# **Using This Documentation**

- Overview Provides information on memory thread placement and optimization techniques for developers.
  - It covers on locality groups and the technologies that are available to optimize the use of computing resources in the Oracle Solaris operating system.
- **Audience** For system administrators, performance engineers, systems programmers, and support engineers, and developers who are writing applications in an environment with multiple CPUs and a non-uniform memory architecture. The programming interfaces and tools that are described in this book give the developer control over the system's behavior and resource allocation.
- Required knowledge Readers of this guide should have advanced knowledge of Oracle Solaris operating system.

#### **Product Documentation Library**

Documentation and resources for this product and related products are available at http://www.oracle.com/pls/topic/lookup?ctx=E53394-01.

#### **Feedback**

Provide feedback about this documentation at http://www.oracle.com/goto/docfeedback.

8

# · · · CHAPTER 1

## Overview of Locality Groups

This chapter covers the following topics:

- "Locality Groups Overview" on page 9
- "MPO Observability Tools" on page 12

#### **Locality Groups Overview**

Shared memory multiprocessor computers contain multiple CPUs. Each CPU can access all of the memory in the system. In some shared memory multiprocessors, the memory architecture enables each CPU to access some areas of memory more quickly than other areas.

When a system with such a memory architecture runs the Oracle Solaris software, providing information to the kernel about the shortest access times between a given CPU and a given area of memory can improve the system's performance. The locality group (lgroup) abstraction has been introduced to handle this information. The lgroup abstraction is part of the Memory Placement Optimization (MPO) feature.

An Igroup is a set of CPU-like and memory-like devices in which each CPU in the set can access any memory in that set within a bounded latency interval. The value of the latency interval represents the least common latency between all the CPUs and all the memory in that Igroup. The latency bound that defines an Igroup does not restrict the maximum latency between members of that Igroup. The value of the latency bound is the shortest latency that is common to all possible CPU-memory pairs in the group.

Lgroups are hierarchical. The lgroup hierarchy is a Directed Acyclic Graph (DAG) and is similar to a tree, except that an lgroup might have more than one parent. The root lgroup contains all the resources in the system and can include child lgroups. Furthermore, the root lgroup can be characterized as having the highest latency value of all the lgroups in the system. All of its child lgroups will have lower latency values. The lgroups closer to the root have a higher latency while lgroups closer to leaves have lower latency.

A computer in which all the CPUs can access all the memory in the same amount of time can be represented with a single Igroup (see Figure 1, "Single Locality Group Schematic," on page

10). A computer in which some of the CPUs can access some areas of memory in a shorter time than other areas can be represented by using multiple lgroups (see Figure 2, "Multiple Locality Groups Schematic," on page 11).

FIGURE 1 Single Locality Group Schematic

# Machine with single latency is represented by one Igroup

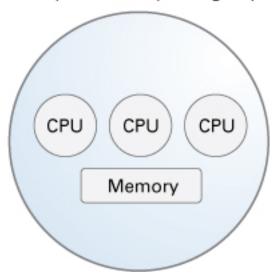

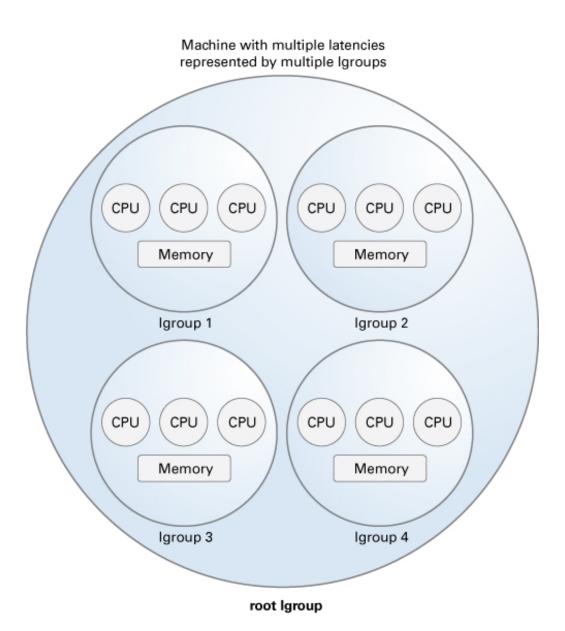

FIGURE 2 Multiple Locality Groups Schematic

The organization of the Igroup hierarchy simplifies the task of finding the nearest resources in the system. Each thread is assigned a home Igroup upon creation. The operating system attempts to allocate resources for the thread from the thread's home Igroup by default. For example, the Oracle Solaris kernel attempts to schedule a thread to run on the CPUs in the thread's home Igroup and allocate the thread's memory in the thread's home Igroup by default. If the desired resources are not available from the thread's home Igroup, the kernel can traverse the Igroup hierarchy to find the next nearest resources from parents of the home Igroup. If the desired resources are not available in the home Igroup's parents, the kernel continues to traverse the Igroup hierarchy to the successive ancestor Igroups of the home Igroup. The root Igroup is the ultimate ancestor of all other Igroups in a system and contains all of the system's resources.

The Memory Placement Optimization (MPO) tools enable developers to tune the performance of the MPO features in cases where the default MPO behaviors do not yield the desired performance.

The Igroup APIs export the Igroup abstraction for applications to use for observability and performance tuning. A new library, called liblgrp, contains the new APIs. Applications can use the APIs to perform the following tasks:

- Traverse the group hierarchy
- Discover the contents and characteristics of a given lgroup
- Affect the thread and memory placement on Igroups

#### **MPO Observability Tools**

The MPO tools help developers to answer questions about system configuration and balance or placement. The tools also provide the basic information and mechanisms that developers need in order to determine whether MPO is successful and to diagnose problems related to MPO.

To determine the degree of success that MPO has in providing useful locality assignments and acceptable performance, it is important to know a given thread's affinities for Igroups, including its home Igroup, and where the thread's memory is allocated.

The MPO observability tools provide developers with the ability to determine the actions taken by the system. The MPO thread and memory placement tools enable developers to act on that information. Developers can also use the <a href="https://document.org/drugs/dt/41/2">dtrace(1M)</a>) tool to gain further insights into the system's behavior.

## MPO Observability Tools

This chapter describes the tools that are available to use the MPO functionality that is available in the Oracle Solaris operating system.

This chapter discusses the following topics:

- "pmadvise Utility" on page 13 describes the tool that applies rules that define the memory use of a process.
- "Using the madv.so.1 Shared Object" on page 15 describes the madv.so.1 shared object and how to use it to configure virtual memory advice.
- "plgrp Tool" on page 17 describes the tool that can display and set a thread's affinity for a locality group.
- "lgrpinfo Tool" on page 19 prints information about the lgroup hierarchy, contents, and characteristics.
- ""Solaris::lgrp" Module" on page 21 describes a Perl interface to the locality group API that is described in Chapter 3, "Locality Group APIs".

#### pmadvise Utility

The pmadvise utility applies rules to a process that define how that process uses memory. The pmadvise utility applies the rules, called *advice*, to the process with the madvise(3C) tool. This tool can apply advice to a specific subrange of locations in memory at a specific time. By contrast, the madv.so.1(1) tool applies the advice throughout the execution of the target program to all segments of a specified type.

The pmadvise utility has the following options:

- -f This option takes control of the target process. This option overrides the control of any other process. See the proc(1) manual page.
- This option specifies the advice to apply to the target process. Specify the advice in this format:

private=advice shared=advice heap=advice stack=advice address:length=advice

The value of the *advice* term can be one of the following:

normal
random
sequential
willneed
dontneed
free
access\_lwp
access\_many
access\_default

You can specify an address and length to specify the subrange where the advice applies. Specify the address in hexadecimal notation and the length in bytes.

If you do not specify the length and the starting address refers to the start of a segment, the pmadvise utility applies the advice to that segment. You can qualify the length by adding the letters K, M, G, T, P, or E to specify kilobytes, megabytes, gigabytes, terabytes, or exabytes, respectively.

This option prints verbose output in the style of the pmap(1) tool that shows the value and locations of the advice rules currently in force.

The pmadvise tool attempts to process all legal options. When the pmadvise tool attempts to process an option that specifies an illegal address range, the tool prints an error message and skips that option. When the pmadvise tool finds a syntax error, it quits without processing any options and prints a usage message.

When the advice for a specific region conflicts with the advice for a more general region, the advice for the more specific region takes precedence. Advice that specifies a particular address range has precedence over advice for the heap and stack regions, and advice for the heap and stack regions has precedence over advice for private and shared memory.

The advice rules in each of the following groups are mutually exclusive from other advice rules within the same group:

MADV\_NORMAL, MADV\_RANDOM, MADV\_SEQUENTIAL
MADV\_WILLNEED, MADV\_DONTNEED, MADV\_FREE
MADV ACCESS DEFAULT, MADV ACCESS LWP, MADV ACCESS MANY

-V

#### Using the madv.so.1 Shared Object

The madv.so.1 shared object enables the selective configuration of virtual memory advice for launched processes and their descendants. To use the shared object, the following string must be present in the environment:

LD\_PRELOAD=\$LD\_PRELOAD:madv.so.1

The madv.so.1 shared object applies memory advice as specified by the value of the MADV environment variable. The MADV environment variable specifies the virtual memory advice to use for all heap, shared memory, and mmap regions in the process address space. This advice is applied to all created processes. The following values of the MADV environment variable affect resource allocation among Igroups:

access_default	This value resets the kernel's expected access pattern to the default.
access_lwp	This value advises the kernel that the next LWP to touch an address range is the LWP that will access that range the most. The kernel allocates the memory and other resources for this range and the LWP accordingly.
access_many	This value advises the kernel that many processes or LWPs will access memory randomly across the system. The kernel allocates the memory and other resources accordingly.

The value of the MADVCFGFILE environment variable is the name of a text file that contains one or more memory advice configuration entries in the form *exec-name:advice-opts*.

The value of *exec-name* is the name of an application or executable. The value of *exec-name* can be a full pathname, a base name, or a pattern string.

The value of *advice-opts* is of the form *region=advice*. The values of *advice* are the same as the values for the MADV environment variable. Replace *region* with any of the following legal values:

madv	Advice applies to all heap, shared memory, and mmap(2) regions in the process address space.
heap	The heap is defined to be the brk(2) area. Advice applies to the existing heap and to any additional heap memory allocated in the future.
shm	Advice applies to shared memory segments. See <a href="https://shmat(2)">shmat(2)</a> for more information on shared memory operations.

ism	Advice applies to shared memory segments that are using the SHM_SHARE_MMU flag. The ism option takes precedence over shm.
dsm	Advice applies to shared memory segments that are using the SHM_PAGEABLE flag. The dsm option takes precedence over shm.
mapshared	Advice applies to mappings established by the ${\tt mmap()}$ system call using the ${\tt MAP\_SHARED}$ flag.
mapprivate	Advice applies to mappings established by the ${\tt mmap()}$ system call using the ${\tt MAP\_PRIVATE}$ flag.
mapanon	Advice applies to mappings established by the mmap() system call using the MAP_ANON flag. The mapanon option takes precedence when multiple options apply.

The value of the MADVERRFILE environment variable is the name of the path where error messages are logged. In the absence of a MADVERRFILE location, the madv.so.1 shared object logs errors by using syslog(3C) with a LOG\_ERR as the severity level and LOG\_USER as the facility descriptor.

Memory advice is inherited. A child process has the same advice as its parent. The advice is set back to the system default advice after a call to <code>exec(2)</code> unless a different level of advice is configured using the <code>madv.so.1</code> shared object. Advice is only applied to <code>mmap()</code> regions explicitly created by the user program. Regions established by the run-time linker or by system libraries that make direct system calls are not affected.

#### madv.so.1 Usage Examples

The following examples illustrate specific aspects of the madv.so.1 shared object.

#### **EXAMPLE 1** Setting Advice for a Set of Applications

This configuration applies advice to all ISM segments for applications with exec() names that begin with foo.

#### **EXAMPLE 2** Excluding a Set of Applications From Advice

This configuration sets advice for all applications with the exception of ls.

#### **EXAMPLE 3** Pattern Matching in a Configuration File

Because the configuration specified in MADVCFGFILE takes precedence over the value set in MADV, specifying \* as the *exec-name* of the last configuration entry is equivalent to setting MADV. This example is equivalent to the previous example.

#### **EXAMPLE 4** Advice for Multiple Regions

This configuration applies one type of advice for mmap() regions and different advice for heap and shared memory regions for applications whose exec() names begin with foo.

#### plgrp Tool

The plgrp utility can display or set the home lgroup and lgroup affinities for one or more processes, threads, or lightweight processes (LWPs). The system assigns a home lgroup to each thread on creation. When the system allocates a CPU or memory resource to a thread, it searches the lgroup hierarchy from the thread's home lgroup for the nearest available resources to the thread's home.

The system chooses a home lgroup for each thread. The thread's affinity for its home lgroup is initially set to none, or no affinity. When a thread sets an affinity for an lgroup in its processor set that is higher than the thread's affinity for its home lgroup, the system moves the thread to that lgroup. The system does not move threads that are bound to a CPU. The system rehomes a thread to the lgroup in its processor set that has the highest affinity when the thread's affinity for its home lgroup is removed (set to none).

For a full description of the different levels of Igroup affinity and their semantics, see the lgrp\_affinity\_set(3LGRP) manual page.

The plgrp tool supports the following options:

-a lgroup list	This option displays the affinities of the processes or threads that you specify for the lgroups in the list.
-Algroup list/none  weak strong [,]	This option sets the affinity of the processes or threads that you specify for the lgroups in the list. You can use a comma separated list of <i>lgroup/affinity</i> assignments to set several affinities at once.
-F	This option takes control of the target process. This option overrides the control of any other process. See the $proc(1)$ manual page.
-h	This option returns the home Igroup of the processes or threads that you specify. This is the default behavior of the plgrp tool when you do not specify any options.
-н lgroup list	This option sets the home lgroup of the processes or threads that you specify. This option sets a strong affinity for the listed lgroup. If you specify more than one lgroup, the plgrp utility will attempt to home the threads to the lgroups in a round robin fashion.

### **Specifying Lgroups**

The value of the *lgroup list* variable is a comma separated list of one or more of the following attributes:

- lgroup ID
- Range of Igroup IDs, specified as start Igroup ID-end Igroup ID
- all
- root
- leaves

The all keyword represents all of the Igroup IDs in the system. The root keyword represents the ID of the root Igroup. The leaves keyword represents the IDs of all of the leaf Igroups. A leaf Igroup is an Igroup that does not have any children.

#### **Specifying Process and Thread Arguments**

The plgrp utility takes one or more space-separated processes or threads as arguments. You can specify processes and threads in a the same syntax that the proc(1) tools use. You can specify a process ID as an integer, with the syntax *pid* or /proc/*pid*. You can use shell expansions with the /proc/*pid* syntax. When you give a process ID alone, the arguments to the plgrp utility include all of the threads of that process.

You can specify a thread explicitly by specifying the process ID and thread ID with the syntax *pid/lwpid*. You can specify multiple threads of a process by defining ranges with can be selected at once by using the - character to define a range, or with a comma-separated list. To specify threads 1, 2, 7, 8, and 9 of a process whose process ID is *pid*, use the syntax *pid/*1, 2, 7-9.

#### **Igrpinfo Tool**

The lgrpinfo tool prints information about the lgroup hierarchy, contents, and characteristics. The lgrpinfo tool is a Perl script that requires the Solaris::Lgrp module. This tool uses the liblgrp(3LIB) API to get the information from the system and displays it in the human-readable form.

The lgrpinfo tool prints general information about all of the lgroups in the system when you call it without any arguments. When you pass lgroup IDs to the lgrpinfo tool at the command line, the tool returns information about the lgroups that you specify. You can specify lgroups with their lgroup IDs or with one of the following keywords:

all This keyword specifies all lgroups and is the default behavior.

root This keyword specifies the root lgroup.

This keyword specifies all of the leaf Igroups. A leaf Igroup is an Igroup

that has no children in the Igroup hierarchy.

intermediate This keyword specifies all of the intermediate Igroups. An intermediate

lgroup is an lgroup that has a parent and children.

When the lgrpinfo tool receives an invalid lgroup ID, the tool prints a message with the invalid ID and continues processing any other lgroups that are passed in the command line. When the lgrpinfo tool finds no valid lgroups in the arguments, it exits with a status of 2.

#### Options for the **lgrpinfo** Tool

When you call the lgrpinfo tool without any arguments, the tool's behavior is equivalent to using the options -celmrt all. The valid options for the lgrpinfo tool are:

- This option prints the topology, CPU, memory, load and latency information for the specified Igroup IDs. This option combines the behaviors of the -tcemrlL options, unless you also specify the -T option. When you specify the -T option, the behavior of the -a option does not include the behavior of the -t option.
- -c This option prints the CPU information.
- -C This option replaces each lgroup in the list with its children. You cannot combine this option with the -P or -T options. When you do not specify any arguments, the tool applies this option to all lgroups.
- -e This option prints lgroup load averages for leaf lgroups.
- This option prints the OS view of the Igroup hierarchy. The tool's default behavior displays the caller's view of the Igroup hierarchy. The caller's view only includes the resources that the caller can use. See the <a href="Igrp\_init(3LGRP">Igrp\_init(3LGRP)</a> manual page for more details on the OS and caller's view.
- -h This option prints the help message for the tool.
- This option prints only IDs that match the IDs you specify. You can combine this option with the -c, -G, -C, or -P options. When you specify the -c option, the tool prints the list of CPUs that are in all of the matching lgroups. When you do not specify the -c option, the tool displays the IDs for the matching lgroups. When you do not specify any arguments, the tool applies this option to all lgroups.
- This option prints information about lgroup latencies. The latency value given for each lgroup is defined by the operating system and is platform-specific. It can only be used for relative comparison of lgroups on the

	running system. It does not necessarily represent the actual latency between hardware devices and may not be applicable across platforms.
-L	This option prints the lgroup latency table. This table shows the relative latency from each lgroup to each of the other lgroups.
-m	This option prints memory information. The tool reports memory sizes in the units that give a size result in the integer range from 0 to 1023. You can override this behavior by using the -u option. The tool will only display fractional results for values smaller than 10.
-P	This option replaces each lgroup in the list with its parent or parents. You cannot combine this option with the -C or -T options. When you do not specify any arguments, the tool applies this option to all lgroups.
-r	This option prints information about Igroup resources. When you specify the -T option, the tool displays information about the resources of the intermediate Igroups only.
-t	This option prints information about Igroup topology.
-Т	This option prints the Igroup topology of a system graphically, as a tree. You can only use this option with the -a, -c, -e, -G, -l, -L, -m, -r, and -u options. To restrict the output to intermediate Igroups, use the -r option. Omit the -t option when you combine the -T option with the -a option. This option does not print information for the root Igroup unless it is the only Igroup.
-uunits	This option specifies memory units. The value of the <i>units</i> argument can be b, k, m, g, t, p, or e for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, or exabytes, respectively.

# "Solaris::lgrp" Module

This Perl module provides a Perl interface to the Igroup APIs that are in liblgrp. This interface provides a way to traverse the Igroup hierarchy, discover its contents and characteristics, and set a thread's affinity for an Igroup. The module gives access to various constants and functions defined in the <code>lgrp\_user.h</code> header file. The module provides the procedural interface and the object interface to the library.

The default behavior of this module does not export anything. You can use the following tags to selectively import the constants and functions that are defined in this module:

:LGRP\_CONSTANTS LGRP\_AFF\_NONE, LGRP\_AFF\_STRONG, LGRP\_AFF\_WEAK, LGRP\_CONTENT\_DIRECT, LGRP\_CONTENT\_HIERARCHY, LGRP\_MEM\_SZ\_FREE, LGRP MEM SZ INSTALLED, LGRP VER CURRENT, LGRP VER NONE, LGRP VIEW CALLER, LGRP VIEW OS, LGRP NONE, LGRP RSRC CPU, LGRP RSRC MEM, LGRP CONTENT ALL, LGRP LAT CPU TO MEM : PROC\_CONSTANTS P\_PID, P\_LWPID, P\_MYID : CONSTANTS :LGRP CONSTANTS, :PROC CONSTANTS : FUNCTIONS lgrp\_affinity\_get(), lgrp\_affinity\_set(), lgrp\_children(), lgrp cookie stale(), lgrp cpus(), lgrp fini(), lgrp home(), lgrp\_init(), lgrp\_latency(), lgrp\_latency\_cookie(), lgrp\_mem\_size(), lgrp\_nlgrps(), lgrp\_parents(), lgrp\_root(), lgrp\_version(), lgrp\_view(), lgrp\_resources(), lgrp\_lgrps(), lgrp\_leaves(), lgrp\_isleaf(), lgrp\_lgrps(), lgrp\_leaves() :ALL() :CONSTANTS(),:FUNCTIONS()

The Perl module has the following methods:

- new()
- cookie()
- stale()
- view()
- root()
- children()
- parents()
- nlgrps()
- mem size()
- cpus()
- isleaf()
- resources()
- version()
- home()
- affinity\_get()
- affinity\_set()

- lgrps()
- leaves()
- latency()

You can export constants with the :CONSTANTS or :ALL tags. You can use any of the constants in the following list in Perl programs.

- LGRP\_NONE
- LGRP\_VER\_CURRENT
- LGRP\_VER\_NONE
- LGRP\_VIEW\_CALLER
- LGRP VIEW OS
- LGRP AFF NONE
- LGRP\_AFF\_STRONG
- LGRP\_AFF\_WEAK
- LGRP CONTENT DIRECT
- LGRP CONTENT HIERARCHY
- LGRP\_MEM\_SZ\_FREE
- LGRP\_MEM\_SZ\_INSTALLED
- LGRP\_RSRC\_CPU
- LGRP RSRC MEM
- LGRP\_CONTENT\_ALL
- LGRP\_LAT\_CPU\_TO\_MEM
- P PID
- P LWPID
- P\_MYID

When an underlying library function fails, the functions in this module return either undef or an empty list. The module can use the following error codes:

EINVAL The value supplied is not valid.

ENOMEM There was not enough system memory to complete an operation.

ESRCH The specified process or thread was not found.

EPERM The effective user of the calling process does not have the appropriate

privileges, and its real or effective user ID does not match the real or

effective user ID of one of the threads.

#### Functions in the Solaris::lgrp Module

lgrp\_init
([LGRP\_VIEW\_CALLER
| LGRP\_VIEW\_OS])

This function initializes the Igroup interface and takes a snapshot of the Igroup hierarchy with the given view. Given the view, the <code>lgrp\_init()</code> function returns a cookie that represents this snapshot of the Igroup hierarchy. Use this cookie with the other routines in the Igroup interface that require the Igroup hierarchy. Call the <code>lgrp\_fini()</code> function with this cookie when the system no longer needs the hierarchy snapshot. Unlike the <code>lgrp\_init(3LGRP)</code> function, this function assumes a value of <code>LGRP\_VIEW\_OS</code> as the default if the system provides no view. This function returns a cookie upon successful completion. If the <code>lgrp\_init(slgrp\_init)</code> function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. See the man page for the <code>lgrp\_init(3LGRP)</code> function for more information.

lgrp\_fini
(\$cookie)

This function takes a cookie, frees the snapshot of the lgroup hierarchy that the <code>lgrp\_init()</code> function created, and cleans up anything else that the <code>lgrp\_init()</code> function set up. After calling this function, do not use the cookie that the lgroup interface returns. This function returns 1 upon successful completion. If the <code>lgrp\_fini</code> function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. See the man page for the <code>lgrp\_fini(3LGRP)</code> function for more information.

lgrp\_view (\$cookie) This function takes a cookie that represents the snapshot of the Igroup hierarchy and returns the snapshot's view of the Igroup hierarchy. If the given view is LGRP\_VIEW\_CALLER, the snapshot contains only the resources that are available to the caller. When the view is LGRP\_VIEW\_OS, the snapshot contains the resources that are available to the operating system. This function returns the view for the snapshot of the Igroup hierarchy that is represented by the given cookie upon successful completion. If the <code>lgrp\_view</code> function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. See the man page for the <code>lgrp\_view(3LGRP)</code> function for more information.

lgrp\_home
(\$idtype, \$id)

This function returns the home Igroup for the given process or thread. To specify a process, give the \$idtype argument the value P\_PID and give the \$id argument the value of the process id. To specify a thread, give the \$idtype argument the value P\_LWPID and give the \$id argument the value of the thread's LWP id. To specify the current process or thread, give the \$id argument the value P MYID. This function returns the id

of the home lgroup of the specified process or thread upon successful completion. If the <code>lgrp\_home</code> function does not complete successfully, it returns a value of <code>undef</code> and sets \$! to indicate the error. See the man page for the <code>lgrp\_home(3LGRP)</code> function for more information.

lgrp\_cookie\_stale
(\$cookie)

This function returns the staleness status of the specified cookie upon successful completion. If the <code>lgrp\_cookie\_stale</code> function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. This function fails and returns <code>EINVAL</code> if the cookie is not valid. See the man page for the <code>lgrp\_cookie\_stale(3LGRP)</code> function for more information.

lgrp\_cpus
(\$cookie, \$lgrp,
\$context)

This function takes a cookie that represents a snapshot of the Igroup hierarchy and returns the list of CPUs that are in the Igroup that is specified by the \$lgrp argument. Give the \$context argument the value LGRP\_CONTENT\_HIERARCHY to make the lgrp\_cpus() function return the list of all the CPUs that are in the specified Igroup, including child Igroups. Give the \$context() argument the value LGRP\_CONTENT\_DIRECT to make the lgrp\_cpus() function return the list of CPUs that are directly contained in the specified Igroup. This function returns the number of CPUs that are in the specified Igroup when you call it in a scalar context. If the lgrp\_cpus function does not complete successfully when you call it in a scalar context, it returns a value of undef and sets \$! to indicate the error. If the lgrp\_cpus function does not complete successfully when you call it in a list context, it returns the empty list and sets \$! to indicate the error. See the man page for the lgrp\_cpus(3LGRP) function for more information.

lgrp\_children
(\$cookie, \$lgrp)

This function takes a cookie that represents a snapshot of the Igroup hierarchy and returns the list of Igroups that are children of the specified Igroup. When called in scalar context, the Igrp\_children() function returns the number of children Igroups for the specified Igroup when you call it in a scalar context. If the Igrp\_children function does not complete successfully when you call it in a scalar context, it returns a value of undef and sets \$! to indicate the error. If the Igrp\_children function does not complete successfully when you call it in a list context, it returns the empty list and sets \$! to indicate the error. See the man page for the Igrp\_children(3LGRP) function for more information.

lgrp\_parents
(\$cookie, \$lgrp)

This function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the list of parent groups of the specified lgroup. When called in scalar context, the <code>lgrp\_parents()</code> function returns

the number of parent lgroups for the specified lgroup when you call it in a scalar context. If the <code>lgrp\_parents</code> function does not complete successfully when you call it in a scalar context, it returns a value of undef and sets \$! to indicate the error. If the <code>lgrp\_parents</code> function does not complete successfully when you call it in a list context, it returns the empty list and sets \$! to indicate the error. See the man page for the <code>lgrp\_parents(3LGRP)</code> function for more information.

lgrp\_nlgrps
(\$cookie)

This function takes a cookie that represents a snapshot of the lgroup hierarchy. It returns the number of lgroups in the hierarchy. This number is always at least one. If the <code>lgrp\_nlgrps</code> function does not complete successfully, it returns a value of undef and sets the value of \$! to <code>EINVAL</code> to indicate that the cookie is invalid. See the man page for the <code>lgrp\_nlgrps(3LGRP)</code> function for more information.

lgrp\_root (\$cookie) This function returns the ID of the root lgroup. If the <code>lgrp\_root</code> function does not complete successfully, it returns a value of undef and sets the value of \$! to <code>EINVAL</code> to indicate that the cookie is invalid. See the man page for the <code>lgrp\_root(3LGRP)</code> function for more information.

lgrp\_mem\_size
(\$cookie, \$lgrp,
\$type, \$content)

This function takes a cookie that represents a snapshot of the Igroup hierarchy. The function returns the memory size of the given Igroup in bytes. Set the value of the \$type argument to LGRP\_MEM\_SZ\_FREE to have the Igrp\_mem\_size() function return the amount of free memory. Set the value of the \$type argument to LGRP\_MEM\_SZ\_INSTALLED to have the Igrp\_mem\_size() function return the amount of installed memory. Set the value of the \$content argument to LGRP\_CONTENT\_HIERARCHY to have the Igrp\_mem\_size() function return results for the specified Igroup and each of its child Igroups. Set the value of the \$content argument to LGRP\_CONTENT\_DIRECT to have the Igrp\_mem\_size() function return results for the specified Igroup only. This function returns the memory size in bytes upon successful completion, the size in bytes is returned. If the Igrp\_mem\_size function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. See the man page for the Igrp\_mem\_size() function for more information.

lgrp\_version
([VERSION])

This function takes an interface version number as the value of the VERSION argument and returns an Igroup interface version. To discover the current Igroup interface version, pass the value of LGRP\_VER\_CURRENT or LGRP\_VER\_NONE in the VERSION argument. The lgrp\_version() function returns the requested version if the system supports that version. The lgrp\_version() function returns LGRP\_VER\_NONE if the system

does not supports the request version. The lgrp version() function returns the current version of the library when you call the function with LGRP VER NONE as the value of the VERSION argument. This code fragment tests whether the version of the interface used by the caller is supported:

lgrp\_version(LGRP\_VER\_CURRENT) == LGRP\_VER CURRENT or die("Built with unsupported lgroup interface");

See the man page for the lgrp version(3LGRP) function for more information.

lgrp affinity set (\$idtype, \$id, \$lgrp, \$affinity)

This function sets the affinity that the LWPs you specify with the \$idtype and \$id arguments have for the given Igroup. You can set the lgroup affinity to LGRP AFF STRONG, LGRP AFF WEAK, or LGRP AFF NONE. When the value of the \$idtype argument is P PID, this function sets the affinity for all the LWPs of the process with the process id specified in the \$id argument. The lgrp affinity set() function sets the affinity for the LWP of the current process with LWP id \$id when the value of the \$idtype argument is P LWPID. You can specify the current LWP or process by assigning the \$id argument a value of P MYID. This function returns 1 upon successful completion. If the lgrp affinity set function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. See the man page for the lgrp affinity set(3LGRP) function for more information.

lgrp\_affinity\_get (\$idtype, \$id, \$lgrp)

This function retrieves the affinity that the LWPs you specify with the \$idtype and \$id arguments have for the given Igroup. When the value of the \$idtype argument is P PID, this function retrieves the affinity for one of the LWPs in the process. The lgrp affinity get() function retrieves the affinity for the LWP of the current process with LWP id \$id when the value of the \$idtype argument is P LWPID. You can specify the current LWP or process by assigning the \$id argument a value of P MYID. This function returns 1 upon successful completion. If the lgrp affinity get function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. See the man page for the lgrp affinity get(3LGRP) function for more information.

(\$cookie, \$from, \$to,

lgrp latency cookie This function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the latency value between a hardware resource in the \$from lgroup to a hardware resource in the \$to lgroup. This function [\$between=LGRP\_LAT\_CPretTring the latency value within a given lgroup when the values of the \$from and \$to arguments are identical. Set the value of the optional

\$between argument to LGRP\_LAT\_CPU\_TO\_MEM to specify the hardware resources to measure the latency between. LGRP\_LAT\_CPU\_TO\_MEM represents the latency from CPU to memory and is the only valid value for this argument in this release. This function returns 1 upon successful completion. If the lgrp\_latency\_cookie function does not complete successfully, it returns a value of undef and sets \$! to indicate the error. See the man page for the lgrp\_latency\_cookie(3LGRP) function for more information.

lgrp\_latency
(\$from, \$to)()

The function is similar to the <code>lgrp\_latency\_cookie()</code> function, but returns the latency between the given lgroups at the given instant in time. Because the system dynamically reallocates and frees lgroups, this function's results are not always consistent across calls. This function is deprecated. Use the <code>lgrp\_latency\_cookie()</code> function instead. See the man page for the <code>lgrp\_latency(3LGRP)</code> function for more information.

lgrp\_resources
(\$cookie, \$lgrp,
\$type)()

This function is only available for version 2 of the API. When you call this function with version 1 of the API, the <code>lgrp\_resources()</code> function returns undef or the empty list and sets the value of <code>\$!</code> to <code>EINVAL</code>. This function returns the list of <code>lgroups</code> that directly contain the specified type of resources. The resources are represented by a set of <code>lgroups</code> in which each <code>lgroup</code> directly contains CPU and/or memory resources. To specify CPU resources, set the value of the <code>\$type</code> argument to <code>LGRP\_RSRC\_CPU</code>. To specify memory resources, set the value of the <code>\$type</code> argument to <code>LGRP\_RSRC\_MEM</code>. If the <code>lgrp\_resources</code> function does not complete successfully, it returns a value of undef or the empty list and sets <code>\$!</code> to indicate the error. See the man page for the <code>lgrp\_resources(3LGRP)</code> function for more information.

lgrp\_lgrps
(\$cookie,
[\$lgrp])()

This function returns the list of all of the Igroups in a hierarchy, starting from the Igroup specified in the \$lgrp argument. This function uses the value returned by the lgrp\_root(\$cookie) function when the \$lgrp argument has no value. The lgrp\_lgrps() function returns the empty list on failure. This function returns the total number of Igroups in the system when you call it in a scalar context.

lgrp\_leaves
(\$cookie,
[\$lgrp])()

This function returns the list of all leaf lgroups in a hierarchy that starts from the lgroup specified in the \$lgrp argument. This function uses the value returned by the lgrp\_root(\$cookie) function when the \$lgrp argument has no value. The lgrp\_leaves() function returns undef or the empty list on failure. This function returns the total number of leaf lgroups in the system when you call it in a scalar context.

lgrp\_isleaf
(\$cookie,
\$lgrp)()

This function returns True if the Igroup specified by the value of the \$lgrp argument is a leaf Igroup. Leaf Igroups have no children. The lgrp\_isleaf() function returns False if the specified Igroup is not a leaf Igroup.

#### Object Methods in the Solaris::lgrp Module

new([\$view]) This method creates a new Sun::Solaris::Lgrp object. An optional argument is passed to the lgrp init() function. This method uses a value for the \$view argument of LGRP VIEW OS by default. This function returns a transparent cookie that is passed to functions that cookie() accept a cookie. version This method returns the current version of the liblgrp(3LIB) library ([\$version]) when you call it without an argument. This is a wrapper for the lgrp\_version() function with LGRP\_VER\_NONE as the default value of the \$version argument. stale() This method returns T if the Igroup information in the object is stale. This method returns F in all other cases. The stale method is a wrapper for the lgrp cookie stale() function. view() This method returns the snapshot's view of the Igroup hierarchy. The view() method is a wrapper for the lgrp view() function. root() This method returns the root Igroup. The root () method is a wrapper for the lgrp root() function. children(\$lgrp) This method returns the list of Igroups that are children of the specified lgroup. The children method is a wrapper for the lgrp children() function. This method returns the list of Igroups that are parents of the specified parents(\$lgrp) lgroup. The parents method is a wrapper for the lgrp parents() function. This method returns the number of Igroups in the hierarchy. The nlgrps() nlgrps() method is a wrapper for the lgrp nlgrps() function. mem\_size(\$lgrp, This method returns the memory size of the given lgroup in bytes. The \$type, \$content) mem size method is a wrapper for the lgrp mem size() function.

This method returns the list of CPUs that are in the Igroup specified by cpus(\$lgrp, \$context) the \$lgrp argument. The cpus method is a wrapper for the lgrp cpus() function. This method returns the list of Igroups that directly contain resources resources(\$lgrp, \$type) of the specified type. The resources method is a wrapper for the lgrp resources() function. This method returns the home Igroup for the given process or thread. The home(\$idtype, \$id) home method is a wrapper for the lgrp home() function. affinity get This method returns the affinity that the LWP has to a given lgroup. The (\$idtype, \$id, affinity get() method is a wrapper for the lgrp affinity get() \$lgrp) function. This method sets the affinities that the LWPs specified by the \$idtype affinity\_set (\$idtype, and \$id arguments have for the given lgroup. The affinity set() \$id, \$lgrp, method is a wrapper for the lgrp affinity set() function. \$affinity) lgrps([\$lgrp]) This method returns the list of all of the Igroups in a hierarchy starting from the Igroup specified by the value of the \$lgrp argument. The hierarchy starts from the root Igroup when you do not specify a value for the \$lgrp argument. The lgrps() method is a wrapper for the lgrp lgrps() function. This method returns the list of all of the leaf lgroups in a hierarchy leaves([\$lgrp]) starting from the Igroup specified by the value of the \$lgrp argument. The hierarchy starts from the root Igroup when you do not specify a value for the \$lgrp argument. The leaves() method is a wrapper for the lgrp leaves() function.

isleaf(\$lgrp)

This method returns True if the Igroup specified by the value of the \$lgrp argument is a leaf Igroup. A leaf Igroup has no children. This method returns False in all other cases. The isleaf method is a wrapper for the Igrp isleaf function.

latency(\$from,
\$to)

This method returns the latency value between a hardware resource in the lgroup specified by the \$from argument to a hardware resource in the lgroup specified by the \$to argument. The latency method uses the lgrp\_latency() function in version 1 of liblgrp. The latency method uses the lgrp\_latency\_cookie() function in newer versions of liblgrp.

# **Locality Group APIs**

This chapter describes the APIs that applications use to interact with locality groups. This chapter discusses the following topics:

- "Verifying the Interface Version" on page 31 describes the functions that give information about the interface.
- "Initializing the Locality Group Interface" on page 32 describes function calls that
  initialize and shut down the portion of the interface that is used to traverse the locality group
  hierarchy and to discover the contents of a locality group.
- "Locality Group Hierarchy" on page 33 describes function calls that navigate the locality group hierarchy and functions that get characteristics of the locality group hierarchy.
- "Locality Group Contents" on page 36 describes function calls that retrieve information about a locality group's contents.
- "Locality Group Characteristics" on page 38 describes function calls that retrieve information about a locality group's characteristics.
- "Locality Groups and Thread and Memory Placement" on page 39 describes how to affect the locality group placement of a thread and its memory.
- "Examples of API Usage" on page 45 contains code that performs example tasks by using the APIs that are described in this chapter.

#### **Verifying the Interface Version**

The lgrp\_version(3LGRP) function must be used to verify the presence of a supported lgroup interface before using the lgroup API. The lgrp\_version() function has the following syntax:

```
#include <sys/lgrp_user.h>
int lgrp version(const int version);
```

The lgrp\_version() function takes a version number for the lgroup interface as an argument and returns the lgroup interface version that the system supports. When the current

implementation of the Igroup API supports the version number in the version argument, the <code>lgrp\_version()</code> function returns that version number. Otherwise, the <code>lgrp\_version()</code> function returns <code>LGRP\_VER\_NONE</code>.

# #Include <sys/lgrp\_user.h> if (lgrp\_version(LGRP\_VER\_CURRENT) != LGRP\_VER\_CURRENT) { fprintf(stderr, "Built with unsupported lgroup interface %d\n", LGRP\_VER\_CURRENT); exit (1); }

# **Initializing the Locality Group Interface**

Applications must call <code>lgrp\_init(3LGRP)</code> in order to use the APIs for traversing the lgroup hierarchy and to discover the contents of the lgroup hierarchy. The call to <code>lgrp\_init()</code> gives the application a consistent snapshot of the lgroup hierarchy. The application developer can specify whether the snapshot contains only the resources that are available to the calling thread specifically or the resources that are available to the operating system in general. The <code>lgrp\_init()</code> function returns a cookie that is used for the following tasks:

- Navigating the Igroup hierarchy
- Determining the contents of an Igroup
- Determining whether the snapshot is current

#### Using lgrp\_init()

The lgrp\_init() function initializes the lgroup interface and takes a snapshot of the lgroup hierarchy.

```
#include <sys/lgrp_user.h>
lgrp_cookie_t lgrp_init(lgrp_view_t view);
```

When the <code>lgrp\_init()</code> function is called with <code>LGRP\_VIEW\_CALLER</code> as the view, the function returns a snapshot that contains only the resources that are available to the calling thread. When the <code>lgrp\_init()</code> function is called with <code>LGRP\_VIEW\_OS</code> as the view, the function returns a snapshot that contains the resources that are available to the operating system. When a thread successfully calls the <code>lgrp\_init()</code> function, the function returns a cookie that is used by any

function that interacts with the Igroup hierarchy. When a thread no longer needs the cookie, call the Igrp fini() function with the cookie as the argument.

The Igroup hierarchy consists of a root Igroup that contains all of the system's CPU and memory resources. The root Igroup might contain other locality groups bounded by smaller latencies.

The lgrp\_init() function can return two errors. When a view is invalid, the function returns EINVAL. When there is insufficient memory to allocate the snapshot of the lgroup hierarchy, the function returns ENOMEM.

#### Using lgrp\_fini()

The lgrp\_fini(3LGRP) function ends the usage of a given cookie and frees the corresponding lgroup hierarchy snapshot.

```
#include <sys/lgrp_user.h>
int lgrp_fini(lgrp_cookie_t cookie);
```

The <code>lgrp\_fini()</code> function takes a cookie that represents an lgroup hierarchy snapshot created by a previous call to <code>lgrp\_init()</code>. The <code>lgrp\_fini()</code> function frees the memory that is allocated to that snapshot. After the call to <code>lgrp\_fini()</code>, the cookie is invalid. Do not use that cookie again.

When the cookie passed to the lgrp fini() function is invalid, lgrp fini() returns EINVAL.

#### **Locality Group Hierarchy**

The APIs that are described in this section enable the calling thread to navigate the lgroup hierarchy. The lgroup hierarchy is a directed acyclic graph that is similar to a tree, except that a node might have more than one parent. The root lgroup represents the whole system and contains all of that system's resources. The root lgroup is the lgroup with the highest latency value in the system. Each of the child lgroups contains a subset of the hardware that is in the root lgroup. Each child lgroup is bounded by a lower latency value. Locality groups that are closer to the root have more resources and a higher latency. Locality groups that are closer to the leaves have fewer resources and a lower latency. An lgroup can contain resources directly within its latency boundary. An lgroup can also contain leaf lgroups that contain their own sets of resources. The resources of leaf lgroups are available to the lgroup that encapsulates those leaf lgroups.

#### Using lgrp\_cookie\_stale()

The <code>lgrp\_cookie\_stale(3LGRP)</code> function determines whether the snapshot of the lgroup hierarchy represented by the given cookie is current.

```
#include <sys/lgrp_user.h>
int lgrp cookie stale(lgrp cookie t cookie);
```

The cookie returned by the <code>lgrp\_init()</code> function can become stale due to several reasons that depend on the view that the snapshot represents. A cookie that is returned by calling the <code>lgrp\_init()</code> function with the view set to <code>LGRP\_VIEW\_OS</code> can become stale due to changes in the lgroup hierarchy such as dynamic reconfiguration or a change in a CPU's online status. A cookie that is returned by calling the <code>lgrp\_init()</code> function with the view set to <code>LGRP\_VIEW\_CALLER</code> can become stale due to changes in the calling thread's processor set or changes in the <code>lgroup</code> hierarchy. A stale cookie is refreshed by calling the <code>lgrp\_fini()</code> function with the old cookie, followed by calling <code>lgrp\_init()</code> to generate a new cookie.

The lgrp cookie stale() function returns EINVAL when the given cookie is invalid.

#### Using lgrp\_view()

The lgrp\_view(3LGRP) function determines the view with which a given lgroup hierarchy snapshot was taken.

```
#include <sys/lgrp_user.h>
lgrp_view_t lgrp_view(lgrp_cookie_t cookie);
```

The <code>lgrp\_view()</code> function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the snapshot's view of the lgroup hierarchy. Snapshots that are taken with the view <code>LGRP\_VIEW\_CALLER</code> contain only the resources that are available to the calling thread. Snapshots that are taken with the view <code>LGRP\_VIEW\_OS</code> contain all the resources that are available to the operating system.

The lgrp view() function returns EINVAL when the given cookie is invalid.

#### Using lgrp nlgrps()

The lgrp\_nlgrps(3LGRP) function returns the number of locality groups in the system. If a system has only one locality group, memory placement optimizations have no effect.

```
#include <sys/lgrp_user.h>
```

```
int lgrp_nlgrps(lgrp_cookie_t cookie);
```

The lgrp\_nlgrps() function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the number of lgroups available in the hierarchy.

The lgrp nlgrps() function returns EINVAL when the cookie is invalid.

#### Using lgrp\_root()

The lgrp root(3LGRP) function returns the root lgroup ID.

```
#include <sys/lgrp_user.h>
lgrp_id_t lgrp_root(lgrp_cookie_t cookie);
```

The lgrp\_root() function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the root lgroup ID.

#### Using lgrp parents()

The lgrp\_parents(3LGRP) function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the number of parent lgroups for the specified lgroup.

If <code>lgrp\_array</code> is not <code>NULL</code> and the value of <code>lgrp\_array\_size</code> is not zero, the <code>lgrp\_parents()</code> function fills the array with parent <code>lgroup</code> IDs until the array is full or all parent <code>lgroup</code> IDs are in the array. The root <code>lgroup</code> has zero parents. When the <code>lgrp\_parents()</code> function is called for the root <code>lgroup</code>, <code>lgrp\_array</code> is not filled in.

The lgrp\_parents() function returns EINVAL when the cookie is invalid. The lgrp\_parents() function returns ESRCH when the specified lgroup ID is not found.

#### Using lgrp\_children()

The lgrp\_children(3LGRP) function takes a cookie that represents the calling thread's snapshot of the lgroup hierarchy and returns the number of child lgroups for the specified lgroup.

If lgrp\_array is not NULL and the value of lgrp\_array\_size is not zero, the lgrp\_children() function fills the array with child lgroup IDs until the array is full or all child lgroup IDs are in the array.

The lgrp\_children() function returns EINVAL when the cookie is invalid. The lgrp\_children() function returns ESRCH when the specified lgroup ID is not found.

#### **Locality Group Contents**

The following APIs retrieve information about the contents of a given lgroup.

The lgroup hierarchy organizes the domain's resources to simplify the process of locating the nearest resource. Leaf lgroups are defined with resources that have the least latency. Each of the successive ancestor lgroups of a given leaf lgroup contains the next nearest resources to its child lgroup. The root lgroup contains all of the resources that are in the domain.

The resources of a given lgroup are contained directly within that lgroup or indirectly within the leaf lgroups that the given lgroup encapsulates. Leaf lgroups directly contain their resources and do not encapsulate any other lgroups.

#### Using lgrp resources()

The lgrp\_resources() function returns the number of resources contained in a specified lgroup.

The <code>lgrp\_resources()</code> function takes a cookie that represents a snapshot of the <code>lgroup</code> hierarchy. That cookie is obtained from the <code>lgrp\_init()</code> function. The <code>lgrp\_resources()</code> function returns the number of resources that are in the <code>lgroup</code> with the ID that is specified by the value of the <code>lgrp</code> argument. The <code>lgrp\_resources()</code> function represents the resources with a set of <code>lgroups</code> that directly contain CPU or memory resources. The <code>lgrp\_rsrc\_t</code> argument can have the following two values:

```
LGRP_RSRC_CPU The lgrp resources() function returns the number of CPU resources.
```

LGRP\_RSRC\_MEM The lgrp\_resources() function returns the number of memory resources.

When the value passed in the <code>lgrpids[]</code> argument is not null and the count argument is not zero, the <code>lgrp\_resources()</code> function stores <code>lgroup IDs</code> in the <code>lgrpids[]</code> array. The number of <code>lgroup IDs</code> stored in the array can be up to the value of the count argument.

The lgrp\_resources() function returns EINVAL when the specified cookie, lgroup ID, or type are not valid. The lgrp\_resources() function returns ESRCH when the function does not find the specified lgroup ID.

## Using lgrp\_cpus()

The lgrp\_cpus(3LGRP) function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the number of CPUs in a given lgroup.

If the <code>cpuid[]</code> argument is not <code>NULL</code> and the CPU count is not zero, the <code>lgrp\_cpus()</code> function fills the array with CPU IDs until the array is full or all the CPU IDs are in the array.

The content argument can have the following two values:

LGRP\_CONTENT\_ALL The lgrp\_cpus() function returns IDs for the CPUs in this lgroup and this lgroup's descendants.

LGRP\_CONTENT\_DIRECT The lgrp\_cpus() function returns IDs for the CPUs in this lgroup only.

The lgrp\_cpus() function returns EINVAL when the cookie, lgroup ID, or one of the flags is not valid. The lgrp\_cpus() function returns ESRCH when the specified lgroup ID is not found.

## Using lgrp mem size()

The <code>lgrp\_mem\_size(3LGRP)</code> function takes a cookie that represents a snapshot of the lgroup hierarchy and returns the size of installed or free memory in the given lgroup. The <code>lgrp\_mem\_size()</code> function reports memory sizes in bytes.

```
#include <sys/lgrp_user.h>
lgrp_mem_size t lgrp_mem_size(lgrp_cookie_t cookie, lgrp_id_t lgrp,
```

```
int type, int content)
```

The type argument can have the following two values:

```
LGRP_MEM_SZ_FREE The lgrp_mem_size() function returns the amount of free memory in bytes.
```

LGRP\_MEM\_SZ\_INSTALLEDThe lgrp\_mem\_size() function returns the amount of installed memory in bytes.

The content argument can have the following two values:

```
LGRP_CONTENT_ALL The lgrp_mem_size() function returns the amount of memory in this lgroup and this lgroup's descendants.
```

LGRP\_CONTENT\_DIRECT The lgrp\_mem\_size() function returns the amount of memory in this lgroup only.

The <code>lgrp\_mem\_size()</code> function returns <code>EINVAL</code> when the cookie, <code>lgroup ID</code>, or one of the flags is not valid. The <code>lgrp\_mem\_size()</code> function returns <code>ESRCH</code> when the specified <code>lgroup ID</code> is not found.

# **Locality Group Characteristics**

The following API retrieves information about the characteristics of a given lgroup.

# Using lgrp\_latency\_cookie()

The lgrp\_latency(3LGRP) function returns the latency between a CPU in one lgroup to the memory in another lgroup.

The <code>lgrp\_latency\_cookie()</code> function takes a cookie that represents a snapshot of the <code>lgroup</code> hierarchy. The <code>lgrp\_init()</code> function creates this cookie. The <code>lgrp\_latency\_cookie()</code> function returns a value that represents the latency between a hardware resource in the <code>lgroup</code> given by the value of the <code>from</code> argument and a hardware resource in the <code>lgroup</code> given by the value of the to argument. If both arguments point to the same <code>lgroup</code>, the <code>lgrp\_latency\_cookie()</code> function returns the latency value within that <code>lgroup</code>.

**Note -** The latency value returned by the <code>lgrp\_latency\_cookie()</code> function is defined by the operating system and is platform-specific. This value does not necessarily represent the actual latency between hardware devices. Use this value only for comparison within one domain.

When the value of the between argument is LGRP\_LAT\_CPU\_TO\_MEM, the lgrp\_latency\_cookie() function measures the latency from a CPU resource to a memory resource.

The <code>lgrp\_latency\_cookie()</code> function returns <code>EINVAL</code> when the <code>lgroup</code> ID is not valid. When the <code>lgrp\_latency\_cookie()</code> function does not find the specified <code>lgroup</code> ID, the "from" <code>lgroup</code> does not contain any CPUs, or the "to" <code>lgroup</code> does not have any memory, the <code>lgrp\_latency\_cookie()</code> function returns <code>ESRCH</code>.

## **Locality Groups and Thread and Memory Placement**

This section discusses the APIs used to discover and affect thread and memory placement with respect to lgroups.

- The lgrp home(3LGRP) function is used to discover thread placement.
- The meminfo(2) system call is used to discover memory placement.
- The MADV\_ACCESS flags to the madvise(3C) function are used to affect memory allocation among lgroups.
- The lgrp\_affinity\_set(3LGRP) function can affect thread and memory placement by setting a thread's affinity for a given lgroup.
- The affinities of an Igroup may specify an order of preference for Igroups from which to allocate resources.
- The kernel needs information about the likely pattern of an application's memory use in order to allocate memory resources efficiently.
- The madvise() function and its shared object analogue madv.so.1 provide this information to the kernel.
- A running process can gather memory usage information about itself by using the meminfo() system call.

## Using lgrp\_home()

The lgrp\_home() function returns the home lgroup for the specified process or thread.

#include <sys/lgrp\_user.h>

```
lgrp_id_t lgrp_home(idtype_t idtype, id_t id);
```

The <code>lgrp\_home()</code> function returns <code>EINVAL</code> when the ID type is not valid. The <code>lgrp\_home()</code> function returns <code>EPERM</code> when the effective user of the calling process is not the superuser and the real or effective user ID of the calling process does not match the real or effective user ID of one of the threads. The <code>lgrp\_home()</code> function returns <code>ESRCH</code> when the specified process or thread is not found.

## Using madvise()

The madvise() function advises the kernel that a region of user virtual memory in the range starting at the address specified in addr and with length equal to the value of the len parameter is expected to follow a particular pattern of use. The kernel uses this information to optimize the procedure for manipulating and maintaining the resources associated with the specified range. Use of the madvise() function can increase system performance when used by programs that have specific knowledge of their access patterns over memory.

```
#include <sys/types.h>
#include <sys/mman.h>
int madvise(caddr t addr, size t len, int advice);
```

The madvise() function provides the following flags to affect how a thread's memory is allocated among lgroups:

MADV\_ACCESS\_DEFAULT This flag resets the kernel's expected access pattern for the specified

range to the default.

MADV\_ACCESS\_LWP This flag advises the kernel that the next LWP to touch the specified

address range is the LWP that will access that range the most. The kernel allocates the memory and other resources for this range and the LWP

accordingly.

MADV\_ACCESS\_MANY This flag advises the kernel that many processes or LWPs will access the

specified address range randomly across the system. The kernel allocates

the memory and other resources for this range accordingly.

The madvise() function can return the following values:

EAGAIN Some or all of the mappings in the specified address range, from addr to

addr+len, are locked for I/O.

EINVAL The value of the addr parameter is not a multiple of the page size as

returned by sysconf(3C), the length of the specified address range is less

than or equal to zero, or the advice is invalid.

An I/O error occurs while reading from or writing to the file system.

ENOMEM Addresses in the specified address range are outside the valid range for

the address space of a process or the addresses in the specified address

range specify one or more pages that are not mapped.

ESTALE The NFS file handle is stale.

## Using meminfo()

The meminfo() function gives the calling process information about the virtual memory and physical memory that the system has allocated to that process.

The meminfo() function can return the following types of information:

MEMINFO\_VPHYSICAL The physical memory address corresponding to the given virtual address.

MEMINFO\_VLGRP The Igroup to which the physical page corresponding to the given virtual

address belongs.

MEMINFO\_VPAGESIZE The size of the physical page corresponding to the given virtual address.

MEMINFO\_VREPLCNT The number of replicated physical pages that correspond to the given

virtual address.

MEMINFO VREPL | n The *n*th physical replica of the given virtual address.

MEMINFO\_VREPL\_LGRP| The lgroup to which the *n*th physical replica of the given virtual address

MEMINFO PLGRP

The Igroup to which the given physical address belongs.

The meminfo() function takes the following parameters:

belongs.

inaddr An array of input addresses.

addr_count	The number of addresses that are passed to meminfo().
info_req	An array that lists the types of information that are being requested.
info_count	The number of pieces of information that are requested for each address in the inaddr array.
outdata	An array where the meminfo() function places the results. The array's size is equal to the product of the values of the info_req and addr_count parameters.
validity	An array of size equal to the value of the addr_count parameter. The validity array contains bitwise result codes. The <i>O</i> th bit of the result code evaluates the validity of the corresponding input address. Each successive bit in the result code evaluates the validity of the response to the members of the info_req array in turn.

The meminfo() function returns EFAULT when the area of memory to which the outdata or validity arrays point cannot be written to. The meminfo() function returns EFAULT when the area of memory to which the info\_req or inaddr arrays point cannot be read from. The meminfo() function returns EINVAL when the value of info count exceeds 31 or is less than 1. The meminfo() function returns EINVAL when the value of addr count is less than zero.

EXAMPLE 6 Use of meminfo() to Print Out Physical Pages and Page Sizes Corresponding to a Set of Virtual Addresses

```
void
print_info(void **addrvec, int how_many)
       static const int info[] = {
               MEMINFO_VPHYSICAL,
               MEMINFO_VPAGESIZE);
       uint64_t * inaddr = alloca(sizeof(uint64_t) * how_many);
       uint64_t * outdata = alloca(sizeof(uint64_t) * how_many * 2;
       uint_t * validity = alloca(sizeof(uint_t) * how_many);
       int i;
       for (i = 0; i < how_many; i++)
                inaddr[i] = (uint64_t *)addr[i];
       if (meminfo(inaddr, how_many, info,
                    sizeof (info)/ sizeof(info[0]),
                    outdata, validity) < 0)</pre>
```

```
for (i = 0; i < how_many; i++) {</pre>
                 if (validity[i] & 1 == 0)
                         printf("address 0x%llx not part of address
                                          space\n",
                                  inaddr[i]);
                 else if (validity[i] & 2 == 0)
                         printf("address 0x%llx has no physical page
                                          associated with it\n",
                                  inaddr[i]);
                 else {
                         char buff[80];
                         if (validity[i] & 4 == 0)
                                  strcpy(buff, "<Unknown>");
                         else
                                  sprintf(buff, "%lld", outdata[i * 2 +
                                                  1]);
                         printf("address \ 0x\%llx \ is \ backed \ by \ physical
                                          page 0x%llx of size %s\n",
                                          inaddr[i], outdata[i * 2], buff);
                 }
        }
}
```

## **Locality Group Affinity**

The kernel assigns a thread to a locality group when the lightweight process (LWP) for that thread is created. That Igroup is called the thread's *home Igroup*. The kernel runs the thread on the CPUs in the thread's home Igroup and allocates memory from that Igroup whenever possible. If resources from the home Igroup are unavailable, the kernel allocates resources from other Igroups. When a thread has affinity for more than one Igroup, the operating system allocates resources from Igroups chosen in order of affinity strength. Lgroups can have one of three distinct affinity levels:

- 1. LGRP\_AFF\_STRONG indicates strong affinity. If this lgroup is the thread's home lgroup, the operating system avoids rehoming the thread to another lgroup if possible. Events such as dynamic reconfiguration, processor, offlining, processor binding, and processor set binding and manipulation might still result in thread rehoming.
- 2. LGRP\_AFF\_WEAK indicates weak affinity. If this lgroup is the thread's home lgroup, the operating system rehomes the thread if necessary for load balancing purposes.
- 3. LGRP\_AFF\_NONE indicates no affinity. If a thread has no affinity to any lgroup, the operating system assigns a home lgroup to the thread.

The operating system uses lgroup affinities as advice when allocating resources for a given thread. The advice is factored in with the other system constraints. Processor binding and processor sets do not change lgroup affinities, but might restrict the lgroups on which a thread can run.

## Using lgrp affinity get()

The lgrp\_affinity\_get(3LGRP) function returns the affinity that a LWP has for a given lgroup.

```
#include <sys/lgrp_user.h>
lgrp affinity t lgrp affinity get(idtype t idtype, id t id, lgrp id t lgrp);
```

The idtype and id arguments specify the LWP that the <code>lgrp\_affinity\_get()</code> function examines. If the value of <code>idtype</code> is <code>P\_PID</code>, the <code>lgrp\_affinity\_get()</code> function gets the lgroup affinity for one of the LWPs in the process whose process ID matches the value of the <code>id</code> argument. If the value of <code>idtype</code> is <code>P\_LWPID</code>, the <code>lgrp\_affinity\_get()</code> function gets the lgroup affinity for the LWP of the current process whose LWP ID matches the value of the <code>id</code> argument. If the value of <code>idtype</code> is <code>P\_MYID</code>, the <code>lgrp\_affinity\_get()</code> function gets the lgroup affinity for the current LWP.

The <code>lgrp\_affinity\_get()</code> function returns <code>EINVAL</code> when the given <code>lgroup</code> or <code>ID</code> type is not valid. The <code>lgrp\_affinity\_get()</code> function returns <code>EPERM</code> when the effective user of the calling process is not the superuser and the <code>ID</code> of the calling process does not match the real or effective user <code>ID</code> of one of the <code>LWPs</code>. The <code>lgrp\_affinity\_get()</code> function returns <code>ESRCH</code> when a given <code>lgroup</code> or <code>LWP</code> is not found.

## Using lgrp affinity set()

The lgrp\_affinity\_set(3LGRP) function sets the affinity that a LWP or set of LWPs have for a given lgroup.

The idtype and id arguments specify the LWP or set of LWPs the <code>lgrp\_affinity\_set()</code> function examines. If the value of <code>idtype</code> is <code>P\_PID</code>, the <code>lgrp\_affinity\_set()</code> function sets the lgroup affinity for all of the LWPs in the process whose process ID matches the value of the <code>id</code> argument to the affinity level specified in the <code>affinity</code> argument. If the value of <code>idtype</code> is <code>P\_LWPID</code>, the <code>lgrp\_affinity\_set()</code> function sets the lgroup affinity for the LWP of the current process whose LWP ID matches the value of the <code>id</code> argument to the affinity level specified in the <code>affinity</code> argument. If the value of <code>idtype</code> is <code>P\_MYID</code>, the <code>lgrp\_affinity\_set()</code> function

sets the Igroup affinity for the current LWP or process to the affinity level specified in the affinity argument.

The <code>lgrp\_affinity\_set()</code> function returns <code>EINVAL</code> when the given <code>lgroup</code>, affinity, or ID type is not valid. The <code>lgrp\_affinity\_set()</code> function returns <code>EPERM</code> when the effective user of the calling process is not the superuser and the ID of the calling process does not match the real or effective user ID of one of the LWPs. The <code>lgrp\_affinity\_set()</code> function returns <code>ESRCH</code> when a given <code>lgroup</code> or <code>LWP</code> is not found.

## **Examples of API Usage**

This section contains code for example tasks that use the APIs that are described in this chapter.

#### **EXAMPLE 7** Move Memory to a Thread

The following code sample moves the memory in the address range between addr and addr+len near the next thread to touch that range.

```
#include <stdio.h>
#include <sys/mman.h>
#include <sys/types.h>

/*
   * Move memory to thread
   */
void
mem_to_thread(caddr_t addr, size_t len)
{
   if (madvise(addr, len, MADV_ACCESS_LWP) < 0)
        perror("madvise");
}</pre>
```

### **EXAMPLE 8** Move a Thread to Memory

This sample code uses the meminfo() function to determine the lgroup of the physical memory backing the virtual page at the given address. The sample code then sets a strong affinity for that lgroup in an attempt to move the current thread near that memory.

```
#include <stdio.h>
#include <sys/lgrp_user.h>
#include <sys/mman.h>
```

```
#include <sys/types.h>
 * Move a thread to memory
*/
int
thread_to_memory(caddr_t va)
 uint64_t
            addr;
 ulong_t
            count;
 lgrp_id_t home;
 uint64 t
            lgrp;
 uint t
            request;
 uint_t
            valid;
 addr = (uint64_t)va;
 count = 1;
 request = MEMINFO_VLGRP;
 if (meminfo(&addr, 1, &request, 1, &lgrp, &valid) != 0) {
 perror("meminfo");
 return (1);
 }
 if (lgrp_affinity_set(P_LWPID, P_MYID, lgrp, LGRP_AFF_STRONG) != 0) {
 perror("lgrp_affinity_set");
 return (2);
 }
 home = lgrp_home(P_LWPID, P_MYID);
 if (home == -1) \{
 perror ("lgrp_home");
 return (3);
 }
 if (home != lgrp)
 return (-1);
 return (0);
}
```

#### **EXAMPLE 9** Walk the lgroup Hierarchy

The following sample code walks through and prints out the Igroup hierarchy.

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/lgrp_user.h>
```

```
#include <sys/types.h>
* Walk and print lgroup hierarchy from given lgroup
 * through all its descendants
 */
int
lgrp_walk(lgrp_cookie_t cookie, lgrp_id_t lgrp, lgrp_content_t content)
{
 lgrp_affinity_t
                    aff;
 lgrp_id_t
                   *children;
 processorid t
                   *cpuids;
 int
                   i;
 int
                   ncpus;
 int
                   nchildren;
 int
                   nparents;
 lgrp_id_t
                   *parents;
 lgrp_mem_size_t
                    size;
 * Print given lgroup, caller's affinity for lgroup,
 * and desired content specified
 printf("LGROUP #%d:\n", lgrp);
 aff = lgrp_affinity_get(P_LWPID, P_MYID, lgrp);
 if (aff == -1)
 perror ("lgrp_affinity_get");
 printf("\tAFFINITY: %d\n", aff);
 printf("CONTENT %d:\n", content);
 * Get CPUs
 ncpus = lgrp_cpus(cookie, lgrp, NULL, 0, content);

printf("free bytes 0x%llx\n", size);
* Get parents
nparents = lgrp_parents(cookie, lgrp, NULL, 0);
printf("\t%d PARENTS: ", nparents);
if (nparents == -1) {
perror("lgrp_parents");
return (-1);
} else if (nparents > 0) {
 parents = malloc(nparents * sizeof (lgrp_id_t));
 nparents = lgrp_parents(cookie, lgrp, parents, nparents);
              if (nparents == -1) {
  free(parents);
                       perror("lgrp_parents");
 return (-1);
              }
 for (i = 0; i < nparents; i++)
 printf("%d ", parents[i]);
 free(parents);
printf("\n");
* Get children
```

```
*/
 nchildren = lgrp_children(cookie, lgrp, NULL, 0);
 printf("\t%d CHILDREN: ", nchildren);
 if (nchildren == -1) {
 perror("lgrp_children");
  return (-1);
 } else if (nchildren > 0) {
  children = malloc(nchildren * sizeof (lgrp_id_t));
  nchildren = lgrp_children(cookie, lgrp, children, nchildren);
                if (nchildren == -1) {
   free(children);
                        perror("lgrp_children");
   return (-1);
                }
  printf("Children: ");
  for (i = 0; i < nchildren; i++)
  printf("%d ", children[i]);
  printf("\n");
  for (i = 0; i < nchildren; i++)
   lgrp_walk(cookie, children[i], content);
 free(children);
 printf("\n");
 return (0);
}
EXAMPLE 10
                Find the Closest Igroup With Available Memory Outside a Given Igroup
#include <stdio.h>
