent. Thus, a `.vacation.msg` file such as

```

Subject: I am on vacation
I am on vacation until July 22.
Your mail regarding "$SUBJECT" will be read when I return.
If you have something urgent, please contact
Joe Jones (jones@fB0).
--John

```

will include the subject of the message in the reply.

No message is sent if the To: or the Cc: line does not list the user to whom the original message was sent or one of a number of aliases for them, if the initial From line includes the string -REQUEST@, or if a Precedence: bulk or Precedence: junk line is included in the header.

vacation will also not respond to mail from either postmaster or Mailer-Daemon.

In addition to the above criteria, if a .vacation.filter file exists, it is used to constrain further the set of addresses to which a reply is sent. Each line in that file should be either a domain name, an email address, a negated domain name or a negated email address. A negated line starts with the single character !.

Each line is compared in the order listed to the sender address. A line containing an email address matches if the sender address is exactly the same except for case, which is ignored. A line containing a domain name matches if the sender address is *something@domain-name* or *something@something.domain-name*. A reply is sent if the first match is an entry that is not negated. If the first match is a negated entry, or if no lines match, then no reply is sent.

A sample filter file might look like the following:

```

!host.subdomain.sun.com
sun.com
!wife@mydomain.com
mydomain.com
onefriend@hisisp.com
anotherfriend@herisp.com

```

Blank lines and lines starting with “#” are ignored.

Files ~/ .forward
~/ .vacation.filter
~/ .vacation.msg

A list of senders is kept in the dbm format files .vacation.pag and .vacation.dir in your home directory. These files are dbm files and cannot be viewed directly with text editors.

Name vc – version control

Synopsis vc [-a] [-t] [-c *char*] [-s]
 [*keyword=value*... *keyword=value*]

Description This command is obsolete and will be removed in the next release.

The `vc` command copies lines from the standard input to the standard output under control of its arguments and of “control statements” encountered in the standard input. In the process of performing the copy operation, user-declared *keywords* may be replaced by their string *value* when they appear in plain text and/or control statements.

The copying of lines from the standard input to the standard output is conditional, based on tests (in control statements) of keyword values specified in control statements or as `vc` command arguments.

A control statement is a single line beginning with a control character, except as modified by the `-t` keyletter (see below). The default control character is colon (:), except as modified by the `-c` keyletter (see below). Input lines beginning with a backslash (\) followed by a control character are not control lines and are copied to the standard output with the backslash removed. Lines beginning with a backslash followed by a non-control character are copied in their entirety.

A keyword is composed of 9 or less alphanumeric; the first must be alphabetic. A value is any ASCII string that can be created with `ed`; a numeric value is an unsigned string of digits. Keyword values may not contain blanks or tabs.

Replacement of keywords by values is done whenever a keyword surrounded by control characters is encountered on a version control statement. The `-a` keyletter (see below) forces replacement of keywords in all lines of text. An uninterpreted control character may be included in a value by preceding it with `\`. If a literal `\` is desired, then it too must be preceded by `\`.

Options The following options are supported:

- a Forces replacement of keywords surrounded by control characters with their assigned value in all text lines and not just in `vc` statements.
- t All characters from the beginning of a line up to and including the first tab character are ignored for the purpose of detecting a control statement. If a control statement is found, all characters up to and including the tab are discarded.
- cchar* Specifies a control character to be used in place of the “:” default.
- s Silences warning messages (not error) that are normally printed on the diagnostic output.

`vc` recognizes the following version control statements:

`:dcl keyword[, ..., keyword]` Declare keywords. All keywords must be declared.

`:asg keyword=value`

Assign values to keywords. An `asg` statement overrides the assignment for the corresponding keyword on the `vc` command line and all previous `asg` statements for that keyword. Keywords that are declared but are not assigned values have null values.

`:if condition`

`...`

`:end`

Skip lines of the standard input. If the condition is true, all lines between the `if` statement and the matching `end` statement are copied to the standard output. If the condition is false, all intervening lines are discarded, including control statements. Note: Intervening `if` statements and matching `end` statements are recognized solely for the purpose of maintaining the proper `if`-`end` matching.

The syntax of a condition is:

```
<cond> ::= [ "not" ] <or>
<or>    ::= <and> | <and> " | " <or>
<and>   ::= <exp> | <exp> "&" <and>
<exp>   ::= "(" <or> ")" | <value> <op> <value>
<op>    ::= "=" | "!=" | "<" | ">"
<value> ::= <arbitrary ASCII string> | <numeric string>
```

The available operators and their meanings are:

=	equal
!=	not equal
&	and
	or
>	greater than
<	less than
()	used for logical groupings
not	may only occur immediately after the <code>if</code> , and when present, inverts the value of the entire condition

The `>` and `<` operate only on unsigned integer values (for example, `: 012 > 12` is false). All other operators take strings as arguments (for example, `: 012 != 12` is true).

The precedence of the operators (from highest to lowest) is:

`= != > <` all of equal precedence

`&`

`|`

Parentheses may be used to alter the order of precedence.

Values must be separated from operators or parentheses by at least one blank or tab.

`: :text`

Replace keywords on lines that are copied to the standard output. The two leading control characters are removed, and keywords surrounded by control characters in text are replaced by their value before the line is copied to the output file. This action is independent of the `-a` keyletter.

`:on`

`:off`

Turn on or off keyword replacement on all lines.

`:ctl char`

Change the control character to *char*.

`:msg message`

Print *message* on the diagnostic output.

`:err message`

Print *message* followed by:

ERROR: err statement on line ... (915)

on the diagnostic output. `vc` halts execution, and returns an exit code of 1.

Name vgrind – grind nice program listings

Synopsis vgrind [-2fntwx] [-d *defs-file*] [-h *header*] [-l *language*]
[-s *n*] [-o *pagelist*] [-P *printer*] [-T *output-device*] *filename...*

Description The vgrind utility formats the program sources named by the *filename* arguments in a nice style using **troff(1)**. Comments are placed in italics, keywords in bold face, and as each function is encountered its name is listed on the page margin.

vgrind runs in two basic modes, filter mode or regular mode. In filter mode, vgrind acts as a filter in a manner similar to **tbl(1)**. The standard input is passed directly to the standard output except for lines bracketed by the troff-like macros:

.vS starts processing
.vE ends processing

These lines are formatted as described above. The output from this filter can be passed to troff for output. There need be no particular ordering with **eqn(1)** or **tbl(1)**.

In regular mode, vgrind accepts input *filenames*, processes them, and passes them to troff for output. Use a hyphen ('-') to specify standard input; otherwise, vgrind will exit without attempting to read from the standard input. Filenames must be specified after all other option arguments.

In regular mode, if the -t or -P option is specified, the output is:

- emitted (in troff format) to stdout if the -t option is specified.
- printed (as PostScript) to the named printer if the -P option is specified.

Otherwise, the output is:

- printed (as PostScript) on the system default printer, if one is defined, and the command's stdout is a tty.
- emitted (as PostScript) to stdout if it is not a tty (that is, if stdout is a pipe or a redirect to a file).

In both modes, vgrind passes any lines beginning with a decimal point without conversion.

Options The following options are supported:

- 2 Produces two-column output. Specifying this option changes the default point size to 8 (as if the -s8 option were supplied). It also arranges for output to appear in landscape mode.
- f Forces filter mode.
- n Does not make keywords boldface.

- w Considers TAB characters to be spaced four columns apart instead of the usual eight.
- x Outputs the index file in a “pretty” format. The index file itself is produced whenever `vgrind` is run with a file called `index` that is present in the current directory. The index of function definitions can then be run off by giving `vgrind` the `-x` option and the file `index` as argument.
- d *defs-file* Specifies an alternate language definitions file (default is `/usr/lib/vgrindefs`).
- h *header* Specifies a header to appear in the center of every output page. Use quotes to specify headers with embedded spaces.
- l *language* Specifies the language to use. Among the *languages* currently known are: Bourne shell (`-lsh`), C (`-lc`, the default), C++ (`-lc++`), C shell (`-lcs`), emacs MLisp (`-lm`), FORTRAN (`-lf`), Icon (`-li`), ISP (`-i`), LDL (`-lldl`), Model (`-lm`), Pascal (`-lp`), and RATFOR (`-lr`).
- P *printer* Sends output to the named *printer*.
- s *n* Specifies a point size to use on output (exactly the same as the argument of a `troff .ps` point size request).

`vgrind` passes the following options to the formatter specified by the TROFF environment variable. See ENVIRONMENT VARIABLES.

- t Similar to the same option in `troff`; that is, formatted text goes to the standard output.
- o *pagelist* Prints only those pages whose page numbers appear in the comma-separated *pagelist* of numbers and ranges. A range *N–M* means pages *N* through *M*; an initial `-N` means from the beginning to page *N*; and a final `-N–` means from *N* to the end.
- T *output-device* Formats output for the specified *output-device*.

Operands The following operand is supported:

- filename* Name of the program source to be processed by `vgrind`. Use ‘-’ to specify the standard input.

Environment Variables In regular mode, `vgrind` feeds its intermediate output to the text formatter given by the value of the TROFF environment variable, or to `/usr/bin/troff` if this variable is not defined in the environment. This mechanism allows for local variations in `troff`’s name.

Files	<code>index</code>	file where source for index is created
	<code>/usr/lib/vgrindefs</code>	language descriptions
	<code>/usr/lib/vfontedpr</code>	preprocessor

`/usr/share/lib/tmac/tmac.vgrind` macro package

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools

See Also [csh\(1\)](#), [ctags\(1\)](#), [eqn\(1\)](#), [tbl\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#), [vgrindefs\(5\)](#)

Bugs `vgrind` assumes that a certain programming style is followed:

C	Function names can be preceded on a line only by SPACE, TAB, or an asterisk (*). The parenthesized arguments must also be on the same line.
FORTRAN	Function names need to appear on the same line as the keywords <code>function</code> or <code>subroutine</code> .
MLisp	Function names should not appear on the same line as the preceding <code>defun</code> .
Model	Function names need to appear on the same line as the keywords <code>is</code> <code>beginproc</code> .
Pascal	Function names need to appear on the same line as the keywords <code>function</code> or <code>procedure</code> .

If these conventions are not followed, the indexing and marginal function name comment mechanisms will fail.

More generally, arbitrary formatting styles for programs usually give unsightly results. To prepare a program for `vgrind` output, use TAB rather than SPACE characters to align source code properly, since `vgrind` uses variable width fonts.

The mechanism of [ctags\(1\)](#) in recognizing functions should be used here.

The `-w` option is annoying, but there is no other way to achieve the desired effect.

The macros defined in `tmac.vgrind` do not coexist gracefully with those of other macro packages, making filter mode difficult to use effectively.

`vgrind` does not process certain special characters in [csh\(1\)](#) scripts correctly.

The `tmac.vgrind` formatting macros wire in the page height and width used in two-column mode, effectively making two column output useless for paper sizes other than the standard American size of 8.5 inches by 11 inches. For other paper sizes, it is necessary to edit the size values given in `tmac.vgrind`. A better solution would be to create a `troff` output device specification intended specifically for landscape output and record size information there.

Name vi, view, vedit – screen-oriented (visual) display editor based on ex

/usr/xpg6/bin/vedit [-] -s [-l] [-L] [-R] [-r *filename*]
 [-S] [-t *tag*] [-v] [-V] [-wn]
 [+*command* | -c *command*] *filename*...

Description The vi (visual) utility is a display-oriented text editor based on an underlying line editor ex. It is possible to use the command mode of ex from within vi and to use the command mode of vi from within ex. The visual commands are described on this manual page; how to set options (like automatically numbering lines and automatically starting a new output line when you type carriage return) and all ex line editor commands are described on the [ex\(1\)](#) manual page.

When using vi, changes you make to the file are reflected in what you see on your terminal screen. The position of the cursor on the screen indicates the position within the file.

The view invocation is the same as vi except that the readonly flag is set.

The `vedit` invocation is intended for beginners. It is the same as `vi` except that the `report` flag is set to 1, the `showmode` and `novice` flags are set, and `magic` is turned off. These defaults make it easier to learn how to use `vi`.

Options The following options are supported:

Invocation Options The following invocation options are interpreted by `vi` (previously documented options are discussed under NOTES):

- `- | -s` Suppresses all interactive user feedback. This is useful when processing editor scripts.
- `-l` Sets up for editing LISP programs.
- `-L` Lists the name of all files saved as the result of an editor or system crash.
- `-r filename` Edits *filename* after an editor or system crash. (Recovers the version of *filename* that was in the buffer when the crash occurred.)
- `-R` Readonly mode. The `readonly` flag is set, preventing accidental overwriting of the file.
- `-S` This option is used in conjunction with the `-t tag` option to tell `vi` that the tags file can not be sorted and that, if the binary search (which relies on a sorted tags file) for *tag* fails to find it, the much slower linear search should also be done. Since the linear search is slow, users of large tags files should ensure that the tags files are sorted rather than use this flag. Creation of tags files normally produces sorted tags files. See [ctags\(1\)](#) for more information on tags files.
- `-t tag` Edits the file containing *tag* and position the editor at its definition. It is an error to specify more than one `-t` option.
- `-v` Starts up in display editing state, using `vi`. You can achieve the same effect by typing the `vi` command itself.
- `-V` Verbose. When `ex` commands are read by means of standard input, the input is echoed to standard error. This can be useful when processing `ex` commands within shell scripts.
- `-wn` Sets the default window size to *n*. This is useful when using the editor over a slow speed line.
- `-command | -c command` Begins editing by executing the specified editor *command* (usually a search or positioning command).

`/usr/xpg4/bin/vi` and `/usr/xpg6/bin/vi` If both the `-t tag` and the `-c command` options are given, the `-t tag` option is processed first. That is, the file containing `tag` is selected by `-t` and then the command is executed.

Operands The following operands are supported:

filename A file to be edited.

Command Summary The vi command modes are summarized in this section.

vi Modes

Command Normal and initial mode. Other modes return to command mode upon completion. ESC (escape) is used to cancel a partial command.

Input Entered by setting any of the following options:

a A i I o O c C s S R

Arbitrary text can then be entered. Input mode is normally terminated with the ESC character, or, abnormally, with an interrupt.

Last line Reading input for `:` `/` `?` or `!`. Terminate by typing a carriage return. An interrupt cancels termination.

Sample Commands In the descriptions, CR stands for carriage return and ESC stands for the escape key.

`<`, `>`

down-arrow

up-arrow arrow keys move the cursor

`h j k l` same as arrow keys

`itextESC` insert *text*

`cwnewESC` change word to *new*

`easESC` pluralize word (end of word; append s; escape from input state)

`x` delete a character

`dw` delete a word

`dd` delete a line

`3dd` delete 3 lines

`u` undo previous change

`ZZ` exit vi, saving changes

`:q!CR` quit, discarding changes

`/textCR` search for *text*

`^U ^D` scroll up or down

`:cmdCR` any `ex` or `ed` command

Counts Before vi
Commands Numbers can be typed as a prefix to some commands. They are interpreted in one of these ways:

line/column number z G |
scroll amount ^D ^U
repeat effect most of the rest

Interrupting, Canceling ESC end insert or incomplete command
DEL (delete or rubout) interrupts

File Manipulation ZZ if file modified, write and exit; otherwise, exit
:wCR write back changes
:w!CR forced write, if permission originally not valid
:qCR quit
:q!CR quit, discard changes
:e *name*CR edit file *name*
:e!CR reedit, discard changes
:e + *name*CR edit, starting at end
:e +*n*CR edit, starting at line *n*
:e #CR edit alternate file
:e! #CR edit alternate file, discard changes
:w *name*CR write file *name*
:w! *name*CR overwrite file *name*
:shCR run shell, then return
:!*cmd*CR run *cmd*, then return
:nCR edit next file in arglist
:n *args*CR specify new arglist
^G show current file and line
:ta *tag*CR position cursor to *tag*

In general, any ex or ed command (such as *substitute* or *global*) can be typed, preceded by a colon and followed by a carriage return.

Positioning Within a File	F	forward screen
	^B	backward screen
	^D	scroll down half screen
	^U	scroll up half screen
	<i>n</i> G	go to the beginning of the specified line (end default), where <i>n</i> is a line number
	<i>/pat</i>	next line matching <i>pat</i>
	? <i>pat</i>	previous line matching <i>pat</i>
	n	repeat last / or ? command
	N	reverse last / or ? command
	<i>/pat/+n</i>	<i>n</i> th line after <i>pat</i>
	? <i>pat?-n</i>	<i>n</i> th line before <i>pat</i>
]]	next section/function
	[[previous section/function
	(beginning of sentence
)	end of sentence
	{	beginning of paragraph
	}	end of paragraph
	%	find matching () or { }
	Adjusting the Screen	^L
^R		clear and redraw window if ^L is → key
zCR		redraw screen with current line at top of window
z-CR		redraw screen with current line at bottom of window
z.CR		redraw screen with current line at center of window
<i>/pat/z-CR</i>		move <i>pat</i> line to bottom of window
<i>zn.CR</i>		use <i>n</i> -line window
^E		scroll window down one line
^Y		scroll window up one line
Marking and Returning		``
	^^	move cursor to first non-white space in line

	<code>mx</code>	mark current position with the ASCII lower-case letter <i>x</i>
	<code>`x</code>	move cursor to mark <i>x</i>
	<code>´x</code>	move cursor to first non-white space in line marked by <i>x</i>
Line Positioning	<code>H</code>	top line on screen
	<code>L</code>	last line on screen
	<code>M</code>	middle line on screen
	<code>+</code>	next line, at first non-white space character
	<code>-</code>	previous line, at first non-white space character
	<code>CR</code>	return, same as <code>+</code>
	<code>down-arrow</code> or <code>j</code>	next line, same column
	<code>up-arrow</code> or <code>k</code>	previous line, same column
Character Positioning	<code>^</code>	first non-white space character
	<code>0</code>	beginning of line
	<code>\$</code>	end of line
	<code>l</code> or <code>→</code>	forward
	<code>h</code> or <code>←</code>	backward
	<code>^H</code>	same as <code>←</code> (backspace)
	<code>space</code>	same as <code>→</code> (space bar)
	<code>fx</code>	find next <i>x</i>
	<code>Fx</code>	find previous <i>x</i>
	<code>tx</code>	move to character following the next <i>x</i>
	<code>Tx</code>	move to character following the previous <i>x</i>
	<code>;</code>	repeat last <code>f</code> , <code>F</code> , <code>t</code> , or <code>T</code>
	<code>,</code>	repeat inverse of last <code>f</code> , <code>F</code> , <code>t</code> , or <code>T</code>
	<code>n </code>	move to column <i>n</i>
	<code>%</code>	find matching <code>()</code> or <code>{ }</code>
Words, Sentences, Paragraphs	<code>w</code>	forward a word
	<code>b</code>	back a word

	e	end of word
)	to next sentence
	}	to next paragraph
	(back a sentence
	{	back a paragraph
	W	forward a blank-delimited word
	B	back a blank-delimited word
	E	end of a blank-delimited word
Corrections During Insert	^H	erase last character (backspace)
	^W	erase last word
	erase	your erase character, same as ^H (backspace)
	kill	your kill character, erase this line of input
	\	quotes your erase and kill characters
	ESC	ends insertion, back to command mode
	Control-C	interrupt, suspends insert mode
	^D	backtab one character; reset left margin of <i>autoindent</i>
	^^D	caret (^) followed by control-d (^D); backtab to beginning of line; do not reset left margin of <i>autoindent</i>
	0^D	backtab to beginning of line; reset left margin of <i>autoindent</i>
	^V	quote non-printable character
Insert and Replace	a	append after cursor
	A	append at end of line
	i	insert before cursor
	I	insert before first non-blank
	o	open line below
	O	open line above
	rx	replace single character with <i>x</i>
	R <i>text</i> ESC	replace characters

Operators Operators are followed by a cursor motion and affect all text that would have been moved over. For example, since `w` moves over a word, `dw` deletes the word that would be moved over. Double the operator, for example `dd`, to affect whole lines.

`d` delete
`c` change
`y` yank lines to buffer
`<` left shift
`>` right shift
`!` filter through command

Miscellaneous Operations `C` change rest of line (`c$`)
`D` delete rest of line (`d$`)
`s` substitute characters (`c\l`)
`S` substitute lines (`cc`)
`J` join lines
`x` delete characters (`d\l`)
`X` delete characters before cursor (`dh`)
`Y` yank lines (`yy`)

Yank and Put Put inserts the text most recently deleted or yanked; however, if a buffer is named (using the ASCII lower-case letters `a - z`), the text in that buffer is put instead.

`3yy` yank 3 lines
`3yl` yank 3 characters
`p` put back text after cursor
`P` put back text before cursor
`"xp` put from buffer `x`
`"xy` yank to buffer `x`
`"xd` delete into buffer `x`

Undo, Redo, Retrieve `u` undo last change
`U` restore current line
`.` repeat last change
`"dp` retrieve `d`'th last delete

Usage See [largefile\(5\)](#) for the description of the behavior of `vi` and `view` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `vi`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLS_PATH`, `PATH`, `SHELL`, and `TERM`.

COLUMNS Override the system-selected horizontal screen size.

EXINIT Determine a list of `ex` commands that are executed on editor start-up, before reading the first file. The list can contain multiple commands by separating them using a vertical-line (`|`) character.

LINES Override the system-selected vertical screen size, used as the number of lines in a screenful and the vertical screen size in visual mode.

Files `/var/tmp` default directory where temporary work files are placed; it can be changed using the `directory` option (see the [ex\(1\)](#) command)

`/usr/share/lib/terminfo/??/*` compiled terminal description database

`/usr/lib/.COREterm/??/*` subset of compiled terminal description database

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Solaris Advanced User's Guide

Author `vi` and `ex` were developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

Notes Two options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see [Intro\(1\)](#)). An `-r` option that is not followed with an option-argument has been replaced by `-L` and `+command` has been replaced by `-c` command.

The message `file too large to recover with -r option`, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the `-r` option is not possible.

The editing environment defaults to certain configuration options. When an editing session is initiated, `vi` attempts to read the `EXINIT` environment variable. If it exists, the editor uses the values defined in `EXINIT`; otherwise the values set in `$HOME/.exrc` are used. If `$HOME/.exrc` does not exist, the default values are used.

To use a copy of `.exrc` located in the current directory other than `$HOME`, set the `exrc` option in `EXINIT` or `$HOME/.exrc`. Options set in `EXINIT` can be turned off in a local `.exrc` only if `exrc` is set in `EXINIT` or `$HOME/.exrc`. In order to be used, `.exrc` in `$HOME` or the current directory must fulfill these conditions:

- It must exist.
- It must be owned by the same userid as the real userid of the process, or the process has appropriate privileges.
- It is not writable by anyone other than the owner.

Tampering with entries in `/usr/share/lib/terminfo/?/*` or `/usr/share/lib/terminfo/?/*` (for example, changing or removing an entry) can affect programs such as `vi` that expect the entry to be present and correct. In particular, removing the “dumb” terminal can cause unexpected problems.

Software tabs using `^T` work only immediately after the *autoindent*.

Left and right shifts on intelligent terminals do not make use of insert and delete character operations in the terminal.

Loading an alternate `malloc()` library using the environment variable `LD_PRELOAD` can cause problems for `/usr/bin/vi`.

The `vi` utility currently has the following limitations:

1. Lines, including the trailing `NEWLINE` character, can contain no more than 4096 bytes.

If a longer line is found, Line too long is displayed in the status line.

2. The editor's temporary work file can be no larger than 128Mb.

If a larger temporary file is needed, Tmp file too large is displayed in the status line.

Name vipw – edit the password file

Synopsis /usr/ucb/vipw

Description vipw edits the password file while setting the appropriate locks, and does any necessary processing after the password file is unlocked. If the password file is already being edited, then you will be told to try again later. The [vi\(1\)](#) editor will be used unless the environment variable VISUAL or EDITOR indicates an alternate editor.

vipw performs a number of consistency checks on the password entry for root, and will not allow a password file with a “mangled” root entry to be installed. It also checks the /etc/shells file to verify the login shell for root.

Files /etc/ptmp

/etc/shells

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

See Also [passwd\(1\)](#), [vi\(1\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

Name volcheck – checks for media in a drive

Synopsis volcheck [-v] [-i *secs*] [-t *secs*] *pathname*

Description The volcheck utility tells volume management to look at each *dev/pathname* in sequence and determine if new media has been inserted in the drive.

The default action is to volcheck all checkable media managed by volume management.

Options The following options are supported:

-i *secs* Set the frequency of device checking to *secs* seconds. The default is 2 seconds. The minimum frequency is 1 second.

-t *secs* Check the named device(s) for the next *secs* seconds. The maximum number of seconds allowed is 28800, which is 8 hours. The frequency of checking is specified by -i. There is no default total time.

-v Verbose.

Operands The following operands are supported:

pathname The path name of a media device.

Files /dev/volctl volume management control port

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/media-volume-manager

See Also [eject\(1\)](#), [rmmount\(1M\)](#), [attributes\(5\)](#)

Name volrmount – call rmmount to mount or unmount media

Synopsis volrmount [-i | -e] [*name* | *nickname*]
volrmount [-d]

Description The volrmount utility calls [rmmount\(1M\)](#) to, in effect, simulate an insertion (-i) or an ejection (-e). Simulating an insertion often means that rmmount will mount the media. Conversely, simulating an ejection often means that rmmount will unmount the media. However, these actions can vary depending on the rmmount configuration and media type.

For example, using default settings, if you insert a music CD, it might not be mounted. However, you can configure rmmount so that it calls workman whenever a music CD is inserted.

The volrmount utility allows you to override volume management's usual handling of media.

Options The following options are supported:

- i Simulates an insertion of the specified media by calling rmmount.
- e Simulates an ejection of the specified media by calling rmmount.
- d Displays the name of the default device for volrmount to handle. This device is used if no *name* or *nickname* is supplied.

Operands The following operands are supported:

name The name that volume management recognizes as the device's name.

nickname A shortened version of the device's name. Following is the list of recognized nicknames:

Nickname	Path
cdrom0	/dev/rdisk/cXtYdZ//label
zip0	/dev/rdisk/cXtYdZ//label
jaz0	/dev/rdisk/cXtYdZ//label
rmdisk0	/dev/rdisk/cXtYdZ//label

Files /dev/volctl volume management control port

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/media-volume-manager

See Also [cpio\(1\)](#), [eject\(1\)](#), [tar\(1\)](#), [rmmount\(1M\)](#), [attributes\(5\)](#)

Name w – display information about currently logged-in users

Synopsis w [-hlsuw] [*user*]

Description The `w` command displays a summary of the current activity on the system, including what each user is doing. The heading line shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes.

The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged on (in *hours:minutes*), the idle time—that is, the number of minutes since the user last typed anything (in *hours:minutes*), the CPU time used by all processes and their children on that terminal (in *minutes:seconds*), the CPU time used by the currently active processes (in *minutes:seconds*), and the name and arguments of the current process.

Options The following options are supported:

- h Suppresses the heading.
- l Produces a long form of output, which is the default.
- s Produces a short form of output. In the short form, the tty is abbreviated, the login time and CPU times are left off, as are the arguments to commands.
- u Produces the heading line which shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes.
- w Produces a long form of output, which is also the same as the default.

Operands *user* Name of a particular user for whom login information is displayed. If specified, output is restricted to that user.

Examples EXAMPLE 1 Sample Output From the `w` Command

```
example% w
```

```
10:54am up 27 day(s), 57 mins, 1 user, load average: 0.28, 0.26, 0.22
User      tty          login@      idle      JCPU      PCPU      what
ralph    console  7:10am     1        10:05    4:31     w
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `w`: `LC_CTYPE`, `LC_MESSAGES`, and `LC_TIME`.

Files `/var/adm/utmpx` user and accounting information

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [ps\(1\)](#), [who\(1\)](#), [whodo\(1M\)](#), [utmpx\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

Notes The notion of the “current process” is unclear. The current algorithm is “the highest numbered process on the terminal that is not ignoring interrupts, or, if there is none, the highest numbered process on the terminal”. This fails, for example, in critical sections of programs like the shell and editor, or when faulty programs running in the background fork and fail to ignore interrupts. In cases where no process can be found, `w` prints `-`.

The CPU time is only an estimate, in particular, if someone leaves a background process running after logging out, the person currently on that terminal is “charged” with the time.

Background processes are not shown, even though they account for much of the load on the system.

Sometimes processes, typically those in the background, are printed with null or garbaged arguments. In these cases, the name of the command is printed in parentheses.

`w` does not know about the conventions for detecting background jobs. It will sometimes find a background job instead of the right one.

Name wait – await process completion

Synopsis

/bin/sh wait [*pid*]...

/bin/jsh /bin/ksh88 wait [*pid*]...

/usr/xpg4/bin/sh wait [% *jobid*...]

/bin/csh wait

ksh wait [*job*...]

Description The shell itself executes `wait`, without creating a new process. If you get the error message `cannot fork, too many processes`, try using the `wait` command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. There is a limit to the number of process IDs associated with your login, and to the number the system can keep track of.

Not all the processes of a pipeline with three or more stages are children of the shell, and thus cannot be waited for.

/bin/sh, /bin/jsh Wait for your background process whose process ID is *pid* and report its termination status. If *pid* is omitted, all your shell's currently active background processes are waited for and the return code is 0. The `wait` utility accepts a job identifier, when Job Control is enabled (`jsh`), and the argument, *jobid*, is preceded by a percent sign (%).

If *pid* is not an active process ID, the `wait` utility returns immediately and the return code is 0.

csh Wait for your background processes.

ksh88 When an asynchronous list is started by the shell, the process ID of the last command in each element of the asynchronous list becomes known in the current shell execution environment.

If the `wait` utility is invoked with no operands, it waits until all process IDs known to the invoking shell have terminated and exit with an exit status of 0.

If one or more *pid* or *jobid* operands are specified that represent known process IDs (or jobids), the `wait` utility waits until all of them have terminated. If one or more *pid* or *jobid* operands are specified that represent unknown process IDs (or jobids), `wait` treats them as if they were known process IDs (or jobids) that exited with exit status 127. The exit status returned by the `wait` utility is the exit status of the process requested by the last *pid* or *jobid* operand.

The known process IDs are applicable only for invocations of `wait` in the current shell execution environment.

ksh wait with no operands, waits until all jobs known to the invoking shell have terminated. If one or more job operands are specified, wait waits until all of them have completed. Each job can be specified as one of the following:

<i>number</i>	<i>number</i> refers to a process ID.
<i>-number</i>	<i>number</i> refers to a process group ID.
<i>%number</i>	<i>number</i> refers to a job number
<i>%string</i>	Refers to a job whose name begins with <i>string</i>
<i>%?string</i>	Refers to a job whose name contains <i>string</i>
<i>%+</i>	
<i>%%</i>	Refers to the current job
<i>%-</i>	Refers to the previous job

If one or more job operands is a process id or process group id not known by the current shell environment, wait treats each of them as if it were a process that exited with status 127.

Operands The following operands are supported:

<i>pid</i>	The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination.
<i>jobid</i>	A job control job ID that identifies a background process group to be waited for. The job control job ID notation is applicable only for invocations of wait in the current shell execution environment, and only on systems supporting the job control option.

Usage On most implementations, wait is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following,

```
(wait)
nohup wait ...
find . -exec wait ... \;
```

it returns immediately because there is no known process IDs to wait for in those environments.

Examples **EXAMPLE 1** Using A Script To Identify The Termination Signal

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably figure out which signal is using kill, as shown by the following (/bin/ksh88 and /usr/xpg4/bin/sh):

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
```

EXAMPLE 1 Using A Script To Identify The Termination Signal (Continued)

```
echo $pid was terminated by a SIG$(kill -l $(( $?-128 ))) signal.
```

EXAMPLE 2 Returning The Exit Status Of A Process

If the following sequence of commands is run in less than 31 seconds (`/bin/ksh88` and `/usr/xpg4/bin/sh`):

```
sleep 257 | sleep 31 &
```

```
jobs -l %%
```

then either of the following commands returns the exit status of the second `sleep` in the pipeline:

```
wait <pid of sleep 31>
wait %%
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `wait`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status

`ksh` The following exit values are returned by the `wait` built-in in `ksh`:

- 0 `wait` was invoked with no operands. All processes known by the invoking process have terminated.
- 127 `job` is a process id or process group id that is unknown to the current shell environment.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Standard	See standards(5) .

See Also [csh\(1\)](#), [jobs\(1\)](#), [ksh\(1\)](#), [ksh88\(1\)](#), [pwait\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name `wc` – display a count of lines, words and characters in a file

Synopsis `/usr/bin/wc [-c | -m | -C] [-lw] [file...]`

Description `wc` reads one or more input files and, by default, for each file writes a line containing the number of NEWLINES, words, and bytes contained in each file followed by the file name to standard output in that order. A word is defined to be a non-zero length string delimited by `isspace(3C)` characters.

If more than one file is specified, `wc` writes a total count for all of the named files with total written instead of the file name.

By default, `wc` writes all three counts. Options can be specified so that only certain counts are written. The `-c` and `-m` options are mutually exclusive.

If no file is specified, or if the file is `-`, `wc` reads from standard input and no filename is written to standard output. The start of the file is defined as the current offset.

Options The following options are supported for both `/usr/bin/wc` and `ksh`. The long form of the options are only available with `ksh`:

`-c` Counts bytes.

`-C` Counts characters. Same as `-m`.

`-l` Counts lines.

`-m` Counts characters. Same as `-C`.

`-w` Counts words delimited by white space characters or new line characters. Delimiting characters are Extended Unix Code (EUC) characters from any code set defined by `isspace(3C)`.

If no option is specified, the default is `-lwc` (counts lines, words, and bytes.)

Operands The following operand is supported:

file A path name of an input file. If no *file* operands are specified, the standard input is used.

Usage See [largefile\(5\)](#) for the description of the behavior of `wc` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `wc`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status 0 Successful completion.
>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	Committed
Standard	See standards(5) .

See Also [cksum\(1\)](#), [isspace\(3C\)](#), [iswalph\(3C\)](#), [iswspace\(3C\)](#), [setlocale\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Name what – extract SCCS version information from a file

Synopsis what [-s] *filename*...

Description The what utility searches each *filename* for occurrences of the pattern `@(#)` that the SCCS `get` command (see [sccs-get\(1\)](#)) substitutes for the `@(#)` ID keyword, and prints what follows up to a `"`, `>`, `NEWLINE`, `\`, or `NULL` character.

Options The following option is supported:

-s Stops after the first occurrence of the pattern.

Examples **EXAMPLE 1** Extracting SCCS version information

If a C program in file `program.c` contains

```
char sccsid[ ] = "@(#)identification information ";
```

and `program.c` is compiled to yield `program.o` and `a.out`, the command:

```
example% what program.c program.o a.out
```

produces:

```
program.c:     identification information
```

```
program.o:     identification information
```

```
a.out:         identification information
```

Exit Status The following exit values are returned:

0 Any matches were found.

1 No matches found.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of what: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/build/make
Interface Stability	Committed
Standard	See standards(5) .

See Also [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-cdc\(1\)](#), [sccs-comb\(1\)](#), [sccs-delta\(1\)](#), [sccs-get\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-rmdel\(1\)](#), [sccs-sact\(1\)](#), [sccs-sccsdiff\(1\)](#), [sccs-unget\(1\)](#), [sccs-val\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics Use the `sccs -help` command for explanations of SCCS commands. See [sccs-help\(1\)](#).

Bugs There is a remote possibility that a spurious occurrence of the `@(#)` pattern could be found by `what`.

Name `whatis` – display a one-line summary about a keyword

Synopsis `whatis command...`

Description `whatis` looks up a given *command* and displays the header line from the manual section. You can then run the `man(1)` command to get more information. If the line starts `name(section)...` you can do `man -ssection name` to get the documentation for it. Try `whatis ed` and then you should do `man -s 1 ed` to get the manual page for `ed(1)`.

`whatis` is actually just the `-f` option to the `man(1)` command.

`whatis` uses the `/usr/share/man/man_index/*` index files. The index files are either automatically generated by an SMF service as described in `man(1)` and `man(5)` or manually generated by using `catman(1M)` with the `-w` option. If the index files do not exist, `whatis` is run slower since it looks directly into manual page files.

Files `/usr/share/man/man_index/*` Table of Contents and keyword database.

Generated files include:

- `/usr/share/man/man_index/man.idx`
- `/usr/share/man/man_index/man.dic`
- `/usr/share/man/man_index/man.frq`
- `/usr/share/man/man_index/man.pos`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools
CSI	Enabled
Interface Stability	Committed

See Also `apropos(1)`, `man(1)`, `catman(1M)`, `attributes(5)`, `man(5)`

Name whereis – locate the binary, source, and manual page files for a command

Synopsis /usr/ucb/whereis [-bmsu] [-BMS *directory...* -f] *filename...*

Description The whereis utility locates source/binary and manuals sections for specified files. The supplied names are first stripped of leading pathname components and any (single) trailing extension of the form *.ext*, for example, *.c*. Prefixes of *s.* resulting from use of source code control are also dealt with. whereis then attempts to locate the desired program in a list of standard places:

```
etc
/sbin
/usr/bin
/usr/lang
/usr/lbin
/usr/lib
/usr/sbin
/usr/ucb
/usr/ucblib
/usr/ucbinclude
/usr/games
/usr/local
/usr/local/bin
/usr/new
/usr/old
/usr/hosts
/usr/include
```

Options The following options are supported:

- b Searches only for binaries.
- B Changes or otherwise limits the places where whereis searches for binaries.
- f Terminates the last directory list and signals the start of file names, and *must* be used when any of the -B, -M, or -S options are used.
- m Searches only for manual sections.
- M Changes or otherwise limits the places where whereis searches for manual sections.
- s Searches only for sources.
- S Changes or otherwise limit the places where whereis searches for sources.
- u Searches for unusual entries. A file is said to be unusual if it does not have one entry of each requested type. Thus 'whereis -m -u *' asks for those files in the current directory which have no documentation.

Examples EXAMPLE 1 Finding files

Find all files in `/usr/bin` which are not documented in `/usr/share/man/man1` with source in `/usr/src/cmd`:

```
example% cd /usr/ucb
```

```
example% whereis -u -M /usr/share/man/man1 -S /usr/src/cmd -f *
```

Files `/usr/src/*`

```
/usr/{doc,man}/*
```

```
/etc, /usr/{lib,bin,ucb,old,new,local}
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

See Also [chdir\(2\)](#), [attributes\(5\)](#)

Bugs Since `whereis` uses [chdir\(2\)](#) to run faster, pathnames given with the `-M`, `-S`, or `-B` must be full; that is, they must begin with a `/`.

Name which – locate a command and display its pathname or alias

Synopsis which [*name*]. . .

Description which takes a list of names and determines which alias or utility would be executed had these names been given as commands.

For each *name* operand, if it names an alias the alias is expanded. Otherwise the user's path is searched for a utility name matching *name*. Aliases are taken from the user's `.cshrc` file. *path* is taken from the current shell execution environment.

Operands The following operand is supported:

name The name of a command to be located.

Exit Status The following exit values are returned:

0 Successful completion.

>0 One or more *name* operands were not located or an error occurred.

Files `~/ .cshrc` source of aliases and path values

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [csh\(1\)](#), [attributes\(5\)](#)

Diagnostics A diagnostic is given for names which are aliased to more than a single word, or if an executable file with the argument name was not found in the path.

Notes The `which` utility is not a shell built-in command.

Bugs To compensate for `~/ .cshrc` files in which aliases depend upon the `prompt` variable being set, `which` sets this variable to NULL. If the `~/ .cshrc` produces output or prompts for input when `prompt` is set, `which` can produce some strange results.

Name who – who is on the system

Synopsis /usr/bin/who [-abdHlmpqrstTu] [*file*]
 /usr/bin/who -q [-n *x*] [*file*]
 /usr/bin/who am i
 /usr/bin/who am I
 /usr/xpg4/bin/who [-abdHlmpqrstTu] [*file*]
 /usr/xpg4/bin/who -q [-n *x*] [*file*]
 /usr/xpg4/bin/who -s [-bdHlmpqrtu] [*file*]
 /usr/xpg4/bin/who am i
 /usr/xpg4/bin/who am I

Description The who utility can list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process-ID of the command interpreter (shell) for each current UNIX system user. It examines the /var/adm/utmpx file to obtain its information. If *file* is given, that file (which must be in utmpx(4) format) is examined. Usually, *file* will be /var/adm/wtmpx, which contains a history of all the logins since the file was last created.

The general format for output is:

```
name [state] line time [idle] [pid] [comment] [exit]
```

where:

<i>name</i>	User's login name
<i>state</i>	Capability of writing to the terminal
<i>line</i>	Name of the line found in /dev
<i>time</i>	Time since user's login
<i>idle</i>	Time elapsed since the user's last activity
<i>pid</i>	User's process id
<i>comment</i>	Comment line in inittab(4)
<i>exit</i>	Exit status for dead processes

Options The following options are supported:

- a Processes /var/adm/utmpx or the named *file* with -b, -d, -l, -p, -r, -t, -T, and -u options turned on.
- b Indicates the time and date of the last reboot.

- d Displays all processes that have expired and not been respawned by `init`. The `exit` field appears for dead processes and contains the termination and exit values (as returned by `wait(3C)`), of the dead process. This can be useful in determining why a process terminated.
- H Outputs column headings above the regular output.
- l Lists only those lines on which the system is waiting for someone to login. The `name` field is `LOGIN` in such cases. Other fields are the same as for user entries except that the `state` field does not exist.
- m Outputs only information about the current terminal.
- n *x* Takes a numeric argument, *x*, which specifies the number of users to display per line. *x* must be at least 1. The `-n` option can only be used with `-q`.
- p Lists any other process that is currently active and has been previously spawned by `init`. The `name` field is the name of the program executed by `init` as found in `/usr/sbin/inittab`. The `state`, `line`, and `idle` fields have no meaning. The `comment` field shows the `id` field of the line from `/usr/sbin/inittab` that spawned this process. See `inittab(4)`.
- q (Quick who) Displays only the names and the number of users currently logged on. When this option is used, all other options are ignored.
- r Indicates the current *run-level* of the `init` process.
- s (Default) Lists only the `name`, `line`, and `time` fields.
- /usr/bin/who -T Same as the `-s` option, except that the `state`, `idle`, `pid`, and `comment` fields are also written. `state` is one of the following characters:
 - + The terminal allows write access to other users.
 - The terminal denies write access to other users.
 - ? The terminal write-access state cannot be determined.
- /usr/xpg4/bin/who -T Same as the `-s` option, except that the `state` field is also written. `state` is one of the characters listed under the `/usr/bin/who` version of this option. If the `-u` option is used with `-T`, the idle time is added to the end of the previous format.
- t Indicates the last change to the system clock (using the `date` utility) by root. See `su(1M)` and `date(1)`.
- u Lists only those users who are currently logged in. The `name` is the user's login name. The `line` is the name of the line as found in the directory `/dev`. The `time` is the time that the user logged in. The `idle` column contains the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has seen activity in the last minute and is therefore current. If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked `old`.

This field is useful when trying to determine whether a person is working at the terminal or not. The *pid* is the process-ID of the user's shell. The *comment* is the comment field associated with this line as found in `/usr/sbin/inittab` (see [inittab\(4\)](#)). This can contain information about where the terminal is located, the telephone number of the dataset, type of terminal if hard-wired, and so forth.

Operands The following operands are supported:

- `am i`
- `am I` In the C locale, limits the output to describing the invoking user, equivalent to the `-m` option. The `am` and `i` or `I` must be separate arguments.
- file* Specifies a path name of a file to substitute for the database of logged-on users that who uses by default.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `who`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

Exit Status The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

- Files**
- `/usr/sbin/inittab` Script for `init`
 - `/var/adm/utmpx` Current user and accounting information
 - `/var/adm/wtmpx` Historic user and accounting information

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/who	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/core-os

/usr/xpg4/bin/who	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	system/xopen/xcu4
	Interface Stability	Committed
	Standard	See standards(5) .

See Also [date\(1\)](#), [login\(1\)](#), [mesg\(1\)](#), [init\(1M\)](#), [su\(1M\)](#), [wait\(3C\)](#), [inittab\(4\)](#), [utmpx\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes *Superuser:* After a shutdown to the single-user state, `who` returns a prompt. Since `/var/adm/utmpx` is updated at login time and there is no login in single-user state, `who` cannot report accurately on this state. The command, `who am i`, however, returns the correct information.

Name whoami – display the effective current username

Synopsis /usr/ucb/whoami

Description whoami displays the login name corresponding to the current effective user ID. If you have used su to temporarily adopt another user, whoami will report the login name associated with that user ID. whoami gets its information from the geteuid and getpwuid library routines (see getuid and [getpwnam\(3C\)](#), respectively).

Files /etc/passwd username data base

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	compatibility/ucb

See Also [su\(1M\)](#), [who\(1\)](#), [getuid\(2\)](#), [getpwnam\(3C\)](#), [attributes\(5\)](#)

Name whocalls – report on the calls to a specific procedure

Synopsis whocalls [-l *wholib*] [-s] *funcname executable*
[*arguments*] . . .

Description whocalls is a simple example of a utility based on the *Link-Auditing* functionality of [ld.so.1\(1\)](#) that permits the tracking of a given function call. See the [Linker and Libraries Guide](#) for a detailed description of the *Link-Auditing* mechanism. The *executable* is run as normal with any associated arguments. Each time the procedure *funcname* is called, both the arguments to that procedure and a stack trace are displayed on standard output.

Options The following options are supported:

- l *wholib* Specifies an alternate *who.so Link-Auditing* library to use.
- s When available, examines and uses the *.symtab* symbol table for local symbols. This is a little more expensive than using the *.dynam* symbol table, but can produce more detailed stack trace information.

Examples EXAMPLE 1 Tracking Function Calls

The following example tracks the calls to `printf()` made by a simple `helloworld` program:

```
example% whocalls printf helloworld
printf(0x106e4, 0xef625310, 0xef621ba8)
    helloworld:main+0x10
    helloworld:_start+0x5c
Hello World
```

[Linker and Libraries Guide](#)

Name whois – Internet user name directory service

Synopsis `whois [-h host] identifier`

Description `whois` searches for an Internet directory entry for an *identifier* which is either a name (such as “Smith”) or a handle (such as “SRI-NIC”). To force a name-only search, precede the name with a period; to force a handle-only search, precede the handle with an exclamation point.

To search for a group or organization entry, precede the argument with * (an asterisk). The entire membership list of the group will be displayed with the record.

You may of course use an exclamation point and asterisk, or a period and asterisk together.

Examples **EXAMPLE 1** Using The `whois` Command

The command:

```
example% whois Smith
```

looks for the name or handle SMITH.

The command:

```
example% whois !SRI-NIC
```

looks for the handle SRI-NIC only.

The command:

```
example% whois .Smith, John
```

looks for the name JOHN SMITH only.

Adding . . . to the name or handle argument will match anything from that point; that is, ZU . . . will match ZUL, ZUM, and so on.

See Also [attributes\(5\)](#)

Name write – write to another user

Synopsis write *user* [*terminal*]

Description The write utility reads lines from the user's standard input and writes them to the terminal of another user. When first invoked, it writes the message:

Message from *sender-login-id* (*sending-terminal*) [date]...

to *user*. When it has successfully completed the connection, the sender's terminal will be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.

If the recipient wants to reply, this can be accomplished by typing

write *sender-login-id* [*sending-terminal*]

upon receipt of the initial message. Whenever a line of input as delimited by a NL, EOF, or EOL special character is accumulated while in canonical input mode, the accumulated data will be written on the other user's terminal. Characters are processed as follows:

- Typing the alert character will write the alert character to the recipient's terminal.
- Typing the erase and kill characters will affect the sender's terminal in the manner described by the [termios\(3C\)](#) interface.
- Typing the interrupt or end-of-file characters will cause write to write an appropriate message (EOT\n in the C locale) to the recipient's terminal and exit.
- Typing characters from LC_CTYPE classifications print or space will cause those characters to be sent to the recipient's terminal.
- When and only when the stty iexten local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.
- Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as '^' followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'.

To write to a user who is logged in more than once, the *terminal* argument can be used to indicate which terminal to write to. Otherwise, the recipient's terminal is the first writable instance of the user found in /usr/adm/utmpx, and the following informational message will be written to the sender's standard output, indicating which terminal was chosen:

```
user is logged on more than one place.  
You are connected to terminal.  
Other locations are:terminal
```

Permission to be a recipient of a `wri te` message can be denied or granted by use of the `mes g` utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The `wri te` utility will fail when the user lacks the appropriate privileges to perform the requested action.

If the character `!` is found at the beginning of a line, `wri te` calls the shell to execute the rest of the line as a command.

`wri te` runs `setgid()` (see [setuid\(2\)](#)) to the group ID `tty`, in order to have write permissions on other users' terminals.

The following protocol is suggested for using `wri te`: when you first write to another user, wait for them to write back before starting to send. Each person should end a message with a distinctive signal (that is, `(o)` for *over*) so that the other person knows when to reply. The signal `(oo)` (for *over and out*) is suggested when conversation is to be terminated.

Operands The following operands are supported:

user User (login) name of the person to whom the message will be written. This operand must be of the form returned by the [who\(1\)](#) utility.

terminal Terminal identification in the same format provided by the `who` utility.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `wri te`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` The addressed user is not logged on or the addressed user denies permission.

Files `/var/adm/utmpx` User and accounting information for `wri te`

`/usr/bin/sh` Bourne shell executable file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
CSI	Enabled
Interface Stability	Committed
Standard	See standards(5) .

See Also [mail\(1\)](#), [mesg\(1\)](#), [pr\(1\)](#), [sh\(1\)](#), [talk\(1\)](#), [who\(1\)](#), [setuid\(2\)](#), [termios\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics	user is not logged on	The person you are trying to write to is not logged on.
	Permission denied	The person you are trying to write to denies that permission (with mesg).
	Warning: cannot respond, set mesg-y	Your terminal is set to mesg n and the recipient cannot respond to you.
	Can no longer write to user	The recipient has denied permission (mesg n) after you had started writing.

Name xargs – construct argument lists and invoke utility

Synopsis xargs [-t] [-p] [-e[*eofstr*]] [-E *eofstr*]
 [-I *replstr*] [-i[*replstr*]] [-L *number*] [-l[*number*]]
 [-n *number* [-x]] [-s *size*] [*utility* [*argument...*]]

Description The xargs utility constructs a command line consisting of the *utility* and *argument* operands specified followed by as many arguments read in sequence from standard input as fit in length and number constraints specified by the options. The xargs utility then invokes the constructed command line and waits for its completion. This sequence is repeated until an end-of-file condition is detected on standard input or an invocation of a constructed command line returns an exit status of 255.

Arguments in the standard input must be separated by unquoted blank characters, or unescaped blank characters or newline characters. A string of zero or more non-double-quote (") and non-newline characters can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe (') and non-newline characters can be quoted by enclosing them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash (\). The *utility* are executed one or more times until the end-of-file is reached. The results are unspecified if the utility named by *utility* attempts to read from its standard input.

The generated command line length is the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The xargs utility limits the command line length such that when the command line is invoked, the combined argument and environment lists can not exceed {ARG_MAX}—2048 bytes. Within this constraint, if neither the -n nor the -s option is specified, the default command line length is at least {LINE_MAX}.

Options The following options are supported:

- 0 Input items are terminated by a null character instead of by white space or a NEWLINE, and the quotes and backslash are not special, that is, every character is taken literally. The end of file string is also disabled and is treated like any other argument. This is useful when input items might contain white space, quote marks, or backslashes. The find -print0 option produces input suitable for this mode.
- e[*eofstr*] Uses *eofstr* as the logical end-of-file string. Underscore (_) is assumed for the logical EOF string if neither -e nor -E is used. When the *eofstr* option-argument is omitted, the logical EOF string capability is disabled and underscores are taken literally. The xargs utility reads standard input until either end-of-file or the logical EOF string is encountered.
- E *eofstr* Specifies a logical end-of-file string to replace the default underscore. xargs reads standard input until either end-of-file or the logical EOF string is encountered. When *eofstr* is a null string, the logical end-of-file string capability is disabled and underscore characters are taken literally.

- I *replstr*** Insert mode. *utility* is executed for each line from standard input, taking the entire line as a single argument, inserting it in *arguments* for each occurrence of *replstr*. A maximum of five arguments in *arguments* can each contain one or more instances of *replstr*. Any blank characters at the beginning of each line are ignored. Constructed arguments cannot grow larger than 255 bytes. Option **-x** is forced on. The **-I** and **-i** options are mutually exclusive; the last one specified takes effect.
- i [*replstr*]** This option is equivalent to **-I *replstr***. The string { } is assumed for *replstr* if the option-argument is omitted.
- L *number*** The *utility* is executed for each non-empty *number* lines of arguments from standard input. The last invocation of *utility* is with fewer lines of arguments if fewer than *number* remain. A line is considered to end with the first newline character unless the last character of the line is a blank character; a trailing blank character signals continuation to the next non-empty line, inclusive. The **-L**, **-l**, and **-n** options are mutually exclusive; the last one specified takes effect.
- l [*number*]** (The letter ell.) This option is equivalent to **-L *number***. If *number* is omitted, 1 is assumed. Option **-x** is forced on.
- n *number*** Invokes *utility* using as many standard input arguments as possible, up to *number* (a positive decimal integer) arguments maximum. Fewer arguments are used if:
- The command line length accumulated exceeds the size specified by the **-s** option (or {LINE_MAX} if there is no **-s** option), or
 - The last iteration has fewer than *number*, but not zero, operands remaining.
- p** Prompt mode. The user is asked whether to execute *utility* at each invocation. Trace mode (**-t**) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response (specific to the user's locale) read from /dev/tty executes the command; otherwise, that particular invocation of *utility* is skipped.
- s *size*** Invokes *utility* using as many standard input arguments as possible yielding a command line length less than *size* (a positive decimal integer) bytes. Fewer arguments are used if:
- The total number of arguments exceeds that specified by the **-n** option, or
 - The total number of lines exceeds that specified by the **-L** option, or
 - End of file is encountered on standard input before *size* bytes are accumulated.

Values of *size* up to at least {LINE_MAX} bytes are supported, provided that the constraints specified in DESCRIPTION are met. It is not considered an error if

a value larger than that supported by the implementation or exceeding the constraints specified in DESCRIPTION is specified. `xargs` uses the largest value it supports within the constraints.

- t Enables trace mode. Each generated command line is written to standard error just prior to invocation.
- x Terminates if a command line containing *number* arguments (see the `-n` option above) or *number* lines (see the `-L` option above) does not fit in the implied or specified size (see the `-s` option above).

Operands The following operands are supported:

- utility* The name of the utility to be invoked, found by search path using the PATH environment variable. (see `environ(5)`.) If *utility* is omitted, the default is the `echo(1)` utility. If the *utility* operand names any of the special built-in utilities in `shell_builtins(1)`, the results are undefined.
- argument* An initial option or operand for the invocation of *utility*.

Usage The 255 exit status allows a utility being used by `xargs` to tell `xargs` to terminate if it knows no further invocations using the current data stream succeeds. Thus, *utility* should explicitly exit with an appropriate value to avoid accidentally returning with 255.

Notice that input is parsed as lines. Blank characters separate arguments. If `xargs` is used to bundle output of commands like `find dir -print` or `ls` into commands to be executed, unexpected results are likely if any filenames contain any blank characters or newline characters. This can be fixed by using `find` to call a script that converts each file found into a quoted string that is then piped to `xargs`. Notice that the quoting rules used by `xargs` are not the same as in the shell. They were not made consistent here because existing applications depend on the current rules and the shell syntax is not fully compatible with it. An easy rule that can be used to transform any string into a quoted form that `xargs` interprets correctly is to precede each character in the string with a backslash (`\`).

On implementations with a large value for `{ARG_MAX}`, `xargs` can produce command lines longer than `{LINE_MAX}`. For invocation of utilities, this is not a problem. If `xargs` is being used to create a text file, users should explicitly set the maximum command line length with the `-s` option.

The `xargs` utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.

Examples EXAMPLE 1 Using the xargs command

The following example moves all files from directory \$1 to directory \$2, and echo each move command just before doing it:

```
example% ls $1 | xargs -I {} -t mv $1/{} $2/{}
```

The following command combines the output of the parenthesised commands onto one line, which is then written to the end of file log:

```
example% (logname; date; printf "%s\n" "$0 $*") | xargs >>log
```

The following command invokes `diff` with successive pairs of arguments originally typed as command line arguments (assuming there are no embedded blank characters in the elements of the original argument list):

```
example% printf "%s\n" "$*" | xargs -n 2 -x diff
```

The user is asked which files in the current directory are to be archived. The files are archived into `arch`; a, one at a time, or b, many at a time:

```
example% ls | xargs -p -L 1 ar -r arch  
ls | xargs -p -L 1 | xargs ar -r arch
```

The following executes with successive pairs of arguments originally typed as command line arguments:

```
example% echo $* | xargs -n 2 diff
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `xargs`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`PATH` Determine the location of *utility*.

Affirmative responses are processed using the extended regular expression defined for the `yesexpr` keyword in the `LC_MESSAGES` category of the user's locale. The locale specified in the `LC_COLLATE` category defines the behavior of ranges, equivalence classes, and multi-character collating elements used in the expression defined for `yesexpr`. The locale specified in `LC_CTYPE` determines the locale for interpretation of sequences of bytes of text data a characters, the behavior of character classes used in the expression defined for the `yesexpr`. See [locale\(5\)](#).

Exit Status The following exit values are returned:

- 0 All invocations of *utility* returned exit status 0.
- 1–125 A command line meeting the specified requirements could not be assembled, one or more of the invocations of *utility* returned a non-zero exit status, or some other error occurred.
- 126 The utility specified by *utility* was found but could not be invoked.

127 The utility specified by *utility* could not be found.

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the `xargs` utility writes a diagnostic message and exit without processing any remaining input.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Name xgettext – extract gettext call strings from C programs

Synopsis xgettext [-ns] [-a [-x *exclude-file*]] [-c *comment-tag*]
[-d *default-domain*] [-j] [-m *prefix*] [-M *suffix*]
[-p *pathname*] -l *filename...*

xgettext -h

Description The xgettext utility is used to automate the creation of portable message files (.po). A .po file contains copies of “C” strings that are found in ANSI C source code in *filename* or the standard input if ‘-’ is specified on the command line. The .po file can be used as input to the [msgfmt\(1\)](#) utility, which produces a binary form of the message file that can be used by application during run-time.

xgettext writes *msgid* strings from [gettext\(3C\)](#) calls in *filename* to the default output file *messages.po*. The default output file name can be changed by -d option. *msgid* strings in [dgettext\(\)](#) calls are written to the output file *domainname.po* where *domainname* is the first parameter to the [dgettext\(\)](#) call.

By default, xgettext creates a .po file in the current working directory, and each entry is in the same order that the strings are extracted from *filenames*. When the -p option is specified, the .po file is created in the *pathname* directory. An existing .po file is overwritten.

Duplicate *msgids* are written to the .po file as comment lines. When the -s option is specified, the .po is sorted by the *msgid* string, and all duplicated *msgids* are removed. All *msgstr* directives in the .po file are empty unless the -m option is used.

Options The following options are supported:

- n Add comment lines to the output file indicating file name and line number in the source file where each extracted string is encountered. These lines appear before each *msgid* in the following format:

```
# # File: filename, line: line-number
```
- s Generate output sorted by *msgids* with all duplicate *msgids* removed.
- a Extract all strings, not just those found in [gettext\(3C\)](#), and [dgettext\(\)](#) calls. Only one .po file is created.
- c *comment-tag* The comment block beginning with *comment-tag* as the first token of the comment block is added to the output .po file as # delimited comments. For multiple domains, xgettext directs comments and messages to the prevailing text domain.
- d *default-domain* Rename default output file from *messages.po* to *default-domain.po*.
- j Join messages with existing message files. If a .po file does not exist, it is created. If a .po file does exist, new messages are appended. Any duplicate *msgids* are commented out in the resulting .po file. Domain

- directives in the existing .po file are ignored. Results not guaranteed if the existing message file has been edited.
- m *prefix* Fill in the *msgstr* with *prefix*. This is useful for debugging purposes. To make *msgstr* identical to *msgid*, use an empty string ("") for *prefix*.
 - M *suffix* Fill in the *msgstr* with *suffix*. This is useful for debugging purposes.
 - p *pathname* Specify the directory where the output files will be placed. This option overrides the current working directory.
 - x *exclude-file* Specify a .po file that contains a list of *msgid*s that are not to be extracted from the input files. The format of *exclude-file* is identical to the .po file. However, only the *msgid* directive line in *exclude-file* is used. All other lines are simply ignored. The -x option can only be used with the -a option.
 - h Print a help message on the standard output.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	text/locale

See Also [msgfmt\(1\)](#), [gettext\(3C\)](#), [attributes\(5\)](#)

Notes `xgettext` is not able to extract cast strings, for example ANSI C casts of literal strings to `(const char *)`. This is unnecessary anyway, since the prototypes in `<libintl.h>` already specify this type.

In messages and translation notes, lines greater than 2048 characters are truncated to 2048 characters and a warning message is printed to `stderr`.

Name xstr – extract strings from C programs to implement shared strings

Synopsis xstr -c *filename* [-v] [-l *array*]
xstr [-l *array*]
xstr *filename* [-v] [-l *array*]

Description xstr maintains a file called `strings` into which strings in component parts of a large program are hashed. These strings are replaced with references to this common area. This serves to implement shared constant strings, which are most useful if they are also read-only.

The command:

```
example% xstr -c filename
```

extracts the strings from the C source in *name*, replacing string references by expressions of the form `&xstr[number]` for some *number*. An appropriate declaration of `xstr` is prepended to the file. The resulting C text is placed in the file `x.c`, to then be compiled. The strings from this file are placed in the `strings` data base if they are not there already. Repeated strings and strings which are suffixes of existing strings do not cause changes to the data base.

After all components of a large program have been compiled, a file declaring the common `xstr` space called `xs.c` can be created by a command of the form:

```
example% xstr
```

This `xs.c` file should then be compiled and loaded with the rest of the program. If possible, the array can be made read-only (shared) saving space and swap overhead.

`xstr` can also be used on a single file. A command:

```
example% xstr filename
```

creates files `x.c` and `xs.c` as before, without using or affecting any `strings` file in the same directory.

It may be useful to run `xstr` after the C preprocessor if any macro definitions yield strings or if there is conditional code which contains strings which may not, in fact, be needed. `xstr` reads from the standard input when the argument `'-'` is given. An appropriate command sequence for running `xstr` after the C preprocessor is:

```
example% cc -E name.c | xstr -c -  
example% cc -c x.c  
example% mv x.o name.o
```

`xstr` does not touch the file `strings` unless new items are added; thus `make(1S)` can avoid remaking `xs.o` unless truly necessary.

- Options**
- `-c filename` Take C source text from *filename*.
 - `-v` Verbose: display a progress report indicating where new or duplicate strings were found.
 - `-l array` Specify the named *array* in program references to abstracted strings. The default array name is `xstr`.
- Files**
- `strings` data base of strings
 - `x.c` massaged C source
 - `xs.c` C source for definition of array `"xstr*(rq`
 - `/tmp/xs*` temp file when `xstr filename` doesn't touch `strings`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [make\(1S\)](#), [attributes\(5\)](#)

Bugs If a string is a suffix of another string in the data base, but the shorter string is seen first by `xstr` both strings will be placed in the data base, when just placing the longer one there would do.

Notes Be aware that `xstr` indiscriminately replaces all strings with expressions of the form `&xstr[number]` regardless of the way the original C code might have used the string. For example, you will encounter a problem with code that uses `sizeof()` to determine the length of a literal string because `xstr` will replace the literal string with a pointer that most likely will have a different size than the string's.

To circumvent this problem:

- use `strlen()` instead of `sizeof()`; note that `sizeof()` returns the size of the array (including the null byte at the end), whereas `strlen()` doesn't count the null byte. The equivalent of `sizeof("xxx")` really is `(strlen("xxx")+1)`.
- use `#define` for operands of `sizeof()` and use the define'd version. `xstr` ignores `#define` statements. Make sure you run `xstr` on *filename* before you run it on the preprocessor.

You will also encounter a problem when declaring an initialized character array of the form

```
char x[] = "xxx";
```

`xstr` will replace `xxx` with an expression of the form `&xstr[number]` which will not compile. To circumvent this problem, use `static char *x = "xxx"` instead of `static char x[] = "xxx"`.

Name yacc – yet another compiler-compiler

Synopsis yacc [-dltVv] [-b *file_prefix*] [-Q [y | n]]
[-P *parser*] [-p *sym_prefix*] *file*

Description The yacc command converts a context-free grammar into a set of tables for a simple automaton that executes an LALR(1) parsing algorithm. The grammar can be ambiguous. Specified precedence rules are used to break ambiguities.

The output file, *y.tab.c*, must be compiled by the C compiler to produce a function `yyparse()`. This program must be loaded with the lexical analyzer program, `yyllex()`, as well as `main()` and `yyerror()`, an error handling routine. These routines must be supplied by the user. The `lex(1)` command is useful for creating lexical analyzers usable by yacc.

Options The following options are supported:

- b *file_prefix* Uses *file_prefix* instead of *y* as the prefix for all output files. The code file *y.tab.c*, the header file *y.tab.h* (created when `-d` is specified), and the description file *y.output* (created when `-v` is specified), is changed to *file_prefix.tab.c*, *file_prefix.tab.h*, and *file_prefix.output*, respectively.
- d Generates the file *y.tab.h* with the `#define` statements that associate the yacc user-assigned “token codes” with the user-declared “token names”. This association allows source files other than *y.tab.c* to access the token codes.
- l Specifies that the code produced in *y.tab.c* does not contain any `#line` constructs. This option should only be used after the grammar and the associated actions are fully debugged.
- p *sym_prefix* Uses *sym_prefix* instead of *yy* as the prefix for all external names produced by yacc. The names affected include the functions `yyparse()`, `yyllex()` and `yyerror()`, and the variables *yylval*, *yychar* and *yydebug*. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names can also be affected by the `-p` option. However, the `-p` option does not affect `#define` symbols generated by yacc.
- P *parser* Allows you to specify the parser of your choice instead of `/usr/share/lib/ccs/yaccpar`. For example, you can specify:

```
example% yacc -P ~/myparser parser.y
```
- Q[y|n] The `-Qy` option puts the version stamping information in *y.tab.c*. This allows you to know what version of yacc built the file. The `-Qn` option (the default) writes no version information.
- t Compiles runtime debugging code by default. Runtime debugging code is always generated in *y.tab.c* under conditional compilation control. By default, this code is not included when *y.tab.c* is compiled. Whether or not

the `-t` option is used, the runtime debugging code is under the control of `YYDEBUG`, a preprocessor symbol. If `YYDEBUG` has a non-zero value, then the debugging code is included. If its value is `0`, then the code is not included. The size and execution time of a program produced without the runtime debugging code is smaller and slightly faster.

- `-v` Prepares the file `y.output`, which contains a description of the parsing tables and a report on conflicts generated by ambiguities in the grammar.
- `-V` Prints on the standard error output the version information for `yacc`.

Operands The following operand is required:

file A path name of a file containing instructions for which a parser is to be created.

Examples **EXAMPLE 1** Accessing the `yacc` Library

Access to the `yacc` library is obtained with library search operands to `cc`. To use the `yacc` library `main`:

```
example% cc y.tab.c -ly
```

Both the `lex` library and the `yacc` library contain `main`. To access the `yacc` `main`:

```
example% cc y.tab.c lex.yy.c -ly -ll
```

This ensures that the `yacc` library is searched first, so that its `main` is used.

The historical `yacc` libraries have contained two simple functions that are normally coded by the application programmer. These library functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
    extern int yyparse();

    setlocale(LC_ALL, "");

    /* If the following parser is one created by lex, the
       application must be careful to ensure that LC_CTYPE
       and LC_COLLATE are set to the POSIX locale. */
    (void) yyparse();
    return (0);
}

#include <stdio.h>

int yyerror(const char *msg)
{
    (void) fprintf(stderr, "%s\n", msg);
}
```

EXAMPLE 1 Accessing the yacc Library *(Continued)*

```

        return (0);
    }

```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of yacc: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

yacc can handle characters from EUC primary and supplementary codesets as one-token symbols. EUC codes can only be single character quoted terminal symbols. yacc expects `yylex()` to return a wide character (`wchar_t`) value for these one-token symbols.

Exit Status The following exit values are returned:

0 Successful completion.
 >0 An error occurred.

Files

<code>y.output</code>	state transitions of the generated parser
<code>y.tab.c</code>	source code of the generated parser
<code>y.tab.h</code>	header file for the generated parser
<code>yacc.act.s</code>	temporary file
<code>yacc.debug</code>	temporary file
<code>yacc.tmp</code>	temporary file
<code>yaccpar</code>	parser prototype for C programs

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	developer/base-developer-utilities
Interface Stability	Committed
Standard	See standards(5) .

See Also [lex\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output. A more detailed report is found in the `y.output` file. Similarly, if some rules are not reachable from the start symbol, this instance is also reported.

Notes Because file names are fixed, at most one yacc process can be active in a given directory at a given time.

Users are encouraged to avoid using \$ as part of any identifier name.

Name yes – generate repetitive affirmative output

Synopsis yes [*term*]. . .

Description The yes utility repeatedly outputs *y*, or if *term* is specified, *term* is output repeatedly. In the output, either *y* or *term* is followed by a NEWLINE. Multiple arguments are output separated by spaces and followed by a NEWLINE. To terminate yes, issue an interrupt character.

yes can be used to respond programatically to programs that require an interactive response.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also [attributes\(5\)](#)

Name ypcat – print values in a NIS database

Synopsis ypcat [-kx] [-d *ypdomain*] *mname*

Description The ypcat command prints out values in the NIS name service map specified by *mname*, which may be either a map name or a map nickname. Since ypcat uses the NIS network services, no NIS server is specified.

Refer to [ypfiles\(4\)](#) for an overview of the NIS name service.

Options

- k Display the keys for those maps in which the values are null or the key is not part of the value. None of the maps derived from files that have an ASCII version in /etc fall into this class.
- d *ypdomain* Specify a domain other than the default domain.
- x Display map nicknames.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also [ypmatch\(1\)](#), [ypfiles\(4\)](#), [attributes\(5\)](#)

Name ypmatch – print the value of one or more keys from a NIS map

Synopsis ypmatch [-k] [-t] [-d *domain*] *key* [*key*]... *mname*
ypmatch -x

Description ypmatch prints the values associated with one or more keys from the NIS's name services map specified by *mname*, which may be either a map name or a map nickname.

Multiple keys can be specified; all keys will be searched for in the same map. The keys must be the same case and length. No pattern matching is available. If a key is not matched, a diagnostic message is produced.

Options The following options are supported:

- k Before printing the value of a key, print the key itself, followed by a colon (:).
- t Inhibit map nickname translation.
- d *domain* Specify a domain other than the default domain.
- x Display the map nickname table. This lists the nicknames the command knows of, and indicates the map name associated with each nickname.

Operands The following operand is supported:

mname The NIS's name services map

Exit Status The following exit values are returned:

- 0 Successful operation.
- 1 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also [ypcat\(1\)](#), [ypfiles\(4\)](#), [attributes\(5\)](#)

Notes ypmatch will fail with an RPC error message on yp operation if enough file descriptors are not available. The number of file descriptors should be increased if this occurs.

Name yppasswd – change your network password in the NIS database

Synopsis yppasswd [*username*]

Description The yppasswd utility changes the network password associated with the user *username* in the Network Information Service (NIS) database. If the user has done a [keylogin\(1\)](#), and a publickey/secretkey pair exists for the user in the NIS `publickey.byname` map, yppasswd also re-encrypts the secretkey with the new password. The NIS password may be different from the local one on your own machine.

yppasswd prompts for the old NIS password, and then for the new one. You must type in the old password correctly for the change to take effect. The new password must be typed twice, to forestall mistakes.

New passwords must be at least four characters long, if they use a sufficiently rich alphabet, and at least six characters long if monospace. These rules are relaxed if you are insistent enough. Only the owner of the name or the super-user may change a password; superuser on the root master will not be prompted for the old password, and does not need to follow password construction requirements.

The NIS password daemon, `rpc.yppasswdd` must be running on your NIS server in order for the new password to take effect.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also [keylogin\(1\)](#), [login\(1\)](#), [passwd\(1\)](#), [getpwnam\(3C\)](#), [getspnam\(3C\)](#), [secure_rpc\(3NSL\)](#), [nsswitch.conf\(4\)](#), [attributes\(5\)](#)

Warnings Even after the user has successfully changed his or her password using this command, the subsequent [login\(1\)](#) using the new password will be successful only if the user's password and shadow information is obtained from NIS. See [getpwnam\(3C\)](#), [getspnam\(3C\)](#), and [nsswitch.conf\(4\)](#).

Notes The use of yppasswd is discouraged, as it is now only a wrapper around the [passwd\(1\)](#) command, which should be used instead. Using [passwd\(1\)](#) with the `-r nis` option will achieve the same results, and will be consistent across all the different name services available.

Bugs The update protocol passes all the information to the server in one RPC call, without ever looking at it. Thus, if you type your old password incorrectly, you will not be notified until after you have entered your new password.

Name ypwhich – return name of NIS server or map master

Synopsis ypwhich [-d *domain*] [[-t] -m [*mname*] | [-Vn] *hostname*]
ypwhich -x

Description ypwhich returns the name of the NIS server that supplies the NIS name services to a NIS client, or which is the master for a map. If invoked without arguments, it gives the NIS server for the local machine. If *hostname* is specified, that machine is queried to find out which NIS master it is using.

Refer to [ypfiles\(4\)](#) for an overview of the NIS name services.

Options

- d *domain* Use *domain* instead of the default domain.
- t This option inhibits map nickname translation.
- m *mname* Find the master NIS server for a map. No *hostname* can be specified with -m. *mname* can be a mapname, or a nickname for a map. When *mname* is omitted, produce a list of available maps.
- x Display the map nickname translation table.
- Vn Version of ypbind, V3 is default.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also [ypfiles\(4\)](#), [attributes\(5\)](#)

Name zlogin – enter a zone

Synopsis zlogin [-dCE] [-e c] [-l username] zonename

zlogin [-ES] [-e c] [-l username] zonename utility
[argument]...

Description The zlogin utility is used to enter an operating system zone. Only a user operating in the global system zone can use this utility, and it must be executed with all privileges. In addition, the user must be authorized to use specific options described in the OPTIONS section.

zlogin checks for authorization strings which optionally include the specified zonename as a suffix, preceded by the slash character. When omitted, the authorization matches any zone.

zlogin operates in one of three modes:

Interactive Mode If no utility argument is given and the stdin file descriptor for the zlogin process is a tty device, zlogin operates in *interactive mode*. In this mode, zlogin creates a new pseudo terminal for use within the login session. Programs requiring a tty device, for example, vi(1), work properly in this mode. In this mode, zlogin invokes login(1) to provide a suitable login session.

Non-Interactive Mode If a utility is specified, zlogin operates in *non-interactive mode*. This mode can be useful for script authors since stdin, stdout, and stderr are preserved and the exit status of utility is returned upon termination. In this mode, zlogin invokes su(1M) in order to set up the user's environment and to provide a login environment.

The specified command is passed as a string and interpreted by a shell running in the non-global zone. See rsh(1).

Console Mode If the -C option is specified, the user is connected to the zone console device and zlogin operates in *console mode*. The zone console is available once the zone is in the installed state. Connections to the console are persistent across reboot of the zone.

Options The following options are supported:

- C Connects to the zone console. Access to the zone console requires the authorization zone.manage/zonename.
- d If the zone halts, disconnect from the console. This option can only be specified along with -C.
- e c Specifies a different escape character, c, for the key sequence used to access extended functions and to disconnect from the login. The default escape character is the tilde (~).

- E Disables the ability to access extended functions or to disconnect from the login by using the escape sequence character.
- l *username* Specifies a different *username* for the zone login. If you do not use this option, the zone username used is root. This option is invalid if the -C option is specified.

The username must be valid in the zone. For interactive logins the authorization `solaris.zone.login/zonename` is required, and password authentication takes place in the zone. For non-interactive logins, or to bypass password authentication, the authorization `solaris.zone.manage/zonename` is required.
- S Safe login mode. `zlogin` does minimal processing and does not invoke `login(1)` or `su(1M)`. The zone username is set to root. The -S option cannot be used if a username is specified through the -l option, and cannot be used with console logins. This mode should only be used to recover a damaged zone when other forms of login have become impossible.

Use of this option requires the authorization `solaris.zone.manage/zonename`.

Escape Sequences Lines that you type that start with the tilde character (~) are “escape sequences”. The escape character can be changed using the -e option.

- ~. Disconnects from the zone. This is not the same as a logout, because the local host breaks the connection with no warning to the zone's end.

Security Once a process has been placed in a zone other than the global zone, the process cannot change zone again, nor can any of its children.

Operands The following operands are supported:

- zonename* The name of the zone to be entered.
- utility* The utility to be run in the specified zone.
- argument...* Arguments passed to the utility.

Exit Status In interactive and non-interactive modes, the `zlogin` utility exits when the command or shell in the non-global zone exits. In non-interactive mode, the exit status of the remote program is returned as the exit status of `zlogin`. In interactive mode and console login mode, the exit status is not returned. `zlogin` returns a 0 exit status as long as no connection-related error occurred.

In all modes, in the event that a connection to the zone cannot be established, the connection fails unexpectedly, or the user is lacking sufficient privilege to perform the requested operation, `zlogin` exits with status 1.

To summarize, the following exit values are returned:

- 0 Successful entry.
- 1 Permission denied, or failure to enter the zone.
- Any Return code from utility, or from [su\(1M\)](#) if operating in non-interactive mode.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	Committed

See Also [login\(1\)](#), [rsh\(1\)](#), [vi\(1\)](#), [su\(1M\)](#), [zoneadm\(1M\)](#), [zonecfg\(1M\)](#), [attributes\(5\)](#), [zones\(5\)](#)

Notes `zlogin` fails if its open files or any portion of its address space corresponds to an NFS file. This includes the executable itself or the shared libraries.

Name zonename – print name of current zone

Synopsis zonename

Description The zonename utility prints the name of the current zone.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also [zlogin\(1\)](#), [zoneadm\(1M\)](#), [zonecfg\(1M\)](#), [attributes\(5\)](#), [zones\(5\)](#)

Name zonestat – report active zone statistics

Synopsis zonestat [-z *zonelist*] [-r *reslist*] [-n *namelist*] [-T u | d | i]
[-R *reports*] [-q] [-x] [-p [-P *lines*]]
[-S *cols*] *interval* [*duration* [*report*]]

Description The zonestat utility reports on the cpu, memory, networking, and resource control utilization of the currently running zones. Each zone's utilization is reported both as a percentage of system resources and the zone's configured limits.

The zonestat utility prints a series of interval reports at the specified interval. It optionally also prints one or more summary reports at a specified interval.

The default output is a summary of cpu, physical, and virtual memory, and networking utilization. The -r option can be used to choose detailed output for specific resources.

Security When run from within a non-global zone (NGZ), only processor sets visible to the NGZ are reported. The NGZ output includes all of other system resources, such as memory and limits.

For all reported resources, the NGZ's usage is output. Usage of each resource by the system, global zone, and all other zones, is reported as used by [system].

For networking resources, only NGZ's usage is output. NGZs do not have visibility to other zones' networking resources and statistics.

proc_info privilege is required to use the zonestat utility. This privilege is a member of the basic privilege set.

Options The following options are supported:

-n *name*[,*name*]

Specify a list resource names on which to report. For pset resources, this is the name of the processor set. For physical-memory, locked-memory, and virtual-memory resources, the only names are mem_default and vm_default. For network resources, this is name of a datalink.

Dedicated-cpu processor sets can be specified by their pset name (SUNWtmp_zonename or by just their zonename.

Processor sets created by psrset can be specified by their pool pset name (SUNWlegacy_pset id), or just by their pset id.

In addition to a comma-separated list, multiple -n options can be specified to report on a set of resources.

-p

Parseable output.

Print output in stable, machine--parseable format. Individual fields are delimited with a colon (:). The line format is:

report type:resource:field[:field]*

If -T is specified each line is prefixed with a timestamp:

The report types are: report-total, report-average, report-high, and interval,

The resource types are: header, footer, summary, physical-memory, virtual-memory, locked-memory, processor-set, processes, lwps, sysv-shared-memory, sysv-shmids, sysv-semids, sysv-msgids, lofi, network.

The header resource is a special resource used to state the beginning of an interval or summary report. All output lines between header resources belong to the same report. Each header has a matching footer.

The remaining fields are resource type specific. See the zonestat utility output for details.

All existing output fields are stable. Future versions might introduce new report and resource types. Future versions might also add additional new fields to the end of existing output n lines.

-P *line*[:*line*]

For parseable output, specify lines to output in parseable output. One or more of the following line types can be chosen:

header, footer	For each interval, and summary report has a header, which prints details such as the interval and count information. After each report, and footer is also printed
resource	The lines describing each resource.
system	The utilization of each resource by the system. This includes the kernel, and any resource consumption not contributed to a specific zone. When zonestat is run from within a non-global-zone, this value is the aggregate resource consumed by the system and all other zones. system utilization for network resource type is not supported.
total	The total utilization of each resource.
zones	Lines detailing the per-zone utilization of each resource.

-q

Quiet mode. Only print summary reports (requires the -R option). All interval reports are omitted.

-r *resource*[:*resource*]

Specify resource types on which to report. The available resources are: physical-memory, virtual-memory, locked-memory, processor-set, processes, shm-memory, shm-ids, sem-ids, msg-ids, lofi, and network.

summary A summary of cpu, physical-memory, virtual memory, and network usage.

memory	physical-memory, virtual-memory, and locked-memory.
psets	processor-set
default-pset	The default pset only.
limits	processes, lwps, lofi.
network	network datalinks.
sysv	shm-memory, shm-ids, sem-ids msg-ids.
all	All resource types.

By default the summary resource is printed.

In addition to a comma-separated list, multiple `-r` options can be specified to report on a set of resources types.

The system's cpus can be partitioned into processor sets (psets). By default, all cpus are in a single pset named `pset_default`.

Memory is not partition-able into sets. The `zonestat` utility output for these resources shows them as named `mem_default` and `vm_default`.

The `all` resource specifies that all resource types should be reported.

`-R report[,report]`

Print a summary report. The supported report types are described below. In addition to a comma-separated list, multiple `-R` options can be specified for a set of summary reports.

total	Prints a summary report detailing the following for each resource:
psets	Total cpu used since start of command invocation. The percent used for each zone includes time that a zone was not running. For instance, if a zone used 100% of the cpu while it was running, but the zone was halted for half of the intervals, then the summary report shows the zone used 50% of the cpu time.
memory, limits, sysv	Average resource used of all intervals reported since command invocation. This average factors in intervals in which a zone was not running. For example if a zone used on average of 100M of physical memory while it was running, and was only running for half the intervals, then the summary report shows that the zone used 50M of physical memory on average.

	network	Sum of all bytes that are transmitted and received by all datalink utilizing physical bandwidth. The sum is calculated since start of command invocation and is normalized to number of bytes per second. The percentage used is based on total available bandwidth.
average		Similar to total, but only intervals in which a zone is running are factored in. For example, if a zone was only running for a single interval, and during that interval, the zone used 200M of virtual memory, then it's average virtual-memory is 200M, regardless of the number of intervals reported before the summary report.
high		Print a summary report detailing the highest usage of each resource and zone during any interval of the zones at utility invocation.
-S col[,col]		
Sort zones utilizing each resource.		
The following sorting columns can be specified:		
name		Sort alpha-numerically by zone name.
used		Sort by quantity of resource used. For networking resource, this is same as sort by bytes.
		This is the default.
cap		Sort by configured cap.
pcap		Sort by percent of cap used.
shr		Sort by allocated share.
pshru		Sort by percent of share used.
bytes		Sort networking by total bytes transmitted and received.
prbyte		Sort networking by percentage of received bytes over the wire.
pobyte		Sort networking by percentage of transmitted bytes over the wire.
maxbw		Sort networking by percentage of bandwidth used.
	cpu	Sort by cpu usage in the summary, This is the default.
	physical-memory	Sort by physical memory usage in the summary.
	virtual-memory	Sort by virtual memory usage in the summary.
	network	Sort by network usage in the summary.
network		Sort by network usage in the summary.

-T u | d | i

Include timestamp of each report. The following formats are supported:

d Standard date format. See [date\(1\)](#). This option is not valid with `--p`.

i Time formatted as the ISO 8601 compliant format:

YYYYMMDDThhmmssZ

u A printed representation of the internal representation of time. See [time\(2\)](#). This is also known as `unix` time.

-x

Display an extended view with more detailed information. For example, when used with network resource, the extended view list details of each virtual datalink.

-z zonename[,zonename]

Specify a list of zones on which to report. By default all zones are reported.

In addition to a comma-separated list, multiple `-z` options can be specified to report on a set of zones. The output includes any resources which have usage by the specified zones.

Operands The following operands are supported:

interval

Specifies the length in seconds to pause between each interval report. An interval of default uses the configured interval of the zones monitoring service. See [zonestatd\(1M\)](#).

interval is required. An *interval* of zero is not permitted. *interval* can be specified as `[nh][nm][ns]`, such as `10s` or `1m`.

duration

Specifies the number of intervals to report. Defaults to infinity if not specified. The command duration is (*interval* * *duration*). A *duration* of zero is invalid. A value of `inf` can also be specified to explicitly choose infinity.

Duration can also be specified as `[nh][nm][ns]`. In this case, *duration* is interpreted as the duration of execution time. The actual *duration* is rounded up to the nearest multiple of the interval.

report

Specify the summary report period. For instance, a report of 4 produces reports every 4 intervals. If the command duration is not a multiple of report, then the last report is of any remaining intervals.

report can also be specified as `[nh][nm][ns]`. In this case, reports are output at the specified time period, rounded up to the nearest interval. If the command *duration* is not a multiple of report, then the last report is of any remaining intervals.

Requires `-R`. If `-R` is specified and *report* is not, the report period is the entire command duration, producing the specified reports at the end of execution.

Output The following list defines the column heading of the command output:

SYSTEM-MEMORY

The total amount of memory available on the physical host.

SYSTEM-LIMIT

The maximum amount of resource available on the physical host.

CPUS

The number of cpus allocated to a processor set

ONLINE

Of the cpus allocated to a processor set, the number of cpus which can execute processes.

MIN/MAX

The minimum and maximum number of cpus which can be allocated to the processor set by the system.

ZONE

The zone using the resource. In addition to zone names, this column can also contain:

[total] The total quantity of resource used system-wide.

[system] The quantity of resource used by the kernel or in a manner not associated with any particular zone.

When `zonestat` is used within a non-global zone, [system] designates the aggregate resource used by the system and by all other zones.

For network resources, system usage of network is not available.

USED

The amount of resource used.

%USED

The amount of resource used as a percent of the total resource.

PCT

The amount of resource used as a percent of the total resource.

%PART

The amount of cpu used as a percentage of the total cpu in a processor-set to which the zone is bound. A zone can only have processes bound to multiple processor sets if it is the global zone, or if `psrset(1M)` psets are used. If multiple binding are found for a zone, it's %PART is the fraction used of all bound psets. For [total] and [system], %PART is the percent used of all cpus on the system.

CAP

If a zone is configured to have a cap on the given resource, the cap is displayed in this column.

%CAP

The amount of resource used as a percent of zone's configured cap.

SHRS

The number of shares allocated to the zone. For the [total] row, this is the total number of shares allocated to all zones sharing the resource. If a zone is not configured to use shares, and is sharing a resource with other zones that are configured to use shares, this column contains no - fss for the zone.

%SHRS

The fraction of the total shares allocated to the zone. For instance, if 2 zones share a processor set, each with 10 shares, then each zone has a %SHR of 50%.

%SHRU

Of the share allocated to the zone, the fraction of resource 100%. Because shares are only enforced when there is resource contention, it is possible for a zone to have a %SHRU in excess of 100%.

TOBYTES

The number of bytes transmitted and received by datalinks or virtual links.

PRBYTE

The number of received bytes that consumes physical bandwidth.

POBYTE

The number of transmitted bytes that consumes physical bandwidth.

%PRBYE

The percentage of available physical bandwidth used to receive PRBYTE.

%POBYE

The percentage of available physical bandwidth used to transmit POBYTE.

%PUSE

The sum of PRBYTE and POBYTE as a percent of the total available physical bandwidth.

LINK

The name of a datalink.

MAXBW

The maximum bandwidth configured on a datalink.

%MAXBW

The sum of all transmitted and received bytes as a percentage of configured maximum bandwidth.

Examples EXAMPLE 1 Using zonestat to Display a Summary of cpu and Memory Utilization

The following command shows a summary of cpu and memory utilization every 5 seconds:

```
# zonestat 5 1
SUMMARY Cpus/Online: 4/4 Physical: 8063M Virtual: 11.8G
```

EXAMPLE 1 Using zonestat to Display a Summary of cpu and Memory Utilization *(Continued)*

```

          ---CPU---  --PHYSMEM--  ---VMEM---  ---NET---
ZONE  USED %PART  USED %USED  USED %USED  PBYTE %PUSE
[total] 0.23 5.76% 3211M 39.8% 4191M 34.6% 350M 18.7%  -
[system] 0.03 0.83% 2791M 34.6% 3890M 32.1%  -  -
global 0.19 4.86% 324M 4.01% 228M 1.89% 200M 10.7%
zoneA 0.00 0.03% 47.9M 0.59% 36.3M 0.30% 100M 5.3%
zoneB 0.00 0.02% 48.1M 0.59% 36.4M 0.30% 50M 2.7%
```

EXAMPLE 2 Using zonestat to Produce Parseable Output

The following command produces parseable output. It prints one line per zone using each pset resource for a 5 second interval:

```
# zonestat -p -P zones -r psets 5 1
```

EXAMPLE 3 Using zonestat to Report on the Default pset

The following command reports on the default pset once a second for one minute:

```
# zonestat -r default-pset 1 1m
```

EXAMPLE 4 Using zonestat to Report Total and High Utilization

The following command monitors silently at a 10 second interval for 24 hours, producing a total and high report every 1 hour:

```
# zonestat -q -R total,high 10s 24h 1h
```

EXAMPLE 5 Using zonestat to Report Datalink Utilization

The following command reports on a datalink named e1000g0 at a 5 second interval for 5 times:

```
# zonestat -r network -n e1000g0 5 5
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid usage.
- 3 svc:system/zones_monitoring: default not running or not responding.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	See below.

Command invocation and parseable output is Committed. Human readable output (default output) is Uncommitted.

See Also [date\(1\)](#), [prctl\(1\)](#), [pooladm\(1M\)](#), [poolcfg\(1M\)](#), [psrset\(1M\)](#), [rcapadm\(1M\)](#), [zoneadm\(1M\)](#), [zonecfg\(1M\)](#), [zonestatd\(1M\)](#), [time\(2\)](#), [timezone\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#), [resource_controls\(5\)](#)

Notes The `zonestat` utility depends on the zones monitoring service: `svc/system/zonestat:default`. If the `zonestat` service is stopped while the `zonestat` utility is running, the `zonestat` command invocation quits without printing additional reports. The reports (-R) is printed if `zonestat` is interrupted (by CTRL/c, SIGINT) before reaching the next report period.
