Preface

This guide describes database features that support application development using SecureFiles and Large Object (LOB) data types and Database File System (DBFS). The information in this guide applies to all platforms, and does not include system-specific information.

- Audience
- Documentation Accessibility
- Related Documents
- Conventions

Audience

Oracle Database SecureFiles and Large Objects Developer's Guide is intended for programmers who develop new applications using LOBs and DBFS, and those who have previously implemented this technology and now want to take advantage of new features.

Efficient and secure storage of multimedia and unstructured data is increasingly important, and this guide is a key resource for this topic within the Oracle Application Developers documentation set.

Feature Coverage and Availability

Oracle Database SecureFiles and Large Objects Developer's Guide contains information that describes the SecureFiles LOB and BasicFiles LOB features and functionality of Oracle Database 12*c* Release 2 (12.2).

Prerequisites for Using LOBs

Oracle Database includes all necessary resources for using LOBs in an application; however, there are some restrictions as described in the "LOB Rules and Restrictions" section.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
`monospace`	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Introduction to Large Objects and SecureFiles

Large Objects are used to hold large amounts of data inside Oracle Database, SecureFiles provides performance comparable to file system performance, and DBFS provides file system interface to files stored in Oracle Database.

- **Changes in Oracle Database**
  The following are the changes in *SecureFiles and Large Objects Developer's Guide for Oracle Database*.

- **What Are Large Objects?**
  Large Objects (LOBs), SecureFiles LOBs, and Database File System (DBFS) work together with various database features to support application development.

- **Where Should We Use LOBs?**
  Large objects are suitable for semistructured and unstructured data.

- **LOB Classifications**
  LOBs store a variety of data such as audio, video, documents, and so on. Based on the type of data stored in the LOB or memory management mechanism used, there are different classifications.

- **LOB Locator and LOB Value**
  A LOB instance has a locator and a value. A LOB locator is a reference, or a *pointer*, to where the LOB value is physically stored. The LOB value is the data stored in the LOB.

- **LOB Restrictions**
  You have to keep a few restrictions in mind while working with LOB data.

- **How to Navigate This Book**
  This section elaborates how to navigate this book using a flow chart that provides information about the relevant chapters you must read for understanding various concepts or performing various tasks.

1.1 Changes in Oracle Database

The following are the changes in *SecureFiles and Large Objects Developer's Guide for Oracle Database*.

- Updates to Oracle Database Security 21c

- Updates to Oracle Database Security 21c
  Oracle Database release 21c has one new security update that applies to all releases starting from release 11.2.

1.1.1 Updates to Oracle Database Security 21c

Oracle Database release 21c has one new security update that applies to all releases starting from release 11.2.

Security Update for Native Encryption

Oracle provides a patch that you can download to address necessary security enhancements that affect native network encryption environments in Oracle Database release 11.2 and later.

This patch is available in My Oracle Support note 2118136.2.

The supported algorithms that have been improved are as follows:

- Encryption algorithms: AES128, AES192 and AES256

- Checksumming algorithms: SHA1, SHA256, SHA384, and SHA512

Algorithms that are deprecated and should not be used are as follows:

- Encryption algorithms: DES, DES40, 3DES112, 3DES168, RC4_40, RC4_56, RC4_128, and RC4_256

- Checksumming algorithm: MD5

If your site requires the use of network native encryption, then you must download the patch that is described in My Oracle Support note 2118136.2. To enable a smooth transition for your Oracle Database installation, this patch provides two parameters that enable you to disable the weaker algorithms and start using the stronger algorithms. You will need to install this patch on both servers and clients in your Oracle Database installation.

An alternative to network native encryption is Transport Layer Security (TLS), which provides protection against person-in-the-middle attacks.

1.2 What Are Large Objects?

Large Objects (LOBs), SecureFiles LOBs, and Database File System (DBFS) work together with various database features to support application development.

Large Objects

The maximum size for a single LOB can range from 8 terabytes to 128 terabytes depending on how your database is configured. Storing data in LOBs enables you to access and manipulate the data efficiently in your application.

SecureFile LOBs

SecureFile LOBs are LOBs that are created in a tablespace managed with Automatic Segment Space Management (ASSM). SecureFiles is the default storage mechanism for LOBs in database tables. Oracle strongly recommends SecureFiles for storing and managing LOBs.

Database File System (DBFS)

Database File System (DBFS) provides a file system interface to files that are stored in an Oracle Database.

Files stored in an Oracle Database are usually stored as SecureFiles LOBs, and path names, directories, and other file system information is stored in the database tables. SecureFiles

LOBs is the default storage method for DBFS, but BasicFiles LOBs can be used in some situations.

With DBFS, you can make references from SecureFiles LOB locators to files stored outside the database. These references are called DBFS Links or Database File System Links.

1.3 Where Should We Use LOBs?

Large objects are suitable for semistructured and unstructured data.

Large object features enable you to store the following types of data in the database and also in the operating system files that are accessed from the database.

- Semistructured data

  Semistructured data has a logical structure that is not typically interpreted by the database, for example, an XML document that your application or an external service processes. Oracle Database provides features such as Oracle XML DB, Oracle Multimedia, and Oracle Spatial and Graph to help your application work with semistructured data.

- Unstructured data

  Unstructured data is easily not broken down into smaller logical structures and is not typically interpreted by the database or your application, such as a photographic image stored as a binary file.

Data unsuited for LOBs

- Simple Structured Data
  Simple structured data can be organized into relational tables that are structured based on business rules.

- Complex Structured Data
  Complex structured data is suited for the object-relational features of the Oracle Database such as collections, references, and user-defined types.

Maximum Size of a LOB

The maximum permissible LOB size for your configuration depends on the block size setting of the tablespace. It is calculated as `(4 gigabytes - 1)*(space usable for data in the LOB block)`. For example, if a LOB is stored in a tablespace of block size 8K, then the approximate maximum LOB size is about 32 terabytes.

1.4 LOB Classifications

LOBs store a variety of data such as audio, video, documents, and so on. Based on the type of data stored in the LOB or memory management mechanism used, there are different classifications.

- Large Object Data Types
  Oracle Database provides a set of large object data types as SQL data types, where the term *LOB* generally refers to the set.

- Types of LOBs
  This section describes the three types of LOB data that Oracle supports.

- LOBs in Object Data Types
  Typically, there is no difference in the use of a LOB instance in a LOB column or in an object data type, as its member.

- Oracle Data Types Stored in LOBs
  Many data types provided with Oracle Database are stored as or created with LOB types.

1.4.1 Large Object Data Types

Oracle Database provides a set of large object data types as SQL data types, where the term *LOB* generally refers to the set.

In general, the descriptions given for the data types in this table and related sections, also apply to the corresponding data types provided for other programmatic environments.

The following table describes each large object data type that the database supports and describes the kind of data that uses it.

Table 1-1   Types of Large Object Data

SQL Data Type	Description
BLOB	Binary Large Object
	Stores any kinds of data in binary format. Used for images, audio, and video.
CLOB	Character Large Object
	Stores string data in the database character set format. Used for large strings or documents that use the database character set exclusively. Characters in the database character set are in a fixed width format.
NCLOB	National Character Set Large Object
	Stores string data in National Character Set format, typically large strings or documents. Supports characters of varying width format.
BFILE	External Binary File
	A binary file stored outside of the database in the host operating system file system, but accessible from database tables. BFILEs can be accessed from your application on a **read-only** basis. Use BFILEs to store static data, such as image data, that is not manipulated in applications.
	Any kind of data, that is, any operating system file, can be stored in a BFILE. For example, you can store character data in a BFILE and then load the BFILE data into a CLOB, specifying the character set upon loading.

1.4.2 Types of LOBs

This section describes the three types of LOB data that Oracle supports.

Persistent LOBs

A persistent LOB is a LOB instance that exists in a table row in the database. Persistent LOBs participate in database transactions. You can recover persistent LOBs in the event of transaction or media failure, and any changes to a persistent LOB value can be committed or rolled back. In other words, all the Atomicity, Consistency, Isolation, and Durability (ACID) properties that apply to database objects apply to persistent LOBs. Persistent LOBs can be of data types BLOB, CLOB and NCLOB.

Temporary LOBs

A temporary LOB instance is created when you instantiate a LOB only within the scope of your local application. Temporary LOBs are transient, just like other local variables in an application. A temporary LOB becomes persistent when you insert it into a table row. Temporary LOBs can be of data types BLOB, CLOB and NCLOB.

BFILEs

`BFILE`s are data objects stored in operating system files, outside the database tablespaces. Data stored in a table column of type `BFILE` is physically located in an operating system file, not in the database.

`BFILE`s are read-only data types. The database allows read-only byte stream access to data stored in `BFILE`s. You cannot write to or update a `BFILE` from within your application.

You typically use `BFILE`s to hold:

- Binary data that does not change while your application is running, such as graphics

- Data that is loaded into other large object types, such as a `BLOB` or `CLOB`, where the data can then be manipulated

- Data that is appropriate for byte-stream access, such as multimedia

Any storage device accessed by your operating system can hold `BFILE` data, including hard disk drives, CD-ROMs, PhotoCDs, and DVDs. The database can access `BFILE`s provided the operating system supports stream-mode access to the operating system files.

> **Note:**
>
> All the information related to BFILEs is exclusively documented either in BFILEs or in Managing LOBs: Database Administration.

1.4.3 LOBs in Object Data Types

Typically, there is no difference in the use of a LOB instance in a LOB column or in an object data type, as its member.

In this guide, the term *LOB attribute* refers to a LOB instance that is a member of an object data type. Unless otherwise specified, discussions that apply to LOB columns also apply to LOB attributes.

1.4.4 Oracle Data Types Stored in LOBs

Many data types provided with Oracle Database are stored as or created with LOB types.

The following list mentions a few data types that you can store with LOB types:

- `VARCHAR2` or `RAW` data types of size greater than 4000 bytes

- `JSON` data type

- `XMLType` stored as `BINARY XML` or `CLOB`

- `VARRAY` stored as LOB

1.5 LOB Locator and LOB Value

A LOB instance has a locator and a value. A LOB locator is a reference, or a *pointer*, to where the LOB value is physically stored. The LOB value is the data stored in the LOB.

A LOB locator can be assigned to any LOB instance of the same type, such as `BLOB`, `CLOB`, `NCLOB`, or `BFILE`. When you use a LOB in an operation such as passing a LOB as a parameter, you are actually passing a LOB locator. For the most part, you can work with a LOB instance in your application without being concerned with the semantics of LOB locators. There is no requirement to dereference LOB locators, as is required with pointers in some programming languages.

There are two different techniques to access and modify LOBs:

* Using LOBs Without Locators
  LOBs can be used in many operations similar to how VARCHAR2 or RAW data types are used. Such LOB operations can be performed without the use of LOB locators.

* Using LOBs with Locators
  You can use the LOB locator to access and modify LOB values by passing the LOB locator to the LOB APIs supplied with the database. These operations support efficient piecewise read and write to LOBs.

1.5.1 Using LOBs Without Locators

LOBs can be used in many operations similar to how VARCHAR2 or RAW data types are used. Such LOB operations can be performed without the use of LOB locators.

LOB operations that are similar to `VARCHAR2` and `RAW` types include:

* SQL and PLSQL built-in functions and implicit assignments

> ✏ **See Also:**
>
> – SQL Semantics for LOBs
> – PL/SQL Semantics for LOBs

* Data interface on LOBs that enables you to insert or select entire LOB data in a LOB column without using a LOB locator as follows:
  – Use a bind variable associated with a LOB column to insert character data into a `CLOB`, or `RAW` data into a `BLOB`. For example, in PLSQL you can insert a `VARCHAR2` buffer into a `CLOB` column, and in OCI you can bind a buffer of type `SQLT_CHAR` to a `CLOB` column.

  – Define an output buffer in your application that holds character data selected from a `CLOB` or `RAW` data selected from a `BLOB`. For example, in PLSQL you can select the `CLOB` output of a query into a `VARCHAR2` buffer, and in OCI you can define a `CLOB` query result item to a buffer of type `SQLT_CHAR`.

> ✏ **See Also:**
>
> Data Interface for LOBs

1.5.2 Using LOBs with Locators

You can use the LOB locator to access and modify LOB values by passing the LOB locator to the LOB APIs supplied with the database. These operations support efficient piecewise read and write to LOBs.

You should use this mode if your application needs to perform random or piecewise read or write calls to LOBs, which means it needs to specify the offset or amount of the operation to read or write a part of the LOB value.

> ✎ **See Also:**
>
> Locator Interface for LOBs

1.6 LOB Restrictions

You have to keep a few restrictions in mind while working with LOB data.

LOB columns are subject to the following rules and restrictions:

- You cannot specify a LOB as a primary key column.

- You cannot specify LOB columns in the `ORDER BY` clause of a query, the `GROUP BY` clause of a query, or an aggregate function.

- You cannot specify a LOB column in a `SELECT... DISTINCT` or `SELECT... UNIQUE` statement or in a join. However, you can specify a LOB attribute of an object type column in a `SELECT... DISTINCT` statement, a query that uses the `UNION`, or a `MINUS` set operator if the object type of the column has a `MAP` or `ORDER` function defined on it.

- Clusters cannot contain LOBs, either as key or nonkey columns.

- Even though compressed `VARRAY` data types are supported, they are less performant.

- The following data structures are supported only as temporary instances. You cannot store these instances in database tables:

  - `VARRAY` of any LOB type

  - `VARRAY` of any type containing a LOB type, such as an object type with a LOB attribute

  - `ANYDATA` of any LOB type

  - `ANYDATA` of any type containing a LOB

- The first (`INITIAL`) extent of a LOB segment must contain at least three database blocks.

- The minimum extent size is 14 blocks. For an 8K block size (the default), this is equivalent to 112K.

- When creating an `AFTER UPDATE` DML trigger, you cannot specify a LOB column in the `UPDATE OF` clause. For a table on which you have defined an `AFTER UPDATE DML` trigger, if you use OCI functions or the `DBMS_LOB` package to change the value of a LOB column or the LOB attribute of an object type column, the database does not fire the DML trigger.

- You cannot specify a LOB column as part of an index key. However, you can specify a LOB column in the indextype specification of a functional or domain index. In addition, Oracle Text lets you define an index on a `CLOB` column.

- In SQL Loader, a field read from a LOB cannot be used as an argument to a clause.

- Case-insensitive searches on `CLOB` columns often do not succeed. If you perform the following case-insensitive search on a `CLOB` column:

```
ALTER SESSION SET NLS_COMP=LINGUISTIC;
ALTER SESSION SET NLS_SORT=BINARY_CI;
SELECT * FROM ci_test WHERE LOWER(clob_col) LIKE 'aa%';
```

  The select fails without the `LOWER` function. You can perform case-insensitive searches with Oracle Text or the `DBMS_LOB.INSTR()` function.

1.7 How to Navigate This Book

This section elaborates how to navigate this book using a flow chart that provides information about the relevant chapters you must read for understanding various concepts or performing various tasks.
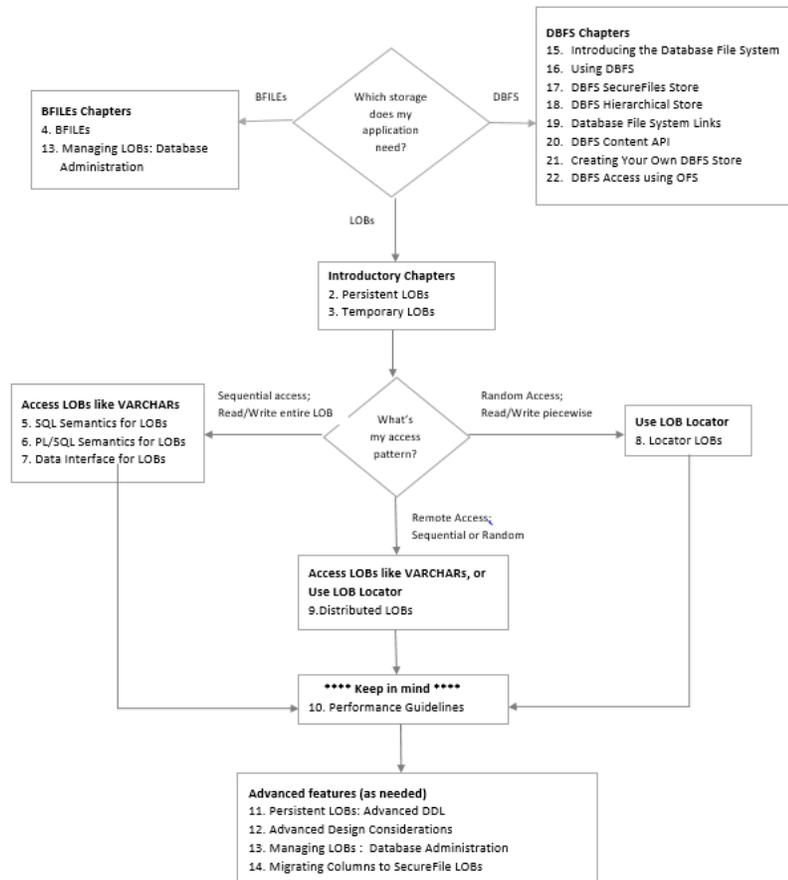

2
Persistent LOBs

A persistent LOB is a LOB instance that exists in a table row in the database. Persistent LOBs can be stored as SecureFiles or BasicFiles.

The term LOB can represent LOBs of either SecureFiles or BasicFiles type, unless the storage type is explicitly indicated. It can be either by name for both storage types, or by reference to archiving or linking, which only applies to the SecureFiles storage type. Oracle strongly recommends SecureFiles for storing and managing LOBs.

SecureFiles LOB storage is the default in the `CREATE TABLE` statement, if no storage type is explicitly specified. All new LOB columns use SecureFiles LOB storage by default, which is the recommended method for storing and managing LOBs. SecureFiles LOB storage is designed to provide great performance and scalability to meet or exceed the performance of traditional network file system. However, you must use BasicFiles LOB storage for LOB storage in tablespaces that are not managed with Automatic Segment Space Management (ASSM). SecureFiles LOBs can only be created in tablespaces managed with Automatic Segment Space Management (ASSM).

- Creating a Table with LOB Columns
  You can use the `CREATE TABLE` statement or an `ALTER TABLE ADD` column statement to create a new LOB column. This section introduces basic DDL operations on LOBs to get you started quickly.

- Inserting and Updating LOB Values in Tables
  Oracle Database provides various methods to insert and update the data available in LOB columns of database tables.

- Selecting LOB Values from Tables
  You can select a LOB into a Character Buffer, a RAW Buffer, or a LOB variable for performing read and write operations.

- Performing DML and Query Operations on LOBs in Nested Tables
  This section describes the `INSERT`, `UPDATE`, and `SELECT` operations on LOBs in Nested Tables. To update LOBs in a nested table, you must lock the row containing the LOB explicitly.

- Performing Parallel DDL, Parallel DML (PDML), and Parallel Query (PQ) Operations on LOBs
  Oracle supports parallel execution of the following operations when performed on partitioned tables with SecureFiles LOBs or BasicFiles LOBs.

- Sharding with LOBs
  LOBs can be used in a sharded environment. This section discusses the interfaces to support LOBs in sharded tables.

2.1 Creating a Table with LOB Columns

You can use the `CREATE TABLE` statement or an `ALTER TABLE ADD` column statement to create a new LOB column. This section introduces basic DDL operations on LOBs to get you started quickly.

Following is an example of creating a table with columns of various LOB types, including LOBs in Object Types and nested tables:

```
CREATE USER pm identified by password;
GRANT CONNECT, RESOURCE to pm IDENTIFIED BY pm;
CONNECT pm/pm

-- Create an object type with a LOB
CREATE TYPE adheader_typ AS OBJECT (
    header_name     VARCHAR2(256),
    creation_date   DATE,
    header_text     VARCHAR(1024),
    logo            BLOB );

CREATE TYPE textdoc_typ AS OBJECT (
    document_typ    VARCHAR2(32),
    formatted_doc   BLOB);

-- Create a nested table type of Object type containing a LOB
CREATE TYPE Textdoc_ntab AS TABLE of textdoc_typ;

-- Create a table of Object type, and specify a default value for LOB column
CREATE TABLE adheader_tab of adheader_typ (
     logo DEFAULT EMPTY_BLOB(),
     CONSTRAINT header_name CHECK (header_name IS NOT NULL),
      header_text DEFAULT NULL);
-- Create a table with columns of different LOB types,
-- and of object type with LOBs, and nested table containing LOB
CREATE TABLE print_media
(product_id NUMBER(6),
ad_id NUMBER(6),
ad_composite BLOB,
ad_sourcetext CLOB,
ad_finaltext CLOB,
ad_fltextn NCLOB,
ad_testdocs_ntab textdoc_tab,
ad_photo BLOB,
ad_graphic BFILE,
ad_header adheader_typ,
press_release LONG) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab;

CREATE UNIQUE INDEX printmedia_pk
  ON print_media (product_id, ad_id);
```

Figure 2-1   print_media table

You can also perform advanced DDL operations, like the following, on LOBs:

- Specify LOB storage parameters: You can override the default LOB storage settings by specifying parameters like `SECUREFILE/BASICFILE`, `TABLESPACE` where the LOB data will be stored, `ENABLE/DISABLE STORAGE IN ROW`, `RETENTION`, caching, logging, etc. You can also specify SecureFile specific parameters like `COMPRESSION`, `DEDUPLICATION` and `ENCRYPTION`.

- Alter an existing LOB column: You can use the `ALTER TABLE MODIFY LOB` syntax to change any LOB storage parameters that don't require LOB data movement and the `ALTER TABLE MOVE LOB` syntax to change any LOB storage parameters that require LOB data movement.

- Create indexes on LOB columns: You can build a functional or a domain index on a LOB column. You cannot build a B-tree or bitmap index on a LOB column.

- Partition a table containing LOB columns: All partitioning schemes supported by Oracle are fully supported on LOBs.

- Use LOBs in Index-Organized tables.

> **See Also:**
>
> Persistent LOBs: Advanced DDL

2.2 Inserting and Updating LOB Values in Tables

Oracle Database provides various methods to insert and update the data available in LOB columns of database tables.

- Inserting and Updating with a Buffer
  You can insert a character string directly into a `CLOB` or `NCLOB` column. Similarly, you can insert a raw buffer into a `BLOB` column. This is the most efficient way to insert data into a LOB.

- Inserting and Updating by Selecting a LOB From Another Table
  You can insert into a LOB column of a table by selecting data from a LOB column of the same table or a different table. You can also insert data into a LOB column of a table by selecting a LOB returned by a SQL operator or a PL/SQL function.

- Inserting and Updating with a NULL or Empty LOB
  You can set a persistent LOB, that is, a LOB column in a table or a LOB attribute in an object type that you defined, to be NULL or empty.

- Inserting and Updating with a LOB Locator
  If you are using a Programmatic Interface, which has a LOB variable that was previously populated by a persistent or temporary LOB locator, then you can insert a row by initializing the LOB bind variable.

2.2.1 Inserting and Updating with a Buffer

You can insert a character string directly into a `CLOB` or `NCLOB` column. Similarly, you can insert a raw buffer into a `BLOB` column. This is the most efficient way to insert data into a LOB.

The following code snippet inserts a character string into a `CLOB` column:

```
/* Store records in the archive table Online_media: */
INSERT INTO Online_media (product_id, product_text) VALUES (3060, 'some text
about this CRT Monitor');
```

The following code snippet updates the value in a `CLOB` column with character buffer:

```
UPDATE Online_media set product_text = 'some other text' where product_id =
3060;
```

> **See Also:**
>
> Data Interface for LOBs for more information about `INSERT` and `UPDATE` operations

2.2.2 Inserting and Updating by Selecting a LOB From Another Table

You can insert into a LOB column of a table by selecting data from a LOB column of the same table or a different table. You can also insert data into a LOB column of a table by selecting a LOB returned by a SQL operator or a PL/SQL function.

Ensure that you meet the following conditions while selecting data from columns that are part of more than one table:

- The LOB data type is the same for both the columns in the tables
- Implicit conversion is allowed between the two LOB data types used in both the columns

When a `BLOB`, `CLOB`, or `NCLOB` is copied from one row to another in the same table or a different table, the actual LOB value is copied, not just the LOB locator.

The following code snippet demonstrates inserting a LOB column from by selecting a LOB from another table. The columns `online_media.product_text` and `print_media.ad_sourcetext` are both `CLOB` types.

```
/* Insert values into Print_media by selecting from Online_media: */
INSERT INTO Print_media (product_id, ad_id, ad_sourcetext)
(SELECT product_id, 11001, product_text FROM Online_media WHERE product_id =
3060);

/* Insert values into Print_media by selecting a SQL function returning a
CLOB */
INSERT INTO Print_media (product_id, ad_id, ad_sourcetext)
(SELECT product_id, 11001, substr(product_text, 5) FROM Online_media WHERE
product_id = 3060);

/* Updating a row by selecting a LOB from another table (persistent LOBs) */

UPDATE Print_media SET ad_sourcetext = (SELECT product_text FROM online_media
WHERE product_id = 3060);
 WHERE product_id = 3060 AND ad_id = 11001;

/* Updating a row by selecting a SQL function returning a CLOB */

UPDATE Print_media SET ad_sourcetext = (SELECT substr(product_text, 5) FROM
online_media WHERE product_id = 3060);
WHERE product_id = 3060 AND ad_id = 11001;
```

The following code snippet demonstrates updating a LOB column from by selecting a LOB from another table.

```
/* Updating a row by selecting a LOB from another table (persistent LOBs) */
UPDATE Print_media SET ad_sourcetext = (SELECT product_text FROM online_media
WHERE product_id = 3060);
WHERE product_id = 3060 AND ad_id = 11001;

/* Updating a row by selecting a SQL function returning a CLOB */
UPDATE Print_media SET ad_sourcetext = (SELECT substr(product_text, 5) FROM
online_media WHERE product_id = 3060)
WHERE product_id = 3060 AND ad_id = 11001;
```

ORACLE

> - *Oracle Database SQL Language Reference* for more information on `INSERT`
> - [Performing Parallel DDL, Parallel DML (PDML), and Parallel Query (PQ) Operations on LOBs](#) for information about how to make the `INSERT AS SELECT` operation run in parallel

2.2.3 Inserting and Updating with a NULL or Empty LOB

You can set a persistent LOB, that is, a LOB column in a table or a LOB attribute in an object type that you defined, to be NULL or empty.

Inserting a NULL LOB value

A persistent LOB set to NULL has no locator. A NULL value is stored in the row in the table, not a locator. This is the same process as for scalar data types. To INSERT a NULL value into a LOB column, simply use a statement like:

```
INSERT INTO print_media(product_id, ad_id, ad_sourcetext) VALUES (1, 1, NULL);
```

This is useful in situations where you want to use a `SELECT` statement, such as the following, to determine whether or not the LOB holds a NULL value:

```
SELECT COUNT (*) FROM print_media WHERE ad_graphic IS NULL;
```

> **⚠ Caution:**
>
> You cannot call `DBMS_LOB` functions or LOB APIs in other Programmatic Interfaces on a NULL LOB, so you must then use a SQL `UPDATE` statement to reset the LOB column to a non-NULL (or empty) value.

Inserting an EMPTY LOB value

Before you can write data to a persistent LOB using an API like `DBMS_LOB.WRITE` or `OCILobWrite2`, the LOB column must be non-`NULL`, that is, it must contain a locator that points to an empty or a populated LOB value.

You can initialize a `BLOB` column value by using the `EMPTY_BLOB()` function as a default predicate. Similarly, a `CLOB` or `NCLOB` column value can be initialized by using the `EMPTY_CLOB()` function. Use the `RETURNING` clause in the `INSERT` and `UPDATE` statement, to minimize the number of round trips while writing the LOB using APIs.

Following PL/SQL block initializes a `CLOB` column with an empty LOB using the `EMPTY_CLOB()` function and also updates the LOB value in a column with an empty `CLOB` using the `EMPTY_CLOB()` function.

```
DECLARE
    c CLOB;
```

```
    amt INTEGER := 11;
    buf VARCHAR(11) := 'Hello there';
BEGIN
  /* Insert empty_clob() */
  INSERT INTO Print_media(product_id, ad_id, ad_sourcetext) VALUES (1, 1,
EMPTY_CLOB()) RETURNING ad_source INTO c;
  /* The following statement updates the persistent LOB directly */
  DBMS_LOB.WRITE(c, amt, 1, buf);

  /* Update column to an empty_clob() */
  UPDATE Print_media SET ad_sourcetext = EMPTY_CLOB() WHERE product_id = 2
AND ad_id = 2 RETURNING ad_source INTO c;
  /* The following statement updates the persistent LOB directly */
  DBMS_LOB.WRITE(c, amt, 1, buf);
END;
/
```

2.2.4 Inserting and Updating with a LOB Locator

If you are using a Programmatic Interface, which has a LOB variable that was previously populated by a persistent or temporary LOB locator, then you can insert a row by initializing the LOB bind variable.

You can populate a LOB variable with a persistent LOB or a temporary LOB by either selecting one out from the database using SQL or by creating a temporary LOB. This section provides information about how to achieve this in various programmatic environments.

- PL/SQL: Inserting a Row by Initializing a LOB Locator Bind Variable
  The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using PL/SQL APIs.

- JDBC (Java): Inserting a Row by Initializing a LOB Locator Bind Variable
  The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using JDBC APIs:

- OCI (C): Inserting a Row by Initializing a LOB Locator Bind Variable
  The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using OCI APIs:

- Pro*C/C++ (C/C++): Inserting a Row by Initializing a LOB Locator Bind Variable
  The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using Pro*C/C++ APIs:

- Pro*COBOL (COBOL): Inserting a Row by Initializing a LOB Locator Bind Variable
  The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using Pro*COBOL APIs:

2.2.4.1 PL/SQL: Inserting a Row by Initializing a LOB Locator Bind Variable

The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using PL/SQL APIs.

```
/* inserting a row through an insert statement */

CREATE OR REPLACE PROCEDURE insertLOB_proc (Lob_loc IN BLOB) IS
BEGIN
  /* Insert the BLOB into the row */
  DBMS_OUTPUT.PUT_LINE('------------ LOB INSERT EXAMPLE ------------');
  INSERT INTO print_media (product_id, ad_id, ad_photo)
```

```
            VALUES (3106, 60315, Lob_loc);
END;
/
```

2.2.4.2 JDBC (Java): Inserting a Row by Initializing a LOB Locator Bind Variable

The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using JDBC APIs:

```java
// Core JDBC classes:
import java.sql.DriverManager;
import java.sql.Connection;
import java.sql.Statement;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;

// Oracle Specific JDBC classes:
import oracle.sql.*;
import oracle.jdbc.driver.*;

public class linsert
{
  public static void main (String args [])
       throws Exception
  {
    // Load the Oracle JDBC driver
    DriverManager.registerDriver (new oracle.jdbc.driver.OracleDriver ());
    // Connect to the database:
    Connection conn =
       DriverManager.getConnection ("jdbc:oracle:oci8:@", "pm", "password");

    // It's faster when auto commit is off:
    conn.setAutoCommit (false);

    // Create a Statement:
    Statement stmt = conn.createStatement ();
    try
    {
       ResultSet rset = stmt.executeQuery (
  "SELECT ad_photo FROM Print_media WHERE product_id = 3106 AND ad_id = 13001");
       if (rset.next())
       {
          // retrieve the LOB locator from the ResultSet
          BLOB adphoto_blob = ((OracleResultSet)rset).getBLOB (1);
          OraclePreparedStatement ops =
          (OraclePreparedStatement) conn.prepareStatement(
"INSERT INTO Print_media (product_id, ad_id, ad_photo) VALUES (2268, "
+ "21001, ?)");
          ops.setBlob(1, adphoto_blob);
          ops.execute();
          conn.commit();
          conn.close();
       }
    }
    catch (SQLException e)
    {
       e.printStackTrace();
    }
  }
}
```

2.2.4.3 OCI (C): Inserting a Row by Initializing a LOB Locator Bind Variable

The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using OCI APIs:

```
/* Insert the Locator into table using Bind Variables. */
#include <oratypes.h>
#include <lobdemo.h>
void insertLOB_proc(OCILobLocator *Lob_loc, OCIEnv *envhp,
                    OCIError *errhp, OCISvcCtx *svchp, OCIStmt *stmthp)
{
  int            product_id;
  OCIBind        *bndhp3;
  OCIBind        *bndhp2;
  OCIBind        *bndhp1;
  text           *insstmt =
   (text *) "INSERT INTO Print_media (product_id, ad_id, ad_sourcetext) \
            VALUES (:1, :2, :3)";

  printf ("----------- OCI Lob Insert Demo --------------\n");
  /* Insert the locator into the Print_media table with product_id=3060 */
  product_id = (int)3060;

  /* Prepare the SQL statement */
  checkerr (errhp, OCIStmtPrepare(stmthp, errhp, insstmt, (ub4)
                                  strlen((char *) insstmt),
                                  (ub4) OCI_NTV_SYNTAX, (ub4)OCI_DEFAULT));

  /* Binds the bind positions */
  checkerr (errhp, OCIBindByPos(stmthp, &bndhp1, errhp, (ub4) 1,
                                (void *) &product_id, (sb4) sizeof(product_id),
                                SQLT_INT, (void *) 0, (ub2 *)0, (ub2 *)0,
                                (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT));

  checkerr (errhp, OCIBindByPos(stmthp, &bndhp1, errhp, (ub4) 2,
                                (void *) &product_id, (sb4) sizeof(product_id),
                                SQLT_INT, (void *) 0, (ub2 *)0, (ub2 *)0,
                                (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT));

  checkerr (errhp, OCIBindByPos(stmthp, &bndhp2, errhp, (ub4) 3,
                                (void *) &Lob_loc, (sb4) 0,  SQLT_CLOB,
                                (void *) 0, (ub2 *)0, (ub2 *)0,
                                (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT));

  /* Execute the SQL statement */
  checkerr (errhp, OCIStmtExecute(svchp, stmthp, errhp, (ub4) 1, (ub4) 0,
                                  (CONST OCISnapshot*) 0, (OCISnapshot*) 0,
                                  (ub4) OCI_DEFAULT));
}
```

2.2.4.4 Pro*C/C++ (C/C++): Inserting a Row by Initializing a LOB Locator Bind Variable

The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using Pro*C/C++ APIs:

```
#include <oci.h>
#include <stdio.h>
#include <sqlca.h>
```

```
void Sample_Error()
{
   EXEC SQL WHENEVER SQLERROR CONTINUE;
   printf("%.*s\n", sqlca.sqlerrm.sqlerrml, sqlca.sqlerrm.sqlerrmc);
   EXEC SQL ROLLBACK WORK RELEASE;
   exit(1);
}

void insertUseBindVariable_proc(Rownum, Lob_loc)
   int Rownum, Rownum2;
   OCIBlobLocator *Lob_loc;
{
   EXEC SQL WHENEVER SQLERROR DO Sample_Error();
   EXEC SQL INSERT INTO Print_media (product_id, ad_id, ad_photo)
      VALUES (:Rownum, :Rownum2, :Lob_loc);
}
void insertBLOB_proc()
{
   OCIBlobLocator *Lob_loc;

   /* Initialize the BLOB Locator: */
   EXEC SQL ALLOCATE :Lob_loc;

   /* Select the LOB from the row where product_id = 2268 and ad_id=21001: */
   EXEC SQL SELECT ad_photo INTO :Lob_loc
      FROM Print_media WHERE product_id = 2268 AND ad_id = 21001;

   /* Insert into the row where product_id = 3106 and ad_id = 13001: */
   insertUseBindVariable_proc(3106, 13001, Lob_loc);

   /* Release resources held by the locator: */
   EXEC SQL FREE :Lob_loc;
}

void main()
{
   char *samp = "pm/password";
   EXEC SQL CONNECT :pm;
   insertBLOB_proc();
   EXEC SQL ROLLBACK WORK RELEASE;
}
```

2.2.4.5 Pro*COBOL (COBOL): Inserting a Row by Initializing a LOB Locator Bind Variable

The following code snippet demonstrates how to insert a row by initializing a LOB locator bind variable using Pro*COBOL APIs:

You can insert a row by initializing a LOB locator bind variable in COBOL (Pro*COBOL).

```
IDENTIFICATION DIVISION.
    PROGRAM-ID. INSERT-LOB.
    ENVIRONMENT DIVISION.
    DATA DIVISION.
    WORKING-STORAGE SECTION.

    01 BLOB1 SQL-BLOB.
    01  USERID  PIC X(11) VALUES "PM/password".
        EXEC SQL INCLUDE SQLCA END-EXEC.
```

```
       PROCEDURE DIVISION.
       INSERT-LOB.

           EXEC SQL WHENEVER SQLERROR DO PERFORM SQL-ERROR END-EXEC.
           EXEC SQL CONNECT :USERID END-EXEC.
    * Initialize the BLOB locator
           EXEC SQL ALLOCATE :BLOB1 END-EXEC.
    * Populate the LOB
           EXEC SQL WHENEVER NOT FOUND GOTO END-OF-BLOB END-EXEC.
           EXEC SQL
             SELECT AD_PHOTO INTO :BLOB1 FROM PRINT_MEDIA
              WHERE PRODUCT_ID = 2268 AND AD_ID = 21001 END-EXEC.

    * Insert the value with PRODUCT_ID of 3060
           EXEC SQL
             INSERT INTO PRINT_MEDIA (PRODUCT_ID, AD_PHOTO)
                VALUES (3060, 11001, :BLOB1)END-EXEC.

    * Free resources held by locator
       END-OF-BLOB.
           EXEC SQL WHENEVER NOT FOUND CONTINUE END-EXEC.
           EXEC SQL FREE :BLOB1 END-EXEC.
           EXEC SQL ROLLBACK WORK RELEASE END-EXEC.
           STOP RUN.

       SQL-ERROR.
           EXEC SQL WHENEVER SQLERROR CONTINUE END-EXEC.
           DISPLAY " ".
           DISPLAY "ORACLE ERROR DETECTED:".
           DISPLAY " ".
           DISPLAY SQLERRMC.
           EXEC SQL ROLLBACK WORK RELEASE END-EXEC.
           STOP RUN.
```

2.3 Selecting LOB Values from Tables

You can select a LOB into a Character Buffer, a RAW Buffer, or a LOB variable for performing read and write operations.

- Selecting a LOB into a Character Buffer or a Raw Buffer
  You can directly select a CLOB or NCLOB value into a character buffer or a BLOB value. This is called the Data Interface, and is the most efficient way for selecting from a LOB column.

- Selecting a LOB into a LOB Variable for Read Operations
  You can select a persistent or temporary LOB into a LOB variable, and then use APIs to perform various read operations on it.

- Selecting a LOB into a LOB Variable for Write Operations
  To perform a write operation using a LOB locator, you must lock the row in the table in order to prevent other database users from writing to the LOB during a transaction.

2.3.1 Selecting a LOB into a Character Buffer or a Raw Buffer

You can directly select a CLOB or NCLOB value into a character buffer or a BLOB value. This is called the Data Interface, and is the most efficient way for selecting from a LOB column.

> ✎ **See Also:**
>
> - Data Interface for LOBs
> - PL/SQL Semantics for LOBs

2.3.2 Selecting a LOB into a LOB Variable for Read Operations

You can select a persistent or temporary LOB into a LOB variable, and then use APIs to perform various read operations on it.

Following code selects a LOB Locator into a variable:

```
DECLARE
    perslob CLOB;
    templob CLOB;
    amt INTEGER := 11;
    buf VARCHAR(100);
BEGIN
    SELECT ad_source, substr(ad_source, 3) INTO perslob, templob FROM
Print_media WHERE product_id = 1 AND ad_id = 1;
    DBMS_LOB.READ(perslob, amt, buf);
    DBMS_LOB.READ(templob, amt, buf);
END;
/
```

> ✎ **See Also:**
>
> - A Selected Locator Becomes a Read-Consistent Locator
> - LOB Locators and Transaction Boundaries

2.3.3 Selecting a LOB into a LOB Variable for Write Operations

To perform a write operation using a LOB locator, you must lock the row in the table in order to prevent other database users from writing to the LOB during a transaction.

You can use one of the following mechanisms for this operation:

- Performing an INSERT or an UPDATE operation with a RETURNING clause.

> ✎ **See Also:**
>
> Inserting and Updating with a NULL or Empty LOB

- Performing a `SELECT` for an `UPDATE` operation. The following code snippet shows how to select a LOB value to perform a write operation using `UPDATE`.

```
DECLARE
    c CLOB;
    amt INTEGER := 9;
    buf VARCHAR(100) := 'New Value';
BEGIN
    SELECT ad_sourcetext INTO c FROM Print_media WHERE product_id = 1 AND
ad_id = 1 FOR UPDATE;
    DBMS_LOB.WRITE(c, amt, 1, buf);
END;
/
```

- Using an OCI `pin` or `lock` function in OCI programs.

2.4 Performing DML and Query Operations on LOBs in Nested Tables

This section describes the `INSERT`, `UPDATE`, and `SELECT` operations on LOBs in Nested Tables. To update LOBs in a nested table, you must lock the row containing the LOB explicitly.

To lock the row containing the LOB, you must specify the `FOR UPDATE` clause in the subquery prior to updating the LOB value. The following example shows how to perform DML and query operations on LOBs in nested tables.

> **Note:**
>
> Locking the row of a parent table does not lock the row of a nested table containing LOB columns.

Example 2-1   Performing DML and Query Operations on LOBs in Nested Tables

```
CONNECT pm/pm;

-------------------------------------------------------------------------
---------- Inserting LOBs in Nested Tables -------------------------------
-------------------------------------------------------------------------

-- INSERT a row into the NT column of print_media with actual data for lob
INSERT INTO print_media (product_id, ad_id, ad_textdocs_ntab)
VALUES
(1, 1, textdoc_tab(textdoc_typ('txt', to_blob('BABABABABABA')),
                textdoc_typ('pdf', to_blob('AAAAAAAAAAAA'))));

-- INSERT a row into the NT column of print_media with empty_lob for the lob
INSERT INTO print_media (product_id, ad_id, ad_textdocs_ntab)
VALUES
(2, 2, textdoc_tab(textdoc_typ('txt', empty_blob()),
                textdoc_typ('pdf', empty_blob()))));
```

```
SET SERVEROUTPUT ON

-------------------------------------------------------------------------
---------- Read/Write LOBs in Nested Tables using locators --------------
-------------------------------------------------------------------------

-- INSERT-RETURNING, then write to the LOBs
DECLARE
  txt textdoc_tab;
BEGIN
  INSERT INTO print_media p(product_id, ad_id, ad_textdocs_ntab) VALUES
    (3, 3, textdoc_tab(textdoc_typ('txt', empty_blob()),
                       textdoc_typ('pdf', empty_blob()))))
  RETURNING p.ad_textdocs_ntab into txt;

  for elem in 1 .. txt.count loop
    DBMS_LOB.WRITEAPPEND(txt(elem).formatted_doc, 2, hextoraw(elem||'FF'));
  end loop;
END;
/

SELECT ad_textdocs_ntab FROM print_media WHERE product_id = 3;

-- SELECT on NT lob, then read
DECLARE
  txt textdoc_tab;
  pos INTEGER;
  amt INTEGER;
  buf RAW(40);
BEGIN
  SELECT ad_textdocs_ntab INTO txt FROM print_media WHERE product_id = 1;

  for elem in 1 .. txt.count loop
    amt := 40;
    pos := 1;
    DBMS_LOB.READ(txt(elem).formatted_doc, amt, pos, buf);
    DBMS_OUTPUT.PUT_LINE(buf);
  end loop;
END;
/

-- SELECT for update on the NT lob, then write
DECLARE
  txt textdoc_tab;
  pos INTEGER;
  amt INTEGER;
  buf RAW(40);
BEGIN
  SELECT ad_textdocs_ntab INTO txt FROM print_media
  WHERE product_id = 1 FOR UPDATE;

  for elem in 1 .. txt.count loop
    DBMS_LOB.WRITEAPPEND(txt(elem).formatted_doc, 2, hextoraw(elem||'FF'));
  end loop;
END;
/
```

```
SELECT ad_textdocs_ntab FROM print_media WHERE product_id = 1;
```

2.5 Performing Parallel DDL, Parallel DML (PDML), and Parallel Query (PQ) Operations on LOBs

Oracle supports parallel execution of the following operations when performed on partitioned tables with SecureFiles LOBs or BasicFiles LOBs.

- `CREATE TABLE AS SELECT`
- `INSERT AS SELECT`
- Multitable `INSERT`
- `SELECT`
- `DELETE`
- `UPDATE`
- `MERGE` (conditional `UPDATE` and `INSERT`)
- `ALTER TABLE MOVE`
- SQL Loader
- Import/Export

Additionally, Oracle supports parallel execution of the following operations when performed on non-partitioned tables with only SecureFile LOBs:

- `CREATE TABLE AS SELECT`
- `INSERT AS SELECT`
- Multitable `INSERT`
- `SELECT`
- `DELETE`
- `UPDATE`
- `MERGE` (conditional `UPDATE` and `INSERT`)
- `ALTER TABLE MOVE`
- SQL Loader

Restrictions on parallel operations with LOBs

- Parallel insert direct load (PIDL) is disabled if a table also has a BasicFiles LOB column, in addition to a SecureFiles LOB column.
- PDML is disabled if LOB column is part of a constraint.
- PDML does not work when there are any domain indexes defined on the LOB column.
- Parallelism must be specified only for top-level non-partitioned tables.
- Use the `ALTER TABLE MOVE` statement with LOB storage clause, to change the storage properties of LOB columns instead of the `ALTER TABLE MODIFY` statement. The `ALTER TABLE MOVE` statement is more efficient because it executes in parallel and does not generate undo logs.

> **See Also:**
>
> *Oracle Database Administrator's Guide* section "Managing Processes for Parallel SQL Execution"
>
> *Oracle Database SQL Language Reference* section "ALTER TABLE"

2.6 Sharding with LOBs

LOBs can be used in a sharded environment. This section discusses the interfaces to support LOBs in sharded tables.

The following interfaces are supported:

- Query and DML statements

    – Cross shard queries involving LOBs are supported.

    – DML statements involving more than one shard are not supported. This behavior is similar to scalar columns.

    – DML statements involving a single shard are supported from coordinator.

    – Locator selected from a shard can be passed as bind value to the same shard.

- `OCILob`
  All non-BFILE related OCILob APIs in a sharding environment are supported, with some restrictions.

  On the coordinator, the `OCI_ATTR_LOB_REMOTE` attribute of a LOB descriptor returns `TRUE` if the LOB was obtained from a sharded table.

  Restrictions: For APIs that take two locators as input, `OCILobAppend`, `OCILobCompare` for example, both of the locators should be obtained from the same shard. If locators are from different shards an error is given.

- `DBMS_LOB`

  All non-BFILE related DBMS_LOB APIs in a sharding environment are supported, with some restrictions. On the coordinator, `DBMS_LOB.isremote` returns `TRUE` if the LOB was obtained from a sharded table.

  Restrictions: For APIs that take two locators as input, `DBMS_LOB.append` and `DBMS_LOB.compare` for example, both of the locators should be obtained from the same shard. If the locators are from different shards an error given.

> **See Also:**

> Sharded Tables

3

Temporary LOBs

Temporary LOBs are transient, just like other local variables in an application. This chapter discusses operations that are specific to temporary LOBs.

- Before You Begin
  Ensure that you go through the topics in this section before you start working with temporary LOBs.
- Temporary LOB APIs in Different Programmatic Interfaces
  This section lists the temporary LOB specific APIs in different Programmatic Interfaces.

3.1 Before You Begin

Ensure that you go through the topics in this section before you start working with temporary LOBs.

- Creating Temporary LOBs
  This section describes how a temporary LOB gets created or generated in a client program.
- Handling Temporary LOBs on the Client Side
  You must consider the aspects discussed in this section while handling the temporary LOBs that are generated by the client programs.

3.1.1 Creating Temporary LOBs

This section describes how a temporary LOB gets created or generated in a client program.

You can create temporary LOB instances in one of the following ways:

- Declare a variable of the given LOB data type and pass it to the temporary LOB creation API. For example, in PL/SQL it is `DBMS_LOB.CREATETEMPORARY`, and in OCI it is `OCILobCreateTemporary()`.
- Invoke a SQL or PL/SQL built-in function that produces a temporary LOB, for example, the `SUBSTR` function.
- Invoke a PL/SQL stored procedure or function that returns a temporary LOB as an `OUT` bind variable or a return value.

The temporary LOB instance exists in your application until it goes out of scope, your session terminates, or you explicitly free the instance.

Temporary LOBs reside in either the PGA memory or the temporary tablespace, depending on their size. Ensure that the PGA memory and the temporary tablespace have space that is large enough for the temporary LOBs used by your application.

> **Note:**
>
> - Oracle highly recommends that you release the temporary LOB instances to free the system resources. Failure to do so may cause accumulation of temporary LOBs and can considerably slow down your system.
>
> - Starting with Oracle Database Release 21c, you do not need to check whether a LOB is temporary or persistent before releasing the temporary LOB. If you call the `DBMS_LOB.FREETEMPORARY` procedure or the `OCILobFreeTemporary()` function on a LOB, it will perform either of the following operations:
>   - For a temporary LOB, it will release the LOB.
>   - For a persistent LOB, it will do nothing (no-op).

> **See Also:**
>
> Performance Guidelines

3.1.2 Handling Temporary LOBs on the Client Side

You must consider the aspects discussed in this section while handling the temporary LOBs that are generated by the client programs.

Preventing Temporary LOB Accumulation

Every time a client program such as JDBC or OCI obtains a LOB locator from SQL or PL/SQL, and you suspect that it is producing a temporary LOB, then free the LOB as soon as your application has consumed the LOB. If you do not free the temporary LOB, then it will lead to accumulation of temporary LOBs, which can considerably slow down your system.

> **Note:**
>
> A temporary LOB duration is always upgraded to `SESSION`, when it is shipped to the client side.

For example, to prevent temporary LOB accumulation, an OCI application must call the `OCILobFreeTemporary()` function in the following scenarios:

- After getting a locator from a define during a `SELECT` statement or an `OUT` bind variable from a PL/SQL procedure or function. It is desirable that you free the temporary LOB as soon as you finish performing the required operations on it. If not, then you must free it before reusing the variable for fetching the next row or for another purpose.

- Before performing a pointer assignment, like `<var1 = var2>`, free the old temporary LOB in the variable `<var1>`.

LOB Assignment
You must take special care when assigning the `OCILobLocator` pointers in an OCI program while using the assignment (=) operator. Pointer assignments create a shallow copy of the LOB. After the pointer assignment, the source and the target LOBs point to the same copy of

data. This means that if you call the `OCILobFreeTemporary()` function on either one of them, then both variables will point to non-existent LOBs.

These semantics are different from using the LOB APIs, such as the `OCILobLocatorAssign()` function to perform assignments. When you use these APIs, the locators logically point to independent copies of data after assignment. This means that eventually the `OCILobFreeTemporary()` function must be called on each LOB descriptor separately, so that it frees all LOBs involved in the operation.

For temporary LOBs, before performing pointer assignments, you must ensure that you free any temporary LOB in the target LOB locator by calling the `OCIFreeTemporary()` function. In contrast, when the `OCILobLocatorAssign()` function is used, the original temporary LOB in the target LOB locator variable, if any, is freed automatically before the assignment happens.

3.2 Temporary LOB APIs in Different Programmatic Interfaces

This section lists the temporary LOB specific APIs in different Programmatic Interfaces.

Most of the examples in the following sections use the `print_media` table. Following is the structure of the `print_media` table.

PRINT_MEDIA Table	
Column name	**Column Type**
product_id	NUMBER (6)
ad_id	NUMBER (6)
ad_composite	BLOB
ad_sourcetext	CLOB
ad_finaltext	CLOB
ad_fltextn	NCLOB
ad_textdocs_ntab	NESTED TABLE
ad_photo	BLOB
ad_graphic	BFILE
ad_header	USER DEFINED TYPE
press_release	LONG

3.2.1 PL/SQL APIs for Temporary LOBs

This section describes the PL/SQL APIs used with temporary LOBs.

> **See Also:**
>
> DBMS_LOB

Table 3-1   DBMS_LOB Functions and Procedures for Temporary LOBs

Function / Procedure	Description
CREATETEMPORARY	Creates a Temporary LOB
ISTEMPORARY	Checks if a LOB locator refers to a temporary LOB
FREETEMPORARY	Frees a temporary LOB

Example 3-1   PL/SQL API for Temporary LOBs

```
DECLARE
  blob1 BLOB;
  clob1 CLOB;
  clob2 CLOB;
  nclob1 NCLOB;
BEGIN
  -- create a temp LOB using CREATETEMPORARY and fill it with data
  DBMS_LOB.CREATETEMPORARY(blob1,TRUE, DBMS_LOB.SESSION);
  writeDataToLOB_proc(blob1);

  -- create a temp LOB using SQL built-in function
  SELECT substr(ad_sourcetext, 5) INTO clob1 FROM print_media WHERE
product_id=1 AND ad_id=1;

  -- create a temp LOB using a PLSQL built-in function
  nclob1 := TO_NCLOB(clob1);
```

```
   -- create a temp LOB using a PLSQL procedure. Assume foo creates a temp lob
and it's parameter is IN/OUT
   foo(clob2);

   -- Other APIs
   CALL_LOB_APIS(blob1, clob1, clob2, nclob1);

   -- free temp LOBs
   DBMS_LOB.FREETEMPORARY(blob1);
   DBMS_LOB.FREETEMPORARY(clob1);
   DBMS_LOB.FREETEMPORARY(clob2);
   DBMS_LOB.FREETEMPORARY(nclob1);

END;
/
show errors;
```

3.2.2 JDBC API for Temporary LOBs

This section describes the PL/SQL APIs used with temporary LOBs.

Table 3-2   jdbc.sql.Clob and java.sql.Blob APIs for Temporary LOBs

Methods	Description
createTemporary	Creates a temporary LOB
isTemporary	Checks if a LOB locator refers to a temporary LOB
freeTemporary	Frees a temporary LOB

Example 3-2   JDBC API for Temporary LOBs

```
public class listempc
{
  public static void main (String args [])
    throws Exception
  {
    Connection conn = LobDemoConnectionFactory.getConnection();

    // SELECT TEMPORARY LOB USING SQL
    Statement stmt = conn.createStatement ();
    ResultSet rset = stmt.executeQuery
          ("SELECT SUBSTR(ad_sourcetext, 5) FROM Print_media WHERE product_id
= 3106 AND ad_id = 1");
    if (rset.next())
    {
      Clob clob = rset.getClob (1);
      System.out.println("Is lob temporary: " + ((CLOB)clob).isTemporary());
```

```
        call_other_apis_to_read_write_from_lob(clob);
        clob.free();
    }
    stmt.close();

    // CREATE TEMPORARY LOB VIA API
    Clob clob = conn.createClob();

    System.out.println( "Is clob temporary: " +
((oracle.jdbc.OracleClob)clob).isTemporary());

    call_other_apis_to_read_write_from_lob(clob);

     // ALWAYS FREE THE TEMPORARY LOB WHEN DONE WITH IT
    clob.free();

    conn.close();
  }
}
```

3.2.3 OCI APIs for Temporary LOBs

This section describes the OCI APIs used with temporary LOBs.

> ✎ **See Also:**
>
> LOB and BFILE Operations

Table 3-3   OCI APIs for Temporary LOBs

Function / Procedure	Description
`OCILobCreateTemporary()`	Creates a Temporary LOB
`OCILobIsTemporary()`	Checks if a LOB locator refers to a temporary LOB
`OCILobFreeTemporary()`	Frees a temporary LOB

Example 3-3   OCI APIs for Temporary LOBs

```
void temp_lob_operations()
{
  OCILobLocator *temp_clob1;
  OCILobLocator *temp_clob2;
  OCIStmt       *stmhp = (OCIStmt *) 0;
  OCIDefine     *dfnhp1;
  ub1            bufp[BUFLEN];
  ub4            amtp = 0;
  ub8            bamtp = 0;
  ub8            camtp = 0;
  ub2            retl1, rcode1;
  sb4            ind_ptr1 = 0;
  boolean        istemp = FALSE;
  char          *sel_stmt = "SELECT SUBSTR(ad_sourcetext, 5) FROM Print_media
WHERE product_id = 3106 AND ad_id = 1";
```

```
      /* allocate lob descriptors */
      checkerr(errhp, OCIDescriptorAlloc((dvoid *) envhp, (dvoid **) &temp_clob1,

BFILEs

`BFILE`s are data objects stored in operating system files, outside the database tablespaces. Data stored in a table column of type `BFILE` is physically located in an operating system file, not in the database. The `BFILE` column stores a reference to the operating system file.

`BFILE`s are read-only data types. The database allows read-only byte stream access to data stored in `BFILE`s. You cannot write to or update a `BFILE` from within your application.

You create `BFILE`s to hold the following types of data:

- Binary data that does not change while your application is running, such as graphics.

- Data that is loaded into other large object types, such as a `BLOB` or `CLOB`, where the data can be manipulated.

- Data that is appropriate for byte-stream access, such as multimedia.

Any storage device accessed by your operating system can hold `BFILE` data, including hard disk drives, CD-ROMs, PhotoCDs, and DVDs. The database can access `BFILE`s provided the operating system supports stream-mode access to the operating system files.

- DIRECTORY Objects
  A `BFILE` locator is initialized by using the function `BFILENAME(DIRECTORY, FILENAME)`. This section describes how to initialize the `DIRECTORY` Object.

- BFILE Locators
  For `BFILE`s, the value is stored in a server-side operating system file, in other words, `BFILE`s are external to the database. The `BFILE` locator that refers to the file is stored in the database row.

- BFILE APIs
  This section discusses the different operations supported through `BFILE`s.

- BFILE APIs in Different Programmatic Interfaces
  This section lists all the APIs from different Programmatic Interfaces supported by Oracle Database.

4.1 DIRECTORY Objects

A `BFILE` locator is initialized by using the function `BFILENAME(DIRECTORY, FILENAME)`. This section describes how to initialize the `DIRECTORY` Object.

A `DIRECTORY` object specifies a *logical alias name* for a physical directory on the database server file system under which the file to be accessed is located. You can access a file in the server file system only if you have the required access privilege on the `DIRECTORY` object. You can also use Oracle Enterprise Manager Cloud Control to manage the `DIRECTORY` objects.

The `DIRECTORY` object provides the flexibility to manage the locations of the files, instead of forcing you to hard-code the absolute path names of physical files in your applications.

A `DIRECTORY` object name is used in conjunction with the `BFILENAME` function, in SQL and PL/SQL, or the `OCILobFileSetName()` function in OCI, for initializing a `BFILE` locator.

- DIRECTORY Name Specification
  You must have `CREATE ANY DIRECTORY` system privilege to create directories.

- Security on Directory Objects
  This section describes the security on `DIRECTORY` objects.

> **✎ See Also:**
>
> - `CREATE DIRECTORY` in *Oracle Database SQL Language Reference*
> - See *Oracle Database Administrator's Guide* for the description of Oracle Enterprise Manager Cloud Control

4.1.1 DIRECTORY Name Specification

You must have `CREATE ANY DIRECTORY` system privilege to create directories.

The naming convention for `DIRECTORY` objects is the same as that for tables and indexes. That is, normal identifiers are interpreted in uppercase, but delimited identifiers are interpreted as is. For example, the following statement:

```
CREATE OR REPLACE DIRECTORY scott_dir AS '/usr/home/scott';
```

creates or redefines a `DIRECTORY` object whose name is '`SCOTT_DIR`' (in uppercase). But if a delimited identifier is used for the `DIRECTORY` name, as shown in the following statement

```
CREATE DIRECTORY "Mary_Dir" AS '/usr/home/mary';
```

then the `DIRECTORY`directory object name is '`Mary_Dir`'. Use '`SCOTT_DIR`' and '`Mary_Dir`' when calling `BFILENAME`. For example:

```
BFILENAME('SCOTT_DIR', 'afile')
BFILENAME('Mary_Dir', 'afile')
```

> **⚠ WARNING:**
>
> The database does not verify that the directory and path name you specify actually exist. You must ensure to specify a valid directory name in your operating system. If your operating system uses case-sensitive path names, then be sure that you specify the directory name in the correct format. There is no requirement to specify a terminating slash (for example, `/tmp/` is not necessary, simply use `/tmp`).
>
> Directory specifications cannot contain ".." anywhere in the path (for example: `../../abc/def` or `abc/../def` or `abc/def/hij..`

On Windows Platform

On Windows platforms the directory names are case-insensitive. Therefore the following two statements refer to the same directory:

```
CREATE DIRECTORY "big_cap_dir" AS "g:\data\source";
```

```
CREATE DIRECTORY "small_cap_dir" AS "G:\DATA\SOURCE";
```

4.1.2 Security on Directory Objects

This section describes the security on `DIRECTORY` objects.

The `DIRECTORY` object model has two distinct levels of security:

- SQL DDL: `CREATE` or `DROP` a `DIRECTORY` object
- SQL DML: `READ` system and object privileges on `DIRECTORY` objects

DBA Privileges: `CREATE / DROP DIRECTORY`

The `DIRECTORY` object is a *system owned* object. Oracle Database supports the following system privileges, which are granted only to DBA:

- `CREATE ANY DIRECTORY`: For creating or altering the `DIRECTORY` object creation
- `DROP ANY DIRECTORY`: For deleting the `DIRECTORY` object

> ⚠ **WARNING:**
>
> Because **`CREATE ANY DIRECTORY`** and **`DROP ANY DIRECTORY`** privileges potentially expose the server file system to all database users, the DBA should be prudent in granting these privileges to normal database users to prevent security breach.

> ✎ **See Also:**
>
> *Oracle Database SQL Language Reference* for information about system owned objects, `CREATE DIRECTORY` and `DROP DIRECTORY`

USER Privileges: READ Permission on the Directory

`READ` permission on the `DIRECTORY` object enables you to read files located under that directory. The creator of the `DIRECTORY` object automatically earns the `READ` privilege.

If you have been granted the `READ` permission with `GRANT` option, then you may in turn grant this privilege to other users or roles and then add them to your privilege domains.

> ✎ **Note:**
>
> The `READ` permission is defined only on the `DIRECTORY` *object*, not on individual files. Hence there is no way to assign different privileges to files in the same directory.

The physical directory that it represents may or may not have the corresponding operating system privileges (*read* in this case) for the Oracle Server process.

It is the responsibility of the DBA to ensure the following:

- That the physical directory exists
- *Read* permission for the Oracle Server process is enabled on the file, the directory, and the path leading to it

ORACLE®

- The directory remains available, and *read* permission remains enabled, for the entire duration of file access by database users

The privilege just implies that as far as the Oracle Server is concerned, you may read from files in the directory. These privileges are checked and enforced by the PL/SQL `DBMS_LOB` package and OCI APIs at the time of the actual file operations.

> ✎ **See Also:**
>
> - [Guidelines for DIRECTORY Usage](#)
>
> - *Oracle Database SQL Language Reference* for information about the `GRANT`, `REVOKE` and `AUDIT` system and object privileges that provide security for `BFILE`s.

Catalog Views on DIRECTORY Objects

Catalog views are provided for `DIRECTORY` objects to enable users to view object names and corresponding paths and privileges. Following are the supported views:

- `ALL_DIRECTORIES` (`OWNER`, `DIRECTORY_NAME`, `DIRECTORY_PATH`)
  This view describes all directories accessible to the user.

- `DBA_DIRECTORIES`(`OWNER`, `DIRECTORY_NAME`, `DIRECTORY_PATH`)
  This view describes all directories specified for the entire database.

4.2 BFILE Locators

For `BFILE`s, the value is stored in a server-side operating system file, in other words, `BFILE`s are external to the database. The `BFILE` locator that refers to the file is stored in the database row.

To associate an operating system file to a `BFILE`, first create a `DIRECTORY` object that is an alias for the full path name to the operating system file. Then, you can initialize an instance of `BFILE` type, using the `BFILENAME` function in SQL or PL/SQL, or `OCILobFileSetName()` in OCI. You can use this `BFILE` instance in one of the following ways:

- If your need for a particular `BFILE` is temporary and limited within the module on which you are working, then you can assign this `BFILE` instance to a PL/SQL or OCI local variable of type `BFILE`. Subsequently, you can use the `BFILE` related APIs on this variable without having to associate this with a column in the database. The `BFILE` API operations on a temporary instance are executed on the client side, without any round-trips to the server.

- You can insert a persistent reference to a `BFILE` in the `BFILE` column using an `INSERT` or `UPDATE` statement. Before using SQL to insert or update a row with a `BFILE`, you must initialize the `BFILE` variable to either `NULL` or a `DIRECTORY` object name and file name.

> ✎ **Note:**
>
> The `OCISetAttr()` function does not allow you to set a `BFILE` locator to `NULL`. To insert a `NULL BFILE` in OCI, you must set the bind value to `NULL`.

It is possible to have multiple `BFILE` columns in the same record or different records referring to the same file. For example, the following `UPDATE` statements set the `BFILE` column of the row with `key_value = 21` in `lob_table` to point to the same file as the row with `key_value = 22`.

```
UPDATE lob_table SET f_lob = (SELECT f_lob FROM lob_table WHERE key_value =
22) WHERE
      key_value = 21;
```

> **See Also:**
>
> Loading BFILEs with SQL*Loader

BFILEs in Objects

If you are using `BFILE`s in objects, you must first set the `BFILE` value, and then flush the object to the database. So, you must first call the `OCIObjectNew()` function, followed by the `OCILobFileSetName()` function and the `OCIObjectFlush()` function respectively.

BFILEs in Shared Server (Multithreaded Server) Mode

The database does not support session migration for `BFILE` data types in shared server (multithreaded server) mode. This implies that in shared server sessions, `BFILE` operations are bound to one shared server, they cannot migrate from one server to another, and open `BFILE` instances can persist beyond the end of a call to a shared server.

Examples of Creating Directory Objects and BFILE Locators

Many examples in the following sections use the `print_media` table. Following is the structure of the table:

Figure 4-1   print_media table

Example 4-1   Inserting BFILEs in SQL and PL/SQL

```
conn system/manager

 -- The DBA creates DIRECTORY object and grants READ to the user
create or replace directory MYDIR as '/your/directory/path/here';
GRANT read ON DIRECTORY MYDIR TO pm;

conn pm/pm

 -- Use BFILENAME to create a BFILE locator for INSERT
INSERT INTO print_media
(product_id, ad_id, ad_composite, ad_sourcetext, ad_graphic)
VALUES
(1, 1, empty_blob(), empty_clob(), BFILENAME('MYDIR','file1.txt'));

-- After this statement, 2 rows point to the same BFILE
```

```
INSERT INTO print_media
(product_id, ad_id, ad_composite, ad_sourcetext, ad_graphic)
    select 2, ad_id, ad_composite, ad_sourcetext, ad_graphic from
print_media;

-- Update the 2nd row to point to a different file
UPDATE print_media SET ad_graphic = BFILENAME('MYDIR','file2.txt')  WHERE
product_id =2;

-- Insert a 3rd row with invalid file name
INSERT INTO print_media
(product_id, ad_id, ad_composite, ad_sourcetext, ad_graphic)
VALUES
(3, 3, empty_blob(), empty_clob(),
BFILENAME('MYDIR','file_does_not_exist.txt'));

-- Insert a NULL for BFILE
INSERT INTO print_media
(product_id, ad_id, ad_composite, ad_sourcetext, ad_graphic)
VALUES
(4, 4, empty_blob(), empty_clob(), NULL);

-- Inserting in PLSQL using a BFILE variable
DECLARE
    f BFILE;
BEGIN
    f := BFILENAME('MYDIR','file5.txt');
    INSERT INTO print_media (product_id, ad_id, ad_composite, ad_sourcetext,
ad_graphic)
    VALUES (5, 5, NULL, NULL, f);
END;
/
SELECT product_id, ad_id, ad_graphic FROM print_media ORDER BY 1,2;
```

Example 4-2   Inserting BFILEs in OCI

```
STATIC TEXT *insstmt = "INSERT INTO print_media (product_id, ad_id,
ad_graphic) VALUES (:1, :1, :2)";
sword insert_bfile()
{
  OCILobLocator *f = (OCILobLocator *)0;

  OCIStmt      *stmthp;
  OCIBind      *bndp1  = (OCIBind *)   0;

}
```

4.3 BFILE APIs

This section discusses the different operations supported through `BFILE`s.

Once you initialize a `BFILE` variable either by using the `BFILENAME` function or an equivalent API, or by using a `SELECT` operation on a BFILE column, you can perform read operations on the `BFILE` using APIs such as `DBMS_LOB`. Note that `BFILE` is a read-only data type. So, you cannot update or delete the operating system files, accessed using `BFILE`s, through the `BFILE` APIs.
The operations performed on `BFILE`s are divided into following categories:

Table 4-1   Operations on BFILEs

Category	Operation	Example function /procedure in **DBMS_LOB** package
Sanity Checking	Check if the `BFILE` exists on the server	`FILEEXISITS`
	Get the `DIRECTORY` object name and file name	`FILEGETNAME`
	Set the name of a `BFILE` in a locator without checking if the directory or file exists	`BFILENAME`
Open / Close	Open a file	`OPEN`
	Check if the file was opened using the input `BFILE` locators	`ISOPEN`
	Close the file	`CLOSE`
	Close all previously opened files	`FILECLOSEALL`
Read Operations	Get the length of the `BFILE`	`GETLENGTH`
	Read data from the `BFILE` starting at the specified offset	`READ`
	Return part of the `BFILE` value starting at the specified offset using `SUBSTR`	`SUBSTR`
	Return the matching position of a pattern in a `BFILE` using `INSTR`	`INSTR`
Operations involving multiple locators	Assign `BFILE` locator `src` to `BFILE` locator `dst`	`dst := src`
	Load `BFILE` data into a LOB	`LOADCLOBFROMFILE`, `LOADBLOBFROMFILE`
	Compare all or part of the value of two `BFILE`s	`COMPARE`

*   Sanity Checking
    Sanity Checking functions on BFILEs enable you to retrieve information about the BFILEs.

*   Opening and Closing a BFILE
    You must `OPEN` a `BFILE` before performing any operations on it, and `CLOSE` it before you terminate your program.

*   Reading from a BFILE
    You can perform many different read operations on the `BFILE` data, including reading its length, reading part of the data, or reading the whole data.

- [Working with Multiple BFILE Locators](#)
  Some `BFILE` operations accept two locators, at least one of which is a `BFILE` locator. For the assignment and the comparison operations involving BFILES, both the locators must be of `BFILE` type.

4.3.1 Sanity Checking

Sanity Checking functions on BFILEs enable you to retrieve information about the BFILEs.

Recall that the `BFILENAME()` and `OCILobFileSetName()` functions do not verify that the directory and path name you specify actually exist. You can use the sanity checking functions to verify that a `BFILE` exists and to extract the directory and file names from a `BFILE` locator.

4.3.2 Opening and Closing a BFILE

You must `OPEN` a `BFILE` before performing any operations on it, and `CLOSE` it before you terminate your program.

A `BFILE` locator operates like a file descriptor available as part of the standard input/output library of most conventional programming languages. This implies that once you define and initialize a `BFILE` locator, and open the file pointed to by this locator, all subsequent operations until the closure of the file must be done from within the same program block using the locator or local copies of it. The `BFILE` locator variable can be used as a parameter to other procedures, member methods, or external function callouts. However, it is recommended that you open and close a file from the same program block at the same nesting level.

You must close all the open `BFILE` instances even in cases, where an exception or unexpected termination of your application occurs. In these cases, if a `BFILE` instance is not closed, then it is still considered open by the database. Ensure that your exception handling strategy does not allow `BFILE` instances to remain open in these situations.

You can close all open `BFILE`s together by using a procedure like `DBMS_LOB.FILECLOSEALL` or `OCILobFileCloseAll()`.

4.3.3 Reading from a BFILE

You can perform many different read operations on the `BFILE` data, including reading its length, reading part of the data, or reading the whole data.

When reading from a large `BFILE`, you can use the streaming read mode in JDBC or OCI. In JDBC, you can achieve this by using the `getBinaryStream()` method. In OCI, you can achieve it in the way as described in the following section.

Streaming Read in OCI

The most efficient way to read large amounts of `BFILE` data is by using the `OCILobRead2()` function with the streaming mechanism enabled, and using polling or callback. To do so, specify the starting point of the read using the `offset` parameter as follows:

```
ub8  char_amt =  0;
ub8  byte_amt =  0;
ub4  offset = 1000;

OCILobRead2(svchp, errhp, locp, &byte_amt, &char_amt, offset, bufp, bufl,
            OCI_ONE_PIECE, 0, 0, 0, 0);
```

When using polling mode, be sure to look at the value of the `byte_amt` parameter after each `OCILobRead2()` call to see how many bytes were read into the buffer, because the buffer may not be entirely full.

When using callbacks, the `lenp` parameter, which is input to the callback, indicates how many bytes are filled in the buffer. Be sure to check the `lenp` parameter during your callback processing because the entire buffer may not be filled with data.

Amount Parameter

- When calling the `DBMS_LOB.READ` API, the size of the `amount` parameter can be larger than the size of the data. However, this parameter should be less than or equal to the size of the buffer. In PL/SQL, the buffer size is limited to 32K.

- When calling the `OCILobRead2()` function, you can pass a value of `UB8MAXVAL` for the `byte_amt` parameter to read to the end of the `BFILE`.

4.3.4 Working with Multiple BFILE Locators

Some `BFILE` operations accept two locators, at least one of which is a `BFILE` locator. For the assignment and the comparison operations involving BFILES, both the locators must be of `BFILE` type.

Loading a LOB with `BFILE` data involves special considerations that we will discuss in the following sections:

Loading a LOB with BFILE Data

In PLSQL, the `DBMS_LOB.LOADFROMFILE` procedure is deprecated in favor of `DBMS_LOB.LOADBLOBFROMFILE` and `DBMS_LOB.LOADCLOBFROMFILE`. Specifically, when you use `DBMS_LOB.LOADCLOBFROMFILE` procedure to load a `CLOB` or `NCLOB` instance, it will perform the character set conversions.

Specifying the Amount of BFILE Data to Load

The value you pass for the amount parameter to functions listed in the table below must be one of the following:

- An amount less than or equal to the actual size (in bytes) of the `BFILE` you are loading.

- The maximum allowable LOB size (in bytes). Passing this value, loads the entire `BFILE`. You can use this technique to load the entire `BFILE` without determining the size of the `BFILE` before loading. To get the maximum allowable LOB size, use the technique described in the following table:

Table 4-2   Maximum LOB Size for Load from File Operations

Environment	Function	To pass maximum LOB size, get value of:
`DBMS_LOB`	`DBMS_LOB.LOADBLOBFROMFILE`	`DBMS_LOB.LOBMAXSIZE`
`DBMS_LOB`	`DBMS_LOB.LOADCLOBFROMFILE`	`DBMS_LOB.LOBMAXSIZE`
`OCI`	`OCILobLoadFromFile2()`	`UB8MAXVAL`
`OCI`	`OCILobLoadFromFile()` (For LOBs less than 4 gigabytes in size.)	`UB4MAXVAL`

Loading a BLOB with BFILE Data

The `DBMS_LOB.LOADBLOBFROMFILE` procedure loads a `BLOB` with data from a `BFILE`. It can be used to load data into any persistent or temporary `BLOB` instance. This procedure returns the new source and the destination offsets of the BLOB, which you can then pass into subsequent calls, when used in a loop.

Loading a CLOB with BFILE Data

The `DBMS_LOB.LOADCLOBFROMFILE` procedure loads a `CLOB` or `NCLOB` with character data from a `BFILE`. It can be used to load data into a persistent or temporary `CLOB` or `NCLOB` instance. You can specify the character set ID of the `BFILE` when calling this procedure and ensure that the character set is properly converted from the `BFILE` data character set to the destination `CLOB` or `NCLOB` character set. This procedure returns the new source and destination offsets of the CLOB or NCLOB, which you can then passe into subsequent calls, when used in a loop.

The following example illustrates:

- How to use `default csid(0)`.

- How to load the entire file without calling `getlength` for the `BFILE`.

- How to find out the actual amount loaded using return offsets.

This example assumes that `ad_source` is a `BFILE` in `UTF8` character set format and the database character set is `UTF8`.

```
CREATE OR REPLACE PROCEDURE loadCLOB1_proc (dst_loc IN OUT CLOB) IS
  src_loc     BFILE := BFILENAME('MEDIA_DIR','monitor_3060.txt') ;
  amt         NUMBER := DBMS_LOB.LOBMAXSIZE;
  src_offset  NUMBER := 1 ;
  dst_offset  NUMBER := 1 ;
  lang_ctx    NUMBER := DBMS_LOB.DEFAULT_LANG_CTX;
  warning     NUMBER;
BEGIN
  DBMS_OUTPUT.PUT_LINE('------------ LOB LOADCLOBFORMFILE EXAMPLE
------------');
  DBMS_LOB.FILEOPEN(src_loc, DBMS_LOB.FILE_READONLY);

  /* The default_csid can be used when the BFILE encoding is in the same
charset
   * as the destination CLOB/NCLOB charset
   */
   DBMS_LOB.LOADCLOBFROMFILE(dst_loc,src_loc, amt, dst_offset,
src_offset,
       DBMS_LOB.DEFAULT_CSID, lang_ctx,warning) ;
  DBMS_OUTPUT.PUT_LINE(' Amount specified ' || amt ) ;
  DBMS_OUTPUT.PUT_LINE(' Number of bytes read from source: ' ||
(src_offset-1));
  DBMS_OUTPUT.PUT_LINE(' Number of characters written to destination: ' ||
(dst_offset-1) );
  IF (warning = DBMS_LOB.WARN_INCONVERTIBLE_CHAR)
  THEN
    DBMS_OUTPUT.PUT_LINE('Warning: Inconvertible character');
  END IF;
  DBMS_LOB.FILECLOSEALL() ;
END;
/
```

The following example illustrates:

- How to get the character set ID from the character set name using the NLS_CHARSET_ID function.

- How to load a stream of data from a single BFILE into different LOBs using the returned offset value and the language context lang_ctx.

- How to read a warning message

This example assumes that ad_file_ext_01 is a BFILE in JA16TSTSET format and the database national character set is AL16UTF16.

```
CREATE OR REPLACE PROCEDURE loadCLOB2_proc (dst_loc1 IN OUT NCLOB,dst_loc2 IN
OUT NCLOB) IS
  src_loc     BFILE := BFILENAME('MEDIA_DIR','monitor_3060.txt');
  amt         NUMBER := 100;
  src_offset  NUMBER := 1;
  dst_offset  NUMBER := 1;
  src_osin    NUMBER;
  cs_id       NUMBER := NLS_CHARSET_ID('JA16TSTSET'); /* 998 */
  lang_ctx    NUMBER := dbms_lob.default_lang_ctx;
  warning     NUMBER;
BEGIN
  DBMS_OUTPUT.PUT_LINE('------------ LOB LOADCLOBFORMFILE EXAMPLE
------------');
  DBMS_LOB.FILEOPEN(src_loc, DBMS_LOB.FILE_READONLY);
  DBMS_OUTPUT.PUT_LINE(' BFILE csid is ' || cs_id) ;

  /* Load the first 1KB of the BFILE into dst_loc1 */

  DBMS_OUTPUT.PUT_LINE(' ----------------------------' ) ;
  DBMS_OUTPUT.PUT_LINE('   First load  ' ) ;
  DBMS_OUTPUT.PUT_LINE(' ----------------------------' ) ;

  DBMS_LOB.LOADCLOBFROMFILE(dst_loc1, src_loc, amt, dst_offset, src_offset,
      cs_id, lang_ctx, warning);

  /* the number bytes read may or may not be 1k */

  DBMS_OUTPUT.PUT_LINE(' Amount specified ' || amt ) ;
  DBMS_OUTPUT.PUT_LINE(' Number of bytes read from source: ' ||
      (src_offset-1));
  DBMS_OUTPUT.PUT_LINE(' Number of characters written to destination: ' ||
      (dst_offset-1) );
  if (warning = dbms_lob.warn_inconvertible_char)
  then
    DBMS_OUTPUT.PUT_LINE('Warning: Inconvertible character');
  end if;

  /* load the next 1KB of the BFILE into the dst_loc2 */

  DBMS_OUTPUT.PUT_LINE(' ----------------------------' ) ;
  DBMS_OUTPUT.PUT_LINE('   Second load  ' ) ;
  DBMS_OUTPUT.PUT_LINE(' ----------------------------' ) ;

  /* Notice we are using the src_offset and lang_ctx returned from the
previous
   * load. We do not use value 1001 as the src_offset here because sometimes
```

```
the
    * actual amount read may not be the same as the amount specified.
    */

  src_osin := src_offset;
  dst_offset := 1;
  DBMS_LOB.LOADCLOBFROMFILE(dst_loc2, src_loc, amt, dst_offset, src_offset,
      cs_id, lang_ctx, warning);
  DBMS_OUTPUT.PUT_LINE(' Number of bytes read from source: ' ||
      (src_offset-src_osin) );
  DBMS_OUTPUT.PUT_LINE(' Number of characters written to destination: ' ||
      (dst_offset-1) );
  if (warning = DBMS_LOB.WARN_INCONVERTIBLE_CHAR)
  then
    DBMS_OUTPUT.PUT_LINE('Warning: Inconvertible character');
  end if;
  DBMS_LOB.FILECLOSEALL() ;

END;
/
```

4.4 BFILE APIs in Different Programmatic Interfaces

This section lists all the APIs from different Programmatic Interfaces supported by Oracle Database.

> **Note:**
>
> The PL/SQL `DBMS_LOB` package provides a rich set of operations on `BFILE`s. If you are using a different Programmatic Interface where some of these operations are not provided, then call the corresponding PL/SQL `DBMS_LOB` procedure or function.

*   PL/SQL APIs for BFILEs
    This section describes the PL/SQL APIs that you can use with BFILEs.

*   JDBC API for BFILEs

> DBMS_LOB

Table 4-3   DBMS_LOB functions and procedures for BFILEs

Category	Function/ Procedure	Description
Sanity Checking	FILEEXISTS	Checks if the BFILE exists on the server
	FILEGETNAME	Gets the DIRECTORY object name and file name
	BFILENAME	Sets the name of a BFILE in a locator without checking if the directory or file exists
Open/Close	OPEN, FILEOPEN	Opens a file. Use OPEN instead of FILEOPEN.
	ISOPEN, FILEISOPEN	Checks if the file was opened using the input BFILE locators. Use ISOPEN instead of FILEISOPEN.
	CLOSE, FILECLOSE	Closes the file. Use CLOSE instead of FILECLOSE.
	FILECLOSEALL	Closes all previously opened files.
Read Operations	GETLENGTH	Gets the length of the BFILE
	READ	Reads data from the BFILE starting at the specified offset.
	SUBSTR	Returns part of the BFILE value starting at the specified offset.
	INSTR	Returns the matching position of the nth occurrence of the pattern in the BFILE.
Operations involving multiple locators	:= (operator)	Assigns a BFILE locator to another
	LOADCLOBFROMFILE	Loads character data from a file into a LOB
	LOADBLOBFROMFILE	Loads binary data from a file into a LOB
	LOADFROMFILE	Loads BFILE data into a LOB (deprecated)
	COMPARE	Compares the value of two BFILEs.

Example 4-3   PL/SQL API for BFILEs

```
declare
  f            BFILE;
  f2           BFILE;
  b            BLOB;

   end if;

   -- Close just f
   DBMS_LOB.CLOSE(f);

   -- Close the rest of bfiles opended
   DBMS_LOB.FILECLOSEALL;

END;
/
```

4.4.2 JDBC API for BFILEs

This section describes the JDBC APIs that you can use to work with BFILEs.

In JDBC, the `oracle.jdbc.OracleBfile` interface provides methods for performing operations on `BFILE` data in the database. It encapsulates the `BFILE` locators, so you do not deal with locators, but instead use methods and properties provided to perform operations and get state information.

To retrieve the locator for the most current row, you must call the `getBFILE()` method on the `OracleResultSet` each time a move operation is made, depending on whether the instance is a `BFILE`.

> ✎ **See Also:**
>
> Working with LOBs and BFILEs

Table 4-4   JDBC APIs for BFILEs

Category	Function/ Procedure	Description
Sanity Checking	`boolean fileExists()`	Checks if the `BFILE` exists on the server

Table 4-4   (Cont.) JDBC APIs for BFILEs

Category	Function/ Procedure	Description
	`public java.lang.String getName()`	Gets the file name
	`public java.lang.String getDirAlias()`	Gets the `DIRECTORY` object name
Open/Close	`public void openFile()`	Opens a file.
	`public boolean isFileOpen()`	Checks if the file was opened using the input `BFILE` locators. .
	`public void closeFile()`	Closes the file. Use `CLOSE` instead of `FILECLOSE`.
Read Operations	`long length()`	Gets the length of the `BFILE`
	`public java.io.InputStream getBinaryStream()`	Reads the `BFILE` as a binary stream.
	`byte[] getBytes(long, int)`	Gets the contents of the `BFILE` as an array of bytes, given an offset
	`int getBytes(long, int, byte[])`	Reads a subset of the `BFILE` into a byte array
	`long position(oracle.jdbc.OracleBfile, long)`	Finds the first appearance of the given `BFILE` contents within the LOB, from the given offset.
	`long position(byte[], long)`	Finds the first appearance of the given byte array within the `BFILE`, from the given offset
Operations involving multiple locators	[use equal sign]	Assigns a `BFILE` locator to another

Example 4-4   JDBC API for BFILEs

```
static void run_query() throws Exception {

  try(
     OracleConnection con = getConnection();
     Statement       stmt = con.createStatement();
     ){

   ResultSet   rs      = null;

   OracleBfile f       = null;
   OracleBfile f2      = null;
   OracleBfile f3      = null;

   InputStream in      = null;
   String      output  = null;
   byte        buffer[] = new byte[15];
   long        pos;

   String      filename = null;
   String      dirname  = null;
   long        len      = 0;
```

```
    rs = stmt.executeQuery("select ad_graphic from print_media where
product_id = 1");
    rs.next();
    f = (OracleBfile)((OracleResultSet)rs).getBfile(1);
    rs.close();

    rs = stmt.executeQuery("select ad_graphic from print_media where
product_id = 2");
    rs.next();
    f2 = (OracleBfile)((OracleResultSet)rs).getBfile(1);
    rs.close();

    stmt.close();

    /*----------------------------------------------------------------*/
    /*-------------------- Sanity Checking --------------------------*/
    /*----------------------------------------------------------------*/

    /*-------------- Determining Whether a BFILE Exists --------------*/
    if (f.fileExists())
      System.out.println("F exists!");
    else
      System.out.println("F does not exist :(");

4.4.3 OCI API for BFILEs

This section describes the OCI APIs that you can use with BFILEs.

> ✎ **See Also:**
>
> LOB and BFILE Operations

Table 4-5   OCI APIs for BFILEs

Category	Function/ Procedure	Description
Sanity Checking	`OCILobFileExists()`	Checks if the `BFILE` exists on the server
	`OCILobFileGetName()`	Gets the `DIRECTORY` object name and the file name
	`OCILobFileSetName()`	Sets the name of a `BFILE` in a locator without checking if the directory or file exists
	`OCILobLocatorIsInit()`	Checks whether a LOB Locator is initialized
Open/Close	`OCILobOpen()` and `OCILobFileOpen()`	Opens a file. Use `OciLobOpen()` instead of `OCILobFileOpen()`.
	`OCILobIsOpen()` and `OCILobFileIsOpen()`	Checks if the file was opened using the input `BFILE` locators. Use `OCILobIsOpen()` instead of `OciLobFileIsOpen()`.
	`OCILobClose()` and `OCILobFileClose()`	Closes the file. Use `OciLobClose()` instead of `OciLobFileClose()`.
	`OCILobFileCloseAll()`	Closes all previously opened files.
Read Operations	`OCILobGetLength2()`	Gets the length of the `BFILE`
	`OCILobRead2()`	Reads data from the `BFILE` starting at the specified offset.
	`OCILobArrayRead()`	Reads data using multiple locators in one round trip.
Operations involving multiple locators	`OCILobLocatorAssign()`	Assigns a `BFILE` locator to another
	`OCILobLoadFromFile2()`	Loads `BFILE` data from a file into a LOB

Example 4-5   OCI API for BFILEs

```
static text *selstmt = (text *) "select ad_graphic, ad_composite,
ad_sourcetext from print_media where product_id = 1 and ad_id = 1 for update"
sword run_query()
{
  OCILobLocator *f = (OCILobLocator *)0;
  OCILobLocator *f2 = (OCILobLocator *)0;

  OCILobLocator *b = (OCILobLocator *)0;
  OCILobLocator *c = (OCILobLocator *)0;

  OCIStmt      *stmthp;

4.4.4 ODP.NET API for BFILEs

This section describes the ODP.NET APIs that you can use with BFILEs.

> **See Also:**
>
> OracleBFile Class

Table 4-6   ODP.NET methods in OracleBfileClass

Category	Function/Description	Description
Sanity Checking	FileExists	Checks if the BFILE exists on the server
	FileName	Sets or gets the file name
	DirectoryName	Sets or gets the DIRECTORY object name
Open/Close	OpenFile	Opens a file. Use OPEN instead of FILEOPEN.
	IsOpen	Checks if the file was opened using the input BFILE locators. Use ISOPEN instead of FILEISOPEN.

Table 4-6 (Cont.) ODP.NET methods in OracleBfileClass

Category	Function/Description	Description
	`CloseFile`	Closes the file.
Read Operations	`Length`	Get the length of the BFILE
	`Value`	Returns the entire LOB data as a string for CLOB and a byte array for BLOB
	`Read`	Reads data from the BFILE starting at the specified offset.
	`Search`	Returns the matching position of the nth occurrence of the pattern in the BFILE.
Operations involving multiple locators	`Compare`	Compares the values of two BFILEs
	`IsEqual`	Check if two LOBs point to the same LOB data

4.4.5 OCCI API for BFILEs

This section describes the OCCI APIs that you can use with `BFILE`s.

In OCCI, the `Bfile` class enables you to instantiate a `Bfile` object in your C++ application. You must then use methods of the `Bfile` class, such as the `setName()` method, to initialize the `Bfile` object, which associates the object properties with an object of type `BFILE` in a `BFILE` column of the database.

> ✎ **See Also:**
>
> Bfile Class

Amount Parameter for OCCI LOB copy() Methods

The `copy()` method on `Clob` and `Blob` enables you to load data from a `BFILE`. You can pass one of the following values for the `amount` parameter to this method:

- An amount smaller than the size of the `BFILE` to load a portion of the data

- An amount equal to the size of the `BFILE` to load all of the data

- The `UB8MAXVAL` constant to load all of the `BFILE` data

You cannot specify an amount larger than the length of the `BFILE`.

Amount Parameter for OCCI read() Operations

The `read()` method on an `Clob`, `Blob`, or `Bfile` object, reads data from a `BFILE`. You can pass one of these values for the amount parameter to specify the amount of data to read:

- An amount smaller than the size of the `BFILE` to load a portion of the data

- An amount equal to the size of the `BFILE` to load all of the data

- An amount equal to zero (`0`) to read until the end of the `BFILE` in streaming mode

You cannot specify an amount larger than the length of the `BFILE`.

Table 4-7   OCCI Methods for BFILEs

Category	Function/ Procedure	Description
Sanity Checking	`fileExists()`	Checks if the `BFILE` exists on the server
	`getFileName()`	Gets the file name
	`getDirAlias()`	Gets the `DIRECTORY` object name
	`setName()`	Sets the name of a `BFILE` in a locator without checking if the directory or file exists.
	`isInitialized()`	Checks whether a `BFILE` is initialized.
Open/Close	`open()`	Opens a file.
	`isOpen()`	Checks if the file was opened using the input BFILE locators.
	`close()`	Closes the file.
Read Operations	`length()`	Gets the length of the `BFILE`
	`read()`	Reads data from the `BFILE` starting at the specified offset.
Operations involving multiple locators	`(operator) =`	Assigns a `BFILE` locator to another. Use the assignment operator (=) or the copy constructor.
	`Blob.copy()` or `Clob.copy()`	Loads `BFILE`data into a LOB

4.4.6 Pro*C/C++ and Pro*COBOL API for BFILES

This section describes Pro*C/C++ and Pro*COBOL APIs APIs you can use for BFILEs.

> **✎ See Also:**
>
> - Pro*C/C++ Programmer's Guide
> - Pro*COBOL Programmer's Guide

Table 4-8   Pro*C/C++ and Pro*COBOL APIs for BFILEs

Category	Function/ Procedure	Description
Sanity Checking	`DESCRIBE[FILEEXISTS]`	Checks if the `BFILE` exists on the server
	`DESCRIBE[DIRECTORY,FILENAME]`	Gets the directory object name and file name
	`FILE SET`	Sets the name of a `BFILE` in a locator without checking if the directory or file exists
Open/Close	`OPEN`	Opens a file.

Table 4-8   (Cont.) Pro*C/C++ and Pro*COBOL APIs for BFILEs

Category	Function/ Procedure	Description
	DESCRIBE[ISOPEN]	Checks if the file was opened using the input BFILE locators.
	CLOSE	Closes the file.
	FILE CLOSE ALL	Closes all previously opened files.
Read Operations	DESCRIBE[LENGTH]	Gets the length of the BFILE
	READ	Reads data from the BFILE starting at the specified offset.
Operations involving multiple locators	ASSIGN	Assigns a BFILE locator to another
	LOAD FROM FILE	Loads BFILE data into a LOB

5

SQL Semantics for LOBs

You can use various SQL mechanisms to operate on LOBs.

You can access `CLOB` and `NCLOB` data types using SQL `VARCHAR2` semantics, such as SQL string operators and functions. These techniques allow you to use LOBs directly in SQL code and provide an alternative to using LOB-specific APIs for some operations, and are beneficial in the following situations:

- When performing operations on LOBs that are relatively small in size, i.e., up to about 100K bytes

- After migrating your database from `LONG` columns to LOB data types, so that any SQL string functions contained in your existing PL/SQL application continue to work

SQL semantics are not recommended in the following situations, you must use LOB APIs instead:

- When using advanced features such as random access and piece-wise fetch.

- When performing operations on LOBs that are relatively large in size (greater than 1MB), because using SQL semantics can impact performance.

> ✏️ **Note:**
>
> SQL semantics are used with persistent and temporary LOBs, and do not apply to BFILEs.

- SQL Functions and Operators Supported for Use with LOBs
  Many SQL operators and functions that take `VARCHAR2` columns as arguments, also accept LOB columns. The following list summarizes those categories of SQL functions and operators that are supported for use with LOBs.

- Detailed Semantics of SQL Operations on LOBs
  This section explains semantics of SQL operations on LOBs in details.

- Restrictions on SQL Operations on LOBs
  There are many SQL operations that are not supported on LOB columns. This section lists those operations.

5.1 SQL Functions and Operators Supported for Use with LOBs

Many SQL operators and functions that take `VARCHAR2` columns as arguments, also accept LOB columns. The following list summarizes those categories of SQL functions and operators that are supported for use with LOBs.

SQL Operations/ Functions	Support
Concatenation	Supported
Comparison	Some comparison functions are not supported for LOBs

SQL Operations/ Functions	Support
Character functions	Supported
Conversion	Some conversion functions are not supported for LOBs
Aggregate functions	Not supported
Unicode functions	Not supported

> **✎ See Also:**
>
> Working with Remote LOBs in SQL and PL/SQL

The following table provides the details on each of the operations that accept `VARCHAR2` types as operands or arguments, or return a `VARCHAR2` value.

- The SQL column identifies the built-in functions and operators that are supported for `CLOB` and `NCLOB` data types. The `LENGTH` function is also supported for the `BLOB` data type.

- The PL/SQL column identifies the PL/SQL built-in functions and operators that are supported on LOBs.

- Functions designated as CNV in the SQL or PL/SQL column in the table are performed by converting the `CLOB` to a character data type, such as `VARCHAR2`. In the SQL environment, only the first 4K bytes of the `CLOB` are converted and used in the operation. In the PL/SQL environment, only the first 32K bytes of the `CLOB` are converted and used in the operation.

Table 5-1   SQL VARCHAR2 Functions and Operators on LOBs

Category	Operator / Function	SQL Example / Comments	SQL	PL/SQL
Concatenation	`||`, `CONCAT()`	`Select clobCol || clobCol2 from tab;`	Yes	Yes
Comparison	`= , !=, >, >=, <, <=, <>, ^=`	`if clobCol=clobCol2 then...`	No	Yes
Comparison	`IN, NOT IN`	`if clobCol NOT IN (clob1, clob2, clob3) then...`	No	Yes
Comparison	`SOME, ANY, ALL`	`if clobCol < SOME (select clobCol2 from...) then...`	No	N/A
Comparison	`BETWEEN`	`if clobCol BETWEEN clobCol2 and clobCol3 then...`	No	Yes
Comparison	`LIKE [ESCAPE]`	`if clobCol LIKE '%pattern%' then...`	Yes	Yes
Comparison	`IS [NOT] NULL`	`where clobCol IS NOT NULL`	Yes	Yes
Character Functions	`INITCAP, NLS_INITCAP`	`select INITCAP(clobCol) from...`	CNV	CNV
Character Functions	`LOWER, NLS_LOWER, UPPER, NLS_UPPER`	`...where LOWER(clobCol1) = LOWER(clobCol2)`	Yes	Yes
Character Functions	`LPAD, RPAD`	`select RPAD(clobCol, 20, ' La') from...`	Yes	Yes
Character Functions	`TRIM, LTRIM, RTRIM`	`...where RTRIM(LTRIM(clobCol,'ab'), 'xy') = 'cd'`	Yes	Yes

Table 5-1 (Cont.) SQL VARCHAR2 Functions and Operators on LOBs

Category	Operator / Function	SQL Example / Comments	SQL	PL/SQL
Character Functions	REPLACE	select REPLACE(clobCol, 'orig','new') from...	Yes	Yes
Character Functions	SOUNDEX	...where SOUNDEX(clobCOl) = SOUNDEX('SMYTHE')	CNV	CNV
Character Functions	SUBSTR	...where substr(clobCol, 1,4) = like 'THIS'	Yes	Yes
Character Functions	TRANSLATE	select TRANSLATE(clobCol, '123abc','NC') from...	CNV	CNV
Character Functions	ASCII	select ASCII(clobCol) from...	CNV	CNV
Character Functions	INSTR	...where instr(clobCol, 'book') = 11	Yes	Yes
Character Functions	LENGTH	...where length(clobCol) != 7;	Yes	Yes
Character Functions	NLSSORT	...where NLSSORT (clobCol,'NLS_SORT = German') > NLSSORT ('S','NLS_SORT = German')	CNV	CNV
Character Functions	INSTRB, SUBSTRB, LENGTHB	These functions are supported only for CLOBs that use single-byte character sets. (LENGTHB is supported for BLOBs and CLOBs.)	Yes	Yes
Character Functions - Regular Expressions	REGEXP_LIKE	This function searches a character column for a pattern. Use this function in the WHERE clause of a query to return rows matching the regular expression you specify.	Yes	Yes
Character Functions - Regular Expressions	REGEXP_REPLACE	This function searches for a pattern in a character column and replaces each occurrence of that pattern with the pattern you specify.	Yes	Yes
Character Functions - Regular Expressions	REGEXP_INSTR	This function searches a string for a given occurrence of a regular expression pattern. You specify which occurrence you want to find and the start position to search from. This function returns an integer indicating the position in the string where the match is found.	Yes	Yes
Character Functions - Regular Expressions	REGEXP_SUBSTR	This function returns the actual substring matching the regular expression pattern you specify.	Yes	Yes
Conversion	CHARTOROWID	CHARTOROWID(clobCol)	CNV	CNV
Conversion	COMPOSE	COMPOSE('string') Returns a Unicode string given a string in the data type CHAR, VARCHAR2, CLOB, NCHAR, NVARCHAR2, NCLOB.	CNV	CNV
Conversion	DECOMPOSE	DECOMPOSE('str' [CANONICAL | COMPATIBILITY]) Valid for Unicode character arguments.	CNV	CNV
Conversion	HEXTORAW	HEXTORAW(CLOB)	No	CNV

Table 5-1   (Cont.) SQL VARCHAR2 Functions and Operators on LOBs

Category	Operator / Function	SQL Example / Comments	SQL	PL/SQL
Conversion	`CONVERT`	`select CONVERT(clobCol,'WE8DEC','WE8HP') from...`	Yes	CNV
Conversion	`TO_DATE`	`TO_DATE(clobCol)`	CNV	CNV
Conversion	`TO_NUMBER`	`TO_NUMBER(clobCol)`	CNV	CNV
Conversion	`TO_TIMESTAMP`	`TO_TIMESTAMP(clobCol)`	No	CNV
Conversion	`TO_MULTI_BYTE` `TO_SINGLE_BYTE`	`TO_MULTI_BYTE(clobCol)` `TO_SINGLE_BYTE(clobCol)`	CNV	CNV
Conversion	`TO_CHAR`	`TO_CHAR(clobCol)`	Yes	Yes
Conversion	`TO_NCHAR`	`TO_NCHAR(clobCol)`	Yes	Yes
Conversion	`TO_LOB`	`INSERT INTO... SELECT TO_LOB(longCol)...` Note that `TO_LOB` can only be used to create or insert into a table with LOB columns as `SELECT FROM` a table with a `LONG` column.	N/A	N/A
Conversion	`TO_CLOB`	`TO_CLOB(varchar2Col)`	Yes	Yes
Conversion	`TO_NCLOB`	`TO_NCLOB(varchar2Clob)`	Yes	Yes
Aggregate Functions	`COUNT`	`select count(clobCol) from...`	No	N/A
Aggregate Functions	`MAX, MIN`	`select MAX(clobCol) from...`	No	N/A
Aggregate Functions	`GROUPING`	`select grouping(clobCol) from... group by cube (clobCol);`	No	N/A
Other Functions	`GREATEST, LEAST`	`select GREATEST (clobCol1, clobCol2) from...`	No	CNV
Other Functions	`DECODE`	`select DECODE(clobCol, condition1, value1, defaultValue) from...`	CNV	CNV
Other Functions	`NVL`	`select NVL(clobCol,'NULL') from...`	Yes	Yes
Other Functions	`DUMP`	`select DUMP(clobCol) from...`	No	N/A
Other Functions	`VSIZE`	`select VSIZE(clobCol) from...`	No	N/A
Unicode	`INSTR2, SUBSTR2, LENGTH2, LIKE2`	These functions use UCS2 code point semantics.	No	CNV
Unicode	`INSTR4, SUBSTR4, LENGTH4, LIKE4`	These functions use UCS4 code point semantics.	No	CNV
Unicode	`INSTRC, SUBSTRC, LENGTHC, LIKEC`	These functions use complete character semantics.	No	CNV

> - *Oracle Database Development Guide* for information on using regular expressions with the database.

5.2 Detailed Semantics of SQL Operations on LOBs

This section explains semantics of SQL operations on LOBs in details.

- Return Datatype for SQL Operations on LOBs
  The return data type of SQL functions on LOBs is dependent on the input parameters.

- NULL vs EMPTY LOB: Semantic Difference between LOBs and VARCHAR2
  For the `VARCHAR2` data type, a string of length zero is indistinguishable from a `NULL` value for the column.

- WHERE Clause Usage with LOBs
  SQL functions with LOBs as arguments, except functions that compare LOB values, are allowed in predicates of the `WHERE` clause.

- CLOBs and NCLOBs Do Not Follow Session Collation Settings
  Learn about various operators on `CLOB`s and `NCLOB`s and compare the operations on `VARCHAR2` and `NVARCHAR2` variables with respect to LOBs in this section.

- Codepoint Semantics
  Codepoint semantics of the `INSTR`, `SUBSTR`, `LENGTH`, and `LIKE` functions differ depending on the data type of the argument passed to the function.

5.2.1 Return Datatype for SQL Operations on LOBs

The return data type of SQL functions on LOBs is dependent on the input parameters.

The return type of a function or operator that takes a LOB or `VARCHAR2` is the same as the data type of the argument passed to the function or operator. Functions that take more than one argument, such as `CONCAT`, return a LOB data type if one or more arguments is a LOB.

Example 5-1   `CONCAT` function returning `CLOB`

```
CONCAT(CLOB, VARCHAR2)CLOB
```
Any LOB instance returned by a SQL function is a temporary LOB instance. LOB instances in tables (persistent LOBs) are not modified by SQL functions, even when the function is used in the `SELECT` list of a query.

5.2.2 NULL vs EMPTY LOB: Semantic Difference between LOBs and VARCHAR2

For the `VARCHAR2` data type, a string of length zero is indistinguishable from a `NULL` value for the column.

For the column of a `LOB` data type, there are three possible states:

1. `NULL`: This means the column has no LOB locator.

2. Zero-length value: This can be achieved by inserting an `EMPTY LOB` into the column, or by using an API such as `DBMS_LOB.TRIM()` to trim the length to zero. In either case, there is a valid LOB locator in the column, but the LOB value length is zero.

3. Non-zero length value.

Due to this difference, the `LENGTH` function differs depending on whether the argument passed is a `LOB` or a character string:

- For a character string of length zero, the `LENGTH` function returns `NULL`.

- For a `CLOB` of length zero, or an empty locator such as that returned by `EMPTY_CLOB()`, the `LENGTH` and `DBMS_LOB.GETLENGTH` functions return 0.

Similarly, when used with LOBs, the `IS NULL` and `IS NOT NULL` operators determine whether a LOB locator is stored in the row:

- When you pass an initialized LOB of length zero to the `IS NULL` function, `FALSE` is returned. These semantics are compliant with the SQL 92 standard.

- When you pass a `VARCHAR2` of length zero to the `IS NULL` function, `TRUE` is returned.

5.2.3 WHERE Clause Usage with LOBs

SQL functions with LOBs as arguments, except functions that compare LOB values, are allowed in predicates of the `WHERE` clause.

The `LENGTH` function, for example, can be included in the predicate of the `WHERE` clause:

```
CREATE TABLE t (n NUMBER, c CLOB);
INSERT INTO t VALUES (1, 'abc');

SELECT * FROM t WHERE c IS NOT NULL;
SELECT * FROM t WHERE LENGTH(c) > 0;
SELECT * FROM t WHERE c LIKE '%a%';
SELECT * FROM t WHERE SUBSTR(c, 1, 2) LIKE '%b%';
SELECT * FROM t WHERE INSTR(c, 'b') = 2;
```

5.2.4 CLOBs and NCLOBs Do Not Follow Session Collation Settings

Learn about various operators on `CLOB`s and `NCLOB`s and compare the operations on `VARCHAR2` and `NVARCHAR2` variables with respect to LOBs in this section.

Standard operators that operate on `CLOB`s and `NCLOB`s without first converting them to `VARCHAR2` or `NVARCHAR2`, are marked as 'Yes' in the SQL or PL/SQL columns of Table 7-1. These operators do not behave linguistically, except for `REGEXP` functions. Binary comparison of the character data is performed irrespective of the `NLS_COMP` and `NLS_SORT` parameter settings.

These `REGEXP` functions are the exceptions, where, if `CLOB` or `NCLOB` data is passed in, the linguistic comparison is similar to the comparison of `VARCHAR2` and `NVARCHAR2` values.

- `REGEXP_LIKE`

- `REGEXP_REPLACE`

- `REGEXP_INSTR`

- `REGEXP_SUBSTR`

- `REGEXP_COUNT`

> **Note:**
>
> CLOBs and NCLOBs support the default USING NLS_COMP option.

> **See Also:**
>
> *Oracle Database Reference* for more information about `NLS_COMP`

5.2.5 Codepoint Semantics

Codepoint semantics of the `INSTR`, `SUBSTR`, `LENGTH`, and `LIKE` functions differ depending on the data type of the argument passed to the function.

These functions use different codepoint semantics depending on whether the argument is a `VARCHAR2` or a `CLOB` type as follows:

- When the argument is a `CLOB`, UCS2 codepoint semantics are used for all character sets.

- When the argument is a character type, such as `VARCHAR2`, the default codepoint semantics are used for the given character set:
  - UCS2 codepoint semantics are used for AL16UTF16 and UTF8 character sets.
  - UCS4 codepoint semantics are used for all other character sets, such as AL32UTF8.

- If you are storing character data in a `CLOB` or `NCLOB`, then note that the amount and offset parameters for any APIs that read or write data to the `CLOB` or `NCLOB` are specified in UCS2 codepoints. In some character sets, a full character consists one or more UCS2 codepoints called a surrogate pair. In this scenario, you must ensure that the amount or offset you specify does not cut into a full character. This avoids reading or writing a partial character.

- Oracle Database helps to detect half surrogate pair on read or write boundaries in case of SQL functions and in case of read/write through LOB APIs. The behavior is as follows:
  - If the starting offset is in the middle of a surrogate pair, an error is raised for both read and write operations.
  - If the read amount reads only a partial character, increment or decrement the amount by 1 to read complete characters.

    > **Note:**
    >
    > The output amount may vary from the input amount.

  - If the write amount overwrites a partial character, an error is raised to prevent the corruption of existing data caused by overwriting of a partial character in the destination `CLOB` or `NCLOB`.

> **Note:**
>
> This check only applies to the existing data in the `CLOB` or `NCLOB`. You must make sure that the incoming buffer for the write operation starts and ends in complete characters.

5.3 Restrictions on SQL Operations on LOBs

There are many SQL operations that are not supported on LOB columns. This section lists those operations.

Table 5-2   Unsupported Usage of LOBs in SQL

SQL Operations Not Supported	Example of unsupported usage
`SELECT DISTINCT`	`SELECT DISTINCT clobCol from...`
`SELECT` clause `ORDER BY`	`SELECT... ORDER BY clobCol`
`SELECT` clause `GROUP BY`	`SELECT avg(num) FROM...` `GROUP BY clobCol`
`UNION, INTERSECT, MINUS` (Note that `UNION ALL` works for LOBs.)	`SELECT clobCol1 from tab1 UNION SELECT clobCol2 from tab2;`
Join queries	`SELECT... FROM... WHERE tab1.clobCol = tab2.clobCol`
Index columns	`CREATE INDEX clobIndx ON tab(clobCol)...`

PL/SQL Semantics for LOBs

This chapter covers topics related to PL/SQL semantics for LOBs.

- **Implicit Conversion with LOBs**
  This section describes the implicit conversion process in PL/SQL from one LOB type to another LOB type or from a LOB type to a non-LOB type.

- **Explicit Data Type Conversion Functions**
  This section describes the explicit conversion functions in SQL and PL/SQL to convert other data types to and from `CLOB`, `NCLOB`, and `BLOB` data types.

- **Temporary LOBs Created by SQL and PL/SQL Built-in Functions**
  When a LOB is returned from a SQL or PL/SQL built-in function, then the result returned is a temporary LOB. Similarly, a LOB returned from a user-defined PL/SQL function or procedure, as a value or an OUT parameter, may be a temporary LOB.

6.1 Implicit Conversion with LOBs

This section describes the implicit conversion process in PL/SQL from one LOB type to another LOB type or from a LOB type to a non-LOB type.

Most of the in the following sections use `print_media` table. Following is the structure of `print_media` table:

Figure 6-1   print_media table

PRINT_MEDIA Table

Column name	Column Type
product_id	NUMBER (6)
ad_id	NUMBER (6)
ad_composite	BLOB
ad_sourcetext	CLOB
ad_finaltext	CLOB
ad_fltextn	NCLOB
ad_textdocs_ntab	NESTED TABLE
ad_photo	BLOB
ad_graphic	BFILE
ad_header	USER DEFINED TYPE
press_release	LONG

- Implicit Conversion Between CLOB and NCLOB Data Types in SQL
  This section describes support for implicit conversions between CLOB and NCLOB data types.

- Implicit Conversions Between CLOB and VARCHAR2
  This section describes support for implicit conversions between CLOB and VARCHAR2 data types.

- Implicit Conversions Between BLOB and RAW
  This section describes support for implicit conversions between BLOB and RAW data types.

- Guidelines and Restrictions for Implicit Conversions with LOBs
  This section describes the techniques that you use to access LOB columns or attributes using the Data Interface for LOBs.

- Detailed Examples for Implicit Conversions with LOBs
  The example in this section demonstrates using multiple VARCHAR and RAW binds in INSERT and UPDATE operations.

6.1.1 Implicit Conversion Between CLOB and NCLOB Data Types in SQL

This section describes support for implicit conversions between CLOB and NCLOB data types.

The database enables you to perform operations such as cross-type assignment and cross-type parameter passing between CLOB and NCLOB data types. The database performs implicit conversions between these types when necessary to preserve properties such as character set formatting.

Note that, when implicit conversions occur, each character in the source LOB is changed to the character set of the destination LOB, if needed. In this situation, some degradation of performance may occur if the data size is large. When the character set of the destination and the source are the same, there is no degradation of performance.

After an implicit conversion between CLOB and NCLOB types, the destination LOB is implicitly created as a temporary LOB. This new temporary LOB is independent from the source LOB. If the implicit conversion occurs as part of a define operation in a SELECT statement, then any modifications to the destination LOB do not affect the persistent LOB in the table that the LOB was selected from as shown in the following example:

```
SQL> -- check lob length before update
SQL> SELECT DBMS_LOB.GETLENGTH(ad_sourcetext) FROM Print_media
  2       WHERE product_id=3106 AND ad_id = 13001;

DBMS_LOB.GETLENGTH(AD_SOURCETEXT)
---------------------------------
        205

SQL>
SQL> DECLARE
  2    clob1 CLOB;
  3    amt NUMBER:=10;
  4  BEGIN
  5    -- select a clob column into a clob, no implicit convesion
  6    SELECT ad_sourcetext INTO clob1 FROM Print_media
  7      WHERE product_id=3106 and ad_id=13001 FOR UPDATE;
  8    -- Trim the selected lob to 10 bytes
  9    DBMS_LOB.TRIM(clob1, amt);
 10  END;
 11  /

PL/SQL procedure successfully completed.

SQL> -- Modification is performed on clob1 which points to the
SQL> -- clob column in the table
SQL> SELECT DBMS_LOB.GETLENGTH(ad_sourcetext) FROM Print_media
  2       WHERE product_id=3106 AND ad_id = 13001;

DBMS_LOB.GETLENGTH(AD_SOURCETEXT)
---------------------------------
         10

SQL>
SQL> ROLLBACK;

Rollback complete.

SQL> -- check lob length before update
SQL> SELECT DBMS_LOB.GETLENGTH(ad_sourcetext) FROM Print_media
  2       WHERE product_id=3106 AND ad_id = 13001;
```

```
DBMS_LOB.GETLENGTH(AD_SOURCETEXT)
---------------------------------
        205

SQL>
SQL> DECLARE
  2    nclob1 NCLOB;
  3    amt NUMBER:=10;
  4  BEGIN
  5
  6    -- select a clob column into a nclob, implicit conversion occurs
  7    SELECT ad_sourcetext INTO nclob1 FROM Print_media
  8       WHERE product_id=3106 AND ad_id=13001 FOR UPDATE;
  9
 10    DBMS_LOB.TRIM(nclob1, amt); -- Trim the selected lob to 10 bytes
 11  END;
 12  /

PL/SQL procedure successfully completed.

SQL> -- Modification to nclob1 does not affect the clob in the table,
SQL> -- because nclob1 is a independent temporary LOB

SQL> SELECT DBMS_LOB.GETLENGTH(ad_sourcetext) FROM Print_media
  2       WHERE product_id=3106 AND ad_id = 13001;

DBMS_LOB.GETLENGTH(AD_SOURCETEXT)
---------------------------------
        205
```

6.1.2 Implicit Conversions Between CLOB and VARCHAR2

This section describes support for implicit conversions between CLOB and VARCHAR2 data types.

Implicit conversions from CLOB to VARCHAR2 and from VARCHAR2 to CLOB data types are supported in PL/SQL.

> **✎ See Also:**
>
> SQL Semantics for LOBs for details on LOB support in SQL statements.

> **✎ Note:**
>
> While this section uses `VARCHAR2` data type as an example for simplicity, other character types like `CHAR` and `LONG` can also participate in implicit conversions with CLOBs.

Assigning a CLOB to a VARCHAR2 in PL/SQL

When assigning a `CLOB` to a `VARCHAR2`, the data stored in the `CLOB` column is retrieved and stored into the `VARCHAR2` buffer. If the buffer is not large enough to contain all the `CLOB` data, then a truncation error is thrown and no data is written to the buffer. This is consistent with `VARCHAR2` semantics. After successful completion of this assignment operation, the `VARCHAR2` variable holds the data as a regular character buffer. This operation can be performed in the following ways:

- `SELECT` persistent or temporary `CLOB` data into a character buffer variable such as `CHAR`, `LONG`, or `VARCHAR2`. In a single `SELECT` statement, you can have more than one of such defines.

- Assign a `CLOB` to a `VARCHAR2`, `CHAR`, or `LONG` variable.

- Pass `CLOB` data types to built-in SQL and PL/SQL functions and operators that accept `VARCHAR2` arguments, such as the `INSTR` function and the `SUBSTR` function.

- Pass `CLOB` data types to user-defined PL/SQL functions that accept `VARCHAR2` or `LONG` data types.

The following example illustrates the way `CLOB` data is accessed when the `CLOB`s are treated as `VARCHAR2`s:

```
DECLARE
  myStoryBuf VARCHAR2(32000);
  myLob  CLOB;
BEGIN
  -- Select a LOB into a VARCHAR2 variable
  SELECT ad_sourcetext INTO myStoryBuf FROM print_media WHERE ad_id = 12001;
  DBMS_OUTPUT.PUT_LINE(myStoryBuf);
  -- Assign a LOB to a VARCHAR2 variable
  SELECT ad_sourcetext INTO myLob FROM print_media WHERE ad_id = 12001;
  myStoryBuf := myLob;
  DBMS_OUTPUT.PUT_LINE(myStoryBuf);
END;
/
```

Assigning a VARCHAR2 to a CLOB in PL/SQL

A `VARCHAR2` can be assigned to a `CLOB` in the following scenarios:

- `INSERT` or `UPDATE` character data stored in `VARCHAR2`, `CHAR`, or `LONG` variables into a `CLOB` column. Multiple such binds are allowed in a single `INSERT` or `UPDATE` statement.

- Assign a `VARCHAR2`, `CHAR`, or `LONG` variable to a `CLOB` variable.

- Pass `VARCHAR2` or `LONG` data types to user-defined PL/SQL functions that accept LOB data types.

```
DECLARE
  myLOB CLOB;
BEGIN
  -- Select a VARCHAR2 into a LOB variable
  SELECT 'ABCDE' INTO myLOB FROM print_media WHERE ad_id = 11001;
  -- myLOB is a temporary LOB.
  -- Use myLOB as a lob locator
  DBMS_OUTPUT.PUT_LINE('Is temp? '||DBMS_LOB.ISTEMPORARY(myLOB));

  -- Insert a VARCHAR2 into a lob column
  INSERT INTO print_media(product_id, ad_id, AD_SOURCETEXT) VALUES (1000, 1,
'ABCDE');

  -- Assign a VARCHAR2 to a LOB variable
  myLob := 'XYZ';
 END;
/
```

6.1.3 Implicit Conversions Between BLOB and RAW

This section describes support for implicit conversions between BLOB and RAW data types.

Most discussions related to PL/SQL semantics for implicit conversion between `CLOB` and `VARCHAR2` data types also apply to the implicit conversion process between `BLOB` and `RAW` data types, unless mentioned otherwise. However, to provide concise description, most examples in this chapter do not explicitly mention `BLOB` and `RAW` data types. The following operations involving BLOB data types support implicit conversions:

- `INSERT` or `UPDATE` binary data stored in `RAW` or `LONG RAW` variables into a `BLOB` column. Multiple such binds are allowed in a single `INSERT` or `UPDATE` statement.

- `SELECT` persistent or temporary `BLOB` data into a binary buffer variable such as `RAW` and `LONGRAW`. Multiple such defines are allowed in a single `SELECT` statement.

- Assign a `BLOB` to a `RAW` or `LONG RAW` variable, or assign a `RAW` or `LONG RAW` to a `BLOB` variable.

- Pass `BLOB` data types to built-in or user-defined PL/SQL functions defined to accept `RAW` or `LONG RAW` data types or pass `RAW` or `LONG RAW` data types to built-in or user-defined PL/SQL functions defined to accept `BLOB` data types.

6.1.4 Guidelines and Restrictions for Implicit Conversions with LOBs

This section describes the techniques that you use to access LOB columns or attributes using the Data Interface for LOBs.

Data from `CLOB` and `BLOB` columns or attributes can be referenced by regular SQL statements, such as `INSERT`, `UPDATE`, and `SELECT`.

There is no piecewise `INSERT`, `UPDATE`, or fetch routine in PL/SQL. Therefore, the amount of data that can be accessed from a LOB column or attribute is limited by the maximum character buffer size in PL/SQL, which is 32767 bytes. For this reason, only LOBs less than 32 kilo bytes in size can be accessed by PL/SQL applications using the data interface for persistent LOBs.

If you must access a LOB with a size more than `32 kilobytes -1` bytes, using the data interface, then you must make JDBC or OCI calls from the PL/SQL code to use the APIs for piecewise insert and fetch.

Use the following guidelines for using the Data Interface to access LOB columns or attributes:

*   `SELECT` operations

    LOB columns or attributes can be selected into character or binary buffers in PL/SQL. If the LOB column or attribute is longer than the buffer size, then an exception is raised without filling the buffer with any data. LOB columns or attributes can also be selected into LOB locators.

*   INSERT operations

    You can `INSERT` into tables containing LOB columns or attributes using regular `INSERT` statements in the `VALUES` clause. The field of the LOB column can be a literal, a character data type, a binary data type, or a LOB locator.

*   `UPDATE` operations

    LOB columns or attributes can be updated as a whole by `UPDATE`... `SET` statements. In the `SET` clause, the new value can be a literal, a character data type, a binary data type, or a LOB locator.

*   There are restrictions for binds of more than 4000 bytes:

    –   If a table has both `LONG` and LOB columns, then you can bind more than 4000 bytes of data to either the `LONG` or LOB columns, but not both in the same statement.

    –   In an `INSERT AS SELECT` operation, binding of any length data to LOB columns is not allowed.

    –   If you bind more than 4000 bytes of data to a `BLOB` or a `CLOB`, and the data consists of a SQL operator, then Oracle Database limits the size of the result to at most 4000 bytes. For example, the following statement inserts only 4000 bytes because the result of `LPAD` is limited to 4000 bytes:

        ```
        INSERT INTO print_media (ad_sourcetext) VALUES (lpad('a', 5000, 'a'));
        ```

    –   The database does not do implicit hexadecimal to `RAW` or `RAW` to hexadecimal conversions on data that is more than 4000 bytes in size. You cannot bind a buffer of character data to a binary data type column, and you cannot bind a buffer of binary data to a character data type column if the buffer is over 4000 bytes in size. Attempting to do so results in your column data being truncated at 4000 bytes.

        For example, you cannot bind a `VARCHAR2` buffer to a `BLOB` column if the buffer is more than 4000 bytes in size. Similarly, you cannot bind a `RAW` buffer to a `CLOB` column if the buffer is more than 4000 bytes in size.

6.1.5 Detailed Examples for Implicit Conversions with LOBs

The example in this section demonstrates using multiple `VARCHAR` and `RAW` binds in `INSERT` and `UPDATE` operations.

Example 6-1   Using Character and RAW Binds in INSERT and UPDATE Operations

The following example demonstrates using Character and `RAW` binds for LOB columns in `INSERT` and `UPDATE` operations

```
DECLARE
  bigtext VARCHAR2(32767);
  smalltext VARCHAR2(2000);
  bigraw RAW (32767);
BEGIN
  bigtext := LPAD('a', 32767, 'a');
  smalltext := LPAD('a', 2000, 'a');
  bigraw := utl_raw.cast_to_raw (bigtext);

  /* Multiple long binds for LOB columns are allowed for INSERT: */
  INSERT INTO print_media(product_id, ad_id, ad_sourcetext, ad_composite)
    VALUES (2004, 1, bigtext, bigraw);

  /* Single long bind for LOB columns is allowed for INSERT: */
  INSERT INTO print_media (product_id, ad_id, ad_sourcetext)
    VALUES (2005, 2, smalltext);

  bigtext := LPAD('b', 32767, 'b');
  smalltext := LPAD('b', 20, 'a');
  bigraw := utl_raw.cast_to_raw (bigtext);

  /* Multiple long binds for LOB columns are allowed for UPDATE: */
  UPDATE print_media SET ad_sourcetext = bigtext, ad_composite = bigraw,
    ad_finaltext = smalltext;

  /* Single long bind for LOB columns is allowed for UPDATE: */
  UPDATE print_media SET ad_sourcetext = smalltext, ad_finaltext = bigtext;

  /* The following is NOT allowed because we are trying to insert more than
     4000 bytes of data in a LONG and a LOB column: */
  INSERT INTO print_media(product_id, ad_id, ad_sourcetext, press_release)
    VALUES (2030, 3, bigtext, bigtext);

  /* Insert of data into LOB attribute is allowed */
  INSERT INTO print_media(product_id, ad_id, ad_header)
    VALUES (2049, 4, adheader_typ(null, null, null, bigraw));

  /* The following is not allowed because we try to perform INSERT AS
     SELECT data INTO LOB */
  INSERT INTO print_media(product_id, ad_id, ad_sourcetext)
    SELECT 2056, 5, bigtext FROM dual;

END;
/
```

Example 6-2   Multiple Defines for LOBs in SELECT

The following example demonstrates performing a SELECT operation to retrieve multiple
persistent or temporary CLOBs from a SQL query into a VARCHAR2 variable, or a BLOB to a RAW
variable.

```
DECLARE
  ad_src_buffer     VARCHAR2(32000);
  ad_comp_buffer    RAW(32000);
BEGIN
  /* This retrieves the LOB columns if they are up to 32000 bytes,
   * otherwise it raises an exception */
  SELECT ad_sourcetext, ad_composite INTO ad_src_buffer, ad_comp_buffer FROM
print_media
     WHERE product_id=2004 AND ad_id=5;
```

```
    /* This retrieves the temporary LOB produced by SUBSTR if it is up to 32000
bytes,
     * otherwise it raises an exception */
   SELECT substr(ad_sourcetext, 2) INTO ad_src_buffer FROM print_media
     WHERE product_id=2004 AND ad_id=5;END;
/
```

Example 6-3   Implicit Conversions between `BLOB` and `RAW`

Implicit assignment works for variables declared explicitly and for variables declared by
referencing an existing column type using the `%TYPE` attribute as show in the following example.
The example assumes that column `long_col` in table `t` has been migrated from a `LONG` to a
`CLOB` column.

```
CREATE TABLE t (long_col LONG); -- Alter this table to change LONG column to
LOB
DECLARE
   a VARCHAR2(100);
   b t.long_col%type; -- This variable changes from LONG to CLOB
BEGIN
   SELECT * INTO b FROM t;
   a := b;  -- This changes from "VARCHAR2 := LONG to VARCHAR2 := CLOB
   b := a;  -- This changes from "LONG := VARCHAR2 to CLOB := VARCHAR2
END;
```

Example 6-4   Calling PL/SQL and C Procedures from PL/SQL

You can call a PL/SQL or C procedure from PL/SQL. You can pass a `CLOB` as an actual
parameter, where a `VARCHAR2` is the formal parameter, or you can pass a `VARCHAR2` as an actual
parameter, where a `CLOB` is the formal parameter. The same holds good for `BLOB`s and `RAW`s.
One example of when these cases can arise is when either the formal or the actual parameter
is an anchored type, that is, the variable is declared using the `table_name.column_name%type`
syntax. PL/SQL procedures or functions can accept a `CLOB` or a `VARCHAR2` as a formal
parameter. This holds for both built-in and user-defined procedures and functions.

The following example demonstrates implicit conversion during procedure calls:

```
CREATE OR REPLACE PROCEDURE foo(vvv IN VARCHAR2, ccc INOUT CLOB) AS
  ...
 BEGIN
  ...
  END;
  /
 DECLARE
  vvv VARCHAR2[32000] := rpad('varchar', 32000, 'varchar')
  ccc CLOB := rpad('clob', 32000, 'clob')
BEGIN
  foo(vvv, ccc); -- No implicit conversion needed here
  foo(ccc, vvv); -- Implicit conversion for both parameters done here
END;
/
```

Example 6-5   Implicit Conversion with PL/SQL built-in functions

The following example illustrates the use of CLOBs in PL/SQL built-in functions.

```
DECLARE
  my_ad CLOB;
  revised_ad CLOB;
  myGist VARCHAR2(100):= 'This is my gist.';
  revisedGist VARCHAR2(100);
BEGIN
  INSERT INTO print_media (product_id, ad_id, ad_sourcetext)
    VALUES (2004, 5, 'Source for advertisement 1');

  -- select a CLOB column into a CLOB variable
  SELECT ad_sourcetext INTO my_ad FROM print_media
    WHERE product_id=2004 AND ad_id=5;

  -- perform VARCHAR2 operations on a CLOB variable
  revised_ad := UPPER(SUBSTR(my_ad, 1, 20));

  -- revised_ad is a temporary LOB
  -- Concat a VARCHAR2 at the end of a CLOB
  revised_ad := revised_ad || myGist;

  -- The following statement raises an error if my_ad is
  -- longer than 100 bytes
  myGist := my_ad;
END;
/
```

6.2 Explicit Data Type Conversion Functions

This section describes the explicit conversion functions in SQL and PL/SQL to convert other data types to and from CLOB, NCLOB, and BLOB data types.

- TO_CLOB(): Converts from VARCHAR2, NVARCHAR2, or NCLOB to a CLOB

- TO_NCLOB(): Converts from VARCHAR2, NVARCHAR2, or CLOB to an NCLOB

- TO_BLOB(varchar|clob, destcsid,[mime_type]): Converts the object from its current character set to the given character set in destcsid. The resultant object is BLOB. Following are various ways in which you can use the conversion function:

  - TO_BLOB(character, destcsid)

  - TO_BLOB(character, destcsid, mime_type)

  - TO_BLOB(clob, destcsid)

  - TO_BLOB(clob, destcsid, mime_type)

  If the destcsid is 0, then it converts to the database character set ID. The parameter mime_type is applicable only to INSERT and UPDATE statements on Secure File LOB columns. If the mime_type parameter is used in SELECT statements or in temporary or BasicFile LOBs, then it is ignored.

- TO_BLOB(varchar): Converts the input to RAW before converting to BLOB. In other words, TO_BLOB(HEXTORAW(varchar)) and TO_BLOB(varchar) are equivalent.

> **Note:**
>
> `TO_BLOB(CLOB)` is not supported.

- `TO_CHAR()`: Converts a `CLOB` to a `CHAR` type. When you use this function to convert a character LOB into the database character set, if the LOB value to be converted is larger than the target type, then the database returns an error. Implicit conversions also raise an error if the LOB data does not fit.

- `TO_NCHAR()`: Converts an `NCLOB` to an `NCHAR` type. When you use this function to convert a character LOB into the national character set, if the LOB value to be converted is larger than the target type, then the database returns an error. Implicit conversions also raise an error if the LOB data does not fit.

- `CAST` does not directly support any of the LOB data types. When you use `CAST` to convert a `CLOB` value into a character data type, an `NCLOB` value into a national character data type, or a `BLOB` value into a `RAW` data type, the database implicitly converts the LOB value to character or raw data and then explicitly casts the resulting value into the target data type. If the resulting value is larger than the target type, then the database returns an error.

6.3 Temporary LOBs Created by SQL and PL/SQL Built-in Functions

When a LOB is returned from a SQL or PL/SQL built-in function, then the result returned is a temporary LOB. Similarly, a LOB returned from a user-defined PL/SQL function or procedure, as a value or an OUT parameter, may be a temporary LOB.

In PL/SQL, a temporary LOB has the same lifetime (duration) as the local PL/SQL program variable in which it is stored. It can be passed to subsequent SQL or PL/SQL `VARCHAR2` functions or queries as a PL/SQL local variable. The temporary LOB goes out of scope at the end of the program block at which time, the LOB is freed. These are the same semantics as those for PL/SQL `VARCHAR2` variables. At any time, nonetheless, you can use a `DBMS_LOB.FREETEMPORARY()` call to release the resources taken by the local temporary LOBs.

> **Note:**
>
> If a SQL or PL/SQL function returns a temporary LOB, or if a LOB is an OUT parameter for a PL/SQL function or procedure, then you must free it as soon as you are done with it. Failure to do so may cause temporary LOB accumulation and can considerably slow down your system.

The following example illustrates implicit creation of temporary LOBs using SQL built-in functions:

```
DECLARE
  vc1 VARCHAR2(32000);
  lb1 CLOB;
  lb2 CLOB;
BEGIN
  SELECT clobCol1 INTO vc1 FROM tab WHERE colID=1;
  -- lb1 is a temporary LOB
  SELECT clobCol2 || clobCol3 INTO lb1 FROM tab WHERE colID=2;
```

```
  lb2 := vc1|| lb1;
  -- lb2 is a still temporary LOB, so the persistent data in the database
  -- is not modified. An update is necessary to modify the table data.
  UPDATE tab SET clobCol1 = lb2 WHERE colID = 1;

DBMS_LOB.FREETEMPORARY(lb2); -- Free up the space taken by lb2

<... some more queries ...>

END; -- at the end of the block, lb1 is automatically freed
```

Here is another example of implicit creation of temporary LOBs using PL/SQL built-in functions.

```
1 DECLARE
2   myStory CLOB;
3   revisedStory CLOB;
4   myGist VARCHAR2(100);
5   revisedGist VARCHAR2(100);
6 BEGIN
7     -- select a CLOB column into a CLOB variable
8     SELECT Story INTO myStory FROM print_media WHERE product_id=10;
9     -- perform VARCHAR2 operations on a CLOB variable
10    revisedStory := UPPER(SUBSTR(myStory, 100, 1));
11    -- revisedStory is a temporary LOB
12    -- Concat a VARCHAR2 at the end of a CLOB
13    revisedStory := revisedStory || myGist;
14    -- The following statement raises an error because myStory is
15    -- longer than 100 bytes
16    myGist := myStory;
17 END;
/
```

Note that in the preceding example:

- In line number 7, a temporary CLOB is implicitly created and is pointed to by the revisedStory CLOB locator.

- In line number 13, myGist is appended to the end of the temporary LOB, which has the same effect as the following code snippet:

```
DBMS_LOB.WRITEAPPEND(revisedStory, myGist, length(myGist));
```

In some scenarios, implicitly created temporary LOBs in PL/SQL statements can change the representation of previously defined LOB locators. The following code snippet explains this scenario:

Change in Locator-Data Linkage

```
1 DECLARE
2     myStory CLOB;
3     amt number:=100;
4     buffer VARCHAR2(100):='some data';
5 BEGIN
6     -- select a CLOB column into a CLOB variable
7     SELECT Story INTO myStory FROM print_media WHERE product_id=10;
8     DBMS_LOB.WRITE(myStory, amt, 1, buf);
9     -- write to the persistent LOB in the table
10
11     myStory:= UPPER(SUBSTR(myStory, 100, 1));
12     -- perform VARCHAR2 operations on a CLOB variable, temporary LOB created.
```

```
13     -- Changes are not reflected in the database table from this point on.
14
15     UPDATE print_media SET Story = myStory WHERE product_id = 10;
16     -- an update is necessary to synchronize the data in the table.
17 END;
```

In the preceding example, `myStory` represents a persistent LOB column in the `print_media` table. The `DBMS_LOB.WRITE` procedure writes the data directly to the table without an `UPDATE` statement in the code.

Subsequently in line number 11, a temporary LOB is created and assigned to `myStory` because `myStory` is now used like a local `VARCHAR2` variable. The LOB locator `myStory` now points to the newly-created temporary LOB.

Therefore, modifications to `myStory` are no longer reflected in the database. To propagate the changes to the database table now, you must use an `UPDATE` statement. Note that for the previous persistent LOB, the `UPDATE` statement is not required.

Data Interface for LOBs

This chapter discusses how to perform DML and Query operations on LOBs. These operations are similar to the ones performed on traditional Character and RAW data types.

- **Overview of the Data Interface for LOBs**
  The data interface for LOBs includes a set of Java and OCI APIs that are extended to work with the LOB data types.

- **Benefits of Using the Data Interface for LOBs**
  This section discusses the benefits of the using the Data Interface for LOBs.

- **Data Interface for LOBs in Java**
  This section discusses the usage of data interface for LOBs in Java.

- **Data Interface for LOBs in OCI**
  This section discusses OCI functions included in the data interface for LOBs. These OCI functions work for LOB data types exactly the same way as they do for `VARCHAR` or `LONG` data types.

7.1 Overview of the Data Interface for LOBs

The data interface for LOBs includes a set of Java and OCI APIs that are extended to work with the LOB data types.

These APIs, originally designed for use with legacy data types such as `VARCHAR2, RAW, LONG,` and `LONG RAW,` can also be used with the corresponding LOB data types shown in the following table. The table shows the legacy data types in the *bind or define type* column and the corresponding supported LOB data type in the *LOB column type* column. You can use the data interface for LOBs to store and manipulate character data and binary data in a LOB column just as if it were stored in the corresponding legacy data type. The data interface supports data size up to two gigabytes minus one (2 GB - 1), the maximum size of an `sb4` data type.

> **✎ Note:**
>
> The data interface works for persistent and temporary LOBs and LOBs that are attributes of objects. In this chapter *LOB columns* means LOB columns and LOB attributes.

While most of this discussion focuses on character data types, the same concepts apply to the full set of character and binary data types listed in the following table. `CLOB` also means `NCLOB` in the table.

Table 7-1   Corresponding LONG and LOB Data Types in OCI

Bind or Define Type	LOB Column Type	Used For Storing
SQLT_AFC(n)	CLOB	Character data
SQLT_CHR	CLOB	Character data

Table 7-1   (Cont.) Corresponding LONG and LOB Data Types in OCI

Bind or Define Type	LOB Column Type	Used For Storing
SQLT_LNG	CLOB	Character data
SQLT_VCS	CLOB	Character data
SQLT_BIN	BLOB	Binary data
SQLT_LBI	BLOB	Binary data
SQLT_LVB	BLOB	Binary data

7.2 Benefits of Using the Data Interface for LOBs

This section discusses the benefits of the using the Data Interface for LOBs.

Following are the benefits of using the Data Interface for LOBs:

* If your application uses `LONG` data types, then you can use the same application with LOB data types with little or no modification of your existing application required. To do so, just convert `LONG` columns in your tables to LOB columns.

> **See Also:**
>
> Migrating Columns to SecureFile LOBs

* The Data Interface gives you the best performance if you know the maximum size of your LOB data, and you intend to read or write the entire LOB. A piecewise `INSERT` or fetch using the data interface makes only 1 round-trip the server, as opposed to using LOB API which makes separate round-trips to get the locator and to read/write data.

* You can read LOB data in one `OCIStmtFetch()` call, instead of fetching the LOB locator first and then calling `OCILobRead2()`. This improves performance when you want to read LOB data starting at the beginning.

* You can use array bind and define interfaces to insert and select multiple rows with LOBs in one round trip. Irrespective of whether the LOB data is inserted or fetched using single piece, piecewise or callbacks, it is inserted or fetched in a single round trip for multiple rows when using array binds or defines.

> **Caution:**
>
> If your application needs to perform random or piecewise read or write calls to LOBs, which means it needs to specify the offset or amount of the operation, then use the LOB APIs instead of the Data Interface.

> **See Also:**
>
> Locator Interface for LOBs

Most of the examples in the following sections use the `print_media` table. Following is the structure of the `print_media` table.

Figure 7-1   print_media Table

PRINT_MEDIA Table	
Column name	**Column Type**
product_id	NUMBER (6)
ad_id	NUMBER (6)
ad_composite	BLOB
ad_sourcetext	CLOB
ad_finaltext	CLOB
ad_fltextn	NCLOB
ad_textdocs_ntab	NESTED TABLE
ad_photo	BLOB
ad_graphic	BFILE
ad_header	USER DEFINED TYPE
press_release	LONG

7.3 Data Interface for LOBs in Java

This section discusses the usage of data interface for LOBs in Java.

You can read and write `CLOB` and `BLOB` data using the same streaming mechanism as for `LONG` and `LONG RAW` data.

For read operations, use the `defineColumnType(nn, Types.LONGVARCHAR)` method or the `defineColumnType(nn, Types.LONGVARBINARY)` method on the persistent or temporary LOBs returned by the `SELECT` statement. This produces a direct stream on the data that is similar to `VARCHAR2` or `RAW` column.

> **Note:**
>
> 1. If you use `VARCHAR` or `RAW` as the `defineColumnType`, then the selected value will be truncated to size 32k.
>
> 2. Standard JDBC methods such as `getString` or `getBytes` on `ResultSet` and `CallableStatement` are not part of the Data Interface as they use the LOB locator underneath.

To insert character data into a LOB column in a `PreparedStatement`, you may use `setBinaryStream()`, `setCharacterStream()`, or `setAsciiStream()` for a parameter which is a `BLOB` or `CLOB`. These methods use the stream interface to create a LOB in the database from the data in the stream. If the length of the data is known, for better performance, use the versions of `setBinaryStream()` or `setCharacterStream` functions which accept the length parameter. The data interface also supports standard JDBC methods such as `setString` or `setBytes` on `PreparedStatement` to write LOB data. It is easier to code, and in many cases faster, to use these APIs for LOB access. All these techniques reduce database round trips and result in improved performance in many cases.

The following code snippets work with all JDBC drivers:

Bind:

This is for the non-streaming mode:

```
...
String sql = "insert into print_media (product_id, ad_id, ad_final_text)" +
            " values (:1, :2, :3)";
    PreparedStatement pstmt = conn.prepareStatement(sql);
    pstmt.setInt( 1, 2 );
    pstmt.setInt( 2, 20);
    pstmt.setString( 3, "Java string" );
    int rows = pstmt.executeUpdate();
...
```

> **Note:**
>
> Oracle supports the non-streaming mode for strings of size up to 2 GB, but your machine's memory may be a limiting factor.

For the streaming mode, the same code as the preceding works, except that the `setString()` statement is replaced by one of the following:

```
pstmt.setCharacterStream( 3, new LabeledReader(), 1000000 );
pstmt.setAsciiStream( 3, new LabeledAsciiInputStream(), 1000000 );
```

> **Note:**
>
> You can use the streaming interface to insert Gigabyte sized character and binary data into a LOB column.

Here, `LabeledReader()` and `LabeledAsciiInputStream()` produce character and ASCII streams respectively. If `ad_finaltext` were a `BLOB` column instead of a `CLOB`, then the preceding example works if the bind is of type `RAW`:

```
pstmt.setBytes( 3, <some byte[] array> );
pstmt.setBinaryStream( 3, new LabeledInputStream(), 1000000 );
```

Here, `LabeledInputStream()` produces a binary stream.

Define:

For non-streaming mode:

```
OracleStatement stmt = (OracleStatement)(conn.createStatement());
  stmt.defineColumnType( 1, Types.VARCHAR );
  ResultSet rst = stmt.executeQuery("select ad_finaltext from print_media" );
  while( rst.next() )
     {
       String s = rst.getString( 1 );
       System.out.println( s );
     }
```

> **Note:**
>
> If the LOB size is greater than 32767 bytes, the data is truncated and no error is thrown.

For streaming mode:

```
OracleStatement stmt = (OracleStatement)(conn.createStatement());
  stmt.defineColumnType( 1, Types.LONGVARCHAR );
  ResultSet rst = stmt.executeQuery("select ad_finaltext from print_media" );
  while(rs.next()) {
    Reader reader = rs.getCharacterStream( 1 );
    int data = 0;
    data = reader.read();
    while( -1 != data ){
      System.out.print( (char)(data) );
      data = reader.read();
      }
    reader.close();
    }
```

> **Note:**
>
> Specifying the datatype as `LONGVARCHAR` lets you select the entire LOB. If the define type is set as `VARCHAR` instead of `LONGVARCHAR`, the data will be truncated at 32k.

If `ad_finaltext` were a `BLOB` column instead of a `CLOB`, then the preceding examples work if the define is of type `LONGVARBINARY`:

```
...
OracleStatement stmt = (OracleStatement)conn.createStatement();

stmt.defineColumnType( 1, Types.INTEGER );
```

```
stmt.defineColumnType( 2, Types.LONGVARBINARY );

ResultSet rset = stmt.executeQuery("SELECT ID, LOBCOL FROM LOBTAB");
    while(rset.next())
    {
             /* using getBytes() */
             /*
             byte[] b = rset.getBytes("LOBCOL");
        System.out.println("ID: " + rset.getInt("ID") + "  length: " +
b.length);
             */

             /* using getBinaryStream() */
             InputStream byte_stream = rset.getBinaryStream("LOBCOL");
             byte [] b = new byte [100000];
             int b_len = byte_stream.read(b);
             System.out.println("ID: " + rset.getInt("ID") + "  length: " +
b_len);

             byte_stream.close();
        }
...
```

7.4 Data Interface for LOBs in OCI

This section discusses OCI functions included in the data interface for LOBs. These OCI functions work for LOB data types exactly the same way as they do for VARCHAR or LONG data types.

Using these functions, you can perform INSERT, UPDATE and fetch operations in OCI on LOBs. These techniques are the same as the ones that you use on the other data types for storing character or binary data.

> **Note:**
>
> You can use array bind and define interfaces to insert and select multiple rows with LOBs in one round trip.

- Binding a LOB in OCI
  This section describes the operations that you can use for binding the LOB data types in OCI.
- Defining a LOB in OCI
  The OCI functions discussed in this section associate a LOB type with a data type and an output buffer.

- Multibyte Character Sets Used in OCI with the Data Interface for LOBs
  This section discusses the functionality of Data Interface for LOBs when the OCI client uses a multibyte character set.

- Getting LOB Length
  This section describes how an OCI application can fetch the LOB length.

- Using OCI Functions to Perform INSERT or UPDATE on LOB Columns
  This section discusses the various techniques you can use to perform `INSERT` or `UPDATE` operations on LOB columns or attributes using the data interface.

- Using OCI Data Interface to Fetch LOB Data
  This section discusses techniques you can use to fetch data from persistent or temporary LOBs in OCI using the data interface.

> Runtime Data Allocation and Piecewise Operations in OCI

7.4.1 Binding a LOB in OCI

This section describes the operations that you can use for binding the LOB data types in OCI.

- Regular, piecewise, and callback binds for `INSERT` and `UPDATE` operations

- Array binds for `INSERT` and `UPDATE` operations

- Parameter passing across PL/SQL and OCI boundaries

Piecewise operations can be performed by polling or by providing a callback. To support these operations, the following OCI functions accept the `LONG` and LOB data types listed in Table 7-1.

- `OCIBindByName()` and `OCIBindByPos()`

  These functions create an association between a program variable and a placeholder in the SQL statement or a PL/SQL block for `INSERT` and `UPDATE` operations.

- `OCIBindDynamic()`

  You use this call to register callbacks for dynamic data allocation for `INSERT` and `UPDATE` operations

- `OCIStmtGetPieceInfo()` and `OCIStmtSetPieceInfo()`

  These calls are used to get or set piece information for piecewise operations.

7.4.2 Defining a LOB in OCI

The OCI functions discussed in this section associate a LOB type with a data type and an output buffer.

The data interface for LOBs enables the following OCI functions to accept the LONG and LOB data types listed in Table 7-1.

You can use the following functions

- `OCIDefineByPos()`

This call associates an item in a `SELECT` list with the type and output data buffer.

- `OCIDefineDynamic()`

    This call registers user callbacks for `SELECT` operations if the `OCI_DYNAMIC_FETCH` mode was selected in `OCIDefineByPos()` function call. You can use the `OCIDataServerLengthGet()` function to retrieve LOB length while using dynamic define callback.

When you use these functions with LOB types, the LOB data, and not the locator, is selected into your buffer. Note that in OCI, you cannot specify the amount you want to read using the data interface for LOBs. You can only specify the buffer length of your buffer. The database only reads whatever amount fits into your buffer and the data is truncated.

7.4.3 Multibyte Character Sets Used in OCI with the Data Interface for LOBs

This section discusses the functionality of Data Interface for LOBs when the OCI client uses a multibyte character set.

When the client character set is in a multibyte format, functions included in the data interface operate the same way with LOB datatypes as they do for `VARCHAR2` or `LONG` data types as follows:

- For a *piecewise* fetch in a multibyte character set, a multibyte character could be cut in the middle, with some bytes at the end of one buffer and remaining bytes in the next buffer.

- For a *regular* fetch, if the buffer cannot hold all bytes of the last character, then Oracle returns as many bytes as fit into the buffer, hence returning partial characters.

7.4.4 Getting LOB Length

This section describes how an OCI application can fetch the LOB length.

To fetch the LOB data length, use the `OCIServerDataLengthGet()` OCI function. When you access a LOB column using the Data Interface, the server first sends the LOB data length, followed by LOB data. The server first communicates the length of the LOB data, before any conversions are made. The OCI client stores the retrieved LOB length in `define` handle. The OCI application can use the `OCIServerDataLengthGet()` function to access the LOB length.

You can access the LOB length in all fetch modes, that is, single piece, piecewise, and callback. You can also access it inside the callback without incurring a round-trip to the server. However, you should not use it before the fetch operation. In case of piecewise or callback operations, you should use it right after the first piece is fetched.

7.4.5 Using OCI Functions to Perform INSERT or UPDATE on LOB Columns

This section discusses the various techniques you can use to perform `INSERT` or `UPDATE` operations on LOB columns or attributes using the data interface.

The operations described in this section assume that you have initialized the OCI environment and allocated all necessary handles.

- Performing Simple INSERT or UPDATE Operations in One Piece
  This section lists the steps to perform simple `INSERT` or `UPDATE` operations in one piece, using the data interface for LOBs.

- Using Piecewise INSERT and UPDATE Operations with Polling
  This section lists the steps to perform piecewise INSERT or UPDATE operations with polling, using the data interface for LOBs.

- Performing Piecewise INSERT and UPDATE Operations with Callback
  This section lists the steps to perform piecewise `INSERT` or `UPDATE` operations with callback, using the data interface for LOBs.

- Performing Array INSERT and UPDATE Operations
  To perform array `INSERT` or `UPDATE` operations using the data interface for LOBs, use any of the techniques discussed in this section.

7.4.5.1 Performing Simple INSERT or UPDATE Operations in One Piece

This section lists the steps to perform simple `INSERT` or `UPDATE` operations in one piece, using the data interface for LOBs.

1. Call `OCIStmtPrepare()` to prepare the statement in `OCI_DEFAULT` mode.

2. Call `OCIBindByName()` or `OCIBindbyPos()` in `OCI_DEFAULT` mode to bind a placeholder for LOB as character data or binary data.

3. Call `OCIStmtExecute()` to do the actual `INSERT` or `UPDATE` operation.

Following is an example of binding character data for `INSERT` and `UPDATE` operations on a LOB column.

```
void simple_insert()
{
/* Insert of data into LOB attributes is allowed. */
   ub1 buffer[8000];
   text *insert_sql = (text *)"INSERT INTO Print_media (ad_header) \
               VALUES (adheader_typ(NULL, NULL, NULL,:1))";
   OCIStmtPrepare(stmthp, errhp, insert_sql, strlen((char*)insert_sql),
            (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);
   OCIBindByPos(stmthp, &bindhp[0], errhp, 1, (dvoid *)buffer, 2000,
            SQLT_LNG, 0, 0, 0, 0, 0, (ub4) OCI_DEFAULT);
   OCIStmtExecute(svchp, stmthp, errhp, 1, 0, (const OCISnapshot*) 0,
               (OCISnapshot*)0, OCI_DEFAULT);
}
```

7.4.5.2 Using Piecewise INSERT and UPDATE Operations with Polling

This section lists the steps to perform piecewise INSERT or UPDATE operations with polling, using the data interface for LOBs.

1. Call `OCIStmtPrepare()` to prepare the statement in `OCI_DEFAULT` mode.

2. Call `OCIBindByName()` or `OCIBindbyPos()` in `OCI_DATA_AT_EXEC` mode to bind a LOB as character data or binary data.

3. Call `OCIStmtExecute()` in default mode. Do each of the following in a loop while the value returned from `OCIStmtExecute()` is `OCI_NEED_DATA`. Terminate your loop when the value returned from `OCIStmtExecute()` is `OCI_SUCCESS`.

   - Call `OCIStmtGetPieceInfo()` to retrieve information about the piece to be inserted.

   - Call `OCIStmtSetPieceInfo()` to set information about piece to be inserted.

The following example illustrates using piecewise INSERT with polling using the data interface for LOBs.

```
void piecewise_insert()
{
  text *sqlstmt = (text *)"INSERT INTO Print_media(Product_id, Ad_id,\
                 Ad_sourcetext) VALUES (:1, :2, :3)";
  ub2 rcode;
  ub1 piece, i;
  word product_id = 2004;
  word ad_id = 2;
  ub4 buflen;
  char buf[5000];

  OCIStmtPrepare(stmthp, errhp, sqlstmt, (ub4)strlen((char *)sqlstmt),
                 (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);
  OCIBindByPos(stmthp, &bndhp[0], errhp, (ub4) 1,
               (dvoid *) &product_id, (sb4) sizeof(product_id), SQLT_INT,
               (dvoid *) 0, (ub2 *)0, (ub2 *)0,
               (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT);
  OCIBindByPos(stmthp, &bndhp[1], errhp, (ub4) 2,
               (dvoid *) &ad_id, (sb4) sizeof(ad_id), SQLT_INT,
               (dvoid *) 0, (ub2 *)0, (ub2 *)0,
               (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT);
  OCIBindByPos(stmthp, &bndhp[2], errhp, (ub4) 3,
               (dvoid *) 0, (sb4) 15000, SQLT_LNG,
               (dvoid *) 0, (ub2 *)0, (ub2 *)0,
               (ub4) 0, (ub4 *) 0, (ub4) OCI_DATA_AT_EXEC);

  i = 0;
  while (1)
  {
    i++;
    retval = OCIStmtExecute(svchp, stmthp, errhp, (ub4) 1, (ub4) 0,
                            (CONST OCISnapshot*) 0, (OCISnapshot*) 0,
                            (ub4) OCI_DEFAULT);
    switch(retval)
    {
    case OCI_NEED_DATA:
      memset((void *)buf, (int)'A'+i, (size_t)5000);
      buflen = 5000;
      if (i == 1) piece = OCI_FIRST_PIECE;
      else if (i == 3) piece = OCI_LAST_PIECE;
      else piece = OCI_NEXT_PIECE;

      if (OCIStmtSetPieceInfo((dvoid *)bndhp[2],
                              (ub4)OCI_HTYPE_BIND, errhp, (dvoid *)buf,
                              &buflen, piece, (dvoid *) 0, &rcode))
        {
          printf("ERROR: OCIStmtSetPieceInfo: %d \n", retval);
          break;
        }

      break;
    case OCI_SUCCESS:
      break;
```

```
      default:
        printf( "oci exec returned %d \n", retval);
        report_error(errhp);
        retval = OCI_SUCCESS;
      } /* end switch */
      if (retval == OCI_SUCCESS)
        break;
    } /* end while(1) */
}
```

7.4.5.3 Performing Piecewise INSERT and UPDATE Operations with Callback

This section lists the steps to perform piecewise `INSERT` or `UPDATE` operations with callback, using the data interface for LOBs.

1. Call `OCIStmtPrepare()` to prepare the statement in `OCI_DEFAULT` mode.

2. Call `OCIBindByName()` or `OCIBindbyPos()` in `OCI_DATA_AT_EXEC` mode to bind a placeholder for the LOB column as character data or binary data.

3. Call `OCIBindDynamic()` to specify the callback.

4. Call `OCIStmtExecute()` in default mode.

You do not need to supply an output callback for pure `IN` binds in OCI to SQL/PLSQL operation. Starting from Oracle Database 21c Release, you do not need to supply an input callback for pure `OUT` binds in OCI to SQL/PLSQL operation.

The following example illustrates binding character data to LOB columns using a piecewise `INSERT` with callback:

```
void callback_insert()
{
  word buflen = 15000;
  word product_id = 2004;
  word ad_id = 3;
  text *sqlstmt = (text *) "INSERT INTO Print_media(Product_id, Ad_id,\
                  Ad_sourcetext) VALUES (:1, :2, :3)";
  word pos = 3;

  OCIStmtPrepare(stmthp, errhp, sqlstmt, (ub4)strlen((char *)sqlstmt),
                 (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT)

```

```
    OCIStmtExecute(svchp, stmthp, errhp, (ub4) 1, (ub4) 0,
                   (const OCISnapshot*) 0, (OCISnapshot*) 0,
                   (ub4) OCI_DEFAULT);
} /* end insert_data() */

/* Inbind callback to specify input data. */
static sb4 insert_cbk(dvoid *ctxp, OCIBind *bindp, ub4 iter, ub4 index,
                        dvoid **bufpp, ub4 *alenpp, ub1 *piecep, dvoid **indpp)
{
  static int a = 0;
  word    j;
  ub4     inpos = *((ub4 *)ctxp);
  char    buf[5000];

  switch(inpos)
  {
  case 3:
    memset((void *)buf, (int) 'A'+a, (size_t) 5000);
    *bufpp = (dvoid *) buf;
    *alenpp = 5000 ;
    a++;
    break;
  default: printf("ERROR: invalid position number: %d\n", inpos);
  }

  *indpp = (dvoid *) 0;
  *piecep = OCI_ONE_PIECE;
  if (inpos == 3)
  {
    if (a<=1)
    {
      *piecep = OCI_FIRST_PIECE;
      printf("Insert callback: 1st piece\n");
    }
    else if (a<3)
    {
      *piecep = OCI_NEXT_PIECE;
      printf("Insert callback: %d'th piece\n", a);
    }
    else {
      *piecep = OCI_LAST_PIECE;
      printf("Insert callback: %d'th piece\n", a);
      a = 0;
    }
  }
  return OCI_CONTINUE;
}
```

7.4.5.4 Performing Array INSERT and UPDATE Operations

To perform array `INSERT` or `UPDATE` operations using the data interface for LOBs, use any of the techniques discussed in this section.

Use the `INSERT` or `UPDATE` operations in conjunction with `OCIBindArrayOfStruct()`, or by specifying the number of iterations (*iter*), with *iter* value greater than 1, in the `OCIStmtExecute()` call. Irrespective of whether the LOB data is inserted using single piece, piecewise or callbacks, it is inserted in a single round trip for multiple rows when using array binds.

The following example illustrates binding character data for LOB columns using an array `INSERT` operation:

```
void array_insert()
{
  ub4 i;
  word buflen;
  word arrbuf1[5];
  word arrbuf2[5];
  text arrbuf3[5][5000];
  text *insstmt = (text *)"INSERT INTO Print_media(Product_id, Ad_id,\
                  Ad_sourcetext) VALUES (:PID, :AID, :SRCTXT)";

  OCIStmtPrepare(stmthp, errhp, insstmt,
                 (ub4)strlen((char *)insstmt), (ub4) OCI_NTV_SYNTAX,
                 (ub4) OCI_DEFAULT);

  OCIBindByName(stmthp, &bndhp[0], errhp,
                (text *) ":PID", (sb4) strlen((char *) ":PID"),
                (dvoid *) &arrbuf1[0], (sb4) sizeof(arrbuf1[0]), SQLT_INT,
                (dvoid *) 0, (ub2 *)0, (ub2 *) 0,
                (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT);

  OCIBindByName(stmthp, &bndhp[1], errhp,
                (text *) ":AID", (sb4) strlen((char *) ":AID"),
                (dvoid *) &arrbuf2[0], (sb4) sizeof(arrbuf2[0]), SQLT_INT,
                (dvoid *) 0, (ub2 *)0, (ub2 *) 0,
                (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT);

  OCIBindByName(stmthp, &bndhp[2], errhp,
                (text *) ":SRCTXT", (sb4) strlen((char *) ":SRCTXT"),
                (dvoid *) arrbuf3[0], (sb4) sizeof(arrbuf3[0]), SQLT_CHR,
                (dvoid *) 0, (ub2 *) 0, (ub2 *) 0,
                (ub4) 0, (ub4 *) 0, (ub4) OCI_DEFAULT);

  OCIBindArrayOfStruct(bndhp[0], errhp sizeof(arrbuf1[0]),
                       indsk, rlsk, rcsk);
  OCIBindArrayOfStruct(bndhp[1], errhp, sizeof(arrbuf2[0]),
                       indsk, rlsk, rcsk);
  OCIBindArrayOfStruct(bndhp[2], errhp, sizeof(arrbuf3[0]),
                       indsk, rlsk, rcsk);

  for (i=0; i<5; i++)
  {
```

```
    arrbuf1[i] = 2004;
    arrbuf2[i] = i+4;
    memset((void *)arrbuf3[i], (int)'A'+i, (size_t)5000);
  }
  OCIStmtExecute(svchp, stmthp, errhp, (ub4) 5, (ub4) 0,
                 (const OCISnapshot*) 0, (OCISnapshot*) 0,
                 (ub4) OCI_DEFAULT);

}
```

7.4.6 Using OCI Data Interface to Fetch LOB Data

This section discusses techniques you can use to fetch data from persistent or temporary LOBs in OCI using the data interface.

- **Performing Simple Fetch Operations in One Piece**
  Follow the steps listed in this section for performing a simple fetch operation on LOBs in one piece, using the data interface for LOBs.

- **Performing a Piecewise Fetch with Polling**
  Follow the steps listed in this section to perform a piecewise fetch operation on a LOB column with polling, using the data interface for LOBs.

- **Performing a Piecewise with Callback**
  Follow the steps listed in this section to perform a piecewise fetch operation on a LOB column with callback, using the data interface for LOBs.

- **Performing an Array Fetch Operation**
  Use any of the techniques discussed in this section to perform an array fetch operation in OCI, using the data interface for LOBs.

7.4.6.1 Performing Simple Fetch Operations in One Piece

Follow the steps listed in this section for performing a simple fetch operation on LOBs in one piece, using the data interface for LOBs.

1. Call `OCIStmtPrepare()` to prepare the `SELECT` statement in `OCI_DEFAULT` mode.

2. Call `OCIDefineByPos()` to define a select list position in `OCI_DEFAULT` mode to define a LOB as character data or binary data.

3. Call `OCIStmtExecute()` to run the `SELECT` statement.

4. Call `OCIStmtFetch()` to do the actual fetch.

The following example illustrates selecting a persistent LOB or temporary LOB using a simple fetch:

```
void simple_fetch()
{
  word retval;
  text buf[15000];
  /*
    This statement returns a persistent LOB, but can be modified to return a
temporary LOB
    using the query 'SELECT SUBSTR(Ad_sourcetext,5) FROM Print_media WHERE
Product_id = 2004'
  */
  text *selstmt = (text *) "SELECT Ad_sourcetext FROM Print_media WHERE\
```

```
                 Product_id = 2004";

    OCIStmtPrepare(stmthp, errhp, selstmt, (ub4)strlen((char *)selstmt),
                   (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);

    retval = OCIStmtExecute(svchp, stmthp, errhp, (ub4) 0, (ub4) 0,
                            (const OCISnapshot*) 0, (OCISnapshot*) 0,
                            (ub4) OCI_DEFAULT);
  while (retval == OCI_SUCCESS || retval == OCI_SUCCESS_WITH_INFO)
  {
    OCIDefineByPos(stmthp, &defhp, errhp, (ub4) 1, (dvoid *) buf,
                   (sb4) sizeof(buf), (ub2) SQLT_CHR, (dvoid *) 0,
                   (ub2 *) 0, (ub2 *) 0, (ub4) OCI_DEFAULT);
    retval = OCIStmtFetch(stmthp, errhp, (ub4) 1,
                          (ub4) OCI_FETCH_NEXT, (ub4) OCI_DEFAULT);
    if (retval == OCI_SUCCESS || retval == OCI_SUCCESS_WITH_INFO)
      printf("buf = %.*s\n", 15000, buf);
  }
}
```

7.4.6.2 Performing a Piecewise Fetch with Polling

Follow the steps listed in this section to perform a piecewise fetch operation on a LOB column with polling, using the data interface for LOBs.

1. Call `OCIStmtPrepare()` to prepare the `SELECT` statement in `OCI_DEFAULT` mode.

2. Call `OCIDefinebyPos()` to define a select list position in `OCI_DYNAMIC_FETCH` mode to define the LOB column as character data or binary data.

3. Call `OCIStmtExecute()` to run the `SELECT` statement.

4. Call `OCIStmtFetch()` in default mode. Optionally, you can use `OCIServerDataLengthGet()` to get the LOB length and use it to allocate the buffer to hold the LOB data. Do each of the following in a loop while the value returned from `OCIStmtFetch()` is `OCI_NEED_DATA`. Terminate your loop when the value returned from `OCIStmtFetch()` is `OCI_SUCCESS`.

    *   Call `OCIStmtGetPieceInfo()` to retrieve information about the piece to be fetched.

    *   Call `OCIStmtSetPieceInfo()` to set information about piece to be fetched.

The following example illustrates selecting a LOB column into a character buffer using a piecewise fetch with polling:

```
void piecewise_fetch()
{
  text buf[15000];
  ub4 buflen=5000;
  word retval;
  text *selstmt = (text *) "SELECT Ad_sourcetext FROM Print_media
                  WHERE Product_id = 2004 AND Ad_id = 2";

  OCIStmtPrepare(stmthp, errhp, selstmt,
                 (ub4) strlen((char *)selstmt),
                 (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);

  OCIDefineByPos(stmthp, &dfnhp, errhp, (ub4) 1,
                 (dvoid *) NULL, (sb4) 100000, SQLT_LNG,
```

```
                        (dvoid *) 0, (ub2 *) 0,
                        (ub2 *) 0, (ub4) OCI_DYNAMIC_FETCH);

    retval = OCIStmtExecute(svchp, stmthp, errhp, (ub4) 0, (ub4) 0,
                            (CONST OCISnapshot*) 0, (OCISnapshot*) 0,
                            (ub4) OCI_DEFAULT);

    retval = OCIStmtFetch(stmthp, errhp, (ub4) 1 ,
                          (ub2) OCI_FETCH_NEXT, (ub4) OCI_DEFAULT);

    while (retval != OCI_NO_DATA && retval != OCI_SUCCESS)
    {
      ub1 piece;
      ub4 iter;
      ub4 idx;

      genclr((void *)buf, 5000);
      switch(retval)
      {
      case OCI_NEED_DATA:
        OCIStmtGetPieceInfo(stmthp, errhp, &hdlptr, &hdltype,
                            &in_out, &iter, &idx, &piece);
        buflen = 5000;
        OCIStmtSetPieceInfo(hdlptr, hdltype, errhp,
                            (dvoid *) buf, &buflen, piece,
                            (CONST dvoid *) &indp1, (ub2 *) 0);
        retval = OCI_NEED_DATA;
        break;
      default:
        printf("ERROR: piece-wise fetching, %d\n", retval);
        return;
      } /* end switch */
      retval = OCIStmtFetch(stmthp, errhp, (ub4) 1 ,
                            (ub2) OCI_FETCH_NEXT, (ub4) OCI_DEFAULT);
      printf("Data : %.5000s\n", buf);
    } /* end while */
}
```

7.4.6.3 Performing a Piecewise with Callback

Follow the steps listed in this section to perform a piecewise fetch operation on a LOB column with callback, using the data interface for LOBs.

1. Call `OCIStmtPrepare()` to prepare the statement in `OCI_DEFAULT` mode.

2. Call `OCIDefinebyPos()` to define a select list position in `OCI_DYNAMIC_FETCH` mode to define the LOB column as character data or binary data.

3. Call `OCIStmtExecute()` to run the `SELECT` statement.

4. Call `OCIDefineDynamic()` to specify the callback.

5. Call `OCIStmtFetch()` in default mode.

6. Inside the callback, you can optionally use `OCIServerDataLengthGet()` to get the LOB length during the first fetch. You can use this value to allocate the buffer to hold LOB data

The following example illustrates selecting a LOB column into a LOB buffer when using a piecewise fetch with callback:

```c
char buf[5000];
void callback_fetch()
{
  word outpos = 1;
  text *sqlstmt = (text *) "SELECT Ad_sourcetext FROM Print_media WHERE
                   Product_id = 2004 AND Ad_id = 3";

  OCIStmtPrepare(stmthp, errhp, sqlstmt, (ub4)strlen((char *)sqlstmt),
                 (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);
  OCIDefineByPos(stmthp, &dfnhp[0], errhp, (ub4) 1,
                 (dvoid *) 0, (sb4)3 * sizeof(buf), SQLT_CHR,
                 (dvoid *) 0, (ub2 *)0, (ub2 *)0,
                 (ub4) OCI_DYNAMIC_FETCH);

  OCIDefineDynamic(dfnhp[0], errhp, (dvoid *) &outpos,
                   (OCICallbackDefine) fetch_cbk);

  OCIStmtExecute(svchp, stmthp, errhp, (ub4) 1, (ub4) 0,
                 (const OCISnapshot*) 0, (OCISnapshot*) 0,
                 (ub4) OCI_DEFAULT);
  buf[ 4999 ] = '\0';
  printf("Select callback: Last piece: %s\n", buf);
}

/* ---------------------------------------------------------------- */
/* Fetch callback to specify buffers. */
/* ---------------------------------------------------------------- */
static sb4 fetch_cbk(dvoid *ctxp, OCIDefine *dfnhp, ub4 iter, dvoid **bufpp,
                     ub4 **alenpp, ub1 *piecep, dvoid **indpp, ub2 **rcpp)
{
  static int a = 0;
  ub4 outpos = *((ub4 *)ctxp);
  ub4 len = 5000;
  switch(outpos)
  {
  case 1:
    a ++;
    *bufpp = (dvoid *) buf;
    *alenpp = &len;
    break;
  default:
    *bufpp = (dvoid *) 0;
    *alenpp = (ub4 *) 0;
    printf("ERROR: invalid position number: %d\n", outpos);
  }
  *indpp = (dvoid *) 0;
  *rcpp = (ub2 *) 0;

  buf[len] = '\0';
  if (a<=1)
  {
    *piecep = OCI_FIRST_PIECE;
    printf("Select callback: 0th piece\n");
```

```
  }
  else if (a<3)
  {
    *piecep = OCI_NEXT_PIECE;
    printf("Select callback: %d'th piece: %s\n", a-1, buf);
  }
  else {
    *piecep = OCI_LAST_PIECE;
    printf("Select callback: %d'th piece: %s\n", a-1, buf);
    a = 0;
  }
  return OCI_CONTINUE;
}
```

This example illustrates selecting a LOB column into a character buffer when using a piecewise fetch with callback, along with fetching the length of LOB data.

```
#define MAX_BUF_SZ 1048576  /* Max allocation size = 1M */
char *buffer = NULL;
ub8   buf_len = 0;

/* Define callback function */
sb4 DefineCbk(void *cbctx, OCIDefine *defnhp, ub4 iter,
              void **bufp, ub4 **alenp, ub1 *piecep,
              void **indp, ub2 **rcodep)
{
  static sword piece = 1;
  boolean isValidLen = FALSE;
  buf_len = 0;

  if (piece == 1)
  {
    OCIServerDataLengthGet(defnhp, &isValidLen, (ub8 *) &buf_len,
                           (OCIError *)cbctx, 0);

    if (buf_len > MAX_BUF_SZ)
      buf_len = MAX_BUF_SZ;

    buffer = (char *)malloc(buf_len);
    *bufp = buffer;
    *alenp = (ub4 *) &buf_len;
  }
  else
  {
    printf("Data = %s\n",buffer);
    buf_len = MAX_BUF_SZ;
  }
  piece++;
  return OCI_CONTINUE;
}

void define_callback()
{
  text      *sqlstmt = (text *)"select lobcol from lob_table";
```

```
     OCIStmtPrepare(stmthp, errhp, sqlstmt, (ub4)strlen( sqlstmt),
                 (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);
     OCIDefineByPos(stmthp, &defhp1, errhp, (ub4)1, (dvoid *)0,
                 (sb4) (10 * MAX_BUF_SZ), SQLT_STR, (dvoid *) 0,
                 (ub2 *) 0, (ub2 *) 0, (ub4)OCI_DYNAMIC_FETCH);
     OCIDefineDynamic(defhp1,errhp, errhp,
                    (OCICallbackDefine)DefineCbk);
     OCIStmtExecute(svchp, stmthp, errhp, (ub4) 0, (ub4) 0,
                 (CONST OCISnapshot *) 0, (OCISnapshot *) 0,
                 (ub4) OCI_DEFAULT);
     OCIStmtFetch(stmthp, errhp, 1, OCI_FETCH_NEXT, OCI_DEFAULT);

   buffer[buf_len] = '\0';
   printf(" Data = %s\n",buffer);
   if (buffer)
     free(buffer);
}
```

7.4.6.4 Performing an Array Fetch Operation

Use any of the techniques discussed in this section to perform an array fetch operation in OCI, using the data interface for LOBs.

Use the techniques discussed below, in conjunction with `OCIDefineArrayOfStruct()`, or by specifying the number of iterations (*iter*), with the value of *iter* greater than 1, in the `OCIStmtExecute()` call. Irrespective of whether the LOB data is fetched using single piece, piecewise or callbacks, it is fetched in a single round trip for multiple rows when using array defines.

The following example illustrates selecting a LOB column into a character buffer using an array fetch:

```
void array_fetch()
{
  word i;
  text arrbuf[5][5000];
  text *selstmt = (text *) "SELECT Ad_sourcetext FROM Print_media WHERE
                 Product_id = 2004 AND Ad_id >=4";

  OCIStmtPrepare(stmthp, errhp, selstmt, (ub4)strlen((char *)selstmt),
                 (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);

  OCIStmtExecute(svchp, stmthp, errhp, (ub4) 0, (ub4) 0,
                 (const OCISnapshot*) 0, (OCISnapshot*) 0, (ub4) OCI_DEFAULT);

  OCIDefineByPos(stmthp, &defhp1, errhp, (ub4) 1,
                   (dvoid *) arrbuf[0], (sb4) sizeof(arrbuf[0]),
                   (ub2) SQLT_CHR, (dvoid *) 0,
                   (ub2 *) 0, (ub2 *) 0, (ub4) OCI_DEFAULT);

  OCIDefineArrayOfStruct(dfnhp1, errhp, sizeof(arrbuf[0]), indsk,
                         rlsk, rcsk);

  retval = OCIStmtFetch(stmthp, errhp, (ub4) 5,
                        (ub4) OCI_FETCH_NEXT, (ub4) OCI_DEFAULT);
```

```
   if (retval == OCI_SUCCESS || retval == OCI_SUCCESS_WITH_INFO)
   {
      printf("%.5000s\n", arrbuf[0]);
      printf("%.5000s\n", arrbuf[1]);
      printf("%.5000s\n", arrbuf[2]);
      printf("%.5000s\n", arrbuf[3]);
      printf("%.5000s\n", arrbuf[4]);
   }
}
```

7.4.7 PL/SQL and C Binds from OCI

Learn about PL/SQL and C Binds from OCI with respect to LOBs in this section.

When you call a PL/SQL procedure from OCI, and have an IN or OUT or IN OUT bind, you should be able to:

• Bind a variable as SQLT_CHR or SQLT_LNG where the formal parameter of the PL/SQL procedure is SQLT_CLOB, or

• Bind a variable as SQLT_BIN or SQLT_LBI where the formal parameter is SQLT_BLOB

The following two cases work:

Calling PL/SQL Out-binds in the "begin foo(:1); end;" Manner

Here is an example of calling PL/SQL out-binds in the "begin foo(:1); end;" Manner:

```
text *sqlstmt = (text *)"BEGIN get_lob(:c); END; " ;
```

Calling PL/SQL Out-binds in the "call foo(:1);" Manner

Here is an example of calling PL/SQL out-binds in the "call foo(:1);" manner:

```
text *sqlstmt = (text *)"CALL get_lob(:c);" ;
```

In both these cases, the rest of the program has these statements:

```
OCIStmtPrepare(stmthp, errhp, sqlstmt, (ub4)strlen((char *)sqlstmt),
            (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);
   curlen = 0;
OCIBindByName(stmthp, &bndhp[3], errhp,
        (text *) ":c", (sb4) strlen((char *) ":c"),
        (dvoid *) buf5, (sb4) LONGLEN, SQLT_CHR,
        (dvoid *) 0, (ub2 *) 0, (ub2 *) 0,
        (ub4) 1, (ub4 *) &curlen, (ub4) OCI_DATA_AT_EXEC);
```

The PL/SQL procedure, get_lob(), is as follows:

```
procedure get_lob(c INOUT CLOB) is  -- This might have been column%type
  BEGIN
  ... /* The procedure body could be in PL/SQL or C*/
  END;
```

8

Locator Interface for LOBs

The Locator Interface for LOBs refers to a set of APIs in different programmatic interfaces, which enables you to perform operations on persistent and temporary LOBs using the LOB locator.

These operations typically take an offset, or an amount parameter, or both, as input argument to facilitate efficient random and piecewise operations on the LOB.

- Before You Begin
  Learn about the concepts that you should know before using the programmatic interfaces to work on LOBs, using the LOB locator.

- PL/SQL API for LOBs
  The `DBMS_LOB` package enables you to access and make changes to LOBs in PL/SQL.

- JDBC API for LOBs
  JDBC supports standard Java interfaces `java.sql.Clob` and `java.sql.Blob` for `CLOB`s and `BLOB`s respectively.

- OCI API for LOBs
  Oracle Call Interface (OCI) LOB functions enable you to access and make changes to LOBs in C.

- ODP.NET API for LOBs
  Oracle Data Provider for .NET (ODP.NET) is an ADO.NET provider for the Oracle Database.

- OCCI API for LOBs
  OCCI provides a seamless interface to manipulate objects of user-defined types as C++ class instances.

- Pro*C/C++ and Pro*COBOL API for LOBs
  This section describes the mapping of Pro*C/C++ and Pro*COBOL locators to locator pointers to access a LOB value.

> ✎ **See Also:**
>
> BFILE APIs for operations involving the BFILE data type.

8.1 Before You Begin

Learn about the concepts that you should know before using the programmatic interfaces to work on LOBs, using the LOB locator.

- Getting a LOB Locator
  All LOB APIs need a valid LOB locator to be passed as an input. This section discusses various methods to populate LOB variables using a LOB locator.

- **LOB Open and Close Operations**
  The LOB APIs include operations that enable you to explicitly open and close a LOB instance.

- **Read and Write at Chunk Boundaries**
  To improve performance, you should perform LOB reads and writes using offsets and amount that are a multiple of the value returned by `GETCHUNKSIZE` function.

- **Prefetching LOB Data and Length**
  In most clients like JDBC, OCI and ODP.NET, the number of server round trips can be reduced by prefetching part of the data and metadata (length and chunk size) along with the LOB locator during the fetch. This applies to persistent LOBs, temporary LOBs, and `BFILE`s.

- **Determining Character Set ID**
  Some LOB APIs such as `DBMS_LOB.LOADCLOBFROMFILE`, `OCILobRead2()` and `OCILobWrite2()` take in a character set ID as an input. To determine the character set ID, you must know the character set name.

- **LOB APIs**
  Once a LOB variable is initialized with either a persistent or a temporary LOB locator, subsequent read operations on the LOB can be performed using APIs such as the `DBMS_LOB` package subprograms.

8.1.1 Getting a LOB Locator

All LOB APIs need a valid LOB locator to be passed as an input. This section discusses various methods to populate LOB variables using a LOB locator.

All LOB APIs need a valid LOB locator to be passed as an input. Use one of the following methods to populate a LOB variable in your application with a LOB locator:

- Persistent LOBs: First create a table with a LOB column, then insert a value into the LOB column and select out the LOB locator. To modify an existing LOB using a LOB locator, you must lock the row in the table in order to prevent other database users from writing to the LOB during a transaction.

  > ✏️ **See Also:**
  >
  > – Persistent LOBs for information on how to create a a table with a LOB column and populate it.
  >
  > – Selecting a LOB into a LOB Variable for Read Operations for information on how to select a LOB locator for LOB read operations.
  >
  > – Selecting a LOB into a LOB Variable for Write Operations for information on how to lock the row for LOB modify operations.

- Temporary LOBs: You can create a temporary LOB by using an API like `DBMS_LOB.CREATETEMPORARY` or by invoking a SQL or PL/SQL function that returns a temporary LOB.

  > ✏️ **See Also:**
  >
  > Temporary LOBs

8.1.2 LOB Open and Close Operations

The LOB APIs include operations that enable you to explicitly open and close a LOB instance.

You can open and close a persistent or temporary LOB instance of any type: `BLOB`, `CLOB` or `NCLOB`. You open a LOB to achieve one or both of the following results:

- Open the LOB in read-only mode

    This ensures that the LOB (both the LOB locator and LOB value) cannot be changed in your session until you explicitly close the LOB. For example, you can open the LOB to ensure that the LOB is not changed by some other part of your program while you are using the LOB in a critical operation. After you perform the operation, you can then close the LOB.

- Open the LOB in read-write mode

    Opening a LOB in read-write mode defers any index maintenance on the LOB column until you close the LOB. Opening a LOB in read-write mode is only useful if there is a functional or domain index on the LOB column, and you do not want the database to perform index maintenance every time you write to the LOB. This technique can improve the performance of your application if you are doing several write operations on the LOB while it is open. Note that any index on the LOB column is not valid until you explicitly close the LOB.

    If you do not explicitly open the LOB instance, then every modification to the LOB implicitly opens and closes the LOB instance. The database performs index maintenance for any functional and domain indexes on the LOB column on each implicit close of the LOB. This means that the indexes on the LOB are updated as soon as any modification to the LOB instance is made. These indexes are always valid and can be used at any time.

The open state of a LOB is associated with the LOB instance, not the LOB locator. The locator does not save any information indicating whether the LOB instance that it points to is open.

You must close any LOB instance that you explicitly open in the following places:

- Between DML statements that start a transaction, including `SELECT ... FOR UPDATE` and `COMMIT`.
- Within an autonomous transaction block.
- Before the end of a session (when there is no transaction in progress in the session).

If you do not explicitly close the LOB instance, then it is implicitly closed at the end of the session and no index triggers are fired, which means that any indexes on the LOB column are not updated. In this situation, you must rebuild your indexes on the LOB column.

Committing a transaction on the open LOB instance causes an error. When this error occurs, the LOB instance is closed implicitly, any modifications to the LOB instance are saved, and the transaction is committed, but any indexes on the LOB column are not updated. In this situation, you must rebuild your indexes on the LOB column.

If you subsequently rollback the transaction, then the LOB instance is rolled back to its previous state, but the LOB instance is no longer explicitly open.

Keep track of the open or closed state of LOBs that you explicitly open. The following actions cause an error:

- Explicitly opening a LOB instance that has been explicitly open earlier.
- Explicitly closing a LOB instance that is has been explicitly closed earlier.

This occurs whether you access the LOB instance using the same locator or different locators.

8.1.3 Read and Write at Chunk Boundaries

To improve performance, you should perform LOB reads and writes using offsets and amount that are a multiple of the value returned by `GETCHUNKSIZE` function.

If it is appropriate for your application, then you should batch reads and writes until you have enough for an entire chunk instead of issuing several LOB read or write calls that operate on the same LOB chunk.

8.1.4 Prefetching LOB Data and Length

In most clients like JDBC, OCI and ODP.NET, the number of server round trips can be reduced by prefetching part of the data and metadata (length and chunk size) along with the LOB locator during the fetch. This applies to persistent LOBs, temporary LOBs, and `BFILE`s.

For small to medium sized LOBs, Oracle recommends setting the prefetch length such that about majority of your LOBs are smaller than the prefetch size.

LOB prefetch size can be set at the session level, and can be overwritten at the statement or the column level.

8.1.5 Determining Character Set ID

Some LOB APIs such as `DBMS_LOB.LOADCLOBFROMFILE`, `OCILobRead2()` and `OCILobWrite2()` take in a character set ID as an input. To determine the character set ID, you must know the character set name.

A user can select from the `V$NLS_VALID_VALUES` view, which lists the names of the character sets that are valid as database and national character sets. Then call the function `NLS_CHARSET_ID` with the desired character set name as the one string argument. The character set ID is returned as an integer.

Although `UTF16` is not allowed as a database or national character set, LOB APIs support it for database conversion purposes. Use character `set ID = 1000` for `UTF16`, or in OCI, you can use `OCI_UTF16ID`.

8.1.6 LOB APIs

Once a LOB variable is initialized with either a persistent or a temporary LOB locator, subsequent read operations on the LOB can be performed using APIs such as the `DBMS_LOB` package subprograms.

The operations supported on LOBs are divided into the following categories:

Table 8-1   Operations supported by LOB APIs

Category	Operation	Example function/procedure in DBMS_LOB or OCILob
Sanity Checking	Check if the LOB variable has been initialized	`OCILobLocatorIsInit`
	Find out if the `BLOB` or `CLOB` locator is a SecureFile	`ISSECUREFILE`
Open/Close	Open a LOB	`OPEN`
	Check is a LOB is open	`ISOPEN`
	Close the LOB	`CLOSE`
Read Operations	Get the length of the LOB	`GETLENGTH`
	Get the LOB storage limit for the database configuration	`GET_STORAGE_LIMIT`
	Get the optimum read or write size	`GETCHUNKSIZE`
	Read data from the LOB starting at the specified offset	`READ`
	Return part of the LOB value starting at the specified offset using `SUBSTR`	`SUBSTR`
	Return the matching position of a pattern in a LOB using `INSTR`	`INSTR`
Modify Operations	Write data to the LOB at a specified offset	`WRITE`
	Write data to the end of the LOB	`WRITEAPPEND`
	Erase part of a LOB, starting at a specified offset	`ERASE`
	Trim the LOB value to the specified shorter length	`TRIM`
Operations involving multiple locators	Check whether the two LOB locators are the same	`OCILobIsEqual`
	Compare all or part of the value of two LOBs	`COMPARE`
	Append a LOB value to another LOB	`APPEND`
	Copy all or part of a LOB to another LOB	`COPY`
	Assign LOB locator `src` to LOB locator `dst`	`dst:=src,` `OCILobLocatorAssign`
	Converts a `BLOB` to a `CLOB` or a `CLOB` to a `BLOB`	`CONVERTTOBLOB,` `CONVERTTOCLOB`
	Load `BFILE` data into a LOB	`LOADCLOBFROMFILE,` `LOADBLOBFROMFILE`
Operations Specific to SecureFiles	Returns options (deduplication, compression, encryption) for SecureFiles.	`GETOPTIONS`
	Sets LOB features (deduplication and compression) for SecureFiles	`SETOPTIONS`
	Gets the content string for a SecureFiles.	`GETCONTENTTYPE`

ORACLE

Table 8-1   (Cont.) Operations supported by LOB APIs

Category	Operation	Example function/procedure in DBMS_LOB or OCILob
	Sets the content string for a SecureFiles.	`SETCONTENTTYPE`
	Delete the data from the LOB at the given offset for the given length	`FRAGMENT_DELETE`
	Insert the given data (< 32KBytes) into the LOB at the given offset	`FRAGMENT_INSERT`
	Move the given amount of bytes from the given offset to the new given offset	`FRAGMENT_MOVE`
	Replace the data at the given offset with the given data (< 32kBytes)	`FRAGMENT_REPLACE`

> - Temporary LOBs
> - BFILEs
> - Comparing the LOB Interfaces

> **Note:**
>
> The `DBMS_LOB` package provides a rich set of operations on LOBs. If you are using a different programmatic interface, where some of these operations are not provided, then call the corresponding PL/SQL procedure or function in `DBMS_LOB` package.

Most of the code examples in the following sections use the `print_media` table with the following structure:

Figure 8-1   print_media table

8.2 PL/SQL API for LOBs

The `DBMS_LOB` package enables you to access and make changes to LOBs in PL/SQL.

> ✏️ **See Also:**
>
> DBMS_LOB for more information on DBMS_LOB package.

Guidelines for Offset and Amount Parameters in DBMS_LOB Operations

The following guidelines apply to the `offset` and `amount` parameters used in the `DBMS_LOB` PL/SQL package procedures:

- For character data in all formats, either in fixed-width or variable-width, the `amount` and `offset` parameters are in characters. This applies to operations on `CLOB` and `NCLOB` data types.

- For binary data, the `offset` and `amount` parameters are in bytes. This applies to operations on `BLOB` data types.

- When using the `DBMS_LOB.READ` procedure, the `amount` parameter should be less than or equal to the size of the buffer, which is limited to 32K. However, the `amount` parameter can be larger than the size of the LOB data.

Table 8-2   DBMS_LOB functions and procedures for LOBs

Category	Function/Procedure	Description
Sanity Checking	ISSECUREFILE	Find out if the `BLOB` or `CLOB` locator is a SecureFile
Open/Close	OPEN	Open a LOB
	ISOPEN	Check if a LOB is open
	CLOSE	Close the LOB
Read Operations	GETLENGTH	
	GET_STORAGE_LIMIT	
	GETCHUNKSIZE	
	READ	
	SUBSTR	
	INSTR	
Modify Operations	WRITE	Write data to the LOB at a specified offset
	WRITEAPPEND	Write data to the end of the LOB
	ERASE	Erase part of a LOB, starting at a specified offset
	TRIM	Trim the LOB value to the specified shorter length
Operations involving multiple locators	COMPARE	Compare all or part of the value of two LOBs
	APPEND	Append a LOB value to another LOB
	COPY	Copy all or part of a LOB to another LOB
	dst := src	Assign LOB locator `src` to LOB locator `dst`
	CONVERTTOBLOB, CONVERTTOCLOB	Converts a `BLOB` to a `CLOB` or a `CLOB` to a `BLOB`
	LOADCLOBFROMFILE, LOADBLOBFROMFILE	Load `BFILE` data into a LOB
Operations specific to SecureFiles	GETOPTIONS	Returns options (deduplication, compression, encryption) for SecureFiles.
	SETOPTIONS	Sets LOB features (deduplication and compression) for SecureFiles
	GETCONTENTTYPE	Gets the content string for a SecureFiles.

Table 8-2   (Cont.) DBMS_LOB functions and procedures for LOBs

Category	Function/Procedure	Description
	SETCONTENTTYPE	Sets the content string for a SecureFiles.
	FRAGMENT_DELETE	Delete the data from the LOB at the given offset for the given length
	FRAGMENT_INSERT	Insert the given data (< 32KBytes) into the LOB at the given offset
	FRAGMENT_MOVE	Move the given amount of bytes from the given offset to the new given offset
	FRAGMENT_REPLACE	Replace the data at the given offset with the given data (< 32kBytes)

Example 8-1   PL/SQL API for LOBs

```
DECLARE
   retval    INTEGER;
   clob1     CLOB;
   clob2     CLOB;
   clob3     CLOB;
   blob1     BLOB;
   buf       VARCHAR2(32767);
   buflen    INTEGER := 32760;
   loblen1   INTEGER;

   -- Following are the variables that you need for the convertToBlob and
convertToClob functions
   amt     NUMBER := 0;
   src     NUMBER := 1 ;
   dst     NUMBER := 1 ;
   lang    NUMBER := 0;
   warn    NUMBER;

 BEGIN
   SELECT ad_sourcetext INTO clob1 FROM print_media

8.3 JDBC API for LOBs

JDBC supports standard Java interfaces `java.sql.Clob` and `java.sql.Blob` for CLOBs and BLOBs respectively.

In JDBC, you do not deal with locators but instead use methods and properties in the Java APIs to perform operations on LOBs.

When BLOB and CLOB objects are retrieved as a part of an `ResultSet`, these objects represent LOB locators of the currently selected row. If the current row changes due to a move operation, for example, `rset.next()`, then the retrieved locator still refers to the original LOB row. You must call `getBLOB()`, `getCLOB()`, or `getBFILE()` on the `ResultSet` each time a move operation is made depending on whether the instance is a BLOB, CLOB or BFILE.

> **See Also:**
>
> Working with LOBs and BFILEs

Prefetching of LOB Data

When using the JDBC client, the number of server round trips can be reduced by prefetching part of the data and metadata (length and chunk size) along with the LOB locator during the fetch. This applies to persistent LOBs, temporary LOBs, and BFILEs. For small to medium sized LOBs, Oracle recommends setting the prefetch length such that about majority of your LOBs are smaller than the prefetch size.

LOB prefetch size can be set at the session level, and can be overwritten at the statement or the column level. The prefetch size values can be:

- -1 to disable prefetching

- 0 to enable prefetching for metadata only

- any value greater than 0 which represents the number of bytes for BLOBs and characters for CLOBs, to be prefetched along with the locator during fetch operations.

Use `prop.setProperty` to set the prefetch size for the session. The default session prefetch size is 32k for the JDBC Thin Driver.

```
prop.setProperty("oracle.jdbc.defaultLobPrefetchSize","64000");
```

You can overwrite the session level default prefetch size at the statement level as follows:

```
((OracleStatement)stmt).setLobPrefetchSize(100000);
```

You can use the following code snippet to fetch the prefetch size of a statement:

```
int pf = ((OracleStatement)stmt).getLobPrefetchSize() ;
```

You can overwrite the session level default prefetch size at the column level as follows:

```
((OracleStatement)stmt).defineColumnType(1, OracleTypes.CLOB, /
*lobPrefetchSize*/
     32000);
```

> **Note:**
>
> About Prefetching LOB Data

Table 8-3   JDBC methods for LOBs

Category	Function / Procedure	Description
Miscellaneous	empty_lob()	Creates an empty LOB
	isSecureFile()	Finds out if the BLOB or CLOB locator is a SecureFile

Table 8-3   (Cont.) JDBC methods for LOBs

Category	Function / Procedure	Description
Open/Close	`open()`	Open a LOB
	`isOpen()`	Check if a LOB is open
	`close()`	Close the LOB
Read Operations	`length()`	Get the length of the LOB
	`getChunkSize()`	Get the optimum read/write size
	`getBytes()`	Read data from the BLOB starting at the specified offset
	`getBinaryStream()`	Streams the BLOB as a binary stream
	`getChars()`	Read data from the CLOB starting at the specified offset
	`getCharacterStream()`	Streams the CLOB as a character stream
	`getAsciiStream()`	Streams the CLOB as an ASCII stream
	`getSubString()`	Return part of the LOB value starting at the specified offset
	`position()`	Return the matching position of a pattern in a LOB
Modify Operations	`setBytes()`	Write data to the BLOB at a specified offset
	`setBinaryStream()`	Sets a binary stream that can be used to write to the `BLOB` value
	`setString()`	Write data to the CLOB at a specified offset
	`setCharacterStream()`	Sets a character stream that can be used to write to the `CLOB` value
	`setAsciiStream()`	Sets an ASCII stream that can be used to write to the `CLOB` value
	`truncate()`	Trim the LOB value to the specified shorter length
Operations involving multiple locators	dst = src	Assign LOB locator src to LOB locator dst

Example 8-3   JDBC API for LOBs

```
static void jdbc_lob_apis() throws Exception {

  System.out.println("Persistent LOBs Test in JDBC "+ TYPE);
  try(
      Connection con = getConnection();
      Statement      stmt = con.createStatement();
      )
  {

    ResultSet   rs     = null;
    Clob   c1     = null;
```

```
Clob   c2      = null;
Reader     in      = null;
long       pos     = 0;
long       len     = 0;

rs = stmt.executeQuery("select ad_sourcetext from print_media where
product_id = 1");
rs.next();
c1 = rs.getCLOB(1);
OracleClob c11 = (OracleClob)c1;
rs.close();

/*------------------------------------------------------------------*/
/*-------------------- Sanity Checking --------------------------*/
/*------------------------------------------------------------------*/
if (c11.isSecureFile())
  System.out.println("C1 is a Securefile LOB");
else
  System.out.println("C1 is a Basicfile LOB");

/*------------------------------------------------------------------*/
/*-------------------- Open/Close ------------------------------*/
/*------------------------------------------------------------------*/

/*-------------------- Opening a CLOB --------------------------*/
c11.open(LargeObjectAccessMode.MODE_READONLY);

/*-------------- Determining Whether a CLOB Is Open ----------------*/
if (c11.isOpen())
  System.out.println("C11 is open!");
else
  System.out.println("C11 is not open");

/*-------------------- Closing a CLOB --------------------------*/
c11.close();

/*------------------------------------------------------------------*/
/*------------------ Reading from a LOB ------------------------*/
/*------------------------------------------------------------------*/

/*-------------------- Get CLOB Length ----------------------*/
len = c1.length();
System.out.println("CLOB length = " + len);

/*-------------------- Reading CLOB Data ----------------------*/
char[] readBuffer = new char[6];
in = c1.getCharacterStream();
in.read(readBuffer,0,5);
in.close();
String lobContent = new String(readBuffer);
System.out.println("Buffer with LOB contents: " + lobContent);

/*-------------------- Substr of a CLOB ----------------------*/
String subs = c1.getSubString(2, 5);
System.out.println("LOB substring: " + subs);
```

```
        /*----------------------- Search for a pattern  --------------------*/
        pos = c1.position("aaa", 1);
        System.out.println("Pattern matched at position = " + pos);

        /*-----------------------------------------------------------------*/
        /*-------------------- Modifying a LOB -----------------------------*/
        /*-----------------------------------------------------------------*/

        rs = stmt.executeQuery("select ad_sourcetext from print_media where
product_id = 1 for update");
        rs.next();
        c2 = rs.getClob(1);
        OracleClob c22 = (OracleClob)c2;

        /*-------------------- Write to a CLOB -----------------------------*/
        c22.open(LargeObjectAccessMode.MODE_READWRITE);
        c2.setString(3,"modified");
        String msubs = c2.getSubString(1, 15);
        System.out.println("Modified LOB substring: " + msubs);

        /*-------------------- Truncate a CLOB -----------------------------*/
        c2.truncate(20);
        len = c2.length();
        System.out.println("Truncated LOB len = " + len);
        c22.close();

    }
}
```

8.4 OCI API for LOBs

Oracle Call Interface (OCI) LOB functions enable you to access and make changes to LOBs in C.

> ✏️ **See Also:**
>
> LOB and BFILE Operations

Prefetching LOB Data in OCI

When using the OCI client, the number of server round trips can be reduced by prefetching part of the data and metadata (length and chunk size) along with the LOB locator during the fetch. This applies to persistent LOBs, temporary LOBs, and BFILEs. For small to medium sized LOBs, Oracle recommends setting the prefetch length such that about majority of your LOBs are smaller than the prefetch size.

LOB prefetch size can be set at the session level, and can be overwritten at the statement or the column level.

Use the `OCIAttrSet()` function to set the prefetch size for the session. The default session prefetch size is 0.

```
default_lobprefetch_size = 32000;
OCIAttrSet(authp, OCI_HTYPE_SESSION, &default_lobprefetch_size , 0,
      OCI_ATTR_DEFAULT_LOBPREFETCH_SIZE, errhp));
```

You can overwrite the session level default prefetch size at the column level. For this, you should first set the column level attribute `OCI_ATTR_LOBPREFETCH_LENGTH` to `TRUE` and then set the column level prefetch size attribute `OCI_ATTR_LOBPREFETCH_SIZE` in the define handle to override the session level default lob prefetch size. The following code snippet demonstrates how to set the prefetch size at session level:

```
prefetch_length = TRUE;
status = OCIAttrSet(defhp, OCI_HTYPE_DEFINE, &prefetch_length, 0,
OCI_ATTR_LOBPREFETCH_LENGTH, errhp);

lpf_size = 32000;
OCIAttrSet(defhp, OCI_HTYPE_DEFINE, &lpf_size, sizeof(ub4),
OCI_ATTR_LOBPREFETCH_SIZE, errhp);
```

You can use the following code snippet to get the prefetch size of a define:

```
ub4 get_lpf_size = 0;
OCIAttrGet(defhp, OCI_HTYPE_DEFINE,&get_lpf_size,
0,OCI_ATTR_LOBPREFETCH_SIZE, errhp);
```

> User Session Handle Attributes

Fixed-width and Varying-width Character Set Rules for OCI

In OCI, for fixed-width client-side character sets, the following rules apply:

- `CLOB`s and `NCLOB`s: `offset` and `amount` parameters are always in characters
- `BLOB`s and `BFILE`s: `offset` and `amount` parameters are always in bytes

The following rules apply only to varying-width client-side character sets:

- **Offset parameter**:

  Regardless of whether the client-side character set is varying-width, the offset parameter is always as follows:

  - `CLOB`s and `NCLOB`s: in characters
  - `BLOB`s and `BFILE`s: in bytes

- **Amount parameter**:

  The amount parameter is always as follows:

  - When referring to a server-side LOB: in characters
  - When referring to a client-side buffer: in bytes

- **OCILobGetLength2()**:

  Regardless of whether the client-side character set is varying-width, the output length is as follows:

  - `CLOB`s and `NCLOB`s: in characters

  - `BLOB`s and `BFILE`s: in bytes

- **OCILobRead2()**:

  With client-side character set of varying-width, `CLOB`s and `NCLOB`s:

  - **Input amount** is in characters. Input amount refers to the number of characters to read from the server-side `CLOB` or `NCLOB`.

  - **Output amount** is in bytes. Output amount indicates how many bytes were read into the buffer `bufp`.

- **OCILobWrite2()**: With client-side character set of varying-width, `CLOB`s and `NCLOB`s:

  - **Input amount** is in bytes. The input amount refers to the number of bytes of data in the input buffer `bufp`.

  - **Output amount** is in characters. The output amount refers to the number of characters written into the server-side `CLOB` or `NCLOB`.

- **Amount Operation for OCILob Operations**: For operations such as `OCILobCopy2()`, `OCILobErase2()`, `OCILobLoadFromFile2()`, and `OCILobTrim2()`, the `amount` parameter is in characters for `CLOB`s and `NCLOB`s irrespective of the client-side character set because all these operations refer to the amount of LOB data on the server.

> **See Also:**
>
> Overview of Globalization Support

Amount Parameter

When using the `OCILobRead2()` and `OCILobWrite2()` functions, in order to read or write the entire LOB. you can set the input `amount` parameter as follows:

Table 8-4   Special Amount Parameter Setting to Read/Write the entire LOB

	OCILobRead2	OCILobWrite2
`piece = OCI_ONE_PIECE`	Set amount to `UB8MAXVAL` to read the entire LOB	
Streaming with Polling	Set amount to 0 to read entire data in a loop	Set amount to 0 to continue writing buffer size amount until `OCI_LAST_PIECE`
Streaming with Callback	Set amount 0 to ensure that the callback is called until the entire data is read	Set amount to 0 to ensure that the callback is called until `OCI_LAST_PIECE` is returned by the callback

Table 8-5   OCI Attributes on the OCILobLocator

ATTRIBUTE	OCIAttrSet	OCIAttrGet
OCI_ATTR_LOBEMPTY	Sets the descriptor to be empty LOB	N/A
OCI_ATTR_LOB_REMOTE	N/A	set to TRUE if the lob locator is from a remote database, set to FALSE otherwise
OCI_ATTR_LOB_TYPE	N/A	holds the LOB type (CLOB / BLOB / BFILE)
OCI_ATTR_LOB_IS_VALUE	N/A	set to TRUE if it is from a value LOB, otherwiseFALSE
OCI_ATTR_LOB_IS_READONLY	N/A	set to TRUE if it is a read-only LOB, otherwise FALSE
OCI_ATTR_LOBPREFETCH_LENGTH	When set to TRUE the attribute will enable prefetching and will prefetch the LOB length and the chunk size while performing select operation of LOB locator	set to TRUE if prefetching is turned on for the locator.
OCI_ATTR_LOBPREFETCH_SIZE	Overrides the default prefetch size for LOBs. Has a prerequisite of the OCI_ATTR_LOBPREFETCH_LENGTH attribute to be set to TRUE.	Returns the prefetch size of the locator.

Table 8-6   OCI Functions for LOBs

Category	Function/Procedure	Description
Sanity Checking	OCILobLocatorIsInit()	Checks whether a LOB locator is initialized.
Open/Close	OCILobOpen()	Open a LOB
	OCILobIsOpen()	Check if a LOB is open
	OCILobClose()	Close the LOB
Read Operations	OCILobGetLength2()	Get the length of the LOB
	OCILobGetStorageLimit()	Get the LOB storage limit for the database configuration
	OCILobGetChunkSize()	Get the optimum read / write size
	OCILobRead2()	Read data from the LOB starting at the specified offset
	OCILobArrayRead()	Reads data using multiple locators in one round trip.
	OCILobCharSetId()	Returns the character set ID of a LOB.
	OCILobCharSetForm()	Returns the character set form of a LOB.
Modify Operations	OCILobWrite2()	Write data to the LOB at a specified offset
	OCILobArrayWrite()	Writes data using multiple locators in one round trip.
	OCILobWriteAppend2()	Write data to the end of the LOB

ORACLE®

Table 8-6   (Cont.) OCI Functions for LOBs

Category	Function/Procedure	Description
	`OCILobErase2()`	Erase part of a LOB, starting at a specified offset
	`OCILobTrim2()`	Trim the LOB value to the specified shorter length
Operations involving multiple locators	`OCILobIsEqual()`	Checks whether two LOB locators refer to the same LOB.
	`OCILobAppend()`	Append a LOB value to another LOB
	`OCILobCopy2()`	Copy all or part of a LOB to another LOB
	`OCILobLocatorAssign()`	Assign one LOB to another
	`OCILobLoadFromFile2()`	Load `BFILE` data into a LOB
Operations specific to SecureFiles	`OCILObGetOptions()`	Returns options (deduplication, compression, encryption) for SecureFiles.
	`OCILObSetOptions()`	Sets LOB features (deduplication and compression) for SecureFiles
	`OCILobGetContentType()`	Gets the content string for a SecureFiles
	`OCILobSetContentType()`	Sets a content string in a SecureFiles

ORACLE

8.4.1 Efficiently Reading LOB Data in OCI

This section describes how to read the contents of a LOB into a buffer.

Streaming Read in OCI

The most efficient way to read large amounts of LOB data is to use `OCILobRead2()` with the streaming mechanism enabled using polling or callback. To do so, specify the starting point of the read using the `offset` parameter as follows:

```
ub8  char_amt =  0;
ub8  byte_amt =  0;
ub4  offset = 1000;

OCILobRead2(svchp, errhp, locp, &byte_amt, &char_amt, offset, bufp, bufl,
            OCI_ONE_PIECE, 0, 0, 0, 0);
```

When using *polling mode*, be sure to look at the value of the `byte_amt` parameter after each `OCILobRead2()` call to see how many bytes were read into the buffer because the buffer may not be entirely full.

When using *callbacks*, the `lenp` parameter, which is input to the callback, indicates how many bytes are filled in the buffer. Be sure to check the `lenp` parameter during your callback processing because the entire buffer may not be filled with data.

LOB Array Read

This section describes how to read LOB data for multiple locators in one round trip, using `OCILobArrayRead()`.

For an OCI application example, assume that the program has a prepared SQL statement such as:

```
SELECT lob1 FROM lob_table;
```

where `lob1` is the LOB column and `lob_array` is an array of define variables corresponding to a LOB column:

```
OCILobLocator * lob_array[10];

...
 for (i=0; i<10, i++)          /* initialize array of locators */
    lob_array[i] = OCIDescriptorAlloc(..., OCI_DTYPE_LOB, ...);

...

OCIDefineByPos(..., 1, (dvoid *) lob_array, ... SQLT_CLOB, ...);

/* Execute the statement with iters = 10 to do an array fetch of 10 locators. */
OCIStmtExecute ( <service context>, <statement handle>, <error handle>,
                 10,    /* iters  */
                 0,     /* row offset */
```

```
                            NULL,  /* snapshot IN */
                            NULL,  /* snapshot out */
                            OCI_DEFAULT /* mode */);
...

  ub4 array_iter = 10;
  char  *bufp[10];
  oraub8 bufl[10];
  oraub8 char_amtp[10];
  oraub8 offset[10];

 for (i=0; i<10; i++)
  {
    bufp[i] = (char *)malloc(1000);
    bufl[i] = 1000;
    offset[i] = 1;
    char_amtp[i] = 1000;  /* Single byte fixed width char set. */
  }

/* Read the 1st 1000 characters for all 10 locators in one
 * round trip. Note that offset and amount need not be
 * same for all the locators. */

OCILobArrayRead(<service context>, <error handle>,
                  &array_iter, /* array size */
                  lob_array,   /* array of locators */
                  NULL,        /* array of byte amounts */
                  char_amtp,   /* array of char amounts */
                  offset,      /* array of offsets */
        (void **)bufp,         /* array of read buffers */
                  bufl,        /* array of buffer lengths */
                  OCI_ONE_PIECE,  /* piece information */
                  NULL,           /* callback context */
                  NULL,           /* callback function */
                  0,              /* character set ID - default */
                  SQLCS_IMPLICIT);/* character set form */

 ...

for (i=0; i<10; i++)
  {
    /* Fill bufp[i] buffers with data to be written */
    strncpy (bufp[i], "Test Data------", 15);
    bufl[i] = 1000;
    offset[i] = 50;
    char_amtp[i] = 15;  /* Single byte fixed width char set. */
  }

/* Write the 15 characters from offset 50 to all 10
 * locators in one round trip. Note that offset and
 * amount need not be same for all the locators. */
 */

OCILobArrayWrite(<service context>, <error handle>,
                  &array_iter, /* array size */
                  lob_array,   /* array of locators */
                  NULL,        /* array of byte amounts */
                  char_amtp,   /* array of char amounts */
                  offset,      /* array of offsets */
            (void **)bufp,     /* array of read buffers */
                  bufl,        /* array of buffer lengths */
                  OCI_ONE_PIECE,  /* piece information */
```

```
                    NULL,          /* callback context */
                    NULL,          /* callback function */
                    0,             /* character set ID - default */
                    SQLCS_IMPLICIT);/* character set form */
...
```

LOB Array Read with Streaming

LOB array APIs can be used to read/write LOB data in multiple pieces. This can be done by using polling method or a callback function.Here data is read/written in multiple pieces sequentially for the array of locators. For polling, the API would return to the application after reading/writing each piece with the `array_iter` parameter (OUT) indicating the index of the locator for which data is read/written. With a callback, the function is called after reading/writing each piece with `array_iter` as IN parameter.

Note that:

- It is possible to read/write data for a few of the locators in one piece and read/write data for other locators in multiple pieces. Data is read/written in one piece for locators which have sufficient buffer lengths to accommodate the whole data to be read/written.

- Your application can use different amount value and buffer lengths for each locator.

- Your application can pass zero as the amount value for one or more locators indicating pure streaming for those locators. In the case of reading, LOB data is read to the end for those locators. For writing, data is written until `OCI_LAST_PIECE` is specified for those locators.

LOB Array Read with Callback

The following example reads 10Kbytes of data for each of 10 locators with 1Kbyte buffer size. Each locator needs 10 pieces to read all the data. The callback function is called 100 (10*10) times to return the pieces sequentially.

```
/* Fetch the locators */
...
    ub4    array_iter = 10;
    char  *bufp[10];
    oraub8 bufl[10];
    oraub8 char_amtp[10];
    oraub8 offset[10];
    sword  st;

    for (i=0; i<10; i++)
    {
      bufp[i] = (char *)malloc(1000);
      bufl[i] = 1000;
      offset[i] = 1;
      char_amtp[i] = 10000;      /* Single byte fixed width char set. */
     }

    st =  OCILobArrayRead(<service context>, <error handle>,
                    &array_iter, /* array size */
                    lob_array,   /* array of locators */
                    NULL,        /* array of byte amounts */
                    char_amtp,   /* array of char amounts */
                    offset,      /* array of offsets */
            (void **)bufp,       /* array of read buffers */
                    bufl,        /* array of buffer lengths */
                    OCI_FIRST_PIECE,  /* piece information */
                    ctx,              /* callback context */
                    cbk_read_lob,     /* callback function */
```

```
                           0,                    /* character set ID - default */
                           SQLCS_IMPLICIT);
...
/* Callback function for LOB array read. */
sb4 cbk_read_lob(dvoid *ctxp, ub4 array_iter, CONST dvoid *bufxp, oraub8 len,
                 ub1 piece, dvoid **changed_bufpp, oraub8 *changed_lenp)
{
   static ub4 piece_count = 0;
   piece_count++;
   switch (piece)
   {
    case OCI_LAST_PIECE:
      /*--- buffer processing code goes here ---*/
      (void) printf("callback read the %d th piece(last piece) for %dth locator \n\n",
                piece_count, array_iter );
      piece_count = 0;
      break;
    case OCI_FIRST_PIECE:
      /*--- buffer processing code goes here ---*/
      (void) printf("callback read the 1st piece for %dth locator\n",
                  array_iter);
      /* --Optional code to set changed_bufpp and changed_lenp if the buffer needs
         to be changed dynamically --*/
      break;
    case OCI_NEXT_PIECE:
      /*--- buffer processing code goes here ---*/
      (void) printf("callback read the %d th piece for %dth locator\n",
                  piece_count, array_iter);
      /* --Optional code to set changed_bufpp and changed_lenp if the  buffer
          must be changed dynamically --*/
      break;
      default:
      (void) printf("callback read error: unkown piece = %d.\n", piece);
      return OCI_ERROR;
   }
    return OCI_CONTINUE;
}
...
```

LOB Array Read in Polling Mode

The following example reads 10Kbytes of data for each of 10 locators with 1Kbyte buffer size. Each locator needs 10 pieces to read the complete data. `OCILobArrayRead()` must be called 100 (10*10) times to fetch all the data.First we call `OCILobArrayRead()` with `OCI_FIRST_PIECE` as `piece` parameter. This call returns the first 1K piece for the first locator.Next `OCILobArrayRead()` is called in a loop until the application finishes reading all the pieces for the locators and returns `OCI_SUCCESS`. In this example it loops 99 times returning the pieces for the locators sequentially.

```
/* Fetch the locators */
...

    /* array_iter parameter indicates the number of locators in the array read.
     * It is an IN parameter for the 1st call in polling and is ignored as IN
     * parameter for subsequent calls. As OUT parameter it indicates the locator
     * index for which the piece is read.
     */

    ub4     array_iter = 10;
    char   *bufp[10];
    oraub8 bufl[10];
    oraub8 char_amtp[10];
```

```
oraub8 offset[10];
sword  st;

for (i=0; i<10; i++)
{
  bufp[i] = (char *)malloc(1000);
  bufl[i] = 1000;
  offset[i] = 1;
  char_amtp[i] = 10000;        /* Single byte fixed width char set. */
}

st =  OCILobArrayRead(<service context>, <error handle>,
                      &array_iter, /* array size */
                      lob_array, /* array of locators */
                      NULL,      /* array of byte amounts */
                      char_amtp, /* array of char amounts */
                      offset,    /* array of offsets */
             (void **)bufp,      /* array of read buffers */
                      bufl,      /* array of buffer lengths */
                      OCI_FIRST_PIECE, /* piece information */
                      NULL,            /* callback context */
                      NULL,            /* callback function */
                      0,               /* character set ID - default */
                      SQLCS_IMPLICIT); /* character set form */

/* First piece for the first locator is read here.
 * bufp[0]          => Buffer pointer into which data is read.
 * char_amtp[0 ]    => Number of characters read in current buffer
 *
 */

While ( st == OCI_NEED_DATA)
{
    st =  OCILobArrayRead(<service context>, <error handle>,
                      &array_iter, /* array size */
                      lob_array, /* array of locators */
                      NULL,      /* array of byte amounts */
                      char_amtp, /* array of char amounts */
                      offset,    /* array of offsets */
             (void **)bufp,      /* array of read buffers */

                      OCI_NEXT_PIECE, /* piece information */
                      NULL,            /* callback context */
                      NULL,            /* callback function */
                      0,               /* character set ID - default */
                      SQLCS_IMPLICIT);

  /* array_iter returns the index of the current array element for which
   * data is read. for example, aray_iter = 1 implies first locator,
   * array_iter = 2 implies second locator and so on.
   *
   * lob_array[ array_iter - 1]=> Lob locator for which data is read.
   * bufp[array_iter - 1]      => Buffer pointer into which data is read.
   * char_amtp[array_iter - 1] => Number of characters read in current buffer
   */

...

    /* Consume the data here */
...
}
```

8.4.2 Efficiently Writing LOB Data in OCI

This section describes how to write the contents of a buffer to a LOB.

Streaming Write in OCI

The most efficient way to write large amounts of LOB data is to use `OCILobWrite2()` with the streaming mechanism enabled, and using polling or a callback. If you know how much data is written to the LOB, then specify that amount when calling `OCILobWrite2()`. This ensures that LOB data on the disk is contiguous. Apart from being spatially efficient, the contiguous structure of the LOB data makes reads and writes in subsequent operations faster.

LOB Array Write with Callback

The following example writes 10Kbytes of data for each of 10 locators with a 1K buffer size. A total of 100 pieces must be written (10 pieces for each locator). The first piece is provided by the `OCILobArrayWrite()` call. The callback function is called 99 times to get the data for subsequent pieces to be written.

```
/* Fetch the locators */
...

    ub4    array_iter = 10;
    char   *bufp[10];
    oraub8 bufl[10];
    oraub8 char_amtp[10];
    oraub8 offset[10];
    sword  st;

    for (i=0; i<10; i++)
    {
      bufp[i] = (char *)malloc(1000);
      bufl[i] = 1000;
      offset[i] = 1;
      char_amtp[i] = 10000;       /* Single byte fixed width char set. */
    }

 st =  OCILobArrayWrite(<service context>, <error handle>,
                        &array_iter, /* array size */
                        lob_array,   /* array of locators */
                        NULL,        /* array of byte amounts */
                        char_amtp,   /* array of char amounts */
                        offset,      /* array of offsets */
               (void **)bufp,        /* array of write buffers */
                        bufl,        /* array of buffer lengths */
                        OCI_FIRST_PIECE,  /* piece information */
                        ctx,              /* callback context */
                        cbk_write_lob     /* callback function */
                        0,                /* character set ID - default */
                        SQLCS_IMPLICIT);

...

/* Callback function for LOB array write. */
sb4 cbk_write_lob(dvoid *ctxp, ub4 array_iter, dvoid *bufxp, oraub8 *lenp,
                  ub1 *piecep, ub1 *changed_bufpp, oraub8 *changed_lenp)
{
 static ub4 piece_count = 0;
 piece_count++;
```

```
 printf (" %dth piece written  for %dth locator \n\n", piece_count, array_iter);

/*-- code to fill bufxp with data goes here. *lenp should reflect the  size and
 *   should be less than or equal to MAXBUFLEN -- */
/* --Optional code to set changed_bufpp and changed_lenp if the buffer must
 *   be changed dynamically --*/

 if (this is the last data buffer for current locator)
    *piecep = OCI_LAST_PIECE;
 else if (this is the first data buffer for the next locator)
    *piecep = OCI_FIRST_PIECE;
    piece_count = 0;
 else
    *piecep = OCI_NEXT_PIECE;

    return OCI_CONTINUE;
   }
...
```

LOB Array Write in Polling Mode

The following example writes 10Kbytes of data for each of `10` locators with a 1K buffer size.
`OCILobArrayWrite()` has to be called `100` (`10` times `10`) times to write all the data. The function
is used in a similar manner to `OCILobWrite2()`.

```
/* Fetch the locators */
...

/* array_iter parameter indicates the number of locators in the array read.
 * It is an IN parameter for the 1st call in polling and is ignored as IN
 * parameter for subsequent calls. As an OUT parameter it indicates the locator
 * index for which the piece is written.
 */

ub4    array_iter = 10;
char  *bufp[10];
oraub8 bufl[10];
oraub8 char_amtp[10];
oraub8 offset[10];
sword  st;
int    i, j;

for (i=0; i<10; i++)
{
  bufp[i] = (char *)malloc(1000);
  bufl[i] = 1000;
  /* Fill bufp here. */
...
  offset[i] = 1;
  char_amtp[i] = 10000;      /* Single byte fixed width char set. */
}

for (i  = 1; i <= 10; i++)
{
 /* Fill up bufp[i-1] here.  The first piece for ith locator would be written from
   bufp[i-1] */
...
    st = OCILobArrayWrite(<service context>, <error handle>,
                      &array_iter, /* array size */
                      lob_array,   /* array of locators */
                      NULL,        /* array of byte amounts */
                      char_amtp,   /* array of char amounts */
```

```
                              offset,       /* array of offsets */
                   (void **)bufp,          /* array of write buffers */
                              bufl,         /* array of buffer lengths */
                              OCI_FIRST_PIECE, /* piece information */
                              NULL,            /* callback context */
                              NULL,            /* callback function */
                              0,               /* character set ID - default */
                              SQLCS_IMPLICIT); /* character set form */

 for ( j = 2; j < 10; j++)
 {
 /* Fill up bufp[i-1] here.  The jth piece for ith locator would be written from
    bufp[i-1] */
 ...
 st = OCILobArrayWrite(<service context>, <error handle>,
                         &array_iter, /* array size */
                         lob_array,   /* array of locators */
                         NULL,        /* array of byte amounts */
                         char_amtp,   /* array of char amounts */
                         offset,      /* array of offsets */
               (void **)bufp,         /* array of write buffers */
                         bufl,        /* array of buffer lengths */
                         OCI_NEXT_PIECE, /* piece information */
                         NULL,           /* callback context */
                         NULL,           /* callback function */
                         0,              /* character set ID - default */
                         SQLCS_IMPLICIT);

    /* array_iter returns the index of the current array element for which
     * data is being written. for example, aray_iter = 1 implies first locator,
     * array_iter = 2 implies second locator and so on. Here i = array_iter.
     *
     * lob_array[ array_iter - 1] => Lob locator for which data is written.
     * bufp[array_iter - 1]       => Buffer pointer from which data is written.
     * char_amtp[ array_iter - 1] => Number of characters written in
     * the piece just written
     */
 }

 /* Fill up bufp[i-1] here.  The last piece for ith locator would be written from
    bufp[i -1] */
 ...
 st = OCILobArrayWrite(<service context>, <error handle>,
                         &array_iter, /* array size */
                         lob_array,   /* array of locators */
                         NULL,        /* array of byte amounts */
                         char_amtp,   /* array of char amounts */
                         offset,      /* array of offsets */
               (void **)bufp,         /* array of write buffers */
                         bufl,        /* array of buffer lengths */
                         OCI_LAST_PIECE,  /* piece information */
                         NULL,            /* callback context */
                         NULL,            /* callback function */
                         0,               /* character set ID - default */
                         SQLCS_IMPLICIT);
 }

 ...
```

8.5 ODP.NET API for LOBs

Oracle Data Provider for .NET (ODP.NET) is an ADO.NET provider for the Oracle Database.

ODP.NET offers fast and reliable access to Oracle data and features from any .NET Core or .NET Framework application. ODP.NET also uses and inherits classes and interfaces available in the Microsoft .NET Class Library. The ODP.NET supports the following LOBs as native data types with .NET: `BLOB`, `CLOB`, `NCLOB`, and `BFILE`.

> ✎ **See Also:**
>
> - LOB Support
> - Obtaining LOB Data

Table 8-7   ODP.NET methods in OracleClob and OracleBlob classes

Category	Function/Procedure	Description
Open/Close	`BeginChunkWrite`	Open a LOB
	`EndChunkWrite`	Close a LOB
	`IsInChunkWriteMode`	Check if a LOB is open
Read Operations	`Length`	Get the length of the LOB
	`OptimumChunkSize`	Get the optimum read/write size
	`Value`	Returns the entire LOB data as a string for CLOB and a byte array for BLOB
	`Read`	Read data from the LOB starting at the specified offset
	`Search`	Return the matching position of a pattern in a LOB using `INSTR`
Modify Operations	`Write`	Write data to the LOB at a specified offset
	`Erase`	Erase part of a LOB, starting at a specified offset
	`SetLength`	Trim the LOB value to the specified shorter length
Operations involving multiple locators	`Compare`	Compare all or part of the value of two LOBs
	`IsEqual`	Check if two LOBs point to the same LOB data
	`Append`	Append a LOB value to another LOB, or append a byte array, string, or character array to an existing LOB
	`CopyTo`	Copy all or part of a LOB to another LOB
	`Clone`	Assign LOB locator `src` to LOB locator `dst`

8.6 OCCI API for LOBs

OCCI provides a seamless interface to manipulate objects of user-defined types as C++ class instances.

Oracle C++ Call Interface (OCCI) is a C++ API for manipulating data in an Oracle database. OCCI is organized as an easy-to-use set of C++ classes that enable a C++ program to connect to a database, run SQL statements, insert/update values in database tables, retrieve results of a query, run stored procedures in the database, and access metadata of database schema objects.

Oracle C++ Call Interface (OCCI) is designed so that you can use OCI and OCCI together to build applications.

The OCCI API provides the following advantages over JDBC and ODBC:

- OCCI encompasses more Oracle functionality than JDBC. OCCI provides all the functionality of OCI that JDBC does not provide.

- OCCI provides *compiled* performance. With compiled programs, the source code is written as close to the computer as possible. Because JDBC is an *interpreted* API, it cannot provide the performance of a compiled API. With an interpreted program, performance degrades as each line of code must be interpreted individually into code that is close to the computer.

- OCCI provides memory management with smart pointers. You do not have to be concerned about managing memory for OCCI objects. This results in robust higher performance application code.

- Navigational access of OCCI enables you to intuitively access objects and call methods. Changes to objects persist without writing corresponding SQL statements. If you use the client side cache, then the navigational interface performs better than the object interface.

- With respect to ODBC, the OCCI API is simpler to use. Because ODBC is built on the C language, OCCI has all the advantages C++ provides over C. Moreover, ODBC has a reputation as being difficult to learn. The OCCI, by contrast, is designed for ease of use.

You can use OCCI to perform random and piecewise operations on LOBs, which means that you specify the offset or amount of the operation to read or write a part of the LOB value.

OCCI provides these classes that allow you to use different types of LOB instances as objects in your C++ application:

- `Clob` class to access and modify data stored in persistent `CLOB`s and `NCLOB`s

- `Blob` class to access and modify data stored in persistent `BLOB`s

> ✎ **See Also:**
>
> Syntax information on these classes and details on OCCI in general is available in the*Oracle C++ Call Interface Programmer's Guide*.

Clob Class

The Clob driver implements a `CLOB` object using an SQL LOB locator. This means that a CLOB object contains a logical pointer to the SQL `CLOB` data rather than the data itself.

The `CLOB` interface provides methods for getting the length of an SQL `CLOB` value, for materializing a `CLOB` value on the client, and getting a substring. Methods in the `ResultSet` and `Statement` interfaces such as `getClob()` and `setClob()` allow you to access SQL `CLOB` values.

Blob Class

Methods in the `ResultSet` and `Statement` interfaces, such as `getBlob()` and `setBlob()`, allow you to access SQL `BLOB` values. The `Blob` interface provides methods for getting the length of a SQL `BLOB` value, for materializing a `BLOB` value on the client, and for extracting a part of the `BLOB`.

Fixed-Width Character Set Rules

In OCCI, for *fixed-width* client-side character sets, these rules apply:

- `Clob`: offset and amount parameters are always in characters

- `Blob`: offset and amount parameters are always in bytes

The following rules apply only to *varying-width* client-side character sets:

- **Offset parameter**: Regardless of whether the client-side character set is varying-width, the offset parameter is always as follows:

  - `Clob()`: in characters

  - `Blob()`: in bytes

- **Amount parameter**: The amount parameter is always as indicated:

  - `Clob`: in characters, when referring to a server-side LOB

  - `Blob`: in bytes, when referring to a client-side buffer

- **length()**: Regardless of whether the client-side character set is varying-width, the output length is as follows:

  - `Clob.length()`: in characters

  - `Blob.length()`: in bytes

- **Clob.read() and Blob.read()**: With client-side character set of varying-width, `CLOB`s and `NCLOB`s:

  - ***Input amount*** is in characters. Input amount refers to the number of characters to read from the server-side `CLOB` or `NCLOB`.

  - ***Output amount*** is in bytes. Output amount indicates how many bytes were read into the OCCI buffer parameter, `buffer`.

- **Clob.write() and Blob.write()**: With client-side character set of varying-width, `CLOB`s and `NCLOB`s:

  - **Input amount** is in bytes. Input amount refers to the number of bytes of data in the OCCI input buffer, `buffer`.

  - **Output amount** is in characters. Output amount refers to the number of characters written into the server-side `CLOB` or `NCLOB`.

- **Amount Parameter for Other OCCI Operations:** For the OCCI LOB operations `Clob.copy()`, `Clob.erase()`, `Clob.trim()` irrespective of the client-side character set, the *amount parameter* is in characters for `CLOB`s and `NCLOB`s. All these operations refer to the amount of LOB data on the server.

> **✎ See also:**
>
> *Oracle Database Globalization Support Guide*

Table 8-8   OCCI Methods for LOBs

Category	Function/Procedure	Description
Sanity Checking	`Clob/Blob.isInitialized`	Checks whether a LOB locator is initialized.
Open/Close	`Clob/Blob.Open()`	Open a LOB
	`Clob/Blob.isOpen()`	Check if a LOB is open
	`Clob/Blob.Close()`	Close the LOB
Read Operations	`Blob/Clob.length()`	Get the length of the LOB
	`Blob/Clob.getChunkSize()`	Get the optimum read or write size
	`Blob/Clob.read()`	Read data from the LOB starting at the specified offset
	`Clob.getCharSetId()`	Return the character set ID of a LOB
	`Clob.getCharSetForm()`	Return the character set form of a LOB.
Modify Operations	`Blob/Clob.write()`	Write data to the LOB at a specified offset
	`Blob/Clob.trim()`	Trim the LOB value to the specified shorter length
Operations involving multiple locators	`Clob/Blob.operator == and !=`	Checks whether two LOB locators refer to the same LOB.
	`Blob/Clob.append()`	Append a LOB value to another LOB
	`Blob/Clob.copy()`	Copy all or part of a LOB to another LOB, or load from a BFILE into a LOB
	`Clob/Blob.operator =`	Assign one LOB to another
Operations specific to securefiles	`Blob/Clob.getOptions()`	Returns options (deduplication, compression, encryption) for SecureFiles.
	`Blob/Clob.setOptions()`	Sets LOB features (deduplication and compression) for SecureFiles
	`Blob/Clob.getContentType()`	Gets the content string for a SecureFiles
	`Blob/Clob.setContentType()`	Sets a content string in a SecureFiles

8.7 Pro*C/C++ and Pro*COBOL API for LOBs

This section describes the mapping of Pro*C/C++ and Pro*COBOL locators to locator pointers to access a LOB value.

Embedded SQL statements enable you to access data stored in BLOBs, CLOBs, and NCLOBs.

> ✎ **See Also:**
>
> *Pro*C/C++ Programmer's Guide* and *Pro*COBOL Programmer's Guide* for detailed documentation, including syntax, host variables, host variable types and example code.

Unlike locators in PL/SQL, locators in Pro*C/C++ and Pro*COBOL are mapped to locator pointers which are then used to refer to the LOB value. To successfully complete an embedded SQL LOB statement you must do the following:

1. Provide an allocated input locator pointer that represents a LOB that exists in the database tablespaces or external file system before you run the statement.
2. SELECT a LOB locator into a LOB locator pointer variable.
3. Use this variable in the embedded SQL LOB statement to access and manipulate the LOB value.

Table 8-9   Pro*C/C++ and Pro*COBOL Embedded SQL Statements for LOBs

Category	Function/Procedure	Description
Open/Close	`OPEN`	Open a LOB
	`DESCRIBE[ISOPEN]`	Check is a LOB is open
	`CLOSE`	Close the LOB
Read Operations	`DESCRIBE[LENGTH]`	Get the length of the LOB
	`DESCRIBE[CHUNKSIZE]`	Get the optimum read or write size
	`READ`	Read data from the LOB starting at a specified offset
Modify Operations	`WRITE`	Write data to the LOB at a specified offset
	`WRITE APPEND`	Write data to the end of the LOB
	`ERASE`	Erase part of a LOB, starting at a specified offset
	`TRIM`	Trim the LOB value to the specified shorter length
Operations involving multiple locators	`APPEND`	Append a LOB value to another LOB
	`COPY`	Copy all or part of a LOB to another LOB
	`ASSIGN`	Assign one LOB to another
	`LOAD FROM FILE`	Load `BFILE` data into a LOB

9

Distributed LOBs

This section describes the ways in which you can work with LOB data in remote tables.

- [Working with Remote LOBs in SQL and PL/SQL](#)
  This section describes the SQL and PL/SQL functions that are supported on remote LOBs.

- [Using the Data Interface on Remote LOBs](#)
  The data interface enables you to bind and define a `CHARACTER` buffer for a `CLOB` column and a `RAW` buffer for a `BLOB` column. This interface is supported for remote LOB columns too.

- [Working with Remote Locators](#)
  You can select a persistent LOB locator from a remote table into a local variable and this can be done in any programmatic interface like PL/SQL, JDBC or OCI. The remote columns can be of type `BLOB`, `CLOB` or `NCLOB`.

> ✎ **See Also:**
>
> [Sharding with LOBs](#)

9.1 Working with Remote LOBs in SQL and PL/SQL

This section describes the SQL and PL/SQL functions that are supported on remote LOBs.

SQL Functions

All the SQL built-in functions and user-defined functions that are supported on local LOBs and BFILEs, are also supported on remote LOBs and BFILEs, as long as the final value returned by the nested functions is not a LOB type. This includes functions for remote persistent and temporary LOBs and for BFILEs.

Most of the examples in the following sections use `print_media` table. Following is the structure of the table:

PRINT_MEDIA Table	
Column name	**Column Type**
product_id	NUMBER (6)
ad_id	NUMBER (6)
ad_composite	BLOB
ad_sourcetext	CLOB
ad_finaltext	CLOB
ad_fltextn	NCLOB
ad_textdocs_ntab	NESTED TABLE
ad_photo	BLOB
ad_graphic	BFILE
ad_header	USER DEFINED TYPE
press_release	LONG

Built-in SQL functions, which are executed on a remote site, can be part of any SQL statement, like SELECT, INSERT, UPDATE, and DELETE. For example:

```
SELECT LENGTH(ad_sourcetext) FROM print_media@remote_site -- CLOB
SELECT LENGTH(ad_fltextn) FROM print_media@remote_site;   -- NCLOB
SELECT LENGTH(ad_composite) FROM print_media@remote_site; -- BLOB
SELECT product_id from print_media@remote_site WHERE LENGTH(ad_sourcetext) >
3;

UPDATE print_media@remote_site SET product_id = 2 WHERE LENGTH(ad_sourcetext)
> 3;

SELECT TO_CHAR(foo@dbs2(...)) FROM dual@dbs2;
-- where foo@dbs2 returns a temporary LOB
```

PL/SQL functions

Built-in and user-defined PL/SQL functions that are executed on the remote site and operate on remote LOBs and BFILEs are allowed, as long as the final value returned by nested functions is not a LOB.

```
SELECT product_id FROM print_media@dbs2 WHERE foo@dbs2(ad_sourcetext, 'aa') >
0;
-- foo is a user-define function returning a NUMBER

DELETE FROM print_media@dbs2 WHERE DBMS_LOB.GETLENGTH@dbs2(ad_graphic) = 0;
```

Restrictions on Remote User Defined Functions

The SQL and PL/SQL functions fall under the following non-comprehensive list of categories:

- SQL functions that are not supported on LOBs
  The SQL functions like the DECODE function, which are not supported for LOBs, are not supported on remote LOBs as well.

- Functions that accept exactly one LOB argument (where all the other arguments are of non-LOB data types) and does not return a LOB
  The functions, like the LENGTH function, are supported. For example:

  ```
  SELECT LENGTH(ad_composite) FROM print_media@remote_site;
  SELECT LENGTH(ad_header.logo) FROM print_media@remote_site; -- LOB in
  object
  SELECT product_id from print_media@remote_site WHERE LENGTH(ad_sourcetext)
  > 3;
  ```

- Functions that return a LOB

  These functions may return the original LOB or produce a temporary LOB. These functions can be performed on the remote site, as long as the result returned to the local site is not a LOB.

  - Functions returning a temporary LOB are: REPLACE, SUBSTR, CONCAT, ||, TRIM, LTRIM, RTRIM, LOWER, UPPER, NLS_LOWER, NLS_UPPER, LPAD, and RPAD.

  - Functions returning the original LOB locator are: NVL, DECODE, and CASE.

  For example, **the following statements are supported:**

  ```
  SELECT TO_CHAR(CONCAT(ad_sourcetext, ad_sourcetext)) FROM
  print_media@remote_site;
  SELECT TO_CHAR(SUBSTR(ad_fltextnfs, 1, 3)) FROM print_media@remote_site;
  ```

  But the **following statements are not supported:**

  ```
  SELECT CONCAT(ad_sourcetext, ad_sourcetext) FROM print_media@remote_site;
  SELECT SUBSTR(ad_sourcetext, 1, 3) FROM print_media@remote_site;
  ```

- Functions that take in more than one LOB argument:

  These are: INSTR, LIKE, REPLACE, CONCAT, ||, SUBSTR, TRIM, LTRIM, RTRIM, LPAD, and RPAD. All these functions are relevant only for CLOBs and NCLOBs.

These functions are supported only if all the LOB arguments are in the same `dblink`, and the value returned is not a LOB. For example, **the following is supported:**

```
SELECT TO_CHAR(CONCAT(ad_sourcetext, ad_sourcetext)) FROM
print_media@remote_site; -- CLOB
SELECT TO_CHAR(CONCAT(ad_fltextn, ad_fltextn)) FROM
print_media@remote_site; -- NCLOB
```

But the following is not supported

```
SELECT TO_CHAR(CONCAT(a.ad_sourcetext, b.ad_sourcetext)) FROM
print_media@db1 a, print_media@db2 b WHERE a.product_id = b.product_id;
```

*   PLSQL functions operating on LOBs:
    A function in one `dblink` cannot operate on LOB data in another dblink. For example, the following statement is not supported:

```
SELECT a.product_id FROM print_media@dbs1 a, print_media@dbs2 b WHERE
CONTAINS@dbs1(b.ad_sourcetext, 'aa') >0;
```

*   Multiple LOBs in a query block:
    One query block cannot contain tables and functions at different `dblinks`. For example, the following statement is not supported

```
SELECT a.product_id FROM print_media@dbs2 a, print_media@dbs3 b
    WHERE CONTAINS@dbs2(a.ad_sourcetext, 'aa') > 0 AND
    foo@dbs3(b.ad_sourcetext) > 0;
--  foo is a user-defined function in dbs3
```

9.2 Using the Data Interface on Remote LOBs

The data interface enables you to bind and define a `CHARACTER` buffer for a `CLOB` column and a `RAW` buffer for a `BLOB` column. This interface is supported for remote LOB columns too.

The advantage of using the data interface over using LOB locators is that it makes only one round-trip to the remote server to fetch the LOB data. If used in as part of an array bind or define, it will use only one round-trip for the entire array operation.

The examples discussed in the book use the `print_media` table created in the following two schemas: `dbs1` and `dbs2`. The `CLOB` column of the `print_media` table used in the examples shown is `ad_finaltext`. The examples provided for PL/SQL, OCI, and Java in the following sections use binds and defines for this one column, but multiple columns can also be accessed. Following is the functionality supported:

*   You can bind and define a `CLOB` as `VARCHAR2 or LONG`, and a `BLOB` as a `RAW` or a `LONG` or a `RAW`.

*   Array binds and defines are supported.

---

*   PL/SQL

*   JDBC

- OCI

- Remote LOBs

PL/SQL

This section describes how to use the remote data interface with LOBs in PL/SQL.

The data interface only supports data of size less than 32KB in PL/SQL. The following snippet shows a PL/SQL example:

```
CONNECT pm/pm
declare
  my_ad varchar(6000) := lpad('b', 6000, 'b');
BEGIN
  INSERT INTO print_media@dbs2(product_id, ad_id, ad_finaltext)
      VALUES (10000, 10, my_ad);
  -- Reset the buffer value
  my_ad := 'a';
  SELECT ad_finaltext INTO my_ad FROM print_media@dbs2
      WHERE product_id = 10000;
END;
/
```

If `ad_finaltext` were a `BLOB` column instead of a `CLOB`, `my_ad` has to be of type `RAW`. If the LOB is greater than 32KB - 1 in size, then PL/SQL raises a truncation error and the contents of the buffer are undefined.

JDBC

This section demonstrates how to use the remote data interface with LOBs in JDBC.

The following code snippets work with all JDBC drivers:

Bind:

This is for the non-streaming mode:

```
...
String sql = "insert into print_media@dbs2 (product_id, ad_id, ad_final_text)" +
             " values (:1, :2, :3)";
    PreparedStatement pstmt = conn.prepareStatement(sql);
    pstmt.setInt( 1, 2 );
    pstmt.setInt( 2, 20);
    pstmt.setString( 3, "Java string" );
    int rows = pstmt.executeUpdate();
...
```

Note: Oracle supports the non-streaming mode for strings of size up to 2 GB. However, the memory size of your computer may be a limiting factor.

For the streaming mode, the same code as the preceding works, except that the `setString()` statement is replaced by one of the following:

```
pstmt.setCharacterStream( 3, new LabeledReader(), 1000000 );
pstmt.setAsciiStream( 3, new LabeledAsciiInputStream(), 1000000 );
```

Note: You can use the streaming interface to insert Gigabyte sized character and binary data into a LOB column.

Here, `LabeledReader()` and `LabeledAsciiInputStream()` produce character and ASCII streams respectively. If `ad_finaltext` were a `BLOB` column instead of a `CLOB`, then the preceding example works if the bind is of type `RAW`:

```
pstmt.setBytes( 3, <some byte[] array> );

pstmt.setBinaryStream( 3, new LabeledInputStream(), 1000000 );
```

Here, `LabeledInputStream()` produces a binary stream.

Define:

For non-streaming mode:

```
OracleStatement stmt = (OracleStatement)(conn.createStatement());
  stmt.defineColumnType( 1, Types.VARCHAR );
  ResultSet rst = stmt.executeQuery("select ad_finaltext from print_media@dbs2" );
  while( rst.next() )
      {
        String s = rst.getString( 1 );
        System.out.println( s );
      }
```

Note: If the LOB size is greater than 32767 bytes, the data is truncated and no error is thrown.

For streaming mode:

```
OracleStatement stmt = (OracleStatement)(conn.createStatement());
  stmt.defineColumnType( 1, Types.LONGVARCHAR );
  ResultSet rs = stmt.executeQuery("select ad_finaltext from print_media@dbs2" );
  while(rs.next()) {
    Reader reader = rs.getCharacterStream( 1 );
    int data = 0;
    data = reader.read();
    while( -1 != data ){
      System.out.print( (char)(data) );
      data = reader.read();
    }
    reader.close();
  }
```

Note: Specifying the datatype as `LONGVARCHAR` lets you select the entire LOB. If the define type is set as `VARCHAR` instead of `LONGVARCHAR`, the data will be truncated at 32k.

If `ad_finaltext` were a `BLOB` column instead of a `CLOB`, then the preceding examples work if the define is of type `LONGVARBINARY`:

```
...
   OracleStatement stmt = (OracleStatement)conn.createStatement();

   stmt.defineColumnType( 1, Types.INTEGER );
   stmt.defineColumnType( 2, Types.LONGVARBINARY );

   ResultSet rset = stmt.executeQuery("SELECT ID, LOBCOL FROM LOBTAB@MYSELF");

   while(rset.next())
    {
     /* using getBytes() */
     /*
     byte[] b = rset.getBytes("LOBCOL");
     System.out.println("ID: " + rset.getInt("ID") + "  length: " + b.length);
     */
```

```
        /* using getBinaryStream() */
        InputStream byte_stream = rset.getBinaryStream("LOBCOL");
        byte [] b = new byte [100000];
        int b_len = byte_stream.read(b);
        System.out.println("ID: " + rset.getInt("ID") + "  length: " + b_len);

        byte_stream.close();
    }
...
```

OCI

This section demonstrates how to use the remote data interface with LOBs in OCI.

The data interface only supports data of size less than 2 gigabytes (the maximum value possible of a variable declared as sb4) for OCI. The following pseudocode can be enhanced to be a part of an OCI program:

```
...
text *sql = (text *)"insert into print_media@dbs2
                      (product_id, ad_id, ad_finaltext)
                      values (:1, :2, :3)";
OCIStmtPrepare(...);
OCIBindByPos(...); /* Bind data for positions 1 and 2
                    * which are independent of LOB */
OCIBindByPos(stmthp, &bndhp[2], errhp, (ub4) 3,
            (dvoid *) charbuf1, (sb4) len_charbuf1, SQLT_CHR,
            (dvoid *) 0, (ub2 *)0, (ub2 *)0, 0, 0, OCI_DEFAULT);
OCIStmtExecute(...);

...

text *sql = (text *)"select ad_finaltext from print_media@dbs2
                     where product_id = 10000";
OCIStmtPrepare(...);
OCIDefineByPos(stmthp, &dfnhp[2], errhp, (ub4) 1,
            (dvoid *) charbuf2, (sb4) len_charbuf2, SQLT_CHR,
            (dvoid *) 0, (ub2 *)0, (ub2 *)0, OCI_DEFAULT);
OCIStmtExecute(...);
...
```

For a BLOB column, you must use the SQLT_BIN type. For example, if you define the ad_finaltext column as a BLOB column instead of a CLOB column, then you must bind and define the column data using the SQLT_BIN type. If the LOB is greater than 2GB - 1 bytes in size, then OCI raises a truncation error and the contents of the buffer are undefined.

Remote LOBs

This section discusses the restrictions on the usage of Data Interface on Remote LOBs.

Certain syntax is not supported for remote LOBs.

• Queries involving more than one database are not supported:

```
SELECT t1.lobcol, a2.lobcol FROM t1, t2.lobcol@dbs2 a2 WHERE
LENGTH(t1.lobcol) = LENGTH(a2.lobcol);
```

Neither is this query (in a PL/SQL block):

```
SELECT t1.lobcol INTO varchar_buf1 FROM t1@dbs1
UNION ALL
SELECT t2.lobcol INTO varchar_buf2 FROM t2@dbs2;
```

- Only binds and defines for data going into remote persistent LOB columns are supported, so that parameter passing in PL/SQL where CHAR data is bound or defined for remote LOBs is not allowed because this could produce a remote temporary LOB, which are not supported. These statements all produce errors:

```
SELECT foo() INTO varchar_buf FROM table1@dbs2; -- foo returns a LOB

SELECT foo()@dbs INTO char_val FROM DUAL; -- foo returns a LOB

SELECT XMLType().getclobval INTO varchar_buf FROM table1@dbs2;
```

- If the remote object is a view such as

```
CREATE VIEW v AS SELECT foo() a FROM ... ; -- foo returns a LOB
/* The local database then tries to get the CLOB data and returns an error */
SELECT a INTO varchar_buf FROM v@dbs2;
```

  This returns an error because it produces a remote temporary LOB, which is not supported.

- RETURNING INTO does not support implicit conversions between CHAR and CLOB.

- PL/SQL parameter passing is not allowed where the actual argument is a LOB type and the remote argument is a VARCHAR2, NVARCHAR2, CHAR, NCHAR, or RAW.

> - Data Interface for LOBs

9.3 Working with Remote Locators

You can select a persistent LOB locator from a remote table into a local variable and this can be done in any programmatic interface like PL/SQL, JDBC or OCI. The remote columns can be of type BLOB, CLOB or NCLOB.

The following SQL statement is the basis for all the examples with remote LOB locator in this chapter.

```
CREATE TABLE lob_tab (c1 NUMBER, c2 CLOB);
```

In the following example, the table lob_tab (with columns c2 of type CLOB and c1 of type number) defined in the remote database is accessible using database link db2 and a local CLOB variable lob_var1.

```
SELECT c2 INTO lob_var1 FROM lob_tab@db2 WHERE c1=1;
SELECT c2 INTO lob_var1 FROM lob_tab@db2 WHERE c1=1 for update;
```

In PL/SQL, the function `dbms_lob.isremote` can be used to check if a particular LOB belongs to a remote table. Similarly, in `OCI`, you can use the `OCI_ATTR_LOB_REMOTE` attribute of `OCILobLocator` to check if a particular LOB belongs to a remote table. For example,

```
IF(dbms_lob.isremote(lob_var1)) THEN
dbms_output.put_line('LOB locator is remote)
ENDIF;
```

- Using Local and Remote Locators as Bind with Queries and DML on Remote Tables
  This section discusses the bind values for queries and DML statements.

- Using Remote Locator
  This section demonstrates the usage of remote locator in PL/SQL and with OCILOB API with examples.

- Restrictions when using remote LOB locators
  Remote LOB locators have the following restrictions:

> **✎ See Also:**
>
> - ISREMOTE Function
> - OCI_ATTR_LOB_REMOTE Attribute

9.3.1 Using Local and Remote Locators as Bind with Queries and DML on Remote Tables

This section discusses the bind values for queries and DML statements.

For the Queries and DMLs (`INSERT`, `UPDATE`, `DELETE`) with bind values, the following four cases are possible. The first case involves local tables and locators and is the standard LOB functionality, while the other three cases are part of the distributed LOBs functionality and have restrictions listed at the end of this section.

- Local table with local locator as bind value.

- Local table with remote locator as bind value

- Remote table with local locator as bind value

- Remote table with remote locator as bind value

Queries of the following form which use remote lob locator as bind value are supported:

```
SELECT name FROM lob_tab@db2 WHERE length(c1)=length(:lob_v1);
```

In the above query, `c1` is an LOB column and `lob_v1` is a remote locator.

DMLs of the following forms using a remote LOB locator will be supported. Here, the bind values can be local or remote persistent LOB locators.

```
UPDATE lob_tab@db2 SET c1=:lob_v1;

INSERT into lob_tab@db2 VALUES (:1, :2);
```

You can pass a remote locator to most built-in SQL functions such as `LENGTH`, `INSTR`, `SUBSTR`, and `UPPER`. For example:

```
Var lob1 CLOB;
BEGIN
    SELECT c2 INTO lob1 FROM lob_tab@db2 WHERE c1=1;
END;
/
SELECT LENGTH(:lob1) FROM DUAL;
```

> **Note:**
>
> DMLs with `returning` clause are not supported on remote tables for both scalar and LOB columns.

9.3.2 Using Remote Locator

This section demonstrates the usage of remote locator in PL/SQL and with OCILOB API with examples.

- PL/SQL
- OCILOB API

PL/SQL

A remote locator can be passed as a parameter to built in PL/SQL functions like `LENGTH`, `INSTR`, `SUBSTR`, `UPPER` and so on which accepts LOB as input. For example,

```
DECLARE
    substr_data VARCHAR2(4000);
    remote_loc CLOB;
BEGIN
    SELECT c2 into remote_loc
    FROM lob_tab@db2 WHERE c1=1;
    substr_data := substr(remote_loc, position, length)
END;
```

All `DBMS_LOB` APIs other than the APIs targeted for BFILEs support operations on remote LOB locators.

The following example shows how to pass remote locator as input to `dbms_lob` operations.

```
DECLARE
  lob CLOB;
  buf VARCHAR2(120) := 'TST';
  amt NUMBER(2);
  len NUMBER(2);
BEGIN
  amt :=30;
```

```
    SELECT c2 INTO lob FROM lob_tab@db2 WHERE c1=3 FOR UPDATE;
    DBMS_LOB.WRITE(lob, amt, 1, buf);
    amt :=30;
    DBMS_LOB.READ(lob, amt, 1, buf);
    len := DBMS_LOB.GETLENGTH(lob);
    DBMS_OUTPUT.PUT_LINE(buf);
    DBMS_OUTPUT.PUT_LINE(amt);
    DBMS_OUTPUT.PUT_LINE('get length output = ' || len);
END;
/
```

OCILOB API

Most OCILOB APIs support operations on remote LOB locators. The following list of OCILOB functions returns an error when a remote LOB locator is passed to them:

- OCILobLocatorAssign

- OCILobArrayRead()

- OCILobArrayWrite()

- OCILobLoadFromFile2()

The following example shows how to pass a remote locator to OCILOB API.

```
void select_read_remote_lob()
{
  text *select_sql = (text *)"SELECT c2 lob_tab@dbs1 where c1=1";
  ub4 amtp = 10;
  ub4 nbytes = 0;
  ub4 loblen=0;
  OCILobLocator * one_lob;
  text strbuf[40];

 /* initialize single locator */
 OCIDescriptorAlloc(envhp, (dvoid **) &one_lob,
                 (ub4) OCI_DTYPE_LOB,
                 (size_t) 0, (dvoid **) 0)

 OCIStmtPrepare(stmthp, errhp, select_sql, (ub4)strlen((char*)select_sql),
                 (ub4) OCI_NTV_SYNTAX, (ub4) OCI_DEFAULT);

 OCIDefineByPos(stmthp, &defp, errhp, (ub4) 1,
                   (dvoid *) &one_lob,
                   (sb4) -1,
                   (ub2) SQLT_CLOB,
                   (dvoid *) 0, (ub2 *) 0,
                   (ub2 *) 0, (ub4) OCI_DEFAULT));

 /* fetch the remote locator into the local variable one_lob */
 OCIStmtExecute(svchp, stmthp, errhp, 1, 0, (OCISnapshot *)0,
                 (OCISnapshot *)0, OCI_DEFAULT);

 /* Get the length of the remote LOB */
 OCILobGetLength(svchp, errhp,
                 (OCILobLocator *) one_lob, (ub4 *)&loblen)
```

```
printf("LOB length = %d\n", loblen);

memset((void*)strbuf, (int)'\0', (size_t)40);

/ * Read the data from the remote LOB */
OCILobRead(svchp, errhp, one_lob, &amtp,
            (ub4) 1, (dvoid *) strbuf, (ub4)& nbytes, (dvoid *)0,
            (OCICallbackLobRead) 0,
            (ub2) 0, (ub1) SQLCS_IMPLICIT));
printf("LOB content = %s\n", strbuf);

}
```

> ✎ **See Also:**
>
> *OCI Programmer's Guide*, for the complete list of `OCILOB` APIs

9.3.3 Restrictions when using remote LOB locators

Remote LOB locators have the following restrictions:

- You cannot select a remote temporary LOB locator into a local variable using the `SELECT` statement. For example,

  ```
  select substr(c2, 3, 1) from lob_tab@db2 where c1=1
  ```

  The preceding query returns an error.

- Remote LOB functionality is not supported for Index Organized tables (IOT). An attempt to get a locator from a remote IOT table will result in an error.

- Both the local database and the remote database have to be of Database release 12.2 or higher version.

- With distributed LOBs functionality, the tables that you use in the `from` clause or `where` clause should be collocated on the same database. If you use emote locators as bind variables in the `where` clauses, then they should belong to the same remote database. You cannot have one locator from one database (say, DB1) and another locator from another database (say, DB2) to be used as bind variables.

- Collocated tables or locators use the same database link. It is possible to have two different DB Links pointing to the same database. In the following example, both `dblink1` and `dblink2` point to the same remote database, but with different authentication methods. Oracle Database *does not* support such operations.

  ```
  INSERT into tab1@dblink1 SELECT * from tab2@dblink2;
  ```

- Any `DBMS_LOB` or `OCILob` APIs that accept two locators must obtain both the LOB locators through the same database link. Operations, as specified in the following example, are *not supported*:

  ```
  SELECT ad_sourcetext INTO clob1 FROM print_media@db1 WHERE product_id =
  10011;
  ```

ORACLE

```
SELECT ad_sourcetext INTO clob2 FROM print_media@db2 WHERE product_id =
10011;
DBMS_LOB.COPY(clob1, clob2, length(clob2));
```

- Bind values should be of the same LOB type as the column LOB type. For example, you must bind NCLOB locators to NCLOB columns and CLOB locators to CLOB columns. Implicit conversion between NCLOB and CLOB types is not supported in case of remote LOBs.

- DML statements with Array Binds are not supported when the bind operation involves a remote locator, or if the table involved is a remote table.

- You cannot select a BFILE column from a remote table into a local variable.

10
Performance Guidelines

This section discusses performance guidelines for applications that use LOB data types.

- **LOB Performance Guidelines**
  This section provides performance guidelines while using LOBs through Data Interface or LOB APIs.

- **Moving Data to LOBs in a Threaded Environment**
  Learn about the recommended procedure to follow while moving data to LOBs in this section.

- **LOB Access Statistics**
  Three session-level statistics specific to LOBs are available to users: LOB reads, LOB writes, and LOB writes unaligned.

10.1 LOB Performance Guidelines

This section provides performance guidelines while using LOBs through Data Interface or LOB APIs.

LOBs can be accessed using the Data Interface or through the LOB APIs.

- **All LOBs**
  Learn about the guidelines to achieve good performance while using LOBs in this section.

- **Performance Guidelines While Using Persistent LOBs**
  In addition to the performance guidelines applicable to all LOBs described earlier, here are some performace guidelines while using persistent LOBs.

- **Temporary LOBs**
  In addition to the performance guidelines applicable to all LOBs described earlier, following are some guidelines for using temporary LOBs:

10.1.1 All LOBs

Learn about the guidelines to achieve good performance while using LOBs in this section.

The following guidelines will help you get the the best performance when using LOBs, and minimize the number of round trips to the server:

- To minimize I/O:

  - Read and write data at block boundaries. This optimizes I/O in many ways, e.g., by minimizing UNDO generation. For temporary LOBs and securefile LOBs, usable data area of the tablespace block size is returned by the following APIs: `DBMS_LOB.GETCHUNKSIZE` in PLSQL, and `OCILobGetChunkSize()` in OCI. When writing in a loop, design your code so that one write call writes everything that needs to go in a database block, thus ensuring that consecutive writes don't write to the same block.

  - Read and write large pieces of data at a time.

- The 2 recommendations above can be combined by reading and writing in large whole number multiples of database block size returned by the `DBMS_LOB.GETCHUNKSIZE/ OCILobGetChunkSize()` API.

- To minimize the number of round trips to the server:

  - If you know the maximum size of your lob data, and you intend to read or write the entire LOB, use the Data Interface as outlined below. You can allocate the entire size of lob as a single buffer, or use piecewise / callback mechanisms.

    * For read operations, define the LOB as character/binary type using the `OCIDefineByPos()` function in OCI and the `DefineColumnType()` function in JDBC.

    * For write operations, bind the LOB as character/binary type using the `OCIBindByPos()` function in OCI and the `setString()` or `setBytes()` methods in JDBC.

  - Otherwise, use the LOB APIs as follows:

    * Use LOB prefetching for reads. Define the LOB prefetch size such that it can accommodate majority of the LOB values in the column.

    * Use piecewise or callback mechanism while using `OCILobRead2` or `OCILobWrite2` operations to minimize the roundtrips to the server.

>
> Data Interface for Persistent LOBs

10.1.2 Performance Guidelines While Using Persistent LOBs

In addition to the performance guidelines applicable to all LOBs described earlier, here are some performace guidelines while using persistent LOBs.

- Maximize writing to a single LOB in consecutive calls within a transaction. Frequently switching across LOBs or having interleaving DML statements prevent caching from reaching its maximum efficiency.

- Avoid taking savepoints or commiting too frequently. This neutralizes the advantage of caching while writing.

> ✏️ **Note:**
>
> Oracle recommends Securefile LOBs for storing persistent LOBs, hence this chapter focuses only on Securefile storage. All mentions of "LOBs" in the persistent LOB context is for Securefile LOBs unless otherwise mentioned.

10.1.3 Temporary LOBs

In addition to the performance guidelines applicable to all LOBs described earlier, following are some guidelines for using temporary LOBs:

- Temporary LOBs reside in the PGA memory or the temporary tablespace, depending on the size. Please ensure that you have a large enough PGA memory and temporary tablespace for the temporary LOBs used by your application.

- Use a separate temporary tablespace for temporary LOB storage instead of the default system tablespace. This avoids device contention when copying data from persistent LOBs to temporary LOBs.

  If you use SQL or PL/SQL semantics for LOBs in your applications, then many temporary LOBs are created silently. Ensure that PGA memory and temporary tablespace for storing these temporary LOBs is large enough for your applications. In particular, these temporary LOBs are silently created when you use the following:

  - SQL functions on LOBs

  - PL/SQL built-in character functions on LOBs

  - Variable assignments from `VARCHAR2`/`RAW` to `CLOB`s/`BLOB`s, respectively.

  - Perform a `LONG`-to-`LOB` migration

- Free up temporary LOBs returned from SQL queries and PL/SQL programs

  In PL/SQL, C (OCI), Java and other programmatic interfaces, SQL query results or PL/SQL program executions return temporary LOBs for operation/function calls on LOBs. For example:

  ```
  SELECT substr(CLOB_Column, 4001, 32000) FROM ...
  ```

  If the query is executed in PL/SQL, then the returned temporary LOBs are automatically freed at the end of a PL/SQL program block. You can also explicitly free the temporary LOBs at any time. In OCI and Java, the returned temporary LOB must be explicitly freed.

  Without proper deallocation of the temporary LOBs returned from SQL queries, you may observe performance degradation.

- In PL/SQL, use NOCOPY to pass temporary LOB parameters by reference whenever possible.

  > ✎ **See Also:**
  >
  > *Oracle Database PL/SQL Language Reference* for more information on passing parameters by reference and parameter aliasing

- Temporary LOBs created with the CACHE parameter set to true move through the buffer cache and avoid the disk access.

- Oracle provides `v$temporary_lobs` view to monitor the use of temporary LOBs across all open sessions. Here is an example:

  ```
  SQL> select * from v$temporary_lobs;

         SID CACHE_LOBS NOCACHE_LOBS ABSTRACT_LOBS     CON_ID
  ---------- ---------- ------------ ------------- ----------
  ```

141	2	3	4	0
146	0	0	1	0
148	0	0	1	0

Following is the interpretation of output:

– The `SID` column is the session ID.

– The `CACHE_LOBS` column shows that session 141 currently has 2 temporary lobs in the temporary tablespace with CACHE turned on.

– The `NOCACHE_LOBS` column shows that session 141 currently has 3 temporary lobs in the temporary tablespace with CACHE turned off.

– The `ABSTRACT_LOBS` column shows that session 141 currently has 4 temporary lobs in the PGA memory.

– The `CON_ID` column is the pluggable database container ID.

• For optimal performance, temporary LOBs use reference on read, copy on write semantics. When a temporary LOB locator is assigned to another locator, the physical LOB data is not copied. Subsequent READ operations using either of the LOB locators refer to the same physical LOB data. On the first WRITE operation after the assignment, the physical LOB data is copied in order to preserve LOB value semantics, that is, to ensure that each locator points to a unique LOB value.

In PL/SQL, reference on read, copy on write semantics are illustrated as follows:

```
LOCATOR1 BLOB;
LOCATOR2 BLOB;
DBMS_LOB.CREATETEMPORARY (LOCATOR1,TRUE,DBMS_LOB.SESSION);

-- LOB data is not copied in this assignment operation:
LOCATOR2 := LOCATOR;
-- These read operations refer to the same physical LOB copy:
DBMS_LOB.READ(LOCATOR1, ...);
DBMS_LOB.GETLENGTH(LOCATOR2, ...);

-- A physical copy of the LOB data is made on WRITE:
DBMS_LOB.WRITE(LOCATOR2, ...);
```

In OCI, to ensure value semantics of LOB locators and data, `OCILobLocatorAssign()` is used to copy temporary LOB locators and the LOB Data. `OCILobLocatorAssign()` does not make a round trip to the server. The physical temporary LOB copy is made when LOB updates happen in the same round trip as the LOB update API as illustrated in the following:

```
OCILobLocator *LOC1;
OCILobLocator *LOC2;
OCILobCreateTemporary(... LOC1, ... TRUE,OCI_DURATION_SESSION);

/* No round-trip is incurred in the following call. */
OCILobLocatorAssign(... LOC1, LOC2);

/* Read operations refer to the same physical LOB copy. */
OCILobRead2(... LOC1 ...)

/* One round-trip is incurred to make a new copy of the
 * LOB data and to write to the new LOB copy.
 */
```

```
OCILobWrite2(... LOC1 ...)

/* LOC2 does not see the same LOB data as LOC1. */
OCILobRead2(... LOC2 ...)
```

If LOB value semantics are not intended, then you can use C pointer assignment so that both locators point to the same data as illustrated in the following code snippet:

```
OCILobLocator *LOC1;
OCILobLocator *LOC2;
OCILobCreateTemporary(... LOC1, ... TRUE,OCI_DURATION_SESSION);

/* Pointer is copied. LOC1 and LOC2 refer to the same LOB data. */
LOC2 = LOC1;

/* Write to LOC2. */
OCILobWrite2(...LOC2...)

/* LOC1 sees the change made to LOC2. */
OCILobRead2(...LOC1...)
```

- Use OCI_OBJECT mode for temporary LOBs

  To improve the performance of temporary LOBs on LOB assignment, use `OCI_OBJECT` mode for `OCILobLocatorAssign()`. In `OCI_OBJECT` mode, the database tries to minimize the number of deep copies to be done. Hence, after `OCILobLocatorAssign()` is done on a source temporary LOB in `OCI_OBJECT` mode, the source and the destination locators point to the same LOB until any modification is made through either LOB locator.

10.2 Moving Data to LOBs in a Threaded Environment

Learn about the recommended procedure to follow while moving data to LOBs in this section.

There are two possible procedures that you can use to move data to LOBs in a threaded environment, one of which should be avoided.

Recommended Procedure

The recommended procedure is as follows:

1. `INSERT` an empty LOB, `RETURNING` the LOB locator.
2. Move data into the LOB using this locator.
3. `COMMIT`. This releases the ROW locks and makes the LOB data persistent.

Alternatively, you can use Data Interface to insert character data or raw data directly for the LOB columns or LOB attributes.

Procedure to Avoid

The following sequence requires a new connection when using a threaded environment, adversely affects performance, and is not recommended:

1. Create an empty (non-`NULL`) LOB
2. Perform `INSERT` using the empty LOB
3. `SELECT-FOR-UPDATE` of the row just entered
4. Move data into the LOB

5. `COMMIT`. This releases the `ROW` locks and makes the LOB data persistent.

10.3 LOB Access Statistics

Three session-level statistics specific to LOBs are available to users: LOB reads, LOB writes, and LOB writes unaligned.

Session statistics are accessible through the `V$MYSTAT`, `V$SESSTAT`, and `V$SYSSTAT` dynamic performance views. To query these views, the user must be granted the privileges `SELECT_CATALOG_ROLE`, `SELECT ON SYS.V_$MYSTAT` view, and `SELECT ON SYS.V_$STATNAME` view.

LOB reads is defined as the number of LOB API read operations performed in the session/system. A single LOB API read may correspond to multiple physical/logical disk block reads.

LOB writes is defined as the number of LOB API write operations performed in the session/system. A single LOB API write may correspond to multiple physical/logical disk block writes.

LOB writes unaligned is defined as the number of LOB API write operations whose start offset or buffer size is not aligned to the LOB block boundary. Writes aligned to block boundaries are the most efficient write operations. The usable LOB block size of a LOB is available through the LOB API (for example, using PL/SQL, by `DBMS_LOB.GETCHUNKSIZE()`).

It is important to note that session statistics are aggregated across operations to all LOBs accessed in a session; the statistics are not separated or categorized by objects (that is, table, column, segment, object numbers, and so on). Oracle recommends that you reconnect to the database for each demonstration to clear the `V$MYSTAT`. This enables you to see how the lob statistics change for the specific operation you are testing, without the potentially obscuring effect of past LOB operations within the same session.

> ✎ **See also:**

11

Persistent LOBs: Advanced DDL

This chapter describes advanced LOB DDL features to make your application more scalable.

> **✐ Note:**
>
> Unless otherwise stated, all features in this chapter apply to both SecureFile and Basicfile LOBs. However, Oracle strongly recommends SecureFiles for storing and managing LOBs.

- **Creating a New LOB Column**
  You can provide the LOB storage characteristics when creating a LOB column using the `CREATE TABLE` statement or the `ALTER TABLE ADD COLUMN` statement.

- **Altering an Existing LOB Column**
  You can use the `ALTER TABLE` statement to change the storage characteristics of a LOB column.

- **Creating an Index on LOB Column**
  The contents of a LOB are often specific to the application, so an index on the LOB column will usually deal with application logic. You can create a function-based or a domain index on a LOB column to improve the performance of queries accessing data stored in LOB columns. You cannot build a B-tree or bitmap index on a LOB column.

- **LOBs in Partitioned Tables**
  Partitioning can simplify the manageability of large database objects. This section discusses various aspects of LOBs in partitioned tables.

- **LOBs in Index Organized Tables**
  Index Organized Tables (IOTs) support LOB and BFILE columns.

11.1 Creating a New LOB Column

You can provide the LOB storage characteristics when creating a LOB column using the `CREATE TABLE` statement or the `ALTER TABLE ADD COLUMN` statement.

For most users, default values for these storage characteristics are sufficient. However, if you want to fine-tune LOB storage, then consider the guidelines discussed in this section.

When defining LOBs in a table, you can explicitly indicate the tablespace and storage characteristics for each persistent LOB column. It is common to use separate tablespaces for large LOBs. SecureFiles is the default storage for LOBs, so the `SECUREFILE` keyword is optional, but is shown for clarity in the following example. The example assumes that `TABLESPACE lobtbs1` is managed with ASSM, because SecureFile LOBs can only be created in tablespaces managed with Automatic Segment Space Management (ASSM).:

```
CREATE TABLE lobtab1 (n NUMBER, c CLOB)
     lob (c) STORE AS SECUREFILE sfsegname
     ( TABLESPACE lobtbs1
       ENABLE STORAGE IN ROW
```

```
        CACHE LOGGING
        RETENTION AUTO
        COMPRESS
        STORAGE (MAXEXTENTS 5)
    );
```

To create a BasicFiles LOB, replace the `SECUREFILE` keyword with the `BASICFILE` keyword in the preceding example, and remove the `COMPRESS` keyword, which is specific to SecureFiles.

The data dictionary views `USER_LOBS`, `ALL_LOBS`, and `DBA_LOBS` provide information specific to a LOB column.

> **Note:**
>
> Oracle recommends Securefile LOBs for storing persistent LOBs, so this chapter focuses only on Securefile storage. All mentions of *LOBs* in the persistent LOB context is for Securefile LOBs, unless mentioned otherwise.

> **Note:**
>
> There are no tablespace or storage characteristics that you can specify for `BFILE`s as they are not stored in the database.

Assigning a LOB Data Segment Name

As shown in the previous example, specifying a name for the LOB data segment (`sfsegname` in the example) makes for a much more intuitive working environment. When querying the LOB data dictionary views `USER_LOBS`, `ALL_LOBS`, and `DBA_LOBS`, you see the LOB data segment that you chose instead of system-generated names.

- CREATE TABLE BNF
  The `CREATE TABLE` statement works with LOB storage using parameters that are specific to SecureFiles, BasicFiles LOB storage, or both.

- ENABLE or DISABLE STORAGE IN ROW
  LOB columns store locators that reference the location of the actual LOB value. This section describes how to enable or disable storage in a table row.

- CACHE, NOCACHE, and CACHE READS
  This section discusses the guidelines to follow while creating tables that contain LOBs.

- LOGGING and FILESYSTEM_LIKE_LOGGING
  You can apply the `LOGGING` parameter to LOBs in the same manner as you apply it for other table operations.

- The RETENTION Parameter
  The `RETENTION` parameter for SecureFile LOBs specifies how the database manages the old versions of the LOB data blocks.

- SecureFiles Compression, Deduplication, and Encryption
  This section discusses the features supported by SecureFiles in addition to those supported by BasicFiles.

- BasicFile Specific Parameters
  This section discusses the storage parameters specific to BasicFiles.

- Restriction on First Extent of a LOB Segment
  This section discusses the first extent requirements on SecureFiles and BasicFiles.
- Summary of CREATE TABLE LOB Storage Parameters for Securefile LOBs
  The table in this section summarizes the parameters of the CREATE TABLE statement that relate to Securefile LOB storage.

11.1.1 CREATE TABLE BNF

The CREATE TABLE statement works with LOB storage using parameters that are specific to SecureFiles, BasicFiles LOB storage, or both.

The following is the syntax for CREATE TABLE in Backus Naur (BNF) notation, parts of which have been simplified to keep the focus on LOB-specific parameters.

> ✎ **See Also:**

> - *Oracle Database SQL Language Reference*

Example 11-1   BNF for CREATE TABLE

```
CREATE ... TABLE [schema.]table ...;

<column_definition> ::= column [datatype]...

<datatype> ::= ... | BLOB | CLOB | NCLOB | BFILE | ...

<column_properties> ::= ... | LOB_storage_clause | ... |
LOB_partition_storage |...

<LOB_storage_clause> ::=
  LOB
  { (LOB_item [, LOB_item ]...)
      STORE AS [ SECUREFILE | BASICFILE ] (LOB_storage_parameters)
  | (LOB_item)
      STORE AS [ SECUREFILE | BASICFILE ]
        { LOB_segname (LOB_storage_parameters)
        | LOB_segname
        | (LOB_storage_parameters)
        }
  }
<LOB_storage_parameters> ::=
  { TABLESPACE tablespace
  | { LOB_parameters [ storage_clause ]
    }
  | storage_clause
  }
    [ TABLESPACE tablespace
    | { LOB_parameters [ storage_clause ]
      }
    ]...
<LOB_parameters> ::=
```

```
    [ { ENABLE | DISABLE } STORAGE IN ROW
    | CHUNK integer
    | PCTVERSION integer
    | RETENTION [ { MAX | MIN integer | AUTO | NONE } ]
    | FREEPOOLS integer
    | LOB_deduplicate_clause
    | LOB_compression_clause
    | LOB_encryption_clause
    | { CACHE |  NOCACHE | CACHE READS } [ logging_clause ] } }
    ]
<LOB_retention_clause> ::=
  {RETENTION [ MAX | MIN integer | AUTO | NONE ]}
<LOB_deduplicate_clause> ::=
  { DEDUPLICATE
  | KEEP_DUPLICATES
  }
<LOB_compression_clause> ::=
  { COMPRESS [ HIGH | MEDIUM | LOW ]
  | NOCOMPRESS
  }
<LOB_encryption_clause> ::=
  { ENCRYPT [ USING 'encrypt_algorithm' ]
    [ IDENTIFIED BY password ]
  | DECRYPT
  }
<LOB_partition_storage> ::=
  {PARTITION partition
  { LOB_storage_clause | varray_col_properties }...
  [ (SUBPARTITION subpartition
  { LOB_partitioning_storage | varray_col_properties }...
  )
  ]
  }
<LOB_partitioning_storage> ::=
  {LOB (LOB_item) STORE AS [BASICFILE | SECUREFILE]
  [ LOB_segname [ ( TABLESPACE tablespace | TABLESPACE SET tablespace_set ) ]
  | ( TABLESPACE tablespace | TABLESPACE SET tablespace_set )
  ]
  }
```

11.1.2 ENABLE or DISABLE STORAGE IN ROW

LOB columns store locators that reference the location of the actual LOB value. This section describes how to enable or disable storage in a table row.

Actual LOB values are stored either in the table row (inline) or outside of the table row (out-of-line), depending on the column properties you specify when you create the table, and depending the size of the LOB. The `ENABLE | DISABLE STORAGE IN ROW` clause is used to indicate whether the LOB should be stored inline (in the row) or out-of-line. The default is `ENABLE STORAGE IN ROW` because it provides a performance benefit for small LOBs.

ENABLE STORAGE IN ROW

If `ENABLE STORAGE IN ROW` is set, the maximum amount of LOB data stored in the row is 4000 bytes. This includes the control information and the LOB value.

If the LOB is stored `IN ROW`,

- Exadata pushdown is enabled for LOBs, including when using securefile compression and encryption.

- In-Memory is enabled for LOBs without securefile compression and encryption.

LOBs larger than approximately 4000 bytes are stored out-of-line. However, the control information is still stored in the row, thus enabling us to read the out-of-line LOB data faster.

DISABLE STORAGE IN ROW

In some cases `DISABLE STORAGE IN ROW` is a better choice. This is because storing the LOB in the row increases the size of the row. This impacts performance if you are doing a lot of base table processing, such as full table scans, multi-row accesses (range scans), or many `UPDATE/SELECT` to columns other than the LOB columns.

11.1.3 CACHE, NOCACHE, and CACHE READS

This section discusses the guidelines to follow while creating tables that contain LOBs.

Use the cache options according to the guidelines in the following table:

Table 11-1   Using CACHE, NOCACHE, and CACHE READS Options

Cache Mode	Frequency of Read	Buffer Cache Behavior
`NOCACHE` (default)	Once or occasionally	LOB values are never brought into the buffer cache.
`CACHE READS`	Frequently	LOB values are brought into the buffer cache only during read operations and not during write operations.
`CACHE`	Read the LOB soon after write	LOB pages are placed in the buffer cache during both read and write operations. For storing semi-structured data consider turning on `CACHE` option.

> **⚠ Caution:**
>
> If your application frequently writes to LOBs, then using the `CACHE` option can potentially age other non-LOB pages out of the buffer cache prematurely.

11.1.4 LOGGING and FILESYSTEM_LIKE_LOGGING

You can apply the `LOGGING` parameter to LOBs in the same manner as you apply it for other table operations.

The default value of this parameter is `LOGGING`. For SecureFiles, the `FILESYSTEM_LIKE_LOGGING` parameter is equivalent to the `NOLOGGING` option.

If you set the `LOGGING` option, then Oracle Database determines the most efficient way to generate the `REDO` and `UNDO` logs for the change. Oracle recommends that you keep the `LOGGING` parameter turned on.

The `FILESYSTEM_LIKE_LOGGING` or the `NOLOGGING` option is useful for bulk loads and inserts. When loading data into the LOB, if you do not care about the `REDO` logs and can restart a failed load, then set the LOB data segment storage characteristics to `FILESYSTEM_LIKE_LOGGING`. This provides good performance for the initial load of data. Once you have completed loading data, Oracle recommends that you use the `ALTER TABLE` statement to modify the LOB storage characteristics for the LOB data segment for normal LOB operations. For example, set the cache option to `CACHE` or `CACHE READS`, along with the `LOGGING` option.

> **See Also:**
>
> Precedence of FORCE LOGGING Settings for more information about overriding the logging behavior at the database level

> **Note:**
>
> For BasicFiles, specifying the `CACHE NOLOGGING` option results in an error.

11.1.5 The RETENTION Parameter

The `RETENTION` parameter for SecureFile LOBs specifies how the database manages the old versions of the LOB data blocks.

Unlike other data types, the old versions of the LOB data blocks for SecureFile LOBs are stored in the LOB segment itself and are used to support consistent read operations. Without the corresponding old versions of the LOB data blocks, reading of a LOB at an earlier SCN may fail with `ORA-1555`. Set the `RETENTION` parameter as per the following guidelines:

Table 11-2   RETENTION parameter behavior

RETENTION Parameter value	Behavior
MAX	Allows the old versions of the LOB data blocks to fill the entire LOB segment. This minimizes the likelihood of an `ORA-1555`, if space usage is not a concern. With this setting, the old versions of the LOB data blocks may cause the LOB segment to grow. If you do not set the `MAXSIZE` attribute, then `MAX` behaves like `AUTO`.
MIN	Limits the retention of old versions of the LOB data blocks to `n` seconds. With this setting, you must also specify the retention duration in number of seconds as `n`. The old versions of the LOB data blocks may also cause the LOB segment to grow.
AUTO	Oracle Database manages the space as efficiently as possible, weighing both time and space needs.
NONE	Set this value if no old version of the LOB data blocks is required for consistent read purposes. This is the most efficient setting in terms of space utilization.

Table 11-2   (Cont.) RETENTION parameter behavior

RETENTION Parameter value	Behavior
not set (sets to DEFAULT)	Uses the `UNDO_RETENTION` setting can be set dynamically or manually. If the `UNDO_RETENTION` parameter is set to a positive value, then it is equivalent to setting the `RETENTION` parameter to `MIN` with the same value for retention duration. If the `UNDO_RETENTION` parameter is set to zero (0), then it is equivalent to setting the `RETENTION` parameter to `NONE`.

The `SHRINK` feature for SecureFile LOBs partially deletes old versions of the LOB data blocks to free extents, regardless of the `RETENTION` parameter setting. Therefore, it is recommended to have the `SHRINK` feature only when the `RETENTION` parameter is set to `NONE`.

The following SQL code snippet helps you determine the `RETENTION` parameter for a LOB segment.

```
SELECT RETENTION_TYPE, RETENTION_VALUE FROM USER_LOBs WHERE ...;
```

11.1.6 SecureFiles Compression, Deduplication, and Encryption

This section discusses the features supported by SecureFiles in addition to those supported by BasicFiles.

SecureFiles LOB storage supports the following three features that are not available with the BasicFiles LOB storage option:

- Compression
- Deduplication
- Encryption

Oracle recommends that you enable compression, deduplication, and encryption through the `CREATE TABLE` statement.

> ⚠ **Caution:**
>
> Enabling table or column level compression or encryption does not compress or encrypt the LOB data. To compress or encrypt the LOB data, use SecureFiles compression or encryption by specifying it in the `LOB_storage_clause`.

> **✎ Note:**
>
> You can enable the compression, deduplication, and encryption features using the `ALTER TABLE` statement. However, if you enable these features using the `ALTER TABLE` statement, then all the data in the SecureFiles LOB storage is read, modified, and written. This can cause the database to lock the table during a potentially lengthy operation. There are online capabilities in the `ALTER TABLE` statement that can help you avoid this issue.

Advanced LOB Compression

Advanced LOB Compression transparently analyzes and compresses SecureFiles LOB data to save disk space and improve performance.

License Requirement: You must have a license for the Oracle Advanced Compression Option to implement Advanced LOB Compression.

Consider the following issues when using the `CREATE TABLE` statement with Advanced LOB Compression:

- Advanced LOB Compression is performed on the server and enables random reads and writes to LOB data. Compression utilities on the client, like `utl_compress`, cannot provide random access.

- Advanced LOB Compression does not enable table or index compression. Conversely, table and index compression do not enable Advanced LOB Compression.

- The `LOW`, `MEDIUM`, and `HIGH` options provide varying degrees of compression. The higher the compression, the higher the latency incurred. The `HIGH` setting incurs more work, but compresses the data better. The default is `MEDIUM`.

   The `LOW` compression option uses an extremely lightweight compression algorithm that removes the majority of the CPU cost that is typical with file compression. Compressed SecureFiles LOBs at the `LOW` level provide a very efficient choice for SecureFiles LOB storage. SecureFiles LOBs compressed at `LOW` generally consume less CPU time and less storage than BasicFiles LOBs, and typically help the application run faster because of a reduction in disk I/O.

- Compression can be specified at the partition level. The `CREATE TABLE` `lob_storage_clause` enables specification of compression for partitioned tables on a per-partition basis.

- The `DBMS_LOB.SETOPTIONS` procedure can enable and disable compression on individual SecureFiles LOBs.

The following examples demonstrate how to issue `CREATE TABLE` statements for specific compression scenarios:

Example 11-2   Creating a SecureFiles LOB Column with LOW Compression

```
CREATE TABLE t1 (a CLOB)
   LOB(a) STORE AS SECUREFILE(
   COMPRESS LOW
   CACHE
   NOLOGGING
 );
```

Example 11-3   Creating a SecureFiles LOB Column with MEDIUM (default) Compression

```
CREATE TABLE t1 ( a CLOB)
    LOB(a) STORE AS SECUREFILE (
        COMPRESS
        CACHE
        NOLOGGING
    );
```

Example 11-4   Creating a SecureFiles LOB Column with HIGH Compression

```
CREATE TABLE t1 ( a CLOB)
    LOB(a) STORE AS SECUREFILE (
        COMPRESS HIGH
        CACHE
    );
```

Example 11-5   Creating a SecureFiles LOB Column with Disabled Compression

```
CREATE TABLE t1 ( a CLOB)
    LOB(a) STORE AS SECUREFILE (
        NOCOMPRESS
        CACHE
    );
```

Example 11-6   Creating a SecureFiles LOB Column with Compression on One Partition

```
CREATE TABLE t1 ( REGION VARCHAR2(20), a BLOB)
    LOB(a) STORE AS SECUREFILE (
       CACHE
    )
    PARTITION BY LIST (REGION) (
        PARTITION p1 VALUES ('x', 'y')
            LOB(a) STORE AS SECUREFILE (
                COMPRESS
            ),
        PARTITION p2 VALUES (DEFAULT)
    );
```

Advanced LOB Deduplication

Advanced LOB Deduplication enables Oracle Database to automatically detect duplicate LOB data within a LOB column or partition, and conserve space by storing only one copy of the data.

License Requirement: You must have a license for the Oracle Advanced Compression Option to implement Advanced LOB Deduplication.

Consider these issues when using CREATE TABLE and Advanced LOB Deduplication.

*   Identical LOBs are good candidates for deduplication. Copy operations can avoid data duplication by enabling deduplication.

*   Duplicate detection happens within a LOB segment. Duplicate detection does not span partitions or subpartitions for partitioned and subpartitioned LOB columns.

*   Deduplication can be specified at a partition level. The CREATE TABLE lob_storage_clause enables specification for partitioned tables on a per-partition basis.

*   The DBMS_LOB.SETOPTIONS procedure can enable or disable deduplication on individual LOBs.

The following examples demonstrate how to issue `CREATE TABLE` statements for specific deduplication scenarios:

Example 11-7   Creating a SecureFiles LOB Column with Deduplication

```
CREATE TABLE t1 ( a CLOB)
    LOB(a) STORE AS SECUREFILE (
        DEDUPLICATE
        CACHE
    );
```

Example 11-8   Creating a SecureFiles LOB Column with Disabled Deduplication

```
CREATE TABLE t1 ( a CLOB)
    LOB(a) STORE AS SECUREFILE (
        KEEP_DUPLICATES
        CACHE
    );
```

Example 11-9   Creating a SecureFiles LOB Column with Deduplication on One Partition

```
CREATE TABLE t1 ( REGION VARCHAR2(20), a BLOB)
    LOB(a) STORE AS SECUREFILE (
        CACHE
)
PARTITION BY LIST (REGION) (
    PARTITION p1 VALUES ('x', 'y')
        LOB(a) STORE AS SECUREFILE (
            DEDUPLICATE
        ),
    PARTITION p2 VALUES (DEFAULT)
);
```

Example 11-10   Creating a SecureFiles LOB column with Deduplication Disabled on One Partition

```
CREATE TABLE t1 ( REGION VARCHAR2(20), ID NUMBER, a BLOB)
    LOB(a) STORE AS SECUREFILE (
        DEDUPLICATE
        CACHE
)
PARTITION BY RANGE (REGION)
    SUBPARTITION BY HASH(ID) SUBPARTITIONS 2 (
      PARTITION p1 VALUES LESS THAN (51)
        lob(a) STORE AS a_t2_p1
        (SUBPARTITION t2_p1_s1 lob(a) STORE AS a_t2_p1_s1,
         SUBPARTITION t2_p1_s2 lob(a) STORE AS a_t2_p1_s2),
      PARTITION p2 VALUES LESS THAN (MAXVALUE)
        lob(a) STORE AS a_t2_p2 ( KEEP_DUPLICATES )
        (SUBPARTITION t2_p2_s1 lob(a) STORE AS a_t2_p2_s1,
         SUBPARTITION t2_p2_s2 lob(a) STORE AS a_t2_p2_s2)
    );
```

SecureFiles Encryption

SecureFiles Encryption introduces a new encryption facility for LOBs. The data is encrypted using Transparent Data Encryption (TDE), which allows the data to be stored securely, and still allows for random read and write access.

License Requirement: You must have a license for the Oracle Advanced Security Option to implement SecureFiles Encryption.

Consider the following issues when using `CREATE TABLE` statement with SecureFiles Encryption:

- Securefile Encryption encrypts the data stored in the SecureFile LOB column, irrespective of whether the data is stored in-row or out-of-line in the LOB segment. Note that table or column level encryption will not encrypt the data stored out-of-line in the LOB segment.

- SecureFile Encryption relies on a wallet, or Hardware Security Model (HSM), to hold the encryption key. The wallet setup is the same as that described for Transparent Data Encryption (TDE) and Tablespace Encryption, so complete that before using SecureFile encryption.

> ✎ **See Also:**
>
> "*Oracle Database Advanced Security Guide* for information about creating and using Oracle wallet with TDE.

- The *encrypt_algorithm* indicates the name of the encryption algorithm. Valid algorithms are: `AES192` (default), `AES128`, and `AES256`.

- The column encryption key is derived from `PASSWORD`, if specified.

- The default for LOB encryption is `SALT`. `NO SALT` is not supported.

- SecureFile Encryption is only supported at the table level on a per-column basis, and not at the per-partition level. Hence all partitions within a LOB column are encrypted.

- `DECRYPT` keeps the LOBs in clear text.

- Key management controls the ability to encrypt or decrypt.

- TDE is not supported by the traditional `import` and `export` utilities or by transportable-tablespace-based `export`. Use the Data Pump `expdb` and `impdb` utilities with encrypted columns instead.

The following examples demonstrate how to issue `CREATE TABLE` statements for specific encryption scenarios:

Example 11-11   Creating a SecureFiles LOB Column with a Specific Encryption Algorithm

```
CREATE TABLE t1 ( a CLOB ENCRYPT USING 'AES128')
    LOB(a) STORE AS SECUREFILE (
        CACHE
    );
```

Example 11-12   Creating a SecureFiles LOB column with encryption for all partitions

```
CREATE TABLE t1 ( REGION VARCHAR2(20), a BLOB)
  LOB(a) STORE AS SECUREFILE (
  ENCRYPT USING 'AES128'
  NOCACHE
  FILESYSTEM_LIKE_LOGGING
)
PARTITION BY LIST (REGION) (
PARTITION p1 VALUES ('x', 'y'),
PARTITION p2 VALUES (DEFAULT)
);
```

Example 11-13   Creating a SecureFiles LOB Column with Encryption Based on a Password Key

```
CREATE TABLE t1 ( a CLOB ENCRYPT IDENTIFIED BY foo)
    LOB(a) STORE AS SECUREFILE (
        CACHE
    );
```

The following example has the same result because the encryption option can be set in the `LOB_encryption_clause` section of the statement:

```
CREATE TABLE t1 (a CLOB)
    LOB(a) STORE AS SECUREFILE (
        CACHE
        ENCRYPT
        IDENTIFIED BY foo
    );
```

Example 11-14   Creating a SecureFiles LOB Column with Disabled Encryption

```
CREATE TABLE t1 ( a CLOB )
    LOB(a) STORE AS SECUREFILE (
        CACHE DECRYPT
    );
```

11.1.7 BasicFile Specific Parameters

This section discusses the storage parameters specific to BasicFiles.

The following storage parameters are specific to BasicFiles:

> ⚠ **Caution:**
>
> Oracle strongly recommends that you use SecureFile LOBs for all your LOB needs.

PCTVERSION

When a BasicFiles LOB is modified, a new version of the BasicFiles LOB page is produced in order to support consistent read operations of prior versions of the BasicFiles LOB value. The `PCTVERSION` parameter is the percentage of all used BasicFiles LOB data space that can be occupied by old versions of BasicFiles LOB data pages. As soon as old versions of BasicFiles LOB data pages start to occupy more than the `PCTVERSION` amount of used BasicFiles LOB space, Oracle Database tries to reclaim the old versions and reuse them. The `PCTVERSION` parameter has the following preset values:

*   Default: 10%
*   Minimum: 0
*   Maximum: 100

If your application requires several BasicFiles LOB updates that are concurrent with heavy reads of BasicFiles LOB columns, then consider using a higher value for the `PCTVERSION` parameter, such as 20%. If persistent BasicFiles LOB instances in your application are created and written just once and are primarily read-only afterward, then updates are infrequent. In this case, consider using a lower value for the `PCTVERSION` parameter, such as 5% or lower. If existing BasicFiles LOBs are known to be read-only, then you can safely set the `PCTVERSION` parameter to 0% because there will never be any pages needed for old versions of data.

ORACLE

> **✎ Note:**
>
> The `PCTVERSION` parameter and the `RETENTION` parameter are mutually exclusive for BasicFiles LOBs, that is, you can specify either the `PCTVERSION` parameter or the `RETENTION` parameter, but not both.

CHUNK

A chunk is one or more Oracle blocks. You can specify the chunk size for the BasicFiles LOB when creating the table that contains the LOB. This corresponds to the data size used by Oracle Database when accessing or modifying the LOB value. Part of the chunk is used to store system-related information and the rest stores the LOB value. The APIs that you use to retrieve the chunk size, return the amount of space used in the LOB chunk to store the LOB value. You can use the following APIs to retrieve the chunk size:

- The `DBMS_LOB.GETCHUNKSIZE` procedure in PL/SQL

- The `OCILobGetChunkSize()` function in OCI

Once you specify the value of the `CHUNK` parameter (when the LOB column is created), you cannot change it without moving the LOB. You can set the `CHUNK` parameter to the data size most frequently accessed or written. It is more efficient to access LOBs in big chunks. If you explicitly specify storage characteristics for the LOB, then make sure that you set the `INITIAL` parameter and the `NEXT` parameter for the LOB data segment storage to a size that is larger than the `CHUNK` size.

For SecureFiles, the `CHUNK` size is an advisory size and is provided for backward compatibility purposes.

FREEPOOLS

Specifies the number of `FREELIST` groups for BasicFiles LOBs, if the database is in automatic undo mode. Under Release 12*c* compatibility, this parameter is ignored when SecureFiles LOBs are created.

FREELISTS or FREELIST GROUPS

Specifies the number of process freelists or freelist groups, respectively, allocated to the segment; `NULL` for partitioned tables. Under Release 12*c* compatibility, these parameters are ignored when SecureFiles LOBs are created.

11.1.8 Restriction on First Extent of a LOB Segment

This section discusses the first extent requirements on SecureFiles and BasicFiles.

First Extent of a SecureFile LOB Segment

A SecureFile LOB segment can only be created in Locally Managed Tablespace with Automatic Segment Space Management (ASSM). The number of blocks required in the first extent depends on the release. Before 21c, the first extent requires at least 16 blocks. After 21c, the number is 32 if the compatible parameter is greater than or equal to 20.1.0.0.0. Segments created in the previous release will continue to work in the new release. However, they will not be automatically upgraded.

The actual size of the first extent depends on the database block_size. If the tablespace is configured to use uniform extent, the extent must be bigger than the aforementioned number.

For example, with `block_size = 8k`, the uniform extent size must be at least 128K pre-21c, or 256K on 21c with compatible parameter set. If the tablespace is configured to use uniform extent that is less than this number, the LOB segment creation will fail.

First Extent of a BasicFile LOB Segment

A BasicFile LOB segment can be created in Dictionary Managed or Locally Managed Tablespaces. The segment requires at least 3 blocks in the first extent. This translates into different extent sizes based on the database block_size. If the tablespace is configured to use uniform extent that contains fewer than 3 blocks, the LOB segment creation will fail.

11.1.9 Summary of CREATE TABLE LOB Storage Parameters for Securefile LOBs

The table in this section summarizes the parameters of the `CREATE TABLE` statement that relate to Securefile LOB storage.

Table 11-3   Parameters of CREATE TABLE Statement Related to LOBs

Parameter	Description
SECUREFILE	Specifies SecureFiles LOBs storage.
	Starting with Oracle Database 12*c*, the SecureFiles LOB storage type, specified by the parameter SECUREFILE, is the default.
	A SecureFiles LOB can only be created in a tablespace managed with Automatic Segment Space Management (ASSM).
BASICFILE	Specifies BasicFiles LOB storage, the original architecture for LOBs.
	You must explicitly specify the parameter BASICFILE to use the BasicFiles LOB storage type.
	For BasicFiles LOBs, specifying any of the SecureFiles LOB options results in an error.
RETENTION	Specifies the retention policy for storing old versions of LOB data to support consistent read. Possible values are: MAX, MIN, AUTO and NONE.
MAXSIZE	Specifies the upper limit of storage space that a LOB may use.
	If this amount of space is consumed, new LOB data blocks are taken from the pool of old versions of LOB data blocks as needed, regardless of time requirements.
CACHE, NOCACHE, CACHE READS	Specifies when the LOB data in brought into the buffer cache. • NOCACHE: Never brought into buffer cache. • CACHE READS: Only during reads. • CACHE: During reads and writes. The default is NOCACHE.
LOGGING, NOLOGGING, or FILESYSTEM_LIKE_LOGGING	Specifies whether to generate REDO and UNDO for changes to the LOB: • LOGGING: Generate REDO and UNDO for the change • FILESYSTEM_LIKE_LOGGING/NOLOGGING: Log only the metadata. The default is LOGGING.

Table 11-3   (Cont.) Parameters of CREATE TABLE Statement Related to LOBs

Parameter	Description
COMPRESS or NOCOMPRESS	The COMPRESS option turns on Advanced LOB Compression, and NOCOMPRESS turns it off.
	The default is NOCOMPRESS.
DEDUPLICATE or KEEP_DUPLICATES	The DEDUPLICATE option enables Advanced LOB Deduplication; it specifies that SecureFiles LOB data that is identical in two or more rows in a LOB column, partition or subpartition must share the same data blocks. The database combines SecureFiles LOBs with identical content into a single copy, reducing storage and simplifying storage management. The opposite of this option is KEEP_DUPLICATES.
	The default is KEEP_DUPLICATES.
ENCRYPT or DECRYPT	The ENCRYPT option turns on SecureFiles Encryption, and encrypts all SecureFiles LOB data using Oracle Transparent Data Encryption (TDE). The DECRYPT options turns off SecureFiles Encryption.
	The default is DECRYPT.

11.2 Altering an Existing LOB Column

You can use the ALTER TABLE statement to change the storage characteristics of a LOB column.

- **ALTER TABLE BNF**
  This section has the syntax for ALTER TABLE in Backus Naur (BNF) notation, parts of which have been simplified to keep the focus on LOB-specific parameters.

- **ALTER TABLE MODIFY vs ALTER TABLE MOVE LOB**
  This section compares the storage characteristics while using ALTER TABLE MODIFY and ALTER TABLE MOVE LOB.

- **ALTER TABLE SecureFiles LOB Features**
  This section discusses the features of SecureFile LOBs that work with the ALTER TABLE statement.

11.2.1 ALTER TABLE BNF

This section has the syntax for ALTER TABLE in Backus Naur (BNF) notation, parts of which have been simplified to keep the focus on LOB-specific parameters.

> ✎ **See Also:**
>
> ALTER TABLE for more information on usage of ALTER TABLE statement.

```
ALTER TABLE [ schema.]table ... [ ... | column_clauses | ... |
move_table_clause] ...;

<column_clauses> ::= ... | modify_LOB_storage_clause ...
```

```
<modify_LOB_storage_clause> ::= MODIFY LOB (LOB_item)
( modify_LOB_parameters )

<modify_LOB_parameters> ::=
{ storage_clause
  | PCTVERSION integer
  | FREEPOOLS integer
  | REBUILD FREEPOOLS
  | LOB_retention_clause
  | LOB_deduplicate_clause
  | LOB_compression_clause
  | { ENCRYPT encryption_spec | DECRYPT }
  | { CACHE
  | { NOCACHE | CACHE READS } [ logging_clause ]
  | allocate_extent_clause
  | shrink_clause
  | deallocate_unused_clause

  }
```

11.2.2 ALTER TABLE MODIFY vs ALTER TABLE MOVE LOB

This section compares the storage characteristics while using `ALTER TABLE MODIFY` and `ALTER TABLE MOVE LOB`.

There are two kinds of changes to existing storage characteristics:

1. Some changes to storage characteristics merely apply to the way the data is accessed and do not require moving the entire existing LOB data. For such changes, use the `ALTER TABLE MODIFY LOB` syntax, which uses the `modify_LOB_storage_clause` from the `ALTER TABLE` BNF. Examples of changes that do not require moving the entire existing LOB data are: `RETENTION`, `PCTVERSION`, `CACHE`, `NOCACHELOGGING`, `NOLOGGING`, or `STORAGE` settings, shrinking the space used by the LOB data, and deallocating unused segments.

    > **✎ See Also:**
    >
    > ALTER TABLE

2. Some changes to storage characteristics require changes to the way the data is stored, hence requiring movement of the entire existing LOB data. For such changes use the `ALTER TABLE MOVE LOB` syntax instead of the `ALTER TABLE MODIFY LOB` syntax because the former performs parallel operations on SecureFiles LOBs columns, making it a resource-efficient approach. The `ALTER TABLE MOVE LOB` syntax can process any arbitrary LOB storage clause represented by the `LOB_storage_clause` in the `ALTER TABLE` BNF, and will move the LOB data to a new location.
    Examples of changes that require moving the entire existing LOB data are: `TABLESPACE`, `ENABLE/DISABLE STORAGE IN ROW`, `CHUNK`, `COMPRESSION`, `DEDUPLICATION` and `ENCRYPTION` settings.

    As an alternative to `ALTER TABLE MOVE LOB`, you can use online redefinition to enable one or more of these features. As with `ALTER TABLE`, online redefinition of SecureFiles LOB columns can be executed in parallel.

> ✎ **See Also:**
>
> - ALTER TABLE for more information about `ALTER TABLE` statement.
> - DBMS_REDEFINITION for more information about `DBMS_REDEFINITION` package.

11.2.3 ALTER TABLE SecureFiles LOB Features

This section discusses the features of SecureFile LOBs that work with the `ALTER TABLE` statement.

- ALTER TABLE with Advanced LOB Compression
  When used with the `ALTER TABLE` statement, advanced LOB compression syntax alters the compression mode of the LOB column. The examples in this section demonstrate how to issue `ALTER TABLE` statements for specific compression scenarios.

- ALTER TABLE with Advanced LOB Deduplication
  When used with the `ALTER TABLE` statement, advanced LOB deduplication syntax alters the deduplication mode of the LOB column. The examples in this section demonstrate how to issue `ALTER TABLE` statements for specific deduplication scenarios.

- ALTER TABLE with SecureFiles Encryption
  The examples in this section demonstrate how to issue ALTER TABLE statements for to enable SecureFiles encryption.

11.2.3.1 ALTER TABLE with Advanced LOB Compression

When used with the `ALTER TABLE` statement, advanced LOB compression syntax alters the compression mode of the LOB column. The examples in this section demonstrate how to issue `ALTER TABLE` statements for specific compression scenarios.

Example: Altering a SecureFiles LOB Column to Enable LOW Compression

```
ALTER TABLE t1 MOVE LOB(a) STORE AS SECUREFILE(COMPRESS LOW)
```

Example: Altering a SecureFiles LOB Column to Disable Compression

```
ALTER TABLE t1 MOVE LOB(a) STORE AS SECUREFILE(NOCOMPRESS)
```

Example: Altering a SecureFiles LOB Column to Enable HIGH Compression

```
ALTER TABLE t1 MOVE LOB(a) STORE AS SECUREFILE(COMPRESS HIGH);
```

Example: Altering a SecureFiles LOB Column to Enable Compression on One partition

```
ALTER TABLE t1 MOVE PARTITION p1 LOB(a) STORE AS SECUREFILE(COMPRESS HIGH);
```

11.2.3.2 ALTER TABLE with Advanced LOB Deduplication

When used with the `ALTER TABLE` statement, advanced LOB deduplication syntax alters the deduplication mode of the LOB column. The examples in this section demonstrate how to issue `ALTER TABLE` statements for specific deduplication scenarios.

Example: Altering a SecureFiles LOB Column to Disable Deduplication

```
ALTER TABLE t1 MOVE LOB(a) STORE AS SECUREFILE(KEEP_DUPLICATES);
```

Example: Altering a SecureFiles LOB Column to Enable Deduplication

```
ALTER TABLE t1 MOVE LOB(a) STORE AS SECUREFILE(DEDUPLICATE);
```

Example: Altering a SecureFiles LOB Column to Enable Deduplication on One Partition

```
ALTER TABLE t1 MOVE PARTITION p1 LOB(a) STORE AS SECUREFILE(DEDUPLICATE);
```

11.2.3.3 ALTER TABLE with SecureFiles Encryption

The examples in this section demonstrate how to issue ALTER TABLE statements for to enable SecureFiles encryption.

Consider the following points when using the `ALTER TABLE` statement with SecureFiles Encryption:

- The `ALTER TABLE` statement enables and disables SecureFiles Encryption. Using the `REKEY` option with the `ALTER TABLE` statement also enables you to encrypt LOB columns with a new key or algorithm.
- The `DECRYPT` option converts encrypted columns to clear text form.

> ✎ **See Also:**
>
> 'CREATE TABLE' Usage Notes for SecureFiles Encryption

Following examples demonstrate how to issue `ALTER TABLE` statements for specific encryption scenarios:

Example: Altering a SecureFiles LOB Column by Encrypting Based on `AES256` encryption

```
ALTER TABLE t1 MOVE LOB(a) STORE AS SECUREFILE(ENCRYPT USING 'AES256');
```

Example: Altering a SecureFiles LOB Column by Encrypting Based on a Password Key

```
ALTER TABLE t1 MOVE LOB(a)
    STORE AS SECUREFILE(ENCRYPT USING 'AES256' IDENTIFIED BY foo);
```

Example: Altering a SecureFiles LOB Column by Regenerating the Encryption key

```
ALTER TABLE t1 REKEY USING 'AES256';
```

ORACLE

11.3 Creating an Index on LOB Column

The contents of a LOB are often specific to the application, so an index on the LOB column will usually deal with application logic. You can create a function-based or a domain index on a LOB column to improve the performance of queries accessing data stored in LOB columns. You cannot build a B-tree or bitmap index on a LOB column.

Function-based and domain indexes are automatically updated when a DML operation is performed on the LOB column, or when a LOB is updated using an API like DBMS_LOB.

You can use the LOB Open/Close API to defer index maintenance to after a bunch of write operations. Opening a LOB in read-write mode defers any index maintenance on the LOB column until you close the LOB. This is useful when you do not want the database to perform index maintenance every time you write to the LOB. This technique can improve the performance of your application if you are doing several write operations on the LOB while it is open. Any index on the LOB column is not valid until you explicitly close the LOB.

- Function-Based Indexing on LOB Columns
  A function-based index is an index built on an expression. It extends your indexing capabilities beyond indexing on a column. A function-based index increases the variety of ways in which you can access data.

- Domain Indexing on LOB Columns
  Indexes created by using Extensible Indexing interfaces are known as Domain indexes.

> ✏ **See Also:**
>
> Before You Begin

11.3.1 Function-Based Indexing on LOB Columns

A function-based index is an index built on an expression. It extends your indexing capabilities beyond indexing on a column. A function-based index increases the variety of ways in which you can access data.

> ✏ **See Also:**
>
> When to Use Function-Based Indexes

The following example demonstrates the creation of a function-based index on a LOB column using a SQL function:

```
-- Function-Based Index using a SQL function
CREATE INDEX ad_sourcetext_idx_sql ON
print_media(to_char(substr(ad_sourcetext,1,10)));
```

The following example demonstrates the creation of a function-based index on a LOB column using a PL/SQL function:

```
-- Function-Based Index using a PL/SQL function
-- LOB can be an input but cannot be the return type of hte function
CREATE OR REPLACE FUNCTION Ret1st2Char(CLobInput CLOB) RETURN CHAR
DETERMINISTIC IS
        First2Char          CHAR(2) ;
        NoOfChar            INTEGER ;
BEGIN
        NoOfChar := 2 ;
        DBMS_LOB.Read(CLobInput, NoOfChar, 1, First2Char) ;
        RETURN First2Char ;
END ;
/

CREATE INDEX ad_sourcetext_idx_plsql on
print_media(Ret1st2Char(ad_sourcetext));
```

11.3.2 Domain Indexing on LOB Columns

Indexes created by using Extensible Indexing interfaces are known as Domain indexes.

The database provides extensible indexing interfaces, a feature which enables you to define new index types as required. This is based on the concept of cooperative indexing where a data cartridge and the database build and maintain indexes for data types such as text and spatial.

The cartridge is responsible for defining the index structure, maintaining the index content during load and update operations, and searching the index during query processing. The index structure can be stored in Oracle as heap-organized, or an index-organized table, or externally as an operating system file.

To support this structure, the database provides an indextype. The purpose of an indextype is to enable efficient search and retrieval functions for complex domains such as text, spatial, image, and OLAP by means of a data cartridge. An indextype is analogous to the sorted or bit-mapped index types that are built-in within the Oracle Server. The difference is that an indextype is implemented by the data cartridge developer, whereas the Oracle kernel implements built-in indexes. Once a new indextype has been implemented by a data cartridge developer, end users of the data cartridge can use it just as they would built-in index types.

When the database system handles the physical storage of domain indexes, data cartridges:

• Define the format and content of an index. This enables cartridges to define an index structure that can accommodate a complex data object. For instance, an inverted index for text documents or a quad-tree for spatial features.

• Build, delete, and update a domain index. The cartridge handles building and maintaining the index structures.

• Access and interpret the content of an index. This capability enables the data cartridge to become an integral component of query processing. That is, the content-related clauses for database queries are handled by the data cartridge.

By supporting domain indexes, the database significantly reduces the effort needed to develop high-performance solutions that access complex data types such as LOBs.

- **Extensible Optimizer**
  Extensible Optmizer enables collection of statistics on user-defined functions and domain indexes.

- **Text Indexes on LOB Columns**
  If the contents of your LOB column correspond to that of a document type, users are allowed to index such a column using Oracle Text indexes.

> **See Also:**
>
> *Oracle Database Data Cartridge Developer's Guide*

11.3.2.1 Extensible Optimizer

Extensible Optmizer enables collection of statistics on user-defined functions and domain indexes.

The SQL optimizer cannot collect statistics over LOB columns nor can it estimate the cost and selectivity of predicates involving LOB columns. Instead, the Extensible Optimizer functionality allows authors of user-defined functions and domain indexes to create statistics collection, selectivity, and cost functions. This information is used by the optimizer in choosing a query plan. The cost-based optimizer is thus extended to use the user-supplied information.

The Extensible Indexing interfaces enable you to define new operators, indextypes, and domain indexes. For such user-defined operators and domain indexes, the Extensible Optimizer interfaces allows users to control the three main components used by the optimizer to select an execution plan: statistics, selectivity, and cost. This allows the cartridge developer to tune the Extensible Optimizer for efficient execution of queries involving predicates or indexes over complex data types such as LOBs.

> **See Also:**
>
> Extensible Optimizer

11.3.2.2 Text Indexes on LOB Columns

If the contents of your LOB column correspond to that of a document type, users are allowed to index such a column using Oracle Text indexes.

For example, consider the following table `DOCUMENT_TABLE` storing text-based documents on a CLOB column:

```
CREATE TABLE document_table (
    docno NUMBER,
    document CLOB);
```

You can index the contents of the DOCUMENT column with one of the Oracle Text indexing options to speed up text-based queries. The following example will create a SEARCH index used for text-search queries over the DOCUMENT column.

```
CREATE INDEX document_index ON document_table (document) INDEXTYPE IS
CTXSYS.CONTEXT;
```

```
CREATE SEARCH INDEX document_index ON document_table (document);
```

> **Note:**
>
> You can create an Oracle Text index on other formats as well. Examples of other formats include PDF, JSON, or XML.

> **See Also:**
>
> Creating Oracle Text Indexes

11.4 LOBs in Partitioned Tables

Partitioning can simplify the manageability of large database objects. This section discusses various aspects of LOBs in partitioned tables.

Very large tables and indexes can be decomposed into smaller and more manageable pieces called partitions, which are entirely transparent to an application. You can partition tables that contain LOB columns. All partitioning schemes supported by Oracle are fully supported on LOBs.

> **See Also:**
>
> Partitions_ Views_ and Other Schema Objects
> Partitioning for All Databases

LOBs can take advantage of all of the benefits of partitioning including the following:

- LOB segments can be spread between several tablespaces to balance I/O load and to make backup and recovery more manageable.
- LOBs in a partitioned table become easier to maintain.
- LOBs can be partitioned into logical groups to speed up operations on LOBs that are accessed as a group.

The following section describes some of the ways you can manipulate LOBs in partitioned tables.

- Partitioning a Table Containing LOB Columns
  All partitioning schemes supported by Oracle are fully supported on LOBs.This section discusses the partitioning of tables with LOB columns.
- Default LOB Storage Attributes
  This section discusses the default LOB storage attributes.
- Partition Maintenance Operation
  This section discusses maintenance operations on partitioned tables with LOB columns.

- Creating an Index on a Table Containing Partitioned LOB Columns
  To improve the performance of queries, you can create local or global indexes on partitioned LOB columns.

11.4.1 Partitioning a Table Containing LOB Columns

All partitioning schemes supported by Oracle are fully supported on LOBs.This section discusses the partitioning of tables with LOB columns.

You can partition a table containing LOB columns using any of the following techniques:

- When the table is created using the `PARTITION BY ...` clause of the `CREATE TABLE` statement.

- Adding a partition to an existing table using the `ALTER TABLE ... ADD PARTITION` clause.

The data dictionary views `USER_LOB_PARTITIONS`, `ALL_LOB_PARTITIONS` and `DBA_LOB_PARTITIONS` provide partition specific information for a LOB column.

Example 11-15   A partitioned table with LOB columns:

```
CREATE TABLE print_media
    ( product_id        NUMBER(6),
      ad_id             NUMBER(6),
      ad_sourcetext     CLOB)
    LOB (ad_sourcetext)  STORE AS SECUREFILE (TABLESPACE tbs_2)
     PARTITION BY RANGE(product_id)
     (PARTITION P1 VALUES LESS THAN (1000)
         LOB (ad_sourcetext) STORE AS BASICFILE (TABLESPACE tbs_1),
      PARTITION P2 VALUES LESS THAN (2000)
         LOB (ad_sourcetext) STORE AS (TABLESPACE tbs_2 COMPRESS HIGH),
      PARTITION P3 VALUES LESS THAN (3000));
```

> ✏️ **See Also:**
>
> Summary of CREATE TABLE LOB Storage Parameters for Securefile LOBs

11.4.2 Default LOB Storage Attributes

This section discusses the default LOB storage attributes.

In the above example, the default storage attribute for LOB column `ad_sourcetext` is mentioned as "`STORE AS SECUREFILE (TABLESPACE tbs_2)`". This means that if no LOB storage clause is provided for any partition, this default will be used. In this example, partition `P3` uses tablespace `tbs_2` since no LOB storage is specified. Similarly, `SECUREFILE` is the default storage and is used by partitions `P2` and `P3`, but partition `P1` overrides it to specify BasicFile storage.

The dictionary views `USER_PART_LOBS`, `ALL_PART_LOBS` and `DBA_PART_LOBS` provide information on default LOB storage options for a LOB column in a table.

The table level default LOB storage attribute can be changed, as shown in the example below:

```
ALTER TABLE print_media MODIFY DEFAULT ATTRIBUTES  LOB (ad_sourcetext)
    (TABLESPACE  tbs_1);
```

The change in the default attribute will not affect the existing partitions. Any new partitions created without LOB storage clause will inherit the default values for that column.

11.4.3 Partition Maintenance Operation

This section discusses maintenance operations on partitioned tables with LOB columns.

All partitioning maintenance operations are supported with LOB columns. Here are some examples:

Example 11-16   Adding Partition containing LOBs

```
ALTER TABLE print_media ADD PARTITION P4 VALUES LESS THAN (4000)
        LOB (ad_sourcetext) STORE AS SECUREFILE(TABLESPACE tbs_2);
```

Example 11-17   Modifying Partition Containing LOBs

```
ALTER TABLE print_media MODIFY PARTITION P3 LOB(ad_sourcetext)
    (RETENTION AUTO);
```

Example 11-18   Moving Partition Containing LOBs

```
ALTER TABLE print_media MOVE PARTITION P1 LOB(ad_sourcetext)
    STORE AS (TABLESPACE tbs_3 COMPRESS LOW);
```

The example above moves a LOB partition into a different tablespace, which can be useful if the tablespace is no longer large enough to hold the partition. Move partition can also be used to perform other operations that require moving the LOB data, such as performing a `COMPRESS` operation on the LOB, or changing the `ENABLE / DISABLE STORAGE IN ROW` option.

Example 11-19   Splitting Partitions Containing LOBs

You can split a partition containing LOBs into two using the `ALTER TABLE ... SPLIT PARTITION` clause. Doing so permits you to place one or both new partitions in a new tablespace. For example:

```
ALTER TABLE print_media SPLIT PARTITION  P1 AT(500) into
(PARTITION P1A LOB(ad_sourcetext) STORE AS (TABLESPACE tbs_1),
PARTITION P1B LOB(ad_sourcetext) STORE AS (TABLESPACE tbs_2)) UPDATE INDEXES;
```

Example 11-20   Merging Partitions Containing LOBs

Merging partitions is useful for reclaiming unused partition space. For example:

```
ALTER TABLE print_media MERGE PARTITIONS P1A, P1B INTO PARTITION P1;
```

ORACLE

Example 11-21   Exchange Partition containing LOB column with non-partitioned table

Exchanging partitions with a table that has partitioned LOB columns using the `ALTER TABLE ... EXCHANGE PARTITION` clause. Exchange partition is a powerful tool to change new data / partitions to a newer storage format without the costly operation of migrating old data. You can exchange partition with LOB data having different storage option, e.g. partition p1 of BasicFile data in Example 11-15 can be exchanged with non-partitioned table with LOB column stored in SecureFile Compressed form:

```
CREATE TABLE print_media_nonpart
    ( product_id NUMBER(6),
      ad_id NUMBER(6),
      ad_sourcetext CLOB)
      LOB (ad_sourcetext) STORE AS SECUREFILE (COMPRESS HIGH);

ALTER TABLE print_media  EXCHANGE PARTITION p1 WITH TABLE print_media_nonpart;
```

11.4.4 Creating an Index on a Table Containing Partitioned LOB Columns

To improve the performance of queries, you can create local or global indexes on partitioned LOB columns.

Only function-based and domain indexes are supported on LOB columns. Other types of indexes, such as unique indexes are not supported with LOBs.

For example:

```
CREATE INDEX ad_sourcetext_idx_sql on print_media
(to_char(substr(ad_sourcetext,1,10)))
     GLOBAL;

CREATE INDEX ad_sourcetext_idx_sql on print_media
(to_char(substr(ad_sourcetext,1,10)))
     LOCAL;
```

11.5 LOBs in Index Organized Tables

Index Organized Tables (IOTs) support LOB and BFILE columns.

For the most part, SQL DDL, DML, and piecewise operations on LOBs in IOTs produce the same results as those for normal tables. The only exception is the default semantics of LOBs during creation. The main differences are:

- **Tablespace Mapping**: By default, or unless specified otherwise, the LOB data and index segments are created in the tablespace in which the primary key index segments of the index organized table are created.

- **Inline as Compared to Out-of-Line Storage**: By default, all LOBs in an index organized table created without an overflow segment are stored out of line. In other words, if an index organized table is created without an overflow segment, then the LOBs in this table have their default storage attributes as `DISABLE STORAGE IN ROW`. If you forcibly try to specify an `ENABLE STORAGE IN ROW` clause for such LOBs, then SQL raises an error.

    On the other hand, if an overflow segment has been specified, then LOBs in index organized tables exactly mimic their semantics in conventional tables.

Example of Index Organized Table (IOT) with LOB Columns

Consider the following example:

```
CREATE TABLE iotlob_tab (c1 INTEGER PRIMARY KEY, c2 BLOB, c3 CLOB, c4
VARCHAR2(20))
  ORGANIZATION INDEX
    TABLESPACE iot_ts
    PCTFREE 10 PCTUSED 10 INITRANS 1 MAXTRANS 1 STORAGE (INITIAL 4K)
    PCTTHRESHOLD 50 INCLUDING c2
  OVERFLOW
    TABLESPACE ioto_ts
    PCTFREE 10 PCTUSED 10 INITRANS 1 MAXTRANS 1 STORAGE (INITIAL 8K) LOB (c2)
    STORE AS lobseg (TABLESPACE lob_ts DISABLE STORAGE IN ROW
                     CHUNK 16384 PCTVERSION 10 CACHE STORAGE (INITIAL 2M)
                     INDEX lobidx_c1 (TABLESPACE lobidx_ts STORAGE (INITIAL 4K)));
```

Executing these statements results in the creation of an index organized table `iotlob_tab` with the following elements:

- A primary key index segment in the tablespace `iot_ts`,

- An overflow data segment in tablespace `ioto_ts`

- Columns starting from column `C3` being explicitly stored in the overflow data segment

- `BLOB` (column `C2`) data segments in the tablespace `lob_ts`

- `BLOB` (column `C2`) index segments in the tablespace `lobidx_ts`

- `CLOB` (column `C3`) data segments in the tablespace `iot_ts`

- `CLOB` (column `C3`) index segments in the tablespace `iot_ts`

- `CLOB` (column `C3`) stored in line by virtue of the IOT having an overflow segment

- `BLOB` (column `C2`) explicitly forced to be stored out of line

> **Note:**
>
> If no overflow had been specified, then both C2 and C3 would have been stored out of line by default.

LOBs in Partitioned Index-Organized Tables

LOB columns and attributes can be stored in partitioned index-organized tables.

Index-organized tables can have LOBs stored as follows; however, partition maintenance operations, such as `MOVE`, `SPLIT`, and `MERGE` are not supported with:

- VARRAY data types stored as LOB data types.

- Abstract data types with LOB attributes.

- Nested tables with LOB types.

Restrictions on Index Organized Tables with LOB Columns

The ALTER TABLE MOVE operation cannot be performed on an index organized table with a LOB column in parallel. Instead, use the `NOPARALLEL` clause to move the LOB column for such tables. For example:

```
ALTER TABLE t1 MOVE LOB(a) STORE AS (<tablespace users>) NOPARALLEL;
```

12

Advanced Design Considerations

This section discusses the design considerations for more advanced application development issues.

- **Read-Consistent Locators**
  Oracle Database provides the same read consistency mechanisms for LOBs as for all other database reads and updates of scalar quantities.

- **LOB Locators and Transaction Boundaries**
  LOB locators can be used in both transactions as well as transaction IDs.

- **LOBs in the Object Cache**
  When you copy one object to another in the object cache with a LOB locator attribute, only the LOB locator is copied.

- **Guidelines for Creating Terabyte sized LOBs**
  To create terabyte LOBs in supported environments, use the following guidelines to make use of all available space in the tablespace for LOB storage.

12.1 Read-Consistent Locators

Oracle Database provides the same read consistency mechanisms for LOBs as for all other database reads and updates of scalar quantities.

Read consistency has some special applications to LOB locators that you must understand. The following sections discuss read consistency and include examples which should be looked at in relationship to each other.

- **A Selected Locator Becomes a Read-Consistent Locator**
  A read-consistent locator contains the snapshot environment as of the point in time of the `SELECT` operation.

- **Example of Updating LOBs and Read-Consistency**
  Read-consistent locators provide the same LOB value regardless of when the `SELECT` occurs. The following example demonstrates the relationship between read-consistency and `UPDATE` operation.

- **Example of Updating LOBs Through Updated Locators**
  Learn about updating LOBs through Locators in this section.

- **Example of Updating a LOB Using SQL DML and DBMS_LOB**
  Using the `print_media` table in the following example, a `CLOB` locator is created as `clob_selected`.

- **Example of Using One Locator to Update the Same LOB Value**
  You may avoid many pitfalls if you use only one locator to update a given LOB value. Learn about it in this section.

- **Example of Updating a LOB with a PL/SQL (DBMS_LOB) Bind Variable**
  Learn about updating a LOB with a PL/SQL bind variable in this section.

- **Example of Deleting a LOB Using Locator**
  Learn about deleting a LOB with a PL/SQL bind variable in this section.

- **Ensuring Read Consistency**
  This script in this section can be used to ensure that hot backups can be taken of tables
  that have `NOLOGGING` or `FILESYSTEM_LIKE_LOGGING` LOBs and have a known recovery point
  without read inconsistencies.

> ✎ **See Also:**
>
> - *Oracle Database Concepts* for general information about read consistency

12.1.1 A Selected Locator Becomes a Read-Consistent Locator

A read-consistent locator contains the snapshot environment as of the point in time of the
`SELECT` operation.

A selected locator, regardless of the existence of the `FOR UPDATE` clause, becomes a *read-consistent locator,* and remains a read-consistent locator until the LOB value is updated
through that locator.

This has some complex implications. Suppose you have created a read-consistent locator (`L1`)
by way of a `SELECT` operation. In reading the value of the persistent LOB through `L1`, note the
following:

- The LOB is read as of the point in time of the `SELECT` statement even if the `SELECT`
  statement includes a `FOR UPDATE`.

- If the LOB value is updated through a different locator (`L2`) in the same transaction, then `L1`
  does not see the `L2` updates.

- `L1` does not see committed updates made to the LOB through another transaction.

- If the read-consistent locator `L1` is copied to another locator `L2` (for example, by a PL/SQL
  assignment of two locator variables — `L2:= L1`), then `L2` becomes a read-consistent
  locator along with `L1` and any data read is read as of the point in time of the `SELECT` for `L1`.

You can use the existence of multiple locators to access different transformations of the LOB
value. However, in doing so, you must keep track of the different values accessed by different
locators.

12.1.2 Example of Updating LOBs and Read-Consistency

Read-consistent locators provide the same LOB value regardless of when the `SELECT` occurs.
The following example demonstrates the relationship between read-consistency and `UPDATE`
operation.

Using the `print_media` table and PL/SQL, three `CLOB` instances are created as potential
locators: `clob_selected`, `clob_update`, and `clob_copied`.

Observe these progressions in the code, from times `t1` through `t6`:

- At the time of the first `SELECT INTO` (at `t1`), the value in `ad_sourcetext` is associated with
  the locator `clob_selected`.

- In the second operation (at `t2`), the value in `ad_sourcetext` is associated with the locator
  `clob_updated`. Because there has been no change in the value of `ad_sourcetext` between
  `t1` and `t2`, both `clob_selected` and `clob_updated` are read-consistent locators that

effectively have the same value even though they reflect snapshots taken at different moments in time.

- The third operation (at `t3`) copies the value in `clob_selected` to `clob_copied`. At this juncture, all three locators see the same value. The example demonstrates this with a series of `DBMS_LOB.READ()` calls.

- At time `t4`, the program uses `DBMS_LOB.WRITE()` to alter the value in `clob_updated`, and a `DBMS_LOB.READ()` reveals a new value.

- However, a `DBMS_LOB.READ()` of the value through `clob_selected` (at `t5`) reveals that it is a read-consistent locator, continuing to refer to the same value as of the time of its `SELECT`.

- Likewise, a `DBMS_LOB.READ()` of the value through `clob_copied` (at `t6`) reveals that it is a read-consistent locator, continuing to refer to the same value as `clob_selected`.

Example 12-1

```
INSERT INTO print_media VALUES (2056, 20020, EMPTY_BLOB(),
    'abcd', EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL);

COMMIT;

DECLARE

12.1.3 Example of Updating LOBs Through Updated Locators

Learn about updating LOBs through Locators in this section.

When you update the value of the persistent LOB through the LOB locator (L1), L1 is updated to contain the current snapshot environment.

This snapshot is as of the time after the operation was completed on the LOB value through locator L1. L1 is then termed an updated locator. This operation enables you to see your own changes to the LOB value on the next read through the same locator, L1.

> **✎ Note:**
>
> The snapshot environment in the locator is *not* updated if the locator is used to merely read the LOB value. It is only updated when you modify the LOB value through the locator using the PL/SQL DBMS_LOB package or the OCI LOB APIs.

Any committed updates made by a different transaction are seen by L1 only if your transaction is a read-committed transaction and if you use L1 to update the LOB value after the other transaction committed.

> **Note:**
>
> When you update a persistent LOB value, the modification is always made to the most current LOB value.

Updating the value of the persistent LOB through any of the available methods, such as OCI LOB APIs or PL/SQL `DBMS_LOB` package, updates the LOB value *and then reselects* the locator that refers to the new LOB value.

> **Note:**
>
> Once you have selected out a LOB locator by whatever means, you can read from the locator but not write into it.
>
> Note that updating the LOB value through SQL is merely an `UPDATE` statement. It is up to you to do the reselect of the LOB locator or use the `RETURNING` clause in the `UPDATE` statement so that the locator can see the changes made by the `UPDATE` statement. Unless you reselect the LOB locator or use the `RETURNING` clause, you may think you are reading the latest value when this is not the case. For this reason you should avoid mixing SQL DML with `OCI` and `DBMS_LOB` piecewise operations.

12.1.4 Example of Updating a LOB Using SQL DML and DBMS_LOB

Using the `print_media` table in the following example, a `CLOB` locator is created as `clob_selected`.

Note the following progressions in the example, from times `t1` through `t3`:

- At the time of the first `SELECT INTO` (at `t1`), the value in `ad_sourcetext` is associated with the locator `clob_selected`.

- In the second operation (at `t2`), the value in `ad_sourcetext` is modified through the `SQL UPDATE` statement, without affecting the `clob_selected` locator. The locator still sees the value of the LOB as of the point in time of the original `SELECT`. In other words, the locator does not see the update made using the SQL `UPDATE` statement. This is illustrated by the subsequent `DBMS_LOB.READ()` call.

- The third operation (at `t3`) re-selects the LOB value into the locator `clob_selected`. The locator is thus updated with the latest snapshot environment which allows the locator to see the change made by the previous SQL `UPDATE` statement. Therefore, in the next `DBMS_LOB.READ()`, an error is returned because the LOB value is empty, that is, it does not contain any data.

```
INSERT INTO Print_media VALUES (3247, 20010, EMPTY_BLOB(),
    'abcd', EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL);

COMMIT;

DECLARE
  num_var           INTEGER;
  clob_selected     CLOB;
  read_amount       INTEGER;
  read_offset       INTEGER;
  buffer            VARCHAR2(20);

BEGIN

  -- At time t1:
  SELECT ad_sourcetext INTO clob_selected
  FROM Print_media
  WHERE ad_id = 20010;

  read_amount := 10;
  read_offset := 1;
  dbms_lob.read(clob_selected, read_amount, read_offset, buffer);
  dbms_output.put_line('clob_selected value: ' || buffer);
  -- Produces the output 'abcd'

  -- At time t2:
  UPDATE Print_media SET ad_sourcetext = empty_clob()
      WHERE ad_id = 20010;
  -- although the most current LOB value is now empty,
  -- clob_selected still sees the LOB value as of the point
  -- in time of the SELECT

  read_amount := 10;
  dbms_lob.read(clob_selected, read_amount, read_offset, buffer);
  dbms_output.put_line('clob_selected value: ' || buffer);
  -- Produces the output 'abcd'

  -- At time t3:
  SELECT ad_sourcetext INTO clob_selected FROM Print_media WHERE
      ad_id = 20010;
  -- the SELECT allows clob_selected to see the most current
  -- LOB value

  read_amount := 10;
  dbms_lob.read(clob_selected, read_amount, read_offset, buffer);
  -- ERROR: ORA-01403: no data found
END;
/
```

12.1.5 Example of Using One Locator to Update the Same LOB Value

You may avoid many pitfalls if you use only one locator to update a given LOB value. Learn about it in this section.

> **Note:**
>
> Avoid updating the same LOB with different locators.

In the following example, using table `print_media`, two `CLOB`s are created as potential locators: `clob_updated` and `clob_copied`.

Note these progressions in the example at times t1 through t5:

- At the time of the first `SELECT INTO` (at `t1`), the value in `ad_sourcetext` is associated with the locator `clob_updated`.

- The second operation (at time `t2`) copies the value in `clob_updated` to `clob_copied`. At this time, both locators see the same value. The example demonstrates this with a series of `DBMS_LOB.READ()` calls.

- At time `t3`, the program uses `DBMS_LOB.WRITE()` to alter the value in `clob_updated`, and a `DBMS_LOB.READ()` reveals a new value.

- However, a `DBMS_LOB.READ()` of the value through `clob_copied` (at time `t4`) reveals that it still sees the value of the LOB as of the point in time of the assignment from `clob_updated` (at `t2`).

- It is not until `clob_updated` is assigned to `clob_copied` (`t5`) that `clob_copied` sees the modification made by `clob_updated`.

```
INSERT INTO PRINT_MEDIA VALUES (2049, 20030, EMPTY_BLOB(),
    'abcd', EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL);

COMMIT;

DECLARE
  num_var          INTEGER;
  clob_updated     CLOB;
  clob_copied      CLOB;
  read_amount      INTEGER;
  read_offset      INTEGER;
  write_amount     INTEGER;
  write_offset     INTEGER;
  buffer           VARCHAR2(20);
BEGIN

-- At time t1:
  SELECT ad_sourcetext INTO clob_updated FROM PRINT_MEDIA
      WHERE ad_id = 20030
      FOR UPDATE;

  -- At time t2:
  clob_copied := clob_updated;
  -- after the assign, clob_copied and clob_updated see the same
  -- LOB value

  read_amount := 10;
  read_offset := 1;
  dbms_lob.read(clob_updated, read_amount, read_offset, buffer);
  dbms_output.put_line('clob_updated value: ' || buffer);
  -- Produces the output 'abcd'

  read_amount := 10;
  dbms_lob.read(clob_copied, read_amount, read_offset, buffer);
  dbms_output.put_line('clob_copied value: ' || buffer);
  -- Produces the output 'abcd'

  -- At time t3:
  write_amount := 3;
  write_offset := 5;
```

```
    buffer := 'efg';
    dbms_lob.write(clob_updated, write_amount, write_offset,
          buffer);

    read_amount := 10;
    dbms_lob.read(clob_updated, read_amount, read_offset, buffer);
    dbms_output.put_line('clob_updated value: ' || buffer);
    -- Produces the output 'abcdefg'

    -- At time t4:
    read_amount := 10;
    dbms_lob.read(clob_copied, read_amount, read_offset, buffer);
    dbms_output.put_line('clob_copied value: ' || buffer);
    -- Produces the output 'abcd'

    -- At time t5:
    clob_copied := clob_updated;

    read_amount := 10;
    dbms_lob.read(clob_copied, read_amount, read_offset, buffer);
    dbms_output.put_line('clob_copied value: ' || buffer);
    -- Produces the output 'abcdefg'
END;
/
```

12.1.6 Example of Updating a LOB with a PL/SQL (DBMS_LOB) Bind Variable

Learn about updating a LOB with a PL/SQL bind variable in this section.

When a LOB locator is used as the source to update another persistent LOB (as in a SQL INSERT or UPDATE statement, the DBMS_LOB.COPY routine, and so on), the snapshot environment in the source LOB locator determines the LOB value that is used as the source.

If the source locator (for example L1) is a read-consistent locator, then the LOB value as of the time of the SELECT of L1 is used. If the source locator (for example L2) is an updated locator, then the LOB value associated with the L2 snapshot environment at the time of the operation is used.

In the following example, three CLOBs are created as potential locators: clob_selected, clob_updated, and clob_copied.

Note these progressions in the example at times t1 through t5:

- At the time of the first SELECT INTO (at t1), the value in ad_sourcetext is associated with the locator clob_updated.

- The second operation (at t2) copies the value in clob_updated to clob_copied. At this juncture, both locators see the same value.

- Then (at t3), the program uses DBMS_LOB.WRITE() to alter the value in clob_updated, and a DBMS_LOB.READ() reveals a new value.

- However, a DBMS_LOB.READ() of the value through clob_copied (at t4) reveals that clob_copied does not see the change made by clob_updated.

- Therefore (at t5), when clob_copied is used as the source for the value of the INSERT statement, the value associated with clob_copied (for example, without the new changes

made by `clob_updated`) is inserted. This is demonstrated by the subsequent
`DBMS_LOB.READ()` of the value just inserted.

```
INSERT INTO PRINT_MEDIA VALUES (2056, 20020, EMPTY_BLOB(),
    'abcd', EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL);

COMMIT;

DECLARE
  num_var          INTEGER;
  clob_selected    CLOB;
  clob_updated     CLOB;
  clob_copied      CLOB;
  read_amount      INTEGER;
  read_offset      INTEGER;
  write_amount     INTEGER;
  write_offset     INTEGER;
  buffer           VARCHAR2(20);
BEGIN

  -- At time t1:
  SELECT ad_sourcetext INTO clob_updated FROM PRINT_MEDIA
      WHERE ad_id = 20020
      FOR UPDATE;

  read_amount := 10;
  read_offset := 1;
  dbms_lob.read(clob_updated, read_amount, read_offset, buffer);
  dbms_output.put_line('clob_updated value: ' || buffer);
  -- Produces the output 'abcd'

  -- At time t2:
  clob_copied := clob_updated;

  -- At time t3:
  write_amount := 3;
  write_offset := 5;
  buffer := 'efg';
  dbms_lob.write(clob_updated, write_amount, write_offset, buffer);

  read_amount := 10;
  dbms_lob.read(clob_updated, read_amount, read_offset, buffer);
  dbms_output.put_line('clob_updated value: ' || buffer);
  -- Produces the output 'abcdefg'
  -- note that clob_copied does not see the write made before
  -- clob_updated

  -- At time t4:
  read_amount := 10;
  dbms_lob.read(clob_copied, read_amount, read_offset, buffer);
  dbms_output.put_line('clob_copied value: ' || buffer);
  -- Produces the output 'abcd'

  -- At time t5:
  -- the insert uses clob_copied view of the LOB value which does
  -- not include clob_updated changes
  INSERT INTO PRINT_MEDIA VALUES (2056, 20022, EMPTY_BLOB(),
    clob_copied, EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL)
    RETURNING ad_sourcetext INTO clob_selected;
```

```
    read_amount := 10;
    dbms_lob.read(clob_selected, read_amount, read_offset, buffer);
    dbms_output.put_line('clob_selected value: ' || buffer);
    -- Produces the output 'abcd'
END;
/
```

12.1.7 Example of Deleting a LOB Using Locator

Learn about deleting a LOB with a PL/SQL bind variable in this section.

The following example illustrates that LOB content through a locator selected at a given point of time is available even though the LOB is deleted in the same transaction.

In the following example, using table `print_media`, two CLOBs are created as potential locators:`clob_selected` and `clob_copied`.

Note these progressions in the example at times `t1` through `t3`:

- At the time of the first `SELECT INTO` (at `t1`), the value in`ad_sourcetext` for `ad_id` value 20020 is associated with the locator `clob_selected`. The value in `ad_sourcetext` for `ad_id` value 20021 is associated with the locator `clob_copied`.

- The second operation (at `t2`) deletes the row with `ad_id` value 20020. However, a `DBMS_LOB.READ()` of the value through `clob_selected` (at `t1`) reveals that it is a read-consistent locator, continuing to refer to the same value as of the time of its SELECT.

- The third operation (at `t3`), copies the LOB data read through `clob_selected` into the LOB `clob_copied`. `DBMS_LOB.READ()` of the value through `clob_selected` and `clob_copied` are now the same and refer to the same value as of the time of `SELECT` of `clob_selected`.

```
INSERT INTO PRINT_MEDIA VALUES (2056, 20020, EMPTY_BLOB(),
    'abcd', EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL);

INSERT INTO PRINT_MEDIA VALUES (2057, 20021, EMPTY_BLOB(),
    'cdef', EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL);

DECLARE
  clob_selected CLOB;
  clob_copied CLOB;
  buffer VARCHAR2(20);
  read_amount INTEGER := 20;
  read_offset INTEGER := 1;

BEGIN
  -- At time t1:
  SELECT ad_sourcetext INTO clob_selected
      FROM PRINT_MEDIA
      WHERE ad_id = 20020
      FOR UPDATE;

  SELECT ad_sourcetext INTO clob_copied
      FROM PRINT_MEDIA
      WHERE ad_id = 20021
      FOR UPDATE;

  dbms_lob.read(clob_selected, read_amount, read_offset,buffer);
  dbms_output.put_line(buffer);
  -- Produces the output 'abcd'

  dbms_lob.read(clob_copied, read_amount, read_offset,buffer);
```

```
       dbms_output.put_line(buffer);
       -- Produces the output 'cdef'

       -- At time t2: Delete the CLOB associated with clob_selected
       DELETE FROM PRINT_MEDIA WHERE ad_id = 20020;

       dbms_lob.read(clob_selected, read_amount, read_offset,buffer);
       dbms_output.put_line(buffer);
       -- Produces the output 'abcd'

       -- At time t3:
       -- Copy using clob_selected
       dbms_lob.copy(clob_copied, clob_selected, 4000, 1, 1);
       dbms_lob.read(clob_copied, read_amount, read_offset,buffer);
       dbms_output.put_line(buffer);
       -- Produces the output 'abcd'

END;
/
```

12.1.8 Ensuring Read Consistency

This script in this section can be used to ensure that hot backups can be taken of tables that have `NOLOGGING` or `FILESYSTEM_LIKE_LOGGING` LOBs and have a known recovery point without read inconsistencies.

```
ALTER DATABASE FORCE LOGGING;
SELECT CHECKPOINT_CHANGE# FROM V$DATABASE;   --Start SCN
```

SCN (System Change Number) is a stamp that defines a version of the database at the time that a transaction is committed.

Perform the backup.

Run the next script:

```
ALTER SYSTEM CHECKPOINT GLOBAL;
SELECT CHECKPOINT_CHANGE# FROM V$DATABASE;   --End SCN
ALTER DATABASE NO FORCE LOGGING;
```

Back up the archive logs generated by the database. At the minimum, archive logs between start SCN and end SCN (including both SCN points) must be backed up.

To restore to a point with no read inconsistency, restore to end SCN as your incomplete recovery point. If recovery is done to an SCN after end SCN, there can be read inconsistency in the `NOLOGGING` LOBs.

For SecureFiles, if a read inconsistency is found during media recovery, the database treats the inconsistent blocks as holes and fills `BLOB`s with `0`'s and `CLOB`s with fill characters.

12.2 LOB Locators and Transaction Boundaries

LOB locators can be used in both transactions as well as transaction IDs.

*   About LOB Locators and Transaction Boundaries
    Learn about LOB locators and transaction boundaries in this section.

- **Read and Write Operations on a LOB Using Locators**
  You can always read LOB data using the locator irrespective of whether or not the locator contains a transaction ID. Learn about various aspects of it in this section.

- **Selecting the Locator Outside of the Transaction Boundary**
  This section has two scenarios that describe techniques for using locators in non-serializable transactions when the locator is selected outside of a transaction.

- **Selecting the Locator Within a Transaction Boundary**
  This section has two scenarios that describe techniques for using locators in non-serializable transactions when the locator is selected within a transaction.

- **LOB Locators Cannot Span Transactions**
  LOB locators that are used to write data cannot span transactions. However, the locator can be used to read the LOB value unless you are in a serializable transaction.

- **Example of Locator Not Spanning a Transaction**
  The example of locator not spanning a transaction uses the `print_media` table.

> ✎ **See Also:**
>
> Locator Interface for LOBs for more information about LOB locators

12.2.1 About LOB Locators and Transaction Boundaries

Learn about LOB locators and transaction boundaries in this section.

Note the following regarding LOB locators and transactions:

- Locators contain transaction IDs when:

  You Begin the Transaction, Then Select Locator: If you begin a transaction and subsequently select a locator, then the locator contains the transaction ID. Note that you can implicitly be in a transaction without explicitly beginning one. For example, `SELECT`... `FOR UPDATE` implicitly begins a transaction. In such a case, the locator contains a transaction ID.

- Locators Do Not Contain Transaction IDs When...

  - You are Outside the Transaction, Then Select Locator: By contrast, if you select a locator outside of a transaction, then the locator does not contain a transaction ID.

  - When Selected Prior to DML Statement Execution: A transaction ID is not assigned until the first DML statement executes. Therefore, locators that are selected prior to such a DML statement do not contain a transaction ID.

12.2.2 Read and Write Operations on a LOB Using Locators

You can always read LOB data using the locator irrespective of whether or not the locator contains a transaction ID. Learn about various aspects of it in this section.

- Cannot Write Using Locator:

  If the locator contains a transaction ID, then you cannot write to the LOB outside of that particular transaction.

- Can Write Using Locator:

If the locator *does not* contain a transaction ID, then you can write to the LOB after beginning a transaction either explicitly or implicitly.

- Cannot Read or Write Using Locator With Serializable Transactions:

  If the locator contains a transaction ID of an older transaction, and the current transaction is serializable, then you cannot read or write using that locator.

- Can Read, Not Write Using Locator With Non-Serializable Transactions:

  If the transaction is non-serializable, then you can read, but not write outside of that transaction.

The examples Selecting the Locator Outside of the Transaction Boundary, Selecting the Locator Within a Transaction Boundary, LOB Locators Cannot Span Transactions, and Example of Locator Not Spanning a Transaction show the relationship between locators and *non-serializable* transactions

12.2.3 Selecting the Locator Outside of the Transaction Boundary

This section has two scenarios that describe techniques for using locators in non-serializable transactions when the locator is selected outside of a transaction.

First Scenario:

1. Select the locator with no current transaction. At this point, the locator does not contain a transaction id.
2. Begin the transaction.
3. Use the locator to read data from the LOB.
4. Commit or rollback the transaction.
5. Use the locator to read data from the LOB.
6. Begin a transaction. The locator does not contain a transaction id.
7. Use the locator to write data to the LOB. This operation is valid because the locator did not contain a transaction id prior to the write. After this call, the locator contains a transaction id.

Second Scenario:

1. Select the locator with no current transaction. At this point, the locator does not contain a transaction id.
2. Begin the transaction. The locator does not contain a transaction id.
3. Use the locator to read data from the LOB. The locator does not contain a transaction id.
4. Use the locator to write data to the LOB. This operation is valid because the locator did not contain a transaction id prior to the write. After this call, the locator contains a transaction id. You can continue to read from or write to the LOB.
5. Commit or rollback the transaction. The locator continues to contain the transaction id.
6. Use the locator to read data from the LOB. This is a valid operation.
7. Begin a transaction. The locator contains the previous transaction id.
8. Use the locator to write data to the LOB. This write operation fails because the locator does not contain the transaction id that matches the current transaction.

12.2.4 Selecting the Locator Within a Transaction Boundary

This section has two scenarios that describe techniques for using locators in non-serializable transactions when the locator is selected within a transaction.

First Scenario:

1. Select the locator within a transaction. At this point, the locator contains the transaction id.

2. Begin the transaction. The locator contains the previous transaction id.

3. Use the locator to read data from the LOB. This operation is valid even though the transaction id in the locator does not match the current transaction.

> ✎ **See Also:**
>
> "Read-Consistent Locators" for more information about using the locator to read LOB data.

4. Use the locator to write data to the LOB. This operation fails because the transaction id in the locator does not match the current transaction.

Second Scenario:

1. Begin a transaction.

2. Select the locator. The locator contains the transaction id because it was selected within a transaction.

3. Use the locator to read from or write to the LOB. These operations are valid.

4. Commit or rollback the transaction. The locator continues to contain the transaction id.

5. Use the locator to read data from the LOB. This operation is valid even though there is a transaction id in the locator and the transaction was previously committed or rolled back.

6. Use the locator to write data to the LOB. This operation fails because the transaction id in the locator is for a transaction that was previously committed or rolled back.

12.2.5 LOB Locators Cannot Span Transactions

LOB locators that are used to write data cannot span transactions. However, the locator can be used to read the LOB value unless you are in a serializable transaction.

Modifying a persistent LOB value through the LOB locator using `DBMS_LOB`, OCI, or SQL `INSERT` or `UPDATE` statements changes the locator from a read-consistent locator to an updated locator.

The `INSERT` or `UPDATE` statement automatically starts a transaction and locks the row. Once this has occurred, the locator cannot be used outside the current transaction to modify the LOB value. In other words, LOB locators that are used to write data cannot span transactions. However, the locator can be used to read the LOB value unless you are in a serializable transaction.

In the following code example, a `CLOB` locator called `clob_updated` is created and following operations are performed:

- At the time of the first SELECT INTO (at t1), the value in ad_sourcetext is associated with the locator clob_updated.

- The second operation (at t2), uses the DBMS_LOB.WRITE function to alter the value in clob_updated, and a DBMS_LOB.READ reveals a new value.

- The commit statement (at t3) ends the current transaction.

- Therefore (at t4), the subsequent DBMS_LOB.WRITE operation fails because the clob_updated locator refers to a different (already committed) transaction. This is noted by the error returned. You must re-select the LOB locator before using it in further DBMS_LOB (and OCI) modify operations.

12.2.6 Example of Locator Not Spanning a Transaction

The example of locator not spanning a transaction uses the print_media table.

```
INSERT INTO PRINT_MEDIA VALUES (2056, 20010, EMPTY_BLOB(),
    'abcd', EMPTY_CLOB(), EMPTY_CLOB(), NULL, NULL, NULL, NULL);

COMMIT;

DECLARE
  num_var          INTEGER;
  clob_updated     CLOB;
  read_amount      INTEGER;
  read_offset      INTEGER;
  write_amount     INTEGER;
  write_offset     INTEGER;
  buffer           VARCHAR2(20);

BEGIN
        -- At time t1:
    SELECT      ad_sourcetext
    INTO        clob_updated
    FROM        PRINT_MEDIA
    WHERE       ad_id = 20010
    FOR UPDATE;
    read_amount := 10;
    read_offset := 1;
    dbms_lob.read(clob_updated, read_amount, read_offset, buffer);
    dbms_output.put_line('clob_updated value: ' || buffer);
    -- This produces the output 'abcd'

    -- At time t2:
    write_amount := 3;
    write_offset := 5;
    buffer := 'efg';
    dbms_lob.write(clob_updated, write_amount, write_offset, buffer);
    read_amount := 10;
    dbms_lob.read(clob_updated, read_amount, read_offset, buffer);
    dbms_output.put_line('clob_updated value: ' || buffer);
    -- This produces the output 'abcdefg'

    -- At time t3:
    COMMIT;

    -- At time t4:
    dbms_lob.write(clob_updated , write_amount, write_offset, buffer);
    -- ERROR: ORA-22990: LOB locators cannot span transactions
```

```
        END;
        /
```

12.3 LOBs in the Object Cache

When you copy one object to another in the object cache with a LOB locator attribute, only the LOB locator is copied.

This means that the LOB attribute in these two different objects contain exactly the same locator that refers to *one and the same* LOB *value*. Only when you flush the target LOB, a separate physical copy of the LOB value is made, which is distinct from the source LOB value.

> **✎ See Also:**
>
> Example of Updating LOBs and Read-Consistency for a description of what version of the LOB value is seen by each object if a write operation is performed through one of the locators.

Therefore, in cases where you want to modify the LOB that was the target of the copy, *you must flush the target object, refresh the target object, and then* write to the LOB through the locator attribute.

Consider the following object cache issues for LOB and BFILE attributes:

- Persistent LOB attributes: Creating an object in the object cache, sets the LOB attribute to empty.

  When you create an object in the object cache that contains a persistent LOB attribute, the LOB attribute is implicitly set to empty. You may not use this empty LOB locator to write data to the LOB. You must first flush the object, thereby inserting a row into the table and creating an empty LOB, that is, a LOB with zero (0) length. Once you refresh the object in the object cache, using the `OCI_PIN_LATEST` function, the real LOB locator is read into the attribute, and you can then call the OCI LOB APIs to write data to the LOB.

- `BFILE` attributes: Creating an object in the object cache, sets the `BFILE` attribute to `NULL`.

  When creating an object with a `BFILE` attribute, the `BFILE` is set to `NULL`. You must update it with a valid `DIRECTORY` object name and file name before reading from the `BFILE`.

12.4 Guidelines for Creating Terabyte sized LOBs

To create terabyte LOBs in supported environments, use the following guidelines to make use of all available space in the tablespace for LOB storage.

- Single Data File Size Restrictions:

  There are restrictions on the size of a single data file for each operating system. Hence, add more data files to the tablespace when the LOB grows larger than the maximum allowed file size of the operating system on which your Oracle Database runs.

- Set MAXEXTENTS to a Suitable Value or UNLIMITED:

  The `MAXEXTENTS` parameter limits the number of extents allowed for the LOB column. A large number of extents are created incrementally as the LOB size grows. Therefore, the parameter should be set to a value that is large enough to hold all the LOBs for the column. Alternatively, you could set it to `UNLIMITED`.

- Use a Large Extent Size:

  For every new extent created, Oracle generates undo information for the header and other metadata for the extent. If the number of extents is large, then the rollback segment can be saturated. To get around this, choose a large extent size, say 100 megabytes, to reduce the frequency of extent creation, or commit the transaction more often to reuse the space in the rollback segment.

- Creating a Tablespace and Table to Store Terabyte LOBs
  The following example illustrates how to create a tablespace and table to store terabyte LOBs.

12.4.1 Creating a Tablespace and Table to Store Terabyte LOBs

The following example illustrates how to create a tablespace and table to store terabyte LOBs.

```
CREATE TABLESPACE lobtbs1 DATAFILE '/your/own/data/directory/lobtbs_1.dat'
SIZE 2000M REUSE ONLINE NOLOGGING DEFAULT STORAGE (MAXEXTENTS UNLIMITED);
ALTER TABLESPACE lobtbs1 ADD DATAFILE
'/your/own/data/directory/lobtbs_2.dat' SIZE 2000M REUSE;

CREATE TABLE print_media_backup
   (product_id NUMBER(6),
    ad_id NUMBER(6),
    ad_composite BLOB,
    ad_sourcetext CLOB,
    ad_finaltext CLOB,
    ad_fltextn NCLOB,
    ad_textdocs_ntab textdoc_tab,
    ad_photo BLOB,
    ad_graphic BLOB,
    ad_header adheader_typ)
   NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab5
   LOB(ad_sourcetext) STORE AS (TABLESPACE lobtbs1 CHUNK 32768 PCTVERSION 0
                                   NOCACHE NOLOGGING
                                   STORAGE(INITIAL 1000M NEXT 1000M MAXEXTENTS
                                   UNLIMITED));
```

13

Managing LOBs: Database Administration

You must perform various administrative tasks to set up, maintain, and use a database that contains LOBs.

> **Note:**
>
> LOBs are not supported when the Container Database root and Pluggable Databases are in different character sets. For more information, refer to Relocating a PDB Using CREATE PLUGGABLE DATABASE.

- Initialization Parameter for SecureFiles LOBs
  As a database administrator, you can configure the conditions that control or allow creation of SecureFiles LOBs or BasicFiles LOBs. Typically, you set up the `DB_SECUREFILE` parameter in the `init.ora` file for this purpose.

- Database Character Set Considerations
  The database character set cannot be changed from a single-byte to a multibyte character set if there are populated user-defined `CLOB` columns in the database tables.

- Database Utilities for Loading Data into LOBs
  Certain utilities are recommended for bulk loading data into LOB columns as part of the database set up or maintenance tasks.

- LOB Migration with Data Pump

- BFILEs Management
  This section describes various administrative tasks to manage databases that contain `BFILE`s.

- Managing LOB Signatures
  This section describes how to configure LOB signatures.

13.4 LOB Migration with Data Pump

See Migrating LOBs with Data Pump.

13.1 Initialization Parameter for SecureFiles LOBs

As a database administrator, you can configure the conditions that control or allow creation of SecureFiles LOBs or BasicFiles LOBs. Typically, you set up the `DB_SECUREFILE` parameter in the `init.ora` file for this purpose.

The `DB_SECUREFILE` initialization parameter is dynamic and can be modified with the `ALTER SYSTEM` statement in the following way:

```
ALTER SYSTEM SET DB_SECUREFILE = 'ALWAYS';
```

The valid values for this parameter are described in the following table:

Value	Description
NEVER	Prevents SecureFiles LOBs from being created. If NEVER is specified, then any LOBs that are specified as SecureFiles LOBs are created as BasicFiles LOBs. If storage options are not specified, then the BasicFiles LOB defaults are used. All SecureFiles LOB-specific storage options and features such as compress, encrypt, and deduplicate throw an exception.
IGNORE	Always create BasicFile LOBs, and ignore any errors that the SecureFile LOB options might cause. If IGNORE is specified, then the SECUREFILE keyword and all SecureFiles LOB options are ignored.
PERMITTED	Allows SecureFiles LOBs to be created, if specified by users. Otherwise, BasicFiles LOBs are created.
PREFERRED(default)	Attempts to create a SecureFiles LOB unless BasicFiles LOB is explicitly specified for the LOB or the parent LOB (if the LOB is in a partition or sub-partition).
ALWAYS	Attempts to create SecureFiles LOBs, but creates any LOBs not in ASSM tablespaces as BasicFiles LOBs, unless the SECUREFILE parameter is explicitly specified. Any BasicFiles LOB storage options specified are ignored, and the SecureFiles LOB defaults are used for all storage options not specified.
FORCE	Attempts to create all LOBs as SecureFiles LOBs even if users specify BASICFILE. This option is not recommended. Instead, PREFERRED or ALWAYS should be used.

13.2 Database Character Set Considerations

The database character set cannot be changed from a single-byte to a multibyte character set if there are populated user-defined CLOB columns in the database tables.

The national character set cannot be changed between AL16UTF16 and UTF8 if there are populated user-defined NCLOB columns in the database tables.

> ✎ **See Also:**
>
> Choosing a Character Set

13.3 Database Utilities for Loading Data into LOBs

Certain utilities are recommended for bulk loading data into LOB columns as part of the database set up or maintenance tasks.

The following utilities are recommended for bulk loading data into LOB columns as part of database setup or maintenance tasks:

- SQL*Loader

- External Tables

- Oracle Data Pump

- Loading LOBs with SQL*Loader
  Learn about conventional and direct-path loads, when Oracle recommends that you use direct-path loads, and what rules and guidelines you should follow to avoid issues.

- Loading BFILEs with SQL*Loader
  This section describes how to load data from files in the file system into a `BFILE` column using SQL*Loader.

- Loading LOBs with External Tables
  External tables are particularly useful for loading large numbers of records from a single file, so that each record appears in its own row in the table.

13.3.1 Loading LOBs with SQL*Loader

Learn about conventional and direct-path loads, when Oracle recommends that you use direct-path loads, and what rules and guidelines you should follow to avoid issues.

There are two options for loading large object (LOB) data:

A **conventional path load** executes SQL `INSERT` statements to populate tables in an Oracle Database.

A **direct-path load** eliminates much of the Oracle Database overhead by formatting Oracle data blocks, and writing the data blocks directly to the database files. Additionally, a direct-path load does not compete with other users for database resources, so it can usually load data at near disk speed. Be aware that there are also other restrictions, security, and backup implications for direct path loads, which you should review.

For each of these options of loading large object data (LOBs), you can use the following techniques to load data into LOBs:

- Loading LOB data from primary data files.

  When you load data from a primary data file, the data for the LOB column is part of the record in the file that you are loading.

- Loading LOB data from a secondary data file using LOB files.

  When you load data from a secondary data file, the data for a LOB column is in a different file from the primary data file. Instead of the data itself, the primary data file contains information about the location of the content of the LOB data in other files.

Recommendations for Using SQL*Loader to Load LOBs

Oracle recommends that you keep the following guidelines and rules in mind when loading LOBs using SQL*Loader:

- Tables that you want to load must already exist in the database. SQL*Loader never creates tables. It loads existing tables that either contain data, or are empty.

- When you load data from LOB files, specify the maximum length of the field corresponding to a LOB-type column. If the maximum length is specified, then SQL*Loader uses this length as a hint to help optimize memory usage. You should ensure that the maximum length you specify does not underestimate the true maximum length.

- If you use conventional path loads, then be aware that failure to load a particular LOB does not result in the rejection of the record containing that LOB; instead, the record ends up containing an empty LOB.

- If you use direct-path loads, then be aware that loading LOBs can take up substantial memory. If the message `SQL*Loader 700 (out of memory)` appears when loading LOBs, then internal code is probably batching up more rows in each load call than can be supported by your operating system and process memory. One way to work around this problem is to use the `ROWS` option to read a smaller number of rows in each data save.

  Only use direct path loads to load XML documents that are known to be valid into XMLtype columns that are stored as CLOBS. Direct path load does not validate the format of XML documents as the are loaded as CLOBs.

  With direct-path loads, errors can be critical. In direct-path loads, the LOB could be **empty** or **truncated**. LOBs are sent in pieces to the server for loading. If there is an error, then the LOB piece with the error is discarded and the rest of that LOB is not loaded. As a result, if the entire LOB with the error is contained in the first piece, then that LOB column is either empty or truncated.

  You can also use the Direct Path API to load LOBs.

Privileges Required for Using SQL*Loader to Load LOBs

The following privileges are required for using SQL*Loader to load LOBs:

- You must have `INSERT` privileges on the table that you want to load.

- You must have `DELETE` privileges on the table that you want to load, if you want to use the `REPLACE` or `TRUNCATE` option to empty out the old data before loading the new data in its place.

Example 13-1   Loading LOB from a primary data file using Delimited Fields

Review this example to see how to load LOB data in delimited fields. Note the callouts "1" and "2" in **bold**:

Control File Contents

```
LOAD DATA
INFILE 'sample.dat' "str '|'"
INTO TABLE person_table
FIELDS TERMINATED BY ','
   (name        CHAR(25),
1  "RESUME"     CHAR(507) ENCLOSED BY '<startlob>' AND '<endlob>')
```

Data File (`sample.dat`)

```
Julia Nayer,<startlob>      Julia Nayer
                            500 Example Parkway
                            jnayer@example.com ...   <endlob>
2  |Bruce Ernst, .......
```

> **✎ Note:**
>
> The callouts, in bold, to the left of the example correspond to the following notes:
>
> 1. `<startlob>` and `<endlob>` are the enclosure strings. With the default byte-length semantics, the maximum length for a LOB that can be read using `CHAR(507)` is 507 bytes. If character-length semantics were used, then the maximum would be 507 characters. For more information, refer to character-length semantics.
>
> 2. If the record separator '`|`' had been placed right after `<endlob>` and followed with the newline character, then the newline would have been interpreted as part of the next record. An alternative would be to make the newline part of the record separator (for example, '`|\n`' or, in hexadecimal notation, `X'7C0A'`).

Example 13-2   Loading a LOB from secondary data file, using Delimited Fields:

In this example, note the callout "1" in **bold**:

Control File Contents

```
LOAD DATA
INFILE 'sample.dat'
INTO TABLE person_table
FIELDS TERMINATED BY ','
   (name      CHAR(20),
1  "RESUME"    LOBFILE( CONSTANT 'jqresume') CHAR(2000)
               TERMINATED BY "<endlob>\n")
```

Data File (sample.dat)

```
Johny Quest,
Speed Racer,
```

Secondary Data File (jqresume.txt)

```
        Johny Quest
    500 Oracle Parkway
       ... <endlob>
        Speed Racer
    400 Oracle Parkway
       ... <endlob>
```

> **Note:**
>
> The callout, in bold, to the left of the example corresponds to the following note:
>
> **1.** Because a maximum length of 2000 is specified for CHAR, SQL*Loader knows what to expect as the maximum length of the field, which can result in memory usage optimization. *If you choose to specify a maximum length, then you should be sure not to underestimate its value.* The TERMINATED BY clause specifies the string that terminates the LOBs. Alternatively, you can use the ENCLOSED BY clause. The ENCLOSED BY clause allows a bit more flexibility with the relative positioning of the LOBs in the LOBFILE, because the LOBs in the LOBFILE do not need to be sequential.

13.3.2 Loading BFILEs with SQL*Loader

This section describes how to load data from files in the file system into a BFILE column using SQL*Loader.

> **Note:**
>
> - The BFILE data type stores unstructured binary data in operating system files outside the database. A BFILE column or attribute stores a file locator that points to a server-side external file containing the data.
>
> - A particular file to be loaded as a BFILE does not have to actually exist at the time of loading. SQL*Loader assumes that the necessary DIRECTORY objects have been created.

> **See Also:**
>
> DIRECTORY Objects for more information

A control file field corresponding to a BFILE column consists of the column name followed by the BFILE directive.

The BFILE directive takes as arguments a DIRECTORY object name followed by a BFILE name. Both of these can be provided as string constants, or they can be dynamically sourced through some other field.

> **See Also:**
>
> *Oracle Database Utilities* for details on SQL*Loader syntax

The following two examples illustrate the loading of BFILEs.

> **Note:**
>
> You need to set up the following data structures for certain examples to work:
>
> ```
> CONNECT pm/pm
> CREATE OR REPLACE DIRECTORY adgraphic_photo as '/tmp';
> CREATE OR REPLACE DIRECTORY adgraphic_dir as '/tmp';
> ```

In the following example, only the file name is specified dynamically. The directory name, adgraphic_photo, is in quotation marks. Therefore, the string is used as is, and is not capitalized.

Control file:

```
LOAD DATA
INFILE sample9.dat
INTO TABLE Print_media
FIELDS TERMINATED BY ','
(product_id  INTEGER EXTERNAL(6),
 FileName    FILLER CHAR(30),
 ad_graphic  BFILE(CONSTANT "adgraphic_photo", FileName))
```

Data file:

```
007, modem_2268.jpg,
008, monitor_3060.jpg,
009, keyboard_2056.jpg,
```

In the following example, the BFILE and the DIRECTORY objects are specified dynamically.

Control file:

```
LOAD DATA
INFILE sample10.dat
INTO TABLE Print_media
FIELDS TERMINATED BY ','
(
 product_id INTEGER EXTERNAL(6),
 ad_graphic BFILE (DirName, FileName),
 FileName  FILLER CHAR(30),
 DirName   FILLER CHAR(30)
)
```

Data file:

```
007,monitor_3060.jpg,ADGRAPHIC_PHOTO,
008,modem_2268.jpg,ADGRAPHIC_PHOTO,
009,keyboard_2056.jpg,ADGRAPHIC_DIR,
```

13.3.3 Loading LOBs with External Tables

External tables are particularly useful for loading large numbers of records from a single file, so that each record appears in its own row in the table.

> **Note:**
>
> Loading LOBs with External Tables

- Overview of LOBs and External Tables
  Learn the benefits of using external tables with your database to read and write data, and to understand how to create them.

13.3.3.1 Overview of LOBs and External Tables

Learn the benefits of using external tables with your database to read and write data, and to understand how to create them.

External tables enable you to treat the contents of external files as if they are rows in a table in your Oracle Database. After you create an external table, you can then use SQL statements to read rows from the external table, and insert them into another table.

To perform these operations, Oracle Database uses one of the following access drivers:

- The `ORACLE_LOADER` access driver reads text files and other file formats, similar to SQL Loader.

- The `ORACLE_DATAPUMP` access driver creates binary files that store data returned by a query. It also returns rows from files in binary format.

When you create an external table, you specify column and data types for the external table. The access driver has a list of columns in the data file, and maps the contents of the field in the data file to the column with the same name in the external table. The access driver takes care of finding the fields in the data source, and converting these fields to the appropriate data type for the corresponding column in the external table. After you create an external table, you can load the target table by using an `INSERT AS SELECT` statement.

One of the advantages of using external tables to load data over SQL Loader is that external tables can load data in parallel. The easiest way to do this is to specify the `PARALLEL` clause as part of `CREATE TABLE` for both the external table and the target table.

Example 13-3

This example creates a table, `CANDIDATE`, that can be loaded by an external table. When it is loaded, it then creates an external table, `CANDIDATE_XT`. Next, it executes an `INSERT` statement to load the table. The `INSERT` statement includes the `+APPEND` hint, which uses direct load to insert the rows into the table `CANDIDATES`. The `PARALLEL` parameter tells SQL that the tables can be accessed in parallel.

The `PARALLEL` parameter setting specifies that there can be four (`4`) parallel query processes reading from `CANDIDATE_XT`, and four parallel processes inserting into `CANDIDATE`. Note that LOBs that are stored as `BASICFILE` cannot be loaded in parallel. You can only load `SECUREFILE` LOBS in parallel. The variable *additional-external-table-info* indicates where additional external table information can be inserted.

```
CREATE TABLE CANDIDATES

  (candidate_id        NUMBER,

   first_name          VARCHAR2(15),
```

```
    last_name           VARCHAR2(20),

    resume              CLOB,

    picture             BLOB

  ) PARALLEL 4;

CREATE TABLE CANDIDATE_XT

  (candidate_id         NUMBER,

   first_name           VARCHAR2(15),

   last_name            VARCHAR2(20),

   resume               CLOB,

   picture              BLOB

  ) PARALLEL 4;

ORGANIZATION EXTERNAL additional-external-table-info PARALLEL 4;

INSERT /*+APPEND*/ INTO CANDIDATE SELECT * FROM CANDIDATE_XT;
```

File Locations for External Tables Created By Access Drivers

All files created or read by `ORACLE_LOADER` and `ORACLE_DATAPUMP` reside in directories pointed to by directory objects. Either the DBA or a user with the `CREATE DIRECTORY` privilege can create a directory object that maps a new to a path on the file system. These users can grant `READ`, `WRITE` or `EXECUTE` privileges on the created directory object to other users. A user granted `READ` privilege on a directory object can use external tables to read files from directory for the directory object. Similarly, a user with `WRITE` privilege on a directory object can use external tables to write files to the directory for the directory object.

Example 13-4   Creating Directory Object

The following example shows how to create a directory object and grant `READ` and `WRITE` access to user `HR`:

```
create directory HR_DIR as /usr/hr/files/exttab;

grant read, write on directory HR_DIR to HR;
```

> **Note:**
>
> When using external tables in an Oracle Real Application Clusters (Oracle RAC) environment, you must make sure that the directory pointed to by the directory object maps to a directory that is accessible from all nodes.

ORACLE

13.5 BFILEs Management

This section describes various administrative tasks to manage databases that contain `BFILE`s.

- **Guidelines for DIRECTORY Usage**
  Learn about the guidelines for efficient management of `DIRECTORY` objects.

- **Rules for Using Directory Objects and BFILEs**
  You can create a directory object or `BFILE` objects if these conditions are met.

- **Setting Maximum Number of Open BFILEs**
  Only limited number of `BFILE`s can be open simultaneously in each session. Learn to define this number in this section.

13.5.1 Guidelines for DIRECTORY Usage

Learn about the guidelines for efficient management of `DIRECTORY` objects.

The main goal of the `DIRECTORY` feature is to enable a simple, flexible, non-intrusive, yet secure mechanism for the DBA to manage access to large files in the server file system. But to realize this goal, it is very important that the DBA follow these guidelines when using `DIRECTORY` objects:

- Do not map a `DIRECTORY` object to a data file directory. A `DIRECTORY` object should not be mapped to physical directories that contain Oracle data files, control files, log files, and other system files. Tampering with these files (accidental or otherwise) could corrupt the database or the server operating system.

- Only the DBA should have system privileges. The system privileges such as `CREATE ANY DIRECTORY` or `DROP ANY DIRECTORY`(granted to the DBA initially) should be used carefully and not granted to other users indiscriminately. In most cases, only the database administrator should have these privileges.

- Use caution when granting the DIRECTORY privilege. Privileges on `DIRECTORY` objects should be granted to different users carefully. The same holds for the use of the `WITH GRANT OPTION` clause when granting privileges to users.

- Do not drop or replace `DIRECTORY` objects when database is in operation. If this were to happen, then operations *from all sessions* on all files associated with this `DIRECTORY` object fail. Further, if a `DROP` or `REPLACE` command is executed before these files could be successfully closed, then the references to these files are lost in the programs, and system resources associated with these files are not be released until the session(s) is shut down.

  The only recourse left to PL/SQL users, for example, is to either run a program block that calls `DBMS_LOB.FILECLOSEALL` and restart their file operations, or exit their sessions altogether. Hence, it is imperative that you use these commands with prudence, and preferably during maintenance downtimes.

- Use caution when revoking a user's privilege on `DIRECTORY` objects. Revoking a user's privilege on a `DIRECTORY` object using the `REVOKE` statement causes all subsequent operations on dependent files from the user's session to fail. The user must either re-acquire the privileges to close the file, or run a `FILECLOSEALL` in the session and restart the file operations.

In general, using `DIRECTORY` objects for managing file access is an extension of system administration work at the operating system level. With some planning, files can be logically organized into suitable directories that have READ privileges for the Oracle process.

`DIRECTORY` objects can be created with `READ` privileges that map to these physical directories, and specific database users granted access to these directories.

> **See Also:**
>
> Security on Directory Objects

13.5.2 Rules for Using Directory Objects and BFILEs

You can create a directory object or `BFILE` objects if these conditions are met.

When you create a directory object or `BFILE` objects, ensure that the following conditions are met:

- The operating system file must not be a symbolic or hard link.
- The operating system directory path named in the Oracle DIRECTORY object must be an existing operating system directory path.
- The operating system directory path named in the Oracle DIRECTORY object should not contain any symbolic links in its components.

13.5.3 Setting Maximum Number of Open BFILEs

Only limited number of `BFILE`s can be open simultaneously in each session. Learn to define this number in this section.

The initialization parameter, `SESSION_MAX_OPEN_FILES`, defines an upper limit on the number of simultaneously open files in a session.

The default value for this parameter is 10. Using this default, you can open a maximum of 10 files at the same time in each session. To alter this limit, the database administrator must change the parameter value in the `init.ora` file**. For example:

```
SESSION_MAX_OPEN_FILES=20
```

If the number of unclosed files reaches the `SESSION_MAX_OPEN_FILES` value, then you cannot open additional files in the session. To close all open files, use the `DBMS_LOB.FILECLOSEALL` call.

> **See Also:**
>
> DIRECTORY Objects

13.6 Managing LOB Signatures

This section describes how to configure LOB signatures.

You can configure signature-based security for large object (`LOB`) locators using the `LOB_SIGNATURE_ENABLE` initialization parameter.

- To enable signature, set the `LOB_SIGNATURE_ENABLE` initialization parameter at `init.ora`, or using the following `ALTER SYSTEM` command. Also ensure that you have set the compatibility to 12.2.0.2 or above.

  ```
  ALTER SYSTEM SET LOB_SIGNATURE_ENABLE = [TRUE|FALSE];
  ```

- The following `ALTER` statement helps to encrypt, re-key, and delete the signature keys.

  ```
  ALTER DATABASE DICTIONARY [ENCRYPT|REKEY|DELETE] CREDENTIALS;
  ```

For more information, refer to the Oracle Database Security Guide.

Migrating Columns to SecureFile LOBs

Oracle recommends that you migrate your existing columns that use the LONG or LONG RAW datatype or BasicFile LOB storage to the SecureFile LOB storage. This chapter covers various techniques to help with this migration.

> **✎ Note:**
>
> All discussions in this chapter are valid for migrating the `LONG` datatype to `CLOB` or `NCLOB`, and the `LONG RAW` datatype to `BLOB`. Most of the text in this chapter talks just about the `LONG` datatype for brevity.

- **Migration Considerations**
  This section discusses various factors to be considered while migrating LOB data types or storage.
- **Migration Methods**
  This section describes various methods you can use to migrate LONG or BasicFile LOB data to SecureFile storage.
- **Other Considerations While Migrating LONG Columns to LOBs**
  This section describes some more considerations when migrating LONG columns to LOBs.

14.1 Migration Considerations

This section discusses various factors to be considered while migrating LOB data types or storage.

Space requirements

Most migration techniques copy the contents of the table into a new space, and free the old space at the end of the operation. This temporarily doubles the space requirements. If space is limited, then you can perform the BasicFile to SecureFile migration one partition at a time.

Preventing Generation of REDO Data When Migrating

Migrating `LONG` datatype or BasicFiles LOB columns to SecureFile generates redo data, which can slow down the performance during the migration.

Redo changes for a column being converted to SecureFiles LOB are logged only if the storage characteristics of the LOB column indicate `LOGGING`. The logging setting (`LOGGING` or `NOLOGGING`) for the LOB column is inherited from the tablespace in which the LOB is created.

You can prevent redo space generation during migration to SecureFiles LOB by following the following steps:

1. Specify the NOLOGGING storage parameter for any new SecureFiles LOB columns.
2. Turn LOGGING on when the migration is complete.

3. Make a backup of the tablespaces containing the table and the LOB column.

14.2 Migration Methods

This section describes various methods you can use to migrate LONG or BasicFile LOB data to SecureFile storage.

- Migrating LOBs with Online Redefinition
  Online redefinition is the recommended method for migrating LONG or BasicFile LOB data to SecureFile storage. While online redefinition for LONG to LOB migration must be performed at the table level, BasicFile to SecureFile migration can be performed at the table or partition level.

- Migrating LOBs with Data Pump
  Oracle Data Pump can either recreate tables as they are in your source database, or recreate LOB columns as SecureFile LOBs.

14.2.1 Migrating LOBs with Online Redefinition

Online redefinition is the recommended method for migrating LONG or BasicFile LOB data to SecureFile storage. While online redefinition for LONG to LOB migration must be performed at the table level, BasicFile to SecureFile migration can be performed at the table or partition level.

Online Redefintion Advantages

- No need not take the table or partition offline

- Can be done in parallel.
  To set up parallel execution of online redefinition, run:

```
ALTER SESSION FORCE PARALLEL DML;
```

Online Redefinition Disadvantages

- Additional storage equal to the entire table or partition required and all LOB segments must be available

- Global indexes must be rebuilt

Example 14-1   Online Redefinition for Migrating Tables from BasicFiles LOB storage to SecureFile LOB storage

```
REM Grant privileges required for online redefinition.
GRANT EXECUTE ON DBMS_REDEFINITION TO pm;
GRANT ALTER ANY TABLE TO pm;
GRANT DROP ANY TABLE TO pm;
GRANT LOCK ANY TABLE TO pm;
GRANT CREATE ANY TABLE TO pm;
GRANT SELECT ANY TABLE TO pm;
REM Privileges required to perform cloning of dependent objects.
GRANT CREATE ANY TRIGGER TO pm;
GRANT CREATE ANY INDEX TO pm;
CONNECT pm/pm

-- This forces the online redefinition to execute in parallel
ALTER SESSION FORCE parallel dml;
```

```
DROP TABLE cust;
CREATE TABLE cust(c_id NUMBER PRIMARY KEY,
    c_zip NUMBER,
    c_name VARCHAR(30) DEFAULT NULL,
    c_lob CLOB
);
INSERT INTO cust VALUES(1, 94065, 'hhh', 'ttt');
-- Creating Interim Table
-- There is no requirement to specify constraints because they are
-- copied over from the original table.
CREATE TABLE cust_int(c_id NUMBER NOT NULL,
    c_zip NUMBER,
    c_name VARCHAR(30) DEFAULT NULL,
    c_lob CLOB
) LOB(c_lob) STORE AS SECUREFILE (NOCACHE FILESYSTEM_LIKE_LOGGING);
DECLARE
    col_mapping VARCHAR2(1000);
BEGIN
-- map all the columns in the interim table to the original table
    col_mapping :=
    'c_id c_id , '||
    'c_zip c_zip , '||
    'c_name c_name, '||
    'c_lob c_lob';
DBMS_REDEFINITION.START_REDEF_TABLE('pm', 'cust', 'cust_int', col_mapping);
END;
/
DECLARE
    error_count pls_integer := 0;
BEGIN
    DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS('pm', 'cust', 'cust_int',
      1, TRUE,TRUE,TRUE,FALSE, error_count);
    DBMS_OUTPUT.PUT_LINE('errors := ' || TO_CHAR(error_count));
END;
/
EXEC DBMS_REDEFINITION.FINISH_REDEF_TABLE('pm', 'cust', 'cust_int');
-- Drop the interim table
DROP TABLE cust_int;
DESC cust;
-- The following insert statement fails. This illustrates
-- that the primary key constraint on the c_id column is
-- preserved after migration.
INSERT INTO cust VALUES(1, 94065, 'hhh', 'ttt');
SELECT * FROM cust;
```

Example 14-2   Online Redefinition for Migrating Tables from the LONG datatype to a SecureFile LOB

The steps for LONG to LOB migration are:

- Create an empty interim table. This table holds the migrated data when the redefinition process is done. In the interim table:

  - Define a CLOB or NCLOB column for each LONG column in the original table that you are migrating.

– Define a `BLOB` column for each `LONG RAW` column in the original table that you are migrating.

• Start the redefinition process. To do so, call `DBMS_REDEFINITION.START_REDEF_TABLE` and pass the column mapping using the `TO_LOB` operator as follows:

```
DBMS_REDEFINITION.START_REDEF_TABLE(
    'schema_name',
    'original_table',
    'interim_table',
    'TO_LOB(long_col_name) lob_col_name',
    'options_flag',
    'orderby_cols');
```

where `long_col_name` is the name of the `LONG` or `LONG RAW` column that you are converting in the original table and `lob_col_name` is the name of the LOB column in the interim table. This LOB column holds the converted data.

• Call the `DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS` procedure as described in the related documentation.

• Call the `DBMS_REDEFINITION.FINISH_REDEF_TABLE` procedure as described in the related documentation.

The following example demonstrates online redefinition for `LONG` to LOB migration.

```
REM Grant privileges required for online redefinition.
GRANT execute ON DBMS_REDEFINITION TO pm;
GRANT ALTER ANY TABLE TO pm;
GRANT DROP ANY TABLE TO pm;
GRANT LOCK ANY TABLE TO pm;
GRANT CREATE ANY TABLE TO pm;
GRANT SELECT ANY TABLE TO pm;

REM Privileges required to perform cloning of dependent objects.
GRANT CREATE ANY TRIGGER TO pm;
GRANT CREATE ANY INDEX TO pm;

CONNECT pm/pm

-- This forces the online redefinition to execute in parallel
ALTER SESSION FORCE parallel dml;

DROP TABLE cust;
CREATE TABLE cust(c_id   NUMBER PRIMARY KEY,
                  c_zip  NUMBER,
                  c_name VARCHAR(30) DEFAULT NULL,
                  c_long LONG
                  );
INSERT INTO cust VALUES(1, 94065, 'hhh', 'ttt');

-- Creating Interim Table
-- There is no requirement to specify constraints because they are
-- copied over from the original table.
CREATE TABLE cust_int(c_id   NUMBER NOT NULL,
                  c_zip   NUMBER,
                  c_name VARCHAR(30) DEFAULT NULL,
```

```
                     c_long CLOB
                     );

DECLARE
 col_mapping VARCHAR2(1000);
BEGIN
--  map all the columns in the interim table to the original table
 col_mapping :=
                'c_id            c_id  , '||
                'c_zip           c_zip , '||
                'c_name          c_name, '||
                'to_lob(c_long)   c_long';

DBMS_REDEFINITION.START_REDEF_TABLE('pm', 'cust', 'cust_int', col_mapping);
END;
/

DECLARE
 error_count PLS_INTEGER := 0;
BEGIN
  DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS('pm', 'cust', 'cust_int',
                                      1, true, true, true, false,
                                      error_count);

  DBMS_OUTPUT.PUT_LINE('errors := ' || to_char(error_count));
END;
/

EXEC  DBMS_REDEFINITION.FINISH_REDEF_TABLE('pm', 'cust', 'cust_int');

-- Drop the interim table
DROP TABLE cust_int;

DESC cust;

-- The following insert statement fails. This illustrates
-- that the primary key constraint on the c_id column is
-- preserved after migration.

INSERT INTO cust VALUES(1, 94065, 'hhh', 'ttt');

SELECT * FROM cust;
```

14.2.2 Migrating LOBs with Data Pump

Oracle Data Pump can either recreate tables as they are in your source database, or recreate LOB columns as SecureFile LOBs.

When Oracle Data Pump recreates tables, by default, it recreates them as they existed in the source database. Therefore, if a LOB column was a BasicFiles LOB in the source database, Oracle Data Pump attempts to recreate it as a BasicFile LOB in the imported database. However, you can force creation of LOBs as SecureFile LOBs in the recreated tables by using a TRANSFORM parameter for the command line, or by using a LOB_STORAGE parameter for the DBMS_DATAPUMP and DBMS_METADATA packages.

Example:

```
impdp system/manager directory=dpump_dir schemas=lobuser dumpfile=lobuser.dmp
    transform=lob_storage:securefile
```

> **Note:**
>
> The transform name is not valid in transportable import.

> **See Also:**
>
> TRANSFORM for using TRANSFORM parameter to convert to SecureFile LOBs

Restrictions on Migrating LOBs with Data Pump

You can't use SecureFile LOBs in non-ASSM tablespace. If the source database contains LOB columns in a tablespace that does not support ASSM, then you'll see an error message when you use Oracle Data Dump to recreate the tables using the securefile clause for LOB columns.

To import non-ASSM tables with LOB columns, run another import for these tables without using `TRANSFORM=LOB_STORAGE:SECUREFILE`.

Example:

```
impdp system/manager directory=dpump_dir schemas=lobuser dumpfile=lobuser.dmp
```

14.3 Other Considerations While Migrating LONG Columns to LOBs

This section describes some more considerations when migrating LONG columns to LOBs.

- Migrating Applications from LONGs to LOBs
  Most APIs that work with `LONG` data types in the PL/SQL, JDBC and OCI environments are enhanced to also work with LOB data types.

- Alternate Methods for LOB Migration
  Online Redefinition is the preferred way for migrating `LONG` data types to LOBs. However, if keeping the application online during the migration is not your primary concern, then you can also use one of the following ways to migrate `LONG` data to LOBs.

14.3.1 Migrating Applications from LONGs to LOBs

Most APIs that work with `LONG` data types in the PL/SQL, JDBC and OCI environments are enhanced to also work with LOB data types.

These APIs are collectively referred to as the data interface for LOBs. Among other things, the data interface provides the following benefits:

- Changes needed are minimal in PL/SQL, JDBC and OCI applications that use tables with columns converted from `LONG` to LOB data types.

- You can work with LOB data types in your application without having to deal with LOB locators.

> **✏️ See Also:**
>
> - Data Interface for LOBs for details on JDBC and OCI APIs included in the data interface.
> - SQL Semantics and LOBs for details on SQL syntax supported for LOB data types.
> - PL/SQL Semantics for LOBs for details on PL/SQL syntax supported for LOB data types.

> **✏️ Note:**
>
> You can use various techniques to do either of the following:
>
> - Convert columns of type `LONG` to either `CLOB` or `NCLOB` columns
> - Convert columns of type `LONG RAW` to `BLOB` type columns
>
> Unless otherwise noted, discussions in this chapter regarding LONG to LOB conversions apply to both of these data type conversions.

However, there are differences between `LONG` and LOB data types that may impact your application migration plans or require you to modify your application.

Identify Application Rewrite Using utldtree.sql

When you migrate your table from `LONG` to LOB column types, certain parts of your PL/SQL application may require rewriting. You can use the utility, `rdbms/admin/utldtree.sql`, to determine which parts.

The `utldtree.sql` utility enables you to recursively see all objects that are dependent on a given object. For example, you can see all objects which depend on a table with a `LONG` column. You can only see objects for which you have permission.

Instructions on how to use `utldtree.sql` are documented in the file itself. Also, `utldtree.sql` is only needed for PL/SQL. For SQL and OCI, you have no requirement to change your applications.

SQL Differences

- Indexes: LONG and LOB data types only support domain and functional indexes.
  - Any domain index on a `LONG` column must be dropped before converting the `LONG` column to LOB column. This index may be manually recreated after the migration.
  - Any function-based index on a `LONG` column is unusable during the conversion process and must be rebuilt after converting. Application code that uses function-based indexing should work without modification after the rebuild.
    To rebuild an index after converting, use the following steps:

1. Select the index from your original table as follows:

```
SELECT index_name FROM user_indexes WHERE table_name='LONG_TAB';
```

> **Note:**
>
> The table name must be capitalized in this query.

2. For each selected index, use the command:

```
ALTER INDEX <index> REBUILD
```

- Constraints: The only constraint allowed on LONG columns are NULL and NOT NULL. All constraints of the LONG columns are maintained for the new LOB columns. To alter the constraints for these columns, or alter any other columns or properties of this table, you have to do so in a subsequent ALTER TABLE statement.

- Default Values: If you do not specify a default value, then the default value for the LONG column becomes the default value of the LOB column.

- Triggers: Most of the existing triggers on your table are still usable. However, you cannot have LOB columns in the UPDATE OF list of an AFTER UPDATE OF trigger. For example, the following create trigger statement is not valid:

```
CREATE TABLE t(lobcol CLOB);
CREATE TRIGGER trig AFTER UPDATE OF lobcol ON t ...;
```

LONG columns are allowed in such triggers. So, you must drop the AFTER UPDATE OF triggers on any LONG columns before migrating to LOBs.

- Clustered tables: LOB columns are not allowed in clustered tables, whereas LONGs are allowed. If a table is a part of a cluster, then any LONG or LONG RAW column cannot be changed to a LOB column.

Empty LOBs Compared to NULL and Zero Length LONGs

A LOB column can hold an *empty* LOB. An empty LOB is a LOB locator that is fully initialized, but not populated with data. Because LONG data types do not use locators, the *empty* concept does not apply to LONG data types.

Both LOB column values and LONG column values, inserted with an initial value of NULL or an empty string literal, have a NULL value. Therefore, application code that uses NULL or zero-length values in a LONG column functions exactly the same after you convert the column to a LOB type column.

In contrast, a LOB initialized to empty has a non-NULL value as illustrated in the following example:

```
CREATE TABLE long_tab(id NUMBER, long_col LONG);
CREATE TABLE lob_tab(id NUMBER, lob_col CLOB);

REM    A zero length string inserts a NULL into the LONG column:
INSERT INTO long_tab values(1, '');

REM    A zero length string inserts a NULL into the LOB column:
```

```
INSERT INTO lob_tab values(1, '');

REM     Inserting an empty LOB inserts a non-NULL value:
INSERT INTO lob_tab values(1, empty_clob());

DROP TABLE long_tab;
DROP TABLE lob_tab;
```

Overloading with Anchored Types

For applications using anchored types, some overloaded variables resolve to different targets during the conversion to LOBs. For example, given the procedure p overloaded with specifications 1 and 2:

```
procedure p(l long) is ...;        -- (specification 1)
procedure p(c clob) is ...;        -- (specification 2)
```

and the procedure call:

```
declare
     var  longtab.longcol%type;
   BEGIN
     ...
   p(var);
     ...
END;
```

Prior to migrating from LONG to LOB columns, this call would resolve to specification 1. Once longtab is migrated to LOB columns this call resolves to specification 2. Note that this would also be true if the parameter type in specification 1 were a CHAR, VARCHAR2, RAW, LONG RAW.

If you have migrated you tables from LONG columns to LOB columns, then you must manually examine your applications and determine whether overloaded procedures must be changed.

Some applications that included overloaded procedures with LOB arguments before migrating may still break. This includes applications that do not use LONG anchored types. For example, given the following specifications (1 and 2) and procedure call for procedure p:

```
procedure p(n number) is ...;      -- (1)
procedure p(c clob) is ...;        -- (2)

p('123');                     -- procedure call
```

Before migrating, the only conversion allowed was CHAR to NUMBER, so specification 1 would be chosen. After migrating, both conversions are allowed, so the call is ambiguous and raises an overloading error.

Some Implicit Conversions Are Not Supported for LOB Data Types

PL/SQL permits implicit conversion from NUMBER, DATE, ROW_ID, BINARY_INTEGER, and PLS_INTEGER data types to a LONG; however, implicit conversion from these data types to a LOB is not allowed.

If your application uses these implicit conversions, then you have to explicitly convert these types using the `TO_CHAR` operator for character data or the `TO_RAW` operator for binary data. For example, if your application has an assignment operation such as:

```
number_var := long_var;   -- The RHS is a LOB variable after converting.
```

then you must modify your code as follows:

```
number_var := TO_CHAR(long_var);
-- Assuming that long_var is of type CLOB after conversion
```

The following conversions are not supported for LOB types:

- `BLOB` to `VARCHAR2`, `CHAR`, or `LONG`

- `CLOB` to `RAW` or `LONG RAW`

This applies to all operations where implicit conversion takes place. For example if you have a `SELECT` statement in your application as follows:

```
SELECT long_raw_column INTO my_varchar2 VARIABLE FROM my_table
```

and `long_raw_column` is a `BLOB` after converting your table, then the `SELECT` statement produces an error. To make this conversion work, you must use the `TO_RAW` operator to explicitly convert the `BLOB` to a `RAW` as follows:

```
SELECT TO_RAW(long_raw_column) INTO my_varchar2 VARIABLE FROM my_table
```

The same holds for selecting a `CLOB` into a `RAW` variable, or for assignments of `CLOB` to `RAW` and `BLOB` to `VARCHAR2`.

14.3.2 Alternate Methods for LOB Migration

Online Redefinition is the preferred way for migrating `LONG` data types to LOBs. However, if keeping the application online during the migration is not your primary concern, then you can also use one of the following ways to migrate `LONG` data to LOBs.

> ✎ **See Also:**
>
> Migration Considerations

Using ALTER TABLE to Convert LONG Columns to LOB Columns

You can use the `ALTER TABLE` statement in SQL to convert a `LONG` column to a LOB column.

To do so, use the following syntax:

```
ALTER TABLE [<schema>.]<table_name>
   MODIFY ( <long_column_name> { CLOB | BLOB | NCLOB }
  [DEFAULT <default_value>]) [LOB_storage_clause];
```

For example, if you had a table that was created as follows:

```
CREATE TABLE Long_tab (id NUMBER, long_col LONG);
```

then you can change the column `long_col` in table `Long_tab` to data type `CLOB` using following `ALTER TABLE` statement:

```
ALTER TABLE Long_tab MODIFY ( long_col CLOB );
```

> **✎ Note:**
>
> The `ALTER TABLE` statement copies the contents of the table into a new space, and frees the old space at the end of the operation. This temporarily doubles the space requirements.

Note that when using the `ALTER TABLE` statement to convert a `LONG` column to a LOB column, only the following options are allowed:

- `DEFAULT` option, which enables you to specify a default value for the LOB column.
- The *LOB_storage_clause*, which enables you to specify the LOB storage characteristics for the converted column. This clause can be specified in the `MODIFY` clause.

Other `ALTER TABLE` options are not allowed when converting a `LONG` column to a LOB type column.

Copying a LONG to a LOB Column Using the TO_LOB Operator

You can use the `CREATE TABLE AS SELECT` statement or the `INSERT AS SELECT` statement with the `TO_LOB` operator to copy data from a `LONG` column to a `CLOB` or `NCLOB` column, or from a `LONG RAW` column to a `BLOB` column. For example, if you have a table with a `LONG` column that was created as follows:

```
CREATE TABLE Long_tab (id NUMBER, long_col LONG);
```

then you can do the following to copy the column to a LOB column:

```
CREATE TABLE Lob_tab (id NUMBER, clob_col CLOB);
INSERT INTO Lob_tab SELECT id, TO_LOB(long_col) FROM long_tab;
COMMIT;
```

If the `INSERT` statement returns an error because of lack of undo space, then you can incrementally migrate `LONG` data to the LOB column using the `WHERE` clause. After you ensure that the data is accurately copied, you can drop the original table and create a view or synonym for the new table using one of the following sequences:

```
DROP TABLE Long_tab;
CREATE VIEW Long_tab (id, long_col) AS SELECT * from Lob_tab;
```

or

```
DROP TABLE Long_tab;
CREATE SYNONYM Long_tab FOR Lob_tab;
```

This series of operations is equivalent to changing the data type of the column `Long_col` of table `Long_tab` from `LONG` to `CLOB`. With this technique, you have to re-create any constraints, triggers, grants, and indexes on the new table.

Use of the `TO_LOB` operator is subject to the following limitations:

- You can use `TO_LOB` to copy data to a LOB column, but not to a LOB attribute of an object type.

- You cannot use `TO_LOB` with a remote table. For example, the following statements do not work:

  ```
  INSERT INTO tb1@dblink (lob_col) SELECT TO_LOB(long_col) FROM tb2;
  INSERT INTO tb1 (lob_col) SELECT TO_LOB(long_col) FROM tb2@dblink;
  CREATE TABLE tb1 AS SELECT TO_LOB(long_col) FROM tb2@dblink;
  ```

- You cannot use the `TO_LOB` operator in the `CREATE TABLE AS SELECT` statement to convert a `LONG` or `LONG RAW` column to a LOB column when creating an index organized table.

  To work around this limitation, create the index organized table, and then do an `INSERT AS SELECT` of the `LONG` or `LONG RAW` column using the `TO_LOB` operator.

- You cannot use `TO_LOB` inside any PL/SQL block.

15
Introducing the Database File System

This chapter describes the Database File System in details.

- **Why a Database File System?**
  Conceptually, a database file system is a file system interface placed on top of files and directories that are stored in database tables.

- **What Is Database File System (DBFS)?**
  Database File System (DBFS) creates a standard file system interface using a server and clients.

15.1 Why a Database File System?

Conceptually, a database file system is a file system interface placed on top of files and directories that are stored in database tables.

Applications commonly use the standard SQL data types, `BLOB`s and `CLOB`s, to store and retrieve files in the Oracle Database, files such as medical images, invoice images, documents, videos, and other files. Oracle Database provides much better security, availability, robustness, transactional capability, and scalability than traditional file systems. Files stored in the database along with relational data are automatically backed up, synchronized to the disaster recovery site using Data Guard, and recovered together.

Database File System (DBFS) is a feature of Oracle Database that makes it easier for users to access and manage files stored in the database. With this interface, access to files in the database is no longer limited to programs specifically written to use `BLOB` and `CLOB` programmatic interfaces. Files in the database can now be transparently accessed using any operating system (OS) program that acts on files. For example, ETL (extraction, transformation, and loading) tools can transparently store staging files in the database and file-based applications can benefit from database features such as Maximum Availability Architecture (MAA) without any changes to the applications.

15.2 What Is Database File System (DBFS)?

Database File System (DBFS) creates a standard file system interface using a server and clients.

- **About DBFS**
  DBFS is similar to NFS in that it provides a shared network file system that looks like a local file system and has both a server component and a client component.

- **DBFS Server**
  An implementation of a file system in the database is called a DBFS content store, for example, the DBFS SecureFiles Store. A DBFS content store allows each database user to create one or more file systems that can be mounted by clients. Each file system has its own dedicated tables that hold the file system content. In DBFS, the file server is the Oracle Database.

- **DBFS Client Access Methods**
  Learn about various methods to access DBFS in this section.

15.2.1 About DBFS

DBFS is similar to NFS in that it provides a shared network file system that looks like a local file system and has both a server component and a client component.

At the core of DBFS is the DBFS Content API, a PL/SQL interface in the Oracle Database. It connects to the DBFS Content SPI, a programmatic interface which allows for the support of different types of storage.

At the programming level, the client calls the DBFS Content API to perform a specific function, such as delete a file. The DBFS Content API `deletefile` function then calls the DBFS Content SPI to perform that function.

Figure 15-1   Database File System (DBFS)
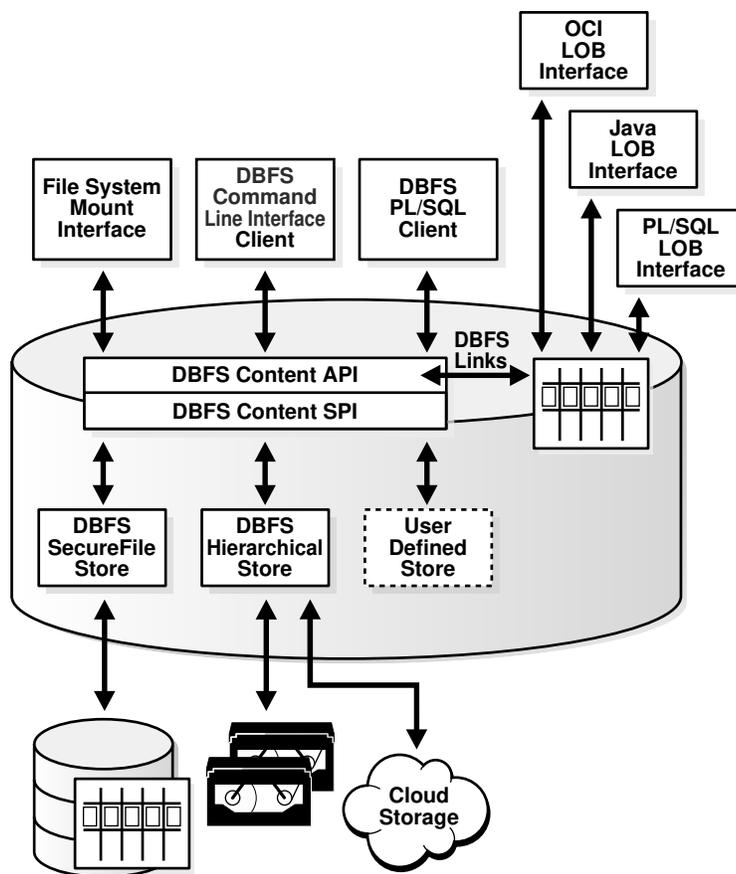

15.2.2 DBFS Server

An implementation of a file system in the database is called a DBFS content store, for example, the DBFS SecureFiles Store. A DBFS content store allows each database user to create one or more file systems that can be mounted by clients. Each file system has its own dedicated tables that hold the file system content. In DBFS, the file server is the Oracle Database.

ORACLE

At the core of DBFS is the DBFS Content API, a PL/SQL interface in the Oracle Database. It connects to the DBFS Content Store Provider Interface, a programmatic interface which allows for the support of different types of storage.

Following are the different types of stores supported by the DBFS Content SPI:

- DBFS SecureFiles Store: A DBFS content store that uses a table with a SecureFiles LOB column to store the file system data. It implements POSIX-like file system capabilities.

- DBFS Hierarchical Store: A DBFS content store that allows files to be written to any tape storage units supported by Oracle Recovery Manager (RMAN) or to a cloud storage system.

- User-defined Store: A content store defined by the user. This allows users to program their own filesystems inside Oracle Database without writing any OS code.

> **See Also:**
>
> - Creating Your Own DBFS Store
> - DBFS Content API
> - DBFS Hierarchical Store

15.2.3 DBFS Client Access Methods

Learn about various methods to access DBFS in this section.

The Database File System offers several access methods.

- PL/SQL Client Interface

  Database applications can access files in the DBFS store directly, through the DBFS Content API PL/SQL interface. The PL/SQL interface allows database transactions and read consistency to span relational and file data.

- DBFS Client Command-Line Interface

  A client command-line interface named `dbfs_client` runs on each file system client computer. `dbfs_client` allows users to copy files in and out of the database from any host on the network. It implements simple file system commands such as list and copy in a manner that is similar to shell utilities `ls` and `cp`. The command interface creates a direct connection to the database without requiring an OS mount of DBFS.

- File System Mount Interface

  On Linux and Solaris, the `dbfs_client` also includes a mount interface that uses the Filesystem in User Space (`FUSE`) kernel module to implement a file-system mount point with transparent access to the files stored in the database. This does not require any changes to the Linux or Solaris kernels. It receives standard file system calls from the `FUSE` kernel module and translates them into OCI calls to the PL/SQL procedures in the DBFS content store.

- DBFS Links

  DBFS Links, Database File System Links, are references from SecureFiles LOB locators to files stored outside the database.

  DBFS Links can be used to migrate SecureFiles from existing tables to other storage.

ORACLE

DBFS SecureFiles Store

There are certain procedures for setting up and using a DBFS SecureFiles Store.

- **Setting Up a SecureFiles Store**
  This section shows how to set up a SecureFiles Store.

- **Using a DBFS SecureFiles Store File System**
  The DBFS Content API provides methods to access and manage a SecureFiles Store file system.

- **About DBFS SecureFiles Store Package, DBMS_DBFS_SFS**
  The SecureFiles Store provider is a default implementation of the DBFS Content API (and is a standard example of a store provider that conforms to the Provider SPI) .

- **Database File System (DBFS)— POSIX File Locking**
  Starting from Oracle Database 12*c* Release 2(12.2), Oracle supports the Database File system `POSIX` File locking feature.

16.1 Setting Up a SecureFiles Store

This section shows how to set up a SecureFiles Store.

- **About Managing Permissions**
  You must be a non-SYS database user for all operational access to the Content API and stores.

- **Creating or Setting Permissions**
  You must grant the `DBFS_ROLE` role to any user that needs to use the DBFS content API.

- **Creating a SecureFiles File System Store**

- **Accessing SecureFiles Store**
  You should never directly access tables that hold data for a SecureFiles Store file systems.

- **Reinitializing SecureFiles Store File Systems**
  You can truncate and re-initialize tables associated with an SecureFiles Store.

- **Comparison of SecureFiles LOBs to BasicFiles LOBs**
  SecureFiles LOBs are only available in Oracle Database 11*g* Release 1 and higher. They are not available in earlier releases.

16.1.1 About Managing Permissions

You must be a non-SYS database user for all operational access to the Content API and stores.

Do not use `SYS` or `SYSTEM` users or `SYSDBA` or `SYSOPER` system privileges. For better security and separation of duty, only allow specific trusted users to access DBFS Content API.

You must grant each user the `DBFS_ROLE` role. Otherwise, the user is not authorized to use the DBFS Content API. A user with suitable administrative privileges (or SYSDBA) can grant the role to additional users as needed.

The `CREATEFILESYSTEM` procedure auto-commits before and after its execution (like a DDL). The method `CREATESTORE` is a wrapper around `CREATEFILESYSTEM`.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for `DBMS_DBFS_SFS` syntax details

16.1.2 Creating or Setting Permissions

You must grant the `DBFS_ROLE` role to any user that needs to use the DBFS content API.

1. Create or determine DBFS Content API target users.

    This example uses this user and password: `sfs_demo`/*password*

    At minimum, this database user must have the `CREATE SESSION`, `CREATE RESOURCE`, and `CREATE VIEW` privileges.

2. Grant the `DBFS_ROLE` role to the user.

    ```
    CONNECT / as sysdba
    GRANT dbfs_role TO sfs_demo;
    ```

This sets up the DBFS Content API for any database user who has the `DBFS_ROLE` role.

16.1.3 Creating a SecureFiles File System Store

The `CREATEFILESYSTEM` procedure auto-commits before and after its execution (like a DDL). The method `CREATESTORE` is a wrapper around `CREATEFILESYSTEM`.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for `DBMS_DBFS_SFS` syntax details

To create a SecureFiles File System Store:

1. Create a Store:

    ```
    connect sfs_demo/<password>
    DECLARE
      BEGIN
        DBMS_DBFS_SFS.CREATEFILESYSTEM(
          store_name => 'FS1',
          tbl_name => 'T1',
          tbl_tbs => null,
          use_bf => false
        );
    ```

```
  END;
/
```

where:

- `store_name` is a case-sensitive, user-unique name.

- `tbl_name` is a valid table name, created in the current schema.

- `tbl_tbs` is a valid ASSM tablespace name for SecureFile Store used for the store table and its dependent segments, such as indexes, LOBs, or nested tables. The default is `NULL` and specifies a tablespace of the current schema.

- `use_bf` specifies that BasicFiles LOBs should be used, if `true`, and if `false` it should be ASSM tablespace.

> **Note:**
>
> The `CREATEFILESYSTEM` procedure auto-commits before and after its execution (like a DDL). The method `CREATESTORE` is a wrapper around `CREATEFILESYSTEM`.

2. Register the Store.

```
CONNECT sfs_demo
Enter password:password
DECLARE
  BEGIN
    DBMS_DBFS_CONTENT.REGISTERSTORE(
      store_name     => 'FS1',
      provider_name => 'secure_file_store',
      provider_package => 'dbms_dbfs_sfs'
    );
    COMMIT;
  END;
/
```

where:

- `store_name` is SecureFiles Store `FS1`, which uses table `SFS_DEMO.T1`.

- `provider_name` is ignored.

- `provider_package` is `DBMS_DBFS_SFS`, for SecureFiles Store reference provider.

This operation associates the SecureFiles Store `FS1` with the `DBMS_DBFS_SFS` provider.

3. Mount the store.

```
CONNECT sfs_demo
Enter password: password
DECLARE
  BEGIN
    DBMS_DBFS_CONTENT.MOUNTSTORE(
      store_name     => 'FS1',
      store_mount    => 'mnt1'
    );
    COMMIT;
```

```
   END;
/
```

where:

- `store_name` is the name of the store we want to mount. In this case the SFS store is `FS1`, which is already created and uses table `SFS_DEMO.T1`.

- `store_mount` is the mount point.

4. [Optional] To see the results of the preceding steps, you can use the following statements.

- To verify SecureFiles Store tables and file systems:

```
SELECT * FROM TABLE(DBMS_DBFS_SFS.LISTTABLES);
SELECT * FROM TABLE(DBMS_DBFS_SFS.LISTFILESYSTEMS);
```

- To verify ContentAPI Stores and mounts:

```
SELECT * FROM TABLE(DBMS_DBFS_CONTENT.LISTSTORES);
SELECT * FROM TABLE(DBMS_DBFS_CONTENT.LISTMOUNTS);
```

- To verify SecureFiles Store features:

```
var fs1f NUMBER;
exec :fs1f := DBMS_DBFS_CONTENT.GETFEATURESBYNAME('FS1');
select * from table(DBMS_DBFS_CONTENT.DECODEFEATURES(:fs1f));
```

- To verify resource and property views:

```
SELECT * FROM DBFS_CONTENT;
SELECT * FROM DBFS_CONTENT_PROPERTIES;
```

16.1.4 Accessing SecureFiles Store

You should never directly access tables that hold data for a SecureFiles Store file systems.

This is the correct way to access the file systems.

- For procedural operations: Use the DBFS Content API (`DBMS_DBFS_CONTENT` methods).

- For SQL operations: Use the resource and property views (`DBFS_CONTENT` and `DBFS_CONTENT_PROPERTIES`).

16.1.5 Reinitializing SecureFiles Store File Systems

You can truncate and re-initialize tables associated with an SecureFiles Store.

- Use the procedure `INITFS()`.

  The procedure executes like a DDL, auto-committing before and after its execution.

The following example uses file system `FS1` and table `SFS_DEMO.T1`, which is associated with the SecureFiles Store `store_name`.

```
CONNECT sfs_demo;
Enter password: password
EXEC DBMS_DBFS_SFS.INITFS(store_name => 'FS1');
```

16.1.6 Comparison of SecureFiles LOBs to BasicFiles LOBs

SecureFiles LOBs are only available in Oracle Database 11*g* Release 1 and higher. They are not available in earlier releases.

You must use BasicFiles LOB storage for LOB storage in tablespaces that are not managed with Automatic Segment Space Management (ASSM).

Compatibility must be at least 11.1.0.0 to use SecureFiles LOBs.

Additionally, you need to specify the following in `DBMS_DBFS_SFS.CREATEFILESYSTEM`:

- To use SecureFiles LOBs (the default), specify `use_bf => false.`
- To use BasicFiles LOBs, specify `use_bf => true.`

16.2 Using a DBFS SecureFiles Store File System

The DBFS Content API provides methods to access and manage a SecureFiles Store file system.

- DBFS Content API Working Example
  You can create new file and directory elements to populate a SecureFiles Store file system.
- Dropping SecureFiles Store File Systems
  You can use the `unmountStore` method to drop SecureFiles Store file systems.

16.2.1 DBFS Content API Working Example

You can create new file and directory elements to populate a SecureFiles Store file system.

If you have executed the steps in "Setting Up a SecureFiles Store", set the DBFS Content API permissions, created at least one SecureFiles Store reference file system, and mounted it under the mount point `/mnt1`, then you can create a new file and directory elements as demonstrated in Example 16-1.

Example 16-1   Working with DBFS Content API

```
CONNECT tjones
Enter password: <password>

DECLARE
   ret INTEGER;
   b   BLOB;
   str VARCHAR2(1000)  := '' || chr(10) ||
    '#include <stdio.h>' || chr(10) ||
    '' || chr(10) ||
    'int main(int argc, char** argv)' || chr(10) ||
    '{' || chr(10) ||
    '    (void) printf("hello world\n");' || chr(10) ||
    '    RETURN 0;' || chr(10) ||
    '}' || chr(10) ||
    '';
   properties       DBMS_DBFS_CONTENT.PROPERTIES_T;
```

```
BEGIN
   properties('posix:mode') := DBMS_DBFS_CONTENT.propNumber(16777);
                                        --  drwxr-xr-x  --
   properties('posix:uid')  := DBMS_DBFS_CONTENT.propNumber(0);
   properties('posix:gid')  := DBMS_DBFS_CONTENT.propNumber(0);
   DBMS_DBFS_CONTENT.createDirectory(
            '/mnt1/FS1',
            properties);

   properties('posix:mode') := DBMS_DBFS_CONTENT.propNumber(33188);
                                        --  -rw-r--r--  --
   DBMS_DBFS_CONTENT.createFile(
            '/mnt1/FS1/hello.c',
            properties,
            b);

    DBMS_LOB.writeappend(b, length(str), utl_raw.cast_to_raw(str));
    COMMIT;
END;
/
SHOW ERRORS;

-- verify newly created directory and file

SELECT pathname, pathtype, length(filedata),
      utl_raw.cast_to_varchar2(filedata)
      FROM dbfs_content
          WHERE pathname LIKE '/mnt1/FS1%'
          ORDER BY pathname;
```

The file system can be populated and accessed from PL/SQL with `DBMS_DBFS_CONTENT`. The file system can be accessed read-only from SQL using the `dbfs_content` and `dbfs_content_properties` views.

The file system can also be populated and accessed using regular file system APIs and UNIX utilities when mounted using FUSE, or by the standalone `dbfs_client` tool (in environments where `FUSE` is either unavailable or not set up).

> ✎ **See Also:**
>
> DBFS Client Access Methods

16.2.2 Dropping SecureFiles Store File Systems

You can use the `unmountStore` method to drop SecureFiles Store file systems.

This method removes all stores referring to the file system from the metadata tables, and drops the underlying file system table. The procedure executes like a DDL, auto-committing before and after its execution.

1. Unmount the store.

   ```
   CONNECT sfs_demo/<password>
   ```

```
DECLARE
  BEGIN
    DBMS_DBFS_CONTENT.UNMOUNTSTORE(
      store_name    => 'FS1',
      store_mount   => 'mntl';
    );
    COMMIT;
END;
/
```

where:

- `store_name` is `FS1`, a case-sensitive unique username.

- `store_mount` is the mount point.

2. Unregister the stores.

```
CONNECT sfs_demo/<password>
EXEC DBMS_DBFS_CONTENT.UNREGISTERSTORE(store_name => 'FS1');
COMMIT;
```

where `store_name` is SecureFiles Store `FS1`, which uses table `SFS_DEMO.T1`.

3. Drop the store.

```
CONNECT sfs_demo/<password>;
EXEC DBMS_DBFS_SFS.DROPFILESYSTEM(store_name => 'FS1');
COMMIT;
```

where `store_name` is SecureFiles Store `FS1`, which uses table `SFS_DEMO.T1`.

16.3 About DBFS SecureFiles Store Package, DBMS_DBFS_SFS

The SecureFiles Store provider is a default implementation of the DBFS Content API (and is a standard example of a store provider that conforms to the Provider SPI) .

To use the `DBMS_DBFS_SFS` package, you must be granted the `DBFS_ROLE` role.

The SecureFiles Store provider is a default implementation of the DBFS Content API (and is a standard example of a store provider that conforms to the Provider SPI) . This enables existing applications to easily add PL/SQL provider implementations and provide access through the DBFS Content API without changing their schemas or their business logic.

16.4 Database File System (DBFS)— POSIX File Locking

Starting from Oracle Database 12*c* Release 2(12.2), Oracle supports the Database File system `POSIX` File locking feature.

The DBFS provides file locking support for the following types of applications:

- `POSIX` applications using `DBFS_CLIENT` (in mount mode) as a front-end interface to DBFS.

> **✎ See Also:**
>
> DBFS Client Access Methods

- Applications using `PL/SQL` as an interface to DBFS.

> **✎ Note:**
>
> Oracle supports only Full-file locks in DBFS. Full-file lock implies locking the entire file from byte zero offset to the end of file.

- **About Advisory Locking**
  Advisory locking is a file locking mechanism that locks the file for a single process.

- **About Mandatory Locking**
  Mandatory locking is a file locking mechanism that takes support from participating processes.

- **File Locking Support**
  Enabling the file locking mechanism helps applications to block files for various file system operations.

- **Compatibility and Migration Factors of Database Filesystem—File Locking**
  The Database Filesystem File Locking feature does not impact the compatibility of `DBFS` and `SFS` store provider with `RDBMS`.

- **Examples of Database File System—File Locking**
  These examples illustrate the advisory locking and the locking functions available on `UNIX` based systems.

- **DBFS Locking Behavior**
  This section describes the DBFS locking behavior.

- **Scheduling File Locks**
  DBFS File Locking feature supports lock scheduling.

16.4.1 About Advisory Locking

Advisory locking is a file locking mechanism that locks the file for a single process.

File locking mechanism cannot independently enforce any form of locking and requires support from the participating processes. For example, if a process `P1` has a `write` lock on file `F1`, the locking API or the operating system does not perform any action to prevent any other process `P2` from issuing a `read` or `write` system call on the file `F1`. This behavior of file locking mechanism is also applicable to other file system operations. The processes that are involved

(in file locking mechanism) must follow a lock or unlock protocol provided in a suitable API form by the user-level library. File locking semantics are guaranteed to work as per POSIX standards.

16.4.2 About Mandatory Locking

Mandatory locking is a file locking mechanism that takes support from participating processes.

Mandatory locking is an enforced locking scheme that does not rely on the participating processes to cooperate and/or follow the locking API. For example, if a process `P1` has taken a `write` lock on file `F1` and if a different process `P2` attempts to issue a `read`/`write` system call (or any other file system operation) on file `F1` , the request is blocked because the concerned file is exclusively locked by process `P1`.

16.4.3 File Locking Support

Enabling the file locking mechanism helps applications to block files for various file system operations.

The `fcntl()`, `lockf()`, and `flock()` system calls in `UNIX` and `LINUX` provide file locking support. These system calls enable applications to use the file locking facility through `dbfs_client-FUSE` callback interface. File Locks provided by `fcntl()` are widely known as POSIX file locks and the file locks provided by `flock()` are known as BSD file locks. The semantics and behavior of POSIX and BSD file locks differ from each other. The locks placed on the same file through `fcntl()` and `flock()` are orthogonal to each other. The semantics of file locking functionality designed and implemented in DBFS is similar to POSIX file locks. In DBFS, semantics of file locks placed through `flock()` system call will be similar to POSIX file locks (such as `fcntl()`) and not BSD file locks. `lockf()` is a library call that is implemented as a wrapper over `fcntl()` system call on most of the UNIX systems, and hence, it provides POSIX file locking semantics. In DBFS, file locks placed through `fcntl()`, `flock()`, and `lockf()` system-calls provide same kind of behavior and semantics of POSIX file locks.

> **Note:**
>
> BSD file locking semantics are not supported.

16.4.4 Compatibility and Migration Factors of Database Filesystem—File Locking

The Database Filesystem File Locking feature does not impact the compatibility of `DBFS` and `SFS` store provider with `RDBMS`.

`DBFS_CLIENT` is a standalone OCI Client and uses `OCI` calls and `DBMS_FUSE API`.

> **Note:**
>
> This feature will be compatible with `OraSDK/RSF` .

16.4.5 Examples of Database File System—File Locking

These examples illustrate the advisory locking and the locking functions available on `UNIX` based systems.

The following example uses two running processes — Process A and Process B.

Example 16-2   No locking

```
Process A opens file:

file_desc = open("/path/to/file", O_RDONLY);
/* Reads data into bufffers */
read(fd, buf1, sizeof(buf));
read(fd, buf2, sizeof(buf));
close(file_desc);
```

Subjected to OS scheduling, `process B` can enter any time and issue a `write` system call affecting the integrity of file data.

Example 16-3   Advisory locking used but process B does not follow the protocol

```
Process A opens file:

file_desc = open("/path/to/file", O_RDONLY);
ret = AcquireLock(file_desc, RD_LOCK);
if(ret)
{
    read(fd, buf1, sizeof(buf));
    read(fd, buf2, sizeof(buf));
    ReleaseLock(file_desc);
}
close(file_desc);
```

Subjected to OS scheduling, `process B` can come in any time and still issue a `write` system call ignoring that `process A` already holds a `read` lock.

```
Process B opens file:

file_desc1 = open("/path/to/file", O_WRONLY);
write(file_desc1, buf, sizeof(buf));
close(file_desc1);
```

The above code is executed and leads to inconsistent data in the file.

Example 16-4   Advisory locking used and processes are following the protocol

```
Process A opens file:

file_desc = open("/path/to/file", O_RDONLY);
ret = AcquireLock(file_desc, RD_LOCK);
if(ret)
{
    read(fd, buf1, sizeof(buf));
    read(fd, buf2, sizeof(buf));
```

```
        ReleaseLock(file_desc);
}
close(file_desc);

Process B opens file:

file_desc1 = open("/path/to/file", O_WRONLY);
ret = AcquireLock(file_desc1, WR_LOCK);
/* The above call will take care of checking the existence of a lock */
if(ret)
{
    write(file_desc1, buf, sizeof(buf));
    ReleaseLock(file_desc1);
} close(file_desc1);
```

`Process B` follows the lock API and this API makes sure that the process does not `write` to the file without acquiring a lock.

16.4.6 DBFS Locking Behavior

This section describes the DBFS locking behavior.

The `DBFS` File Locking feature exhibits the following behaviors:

- File locks in `DBFS` are implemented with idempotent functions. If a process issues "N" `read` or `write` lock calls on the same file, only the first call will have an effect, and the subsequent "N-1" calls will be treated as redundant and returns No Operation (NOOP).

- File can be unlocked exactly once. If a process issues "N" `unlock` calls on the same file, only the first call will have an effect, and the subsequent "N-1" calls will be treated as redundant and returns NOOP.

- Lock conversion is supported only from `read` to `write`. If a process `P` holds a `read` lock on file `F` (and `P` is the only process holding the `read` lock), then a `write` lock request by `P` on file `F` will convert the `read` lock to `exclusive`/`write` lock.

16.4.7 Scheduling File Locks

DBFS File Locking feature supports lock scheduling.

This facility is implemented purely on the DBFS client side. Lock request scheduling is required when client application uses blocking call semantics in their `fcntl()`, `lockf()`, and `flock()` calls.

There are two types of scheduling:

- Greedy Scheduling
- Fair Scheduling

Oracle provides the following command line option to switch the scheduling behavior.

`Mount -o lock_sched_option = `*lock_sched_option Value*`;`

Table 16-1   `lock_sched_option` Value Description

Value	Description
1	Sets the scheduling type to Greedy Scheduling. (Default)
2	Sets the scheduling type to Fair Scheduling.

> **Note:**
>
> Lock Request Scheduling works only on per `DBFS_CLIENT` mount basis. For example, lock requests are not scheduled across multiple mounts of the same file system.

- Greedy Scheduling
  In this scheduling technique, the file lock requests does not follow any guaranteed order.

- Fair Scheduling
  The fair scheduling technique is implemented using a queuing mechanism on per file basis.

16.4.7.1 Greedy Scheduling

In this scheduling technique, the file lock requests does not follow any guaranteed order.

> **Note:**
>
> This is the default scheduling option provided by `DBFS_CLIENT`.

If a file `F` is `read` locked by process `P1`, and if processes `P2` and `P3` submit blocking `write` lock requests on file `F`, the processes `P2` and `P3` will be blocked (using a form of spin lock) and made to wait for its turn to acquire the lock. During the wait, if a process `P4` submits a `read` lock request (blocking call or a non-blocking call) on file `F`, `P4` will be granted the `read` lock even if there are two processes (`P2` and `P3`) waiting to acquire the `write` lock. Once both `P1` and `P4` release their respective `read` locks, one of `P2` and `P3` will succeed in acquiring the lock. But, the order in which processes `P2` and `P3` acquire the lock is not determined. It is possible that process `P2` would have requested first, but the process `P3`'s request might get unblocked and acquire the lock and the process `P2` must wait for `P3` to release the lock.

16.4.7.2 Fair Scheduling

The fair scheduling technique is implemented using a queuing mechanism on per file basis.

For example, if a file `F` is read locked by process `P1`, and processes `P2` and `P3` submit blocking write lock requests on file `F`, these two processes will be blocked (using a form of spin lock) and will wait to acquire the lock. The requests will be queued in the order received by the DBFS client. If a process `P4` submits a read lock request (blocking call or a non-blocking call) on file `F`, this request will be queued even though a read lock can be granted to this process.

DBFS Client ensures that after `P1` releases its read lock, the order in which lock requests are honored is P2->P3 -> P4.

This implies that `P2` will be the first one to get the lock. Once `P2` releases its lock, `P3` will get the lock and so on.

17

Using DBFS

The DBFS File System implementation includes creating and accessing the file system and managing it.

- **Installing DBFS**
  DBFS is a part of the Oracle Database installation.

- **Creating a DBFS File System**
  You can create a partitioned or non-partitioned DBFS File system.

- **Accessing DBFS File System**
  This section describes the various interfaces through which you can access the DBFS File System.

- **Maintaining DBFS**
  DBFS administration includes tools that perform diagnostics, manage failover, perform backup, and so on.

- **Shrinking and Reorganizing DBFS Filesystems**
  DBFS uses Online File system Reorganization to shrink itself, enabling the release of allocated space back to the containing tablespace.

- **Dropping a File System**
  You can drop a file system by running `DBFS_DROP_FILESYSTEM.SQL`.

17.6 Dropping a File System

You can drop a file system by running `DBFS_DROP_FILESYSTEM.SQL`.

> ⚠ **Caution:**
>
> When you drop a file system, it deletes all the files and associated metadata. You won't be able to access the files.

1. Log in to the database instance:

   ```
   $ sqlplus dbfs_user/@db_server
   ```

2. Enter the following command:

   ```
   @$ORACLE_HOME/rdbms/admin/dbfs_drop_filesystem.sql file_system_name
   ```

When you drop a file system, it deletes all the files and associated metadata. You won't be able to access the files. If you want to access the file system after dropping a DBFS, you can restore the file system from a database backup or file system backup.

Depending on the backup policy in your organization, you may have a database backup or file system backup. To restore from a database backup, you'll have to restore the entire database and then use the restored file system. To restore the file system from a file system backup, create a new DBFS and restore the file system from the file system backup.

17.1 Installing DBFS

DBFS is a part of the Oracle Database installation.

`$ORACLE_HOME/rdbms/admin` contains these DBFS utility packages:

- Content API (CAPI)
- SecureFiles Store (SFS)

`$ORACLE_HOME/bin` contains:

- `dbfs_client` executable

`$ORACLE_HOME/rdbms/admin` contains:

- SQL (`.plb` extension) scripts for the content store

17.2 Creating a DBFS File System

You can create a partitioned or non-partitioned DBFS File system.

For both partitioned and non-partitioned DBFS, you can specify one or more of the following storage properties to specify how your files are stored in DBFS: compression and deduplication.

For example, you can configure DBFS as a compressed file system with partitioning. At the time of creating a DBFS file system, you must specify the set of features that you want to enable for the file system.

After creating a DBFS, you can track the usage of the DBFS. If you want to change the storage properties of the DBFS, you can reorganize the DBFS. You can update the metadata of the DBFS by changing the values for parameters, such as `deduplicate`, `compress`, and `partition`. For example, you may have created a DBFS to store all the files in the compressed format. If you want to change this property, you can reorganize the DBFS.

- About the Create File System Command
  Use this command to quickly create, register, and mount a file system.

- Privileges Required to Create a DBFS File System
  Database users must certain privileges to create a file system.

- Creating a Non-Partitioned File System
  You can create a file system by running `DBFS_CREATE_FILESYSTEM.SQL` while logged in as a user with DBFS administrator privileges.

- Creating a Partitioned File System
  Files in DBFS are hash partitioned. Partitioning creates multiple physical segments in the database, and files are distributed randomly in these partitions.

- Enabling Advanced SecureFiles LOB Features for DBFS
  Using the `@dbfs_create_filesystem.sql` command, you can create a partitioned or non-partitioned file system with the compression and deduplicate options. If you want to specify additional options while creating the file system, use the `DBMS_DBFS_SFS.CREATEFILESYSTEM` procedure.

17.2.1 About the Create File System Command

Use this command to quickly create, register, and mount a file system.

Syntax

```
$ sqlplus @dbfs_create_filesystem.sql tablespace_name file_system_name
  [compress-high | compress-medium | compress-low | nocompress]
  [deduplicate | nodeduplicate]
  [partition | non-partition | partition-by-itemname | partition-by-guid | partition-by-
path]
```

Where the mandatory parameters are:

- *tablespace_name* is the tablespace in which you want to create a file system.

- *file_system_name* is the unique name of the file system that you want to create.

The optional parameters are:

- `compress`: when you use this option DBFS compresses the files, and then stores the files. Use this option to reduce the storage space consumed by the files. Note that it takes more time to read and write to compressed files as the files have to be decompressed before you can read or write to the file.
  You can specify one of the following options: `compress`, `compress-high`, `compress-medium`, `compress-low`. When you specify `compress` or `compress-medium`, the compression level is medium.

  Generally, the compression level `compress-low` performs best and still provides a good compression ratio. Compression levels `compress-high` and `compress-medium` provide significantly better compression ratios, but compression times can be correspondingly longer. Oracle recommends using NONE or LOW when write performance is critical, such as when files in the DBFS store are updated frequently. If space is critical and the best possible compression ratio is desired, use `compress-high` or `compress-medium`. Files are compressed as they are paged out of the cache into the staging area. Therefore, compression also benefits by storing smaller files in the staging area and effectively increasing the total available capacity of the staging area.

  If you don't specify any option to compress the files, `nocompress` is the default value.

- `deduplicate`: when you use this option, DBFS maintains a single copy of the file to save storage space even if you have multiple copies of the file in different folders. Let's consider that 100 users in an e-commerce company require access to the postal zip codes. Using deduplication, even if all 100 users store the file in different folders, the DBFS maintains a single copy of the file that contains the postal ZIP codes and the DBFS doesn't store multiple copies of the file. The reduction of duplication saves space. If user A updates the file containing postal zip codes, the updated file is stored as a separate copy in the DBFS. The next time user A wants to access the file, user A is pointed to the updated copy of the file while the remaining users are still pointed to the original file. Note that it takes more time to update and write to the DBFS when you use the deduplicate option. `nodeduplicate` is the default value.

- `partition`: use this option to create a partitioned file system, and then specify any one of the following values as the hash key.

  - `partition` and `partition-by-itemname`: uses the item name as the partition key. The item name is the last component in the path name. Use this option to partition files based on the last component in the file path. For example, if `/directory1/subdirectory2/filename.txt` is the entire path, then `filename.txt` is the last

component in the path and `filename.txt` is used as the partition key. If you use the `partition` option, then the file system is partitioned using the item name as the partition key.

- `partition-by-guid`: uses the globally unique identifier (GUID) assigned to the file by DBFS as the partition key. DBFS assigns a GUID to each file. Use this option to partition the files based on the internally-generated GUID.

- `partition-by-path`: uses the entire path of the file as the partition key. For example, if the file is `/directory1/subdirectory2/filename.txt`, then the entire `/directory1/subdirectory2/filename.txt` is considered as the partition key.

If you specify only the `partition` option, then it defaults to `partition-by-itemname`, where item name refers to the name of the file or directory.

Using the `@dbfs_create_filesystem.sql` command, you can create a file system with the options described in this section. If you want to specify additional options while creating the file system, you can use the `DBMS_DBFS_SFS.CREATEFILESYSTEM` procedure.

> ✎ **See Also:**
>
> - CREATEFILESYSTEM Procedure in *PL/SQL Packages and Types Reference*.
> - Persistent LOBs and Creating a Partitioned File System for more information about the features of SecureFiles LOBs.

17.2.2 Privileges Required to Create a DBFS File System

Database users must certain privileges to create a file system.

Following is the minimum set of privileges required for a database user to create a file system:

- `GRANT CONNECT`
- `CREATE SESSION`
- `RESOURCE`, `CREATE TABLE`
- `CREATE PROCEDURE`
- `DBFS_ROLE`

17.2.3 Creating a Non-Partitioned File System

You can create a file system by running `DBFS_CREATE_FILESYSTEM.SQL` while logged in as a user with DBFS administrator privileges.

Before you begin, ensure that you create the file system in an ASSM tablespace to support SecureFile store. For information about creating an ASSM tablespace, see Creating a SecureFiles File System Store.

To create a non-partitioned file system:

1. Log in to the database instance as a user with DBFS administrator privileges.

   ```
   $ sqlplus dbfs_user/@db_server
   ```

2. Enter the following command to create the file system.

Syntax

```
@$ORACLE_HOME/rdbms/admin/dbfs_create_filesystem.sql tablespace_name
     file_system_name
 [compress-high | compress-medium | compress-low | nocompress]
 [deduplicate | nodeduplicate]
 non-partition
```

Example

For example, to create a file system called `staging_area` in an existing ASSM tablespace `dbfs_tbspc`:

```
$ sqlplus dbfs_user/db_server
  @$ORACLE_HOME/rdbms/admin/dbfs_create_filesystem.sql
  dbfs_tbspc staging_area nocompress nodeduplicate non-partition
```

17.2.4 Creating a Partitioned File System

Files in DBFS are hash partitioned. Partitioning creates multiple physical segments in the database, and files are distributed randomly in these partitions.

You can create a partitioned file system by running `DBFS_CREATE_FILESYSTEM.SQL` while logged in as a user with DBFS administrator privileges.

The tablespace in which you create the file system should be an ASSM tablespace to support Securefile store. Before you begin, ensure that you create the file system in an ASSM tablespace to support SecureFile store. For information about creating an ASSM tablespace, see Creating a SecureFiles File System Store.

1. Log in to the database instance:

   ```
   $ sqlplus dbfs_user/@db_server
   ```

2. Enter one of the following commands to create the file system based on your requirement.

   Syntax

   ```
   @$ORACLE_HOME/rdbms/admin/dbfs_create_filesystem_advanced.sql tablespace_name
         file_system_name [compress-high | compress-medium | compress-low |
   nocompress]
    [deduplicate | nodeduplicate]
    [partition | partition-by-itemname | partition-by-guid | partition-by-path]
   ```

   Examples

   • For example, to create a partitioned file system called `staging_area` in an existing ASSM tablespace `dbfs_tbspc`:

     ```
     $ sqlplus dbfs_user/@db_server
           @$ORACLE_HOME/rdbms/admin/dbfs_create_filesystem_advanced.sql dbfs_tbspc
           staging_area nocompress nodeduplicate partition
     ```

   • For example, to create a partitioned file system called `staging_area` in an existing ASSM tablespace `dbfs_tbspc` with the storage properties compress and deduplicate.

     ```
     $ sqlplus dbfs_user/@db_server
           @$ORACLE_HOME/rdbms/admin/dbfs_create_filesystem_advanced.sql dbfs_tbspc
           staging_area compress-medium deduplicate partition
     ```

17.2.5 Enabling Advanced SecureFiles LOB Features for DBFS

Using the `@dbfs_create_filesystem.sql` command, you can create a partitioned or non-partitioned file system with the compression and deduplicate options. If you want to specify additional options while creating the file system, use the `DBMS_DBFS_SFS.CREATEFILESYSTEM` procedure.

For information about all the additional options that you can use with the `DBMS_DBFS_SFS.CREATEFILESYSTEM` procedure, see CREATEFILESYSTEM Procedure in *PL/SQL Packages and Types Reference*.

Use the `@dbfs_create_filesystem.sql` command to quickly create, register, and mount a file system. When you use the `DBMS_DBFS_SFS.CREATEFILESYSTEM` procedure to enable additional options while creating a file system, you must additionally run commands to register and mount the file system that you create.

Let's use the `DBMS_DBFS_SFS.CREATEFILESYSTEM` procedure to create a file system with the encryption option.

Before you begin, ensure that you have created a wallet with the encryption key. See Administer Key Management in *SQL Language Reference*.

To create a file system with the encryption option:

1. Run the following command.
   Syntax

   ```
   exec
   dbms_dbfs_sfs.createFilesystem('store_name',tbl_tbs=>'tablespace_name',do_e
   ncrypt=> true | false,encryption=> encryption_type, do_dedup=> true |
   false,do_compress=>true | false);
   ```

   For reference information about the command options, see CREATEFILESYSTEM Procedure in *PL/SQL Packages and Types Reference*.

   Example

   For example, to create a file system in `Test3` store in the `test_fs1` tablespace with the default encryption, compression, and deduplicate options:

   ```
   exec dbms_dbfs_sfs.createFilesystem('test_fs1', tbl_tbs=>'Test3',
   do_encrypt=>true, encryption=>dbms_dbfs_sfs.ENCRYPTION_DEFAULT,
   do_dedup=>true, do_compress=>true);
   ```

   The file system is created with the option you have specified.

2. Run the following command to register the file system that you have created.
   Syntax

   ```
   dbms_dbfs_content.registerStore(store_name => 'filesystem_name',
   provider_name => 'posix',provider_package => 'dbms_dbfs_sfs') ;
   ```

   Example

For example, run the following command to register the `test_fs1` file system.

```
dbms_dbfs_content.registerStore(store_name => 'test_fs1', provider_name =>
'posix', provider_package => 'dbms_dbfs_sfs') ;
```

3. Run the following command to mount the file system that you have created.

   Syntax

   ```
   dbms_dbfs_content.mountStore(store_name  => 'filesystem_name', store_mount
   => 'filesystem_name');
   ```

   Example

   For example, run the following command to mount the `test_fs1` file system.

   ```
   dbms_dbfs_content.mountStore(store_name  => 'test_fs1', store_mount =>
   'test_fs1');
   ```

17.3 Accessing DBFS File System

This section describes the various interfaces through which you can access the DBFS File System.

- **DBFS Client Prerequisites**
  The DBFS File System client side application, which is named `dbfs_client`, runs on each system that will access to DBFS.

- **Multiple Mount Points on DBFS Client**
  Starting from Oracle Database Release 21c, a single Database File System (DBFS) client instance can mount multiple DBFS, owned by different database users across different database instances.

- **Manager File System**
  The Manager File System is the interface between the OS user and the DBFS Client. The OS user can communicate with the Client through limited File System commands.

- **DBFS Client Command-Line Interface Operations**
  The DBFS client command-line interface allows you to directly access files stored in DBFS.

- **DBFS Mounting Interface (Linux and Solaris Only)**
  You can mount DBFS using the `dbfs_client` in Linux and Solaris only.

- **File System Security Model**
  The database manages security in DBFS. It does not use the operating system security model.

- **HTTP, WebDAV, and FTP Access to DBFS**
  Components that enable HTTP, WebDAV, and FTP access to DBFS over the Internet use various XML DB server protocols.

17.3.1 DBFS Client Prerequisites

The DBFS File System client side application, which is named `dbfs_client`, runs on each system that will access to DBFS.

The prerequisites for the DBFS File System Client, `dbfs_client`, are:

- The `dbfs_client` host must have the Oracle client libraries installed.

- The `dbfs_client` can be used as a direct RDBMS client using the DBFS Command Interface on Linux, Linux.X64, Solaris, Solaris64, AIX, HPUX and Windows platforms.

- The `dbfs_client` can only be used as a mount client on Linux, Linux.X64, and Solaris 11 platforms. The `dbfs_client` host must have the `FUSE` Linux package or the Solaris `libfuse` package installed.

> **See Also:**
>
> DBFS Mounting Interface (Linux and Solaris Only) for further details.

The DBFS client command-line interface allows you to perform many pre-defined commands, such as copy files in and out of the DBFS filesystem from any host on the network.

The command-line interface has slightly better performance than the DBFS client mount interface because it does not mount the file system, thus bypassing the user space file system. However, it is not transparent to applications.

The DBFS client mount interface allows DBFS to be mounted through a file system mount point thus providing transparent access to files stored in DBFS with generic file system operations.

To run DBFS commands, specify `--command` to the DBFS client.

17.3.2 Multiple Mount Points on DBFS Client

Starting from Oracle Database Release 21c, a single Database File System (DBFS) client instance can mount multiple DBFS, owned by different database users across different database instances.

To enable access to multiple database users, the DBFS client has to manage multiple mount points. Each mount point enables one database user to access DBFS.

When the DBFS client provides access to a single database user through a single mount point, it is termed as Single User Mount Version (SUMV) mode and when the DBFS client provides access to multiple database users through multiple mount points, it is termed as Multi User Mount Version (MUMV) mode.

You can start a DBFS client in either of these modes. However, once you start the client in any mode, you cannot switch to the other mode without restarting the client. If a DBFS client is started in the MUMV mode, then the client creates a pseudo file system called Manager File System (MFS), which acts as an interface between the OS user and the DBFS client.

You can start the MUMV mode in two variants, one that can mount DBFS across multiple container databases or one that can mount only DBFS belonging to different pluggable databases of a single container database. The MUMV variant that mounts DBFS from multiple databases is termed as the Cross-Database variant and the one that mounts DBFS for multiple PDBs of a single container database as the CDB variant. Both the variants are started by specifying only the MFS mount points during start up. The DBFS mounts are added by setting extended attributes on the MFS mount point.

- MUMV for CDB Variant
  The CDB variant of the Multi User Mount Version (MUMV) mode manages the mount points of Database File System (DBFS) that belong to different pluggable databases (PDBs) of a single container database (CDB).

- MUMV for Cross-Database Variant
  The Cross-Database variant of the Multi User Mount Version (MUMV) mode manages mount points for Database File System (DBFS) in multiple databases.

17.3.2.1 MUMV for CDB Variant

The CDB variant of the Multi User Mount Version (MUMV) mode manages the mount points of Database File System (DBFS) that belong to different pluggable databases (PDBs) of a single container database (CDB).

Remember the following points while working with the CDB variant of the MUMV mode:

- The DBFS client, managing multiple DBFS mount points of a single container, should be provided with the credentials to connect to a common user of the CDB at `CDB$ROOT`. The DBFS to be mounted, should be created in or exported to this common user in the PDBs.

- A mount point must be specified for the DBFS in every PDB in the given container. The DBFS client connects to the `CDB$ROOT`, using common user credentials, and then switches to the required PDB to access the DBFS through the specified mount point.

17.3.2.2 MUMV for Cross-Database Variant

The Cross-Database variant of the Multi User Mount Version (MUMV) mode manages mount points for Database File System (DBFS) in multiple databases.

Remember the following points while working with the Cross-Database variant of the MUMV mode:

- The DBFS client must have the credentials of a database user on each database to manage the respective DBFS mount points.

- A DBFS mount point must be specified for each database user and a DBFS must be created in their respective schemas.

17.3.3 Manager File System

The Manager File System is the interface between the OS user and the DBFS Client. The OS user can communicate with the Client through limited File System commands.

The Manager File System (MFS) is enabled only in the Multi User Mount Version (MUMV) mode. It treats the various mount points managed by the DBFS Client as files. The MFS provides an easy interface for the OS users to manage multiple mount points.

The MFS does not create or store files on the disk. Only a limited file system operations are allowed on the MFS mount point.

No OS user can create files or directories under the MFS.

- Adding a DBFS Mount Point
  You can add DBFS mount points by specifying extended attributes on the MFS mount points.

- Listing DBFS Mount Points
  Each DBFS mount point has a corresponding file under the MFS directory, `/mnt/mfs`. So, you can use the standard Linux command `ls` to list the DBFS mount points.

- Unmounting a DBFS Mount Point
  The procedure to unmount a DBFS mount point is the same for both the CDB variant and the Cross-Database variant of the MUMV mode.

- Configuration Parameters of DBFS Client
  All configuration parameters of DBFS client in Single User Mount Version (SUMV) mode
  can also be used with the DBFS client in Multi User Mount Version (MUMV) mode at the
  time of start up.

- Diagnosability of DBFS Client
  Starting from Oracle Database Release 21c, the DBFS Client writes an alert file in the
  client trace directory of the configured Automatic Diagnostic Repository (ADR) base.

17.3.3.1 Adding a DBFS Mount Point

You can add DBFS mount points by specifying extended attributes on the MFS mount points.

> **Note:**
>
> The MUMV mode works only in wallet mode, even if you do not specify the `-o`
> `wallet` option. As there is no way to provide passwords in the DBFS commend-line
> interface, you must add all the credentials required by the DBFS client in the wallet.

While using a CDB variant of the MUMV mode, add the mount points for each of the PDB in
the CDB by setting the extended attribute on the `/mnt/mfs` directory, where `/mnt/mfs` is the
MFS mount point.

Defining the Mount Points in a CDB Variant

Perform the following steps to define the mount points in a CDB variant of the MUMV mode:

1. Start the DBFS client to connect to the common user at the `CDB$ROOT`, specifying the MFS
   mount point and the wallet alias at the start up:

   ```
   % dbfs_client -o mfs_mount=/mnt/mfs -o cdb=inst_cdb
   ```

   Where, `/mnt/mfs` is the MFS mount point. It can be any empty directory of your choice.
   `inst_cdb` is the alias insert into the wallet that can connect to the common user in
   `CDB$ROOT`.

2. Add a DBFS mount point by setting an extended attribute in the following way:

   ```
   % setfattr -n mount_pdb -v " pdb1 /mnt/mp1" /mnt/mfs/
   ```

   Where:

   - `mount_pdb` is the name of the extended attribute to mount a DBFS mount point in CDB
     variant

   - `pdb1` is the name of the PDB in the particular CDB, which is pointed to by `inst_cdb`

   - `/mnt/mp1` is the mount directory, where the DBFS present in the common user in the
     PDB `pdb1`, should be mounted

   - `/mnt/mfs` is the MFS mount directory that was used during the start up of the
     `dbfs_client` command

3. (Optional) Add more DBFS mount points by setting the same extended attribute with different arguments in the following way:

```
% setfattr -n mount_pdb  -v " pdb2 /mnt/mp2" /mnt/mfs
% setfattr -n mount_pdb  -v " pdb3 /mnt/mp3" /mnt/mfs
```

Where, `pdb2` and `pdb3` are the actual names of the PDBs in the container.

Defining the Mount Points in a Cross-Database Variant

Perform the following steps to define the mount points in a Cross-Database variant of the MUMV mode:

1. Start the DBFS client in MUMV Cross-Database variant by specifying the MFS mount point at the start up in the following way:

```
% dbfs_client -o mfs_mount=/mnt/mfs
```

Where, `/mnt/mfs` is the MFS mount point. It can be any empty directory of your choice

2. Add a DBFS mount point by setting an extended attribute in the following way:

```
% setfattr -n mount -v " inst1 /mnt/mp1" /mnt/mfs/
```

Where,

- `mount` is the name of the extended attribute to mount a DBFS mount in Cross-Database variant

- `inst1` is the wallet alias that connects to the DB user, for which DBFS needs to be mounted

- `/mnt/mp1` is the mount directory, where the DBFS should be mounted

- `/mnt/mfs` is the MFS mount directory that was used during the start up of the `dbfs_client` command

3. (Optional) Add more DBFS mount points by setting the same extended attribute with different arguments in the following way:

```
% setfattr -n mount -v "inst2 /mnt/mp2" /mnt/mfs/
% setfattr -n mount -v "inst3 /mnt/mp3" /mnt/mfs/
```

Where, `inst2` and `inst3` are aliases that must exist in the wallet. The DBFS client must have the credentials to connect to the user in the database and they should have at least one DBFS created in their schema.

17.3.3.2 Listing DBFS Mount Points

Each DBFS mount point has a corresponding file under the MFS directory, `/mnt/mfs`. So, you can use the standard Linux command `ls` to list the DBFS mount points.

The following code snippet shows how to list all the DBFS mount points:

```
% ls  -l  /mnt/mfs
```

The content of each file under the `/mnt/mfs` directory, provides details about the parameters used in the corresponding mount point.

The MFS is a *read-only* file system. You cannot create any file or directory within it using any application, apart from the DBFS Client. Anything that appears as a file or a directory under the MFS, is defined by the DBFS Client.

17.3.3.3 Unmounting a DBFS Mount Point

The procedure to unmount a DBFS mount point is the same for both the CDB variant and the Cross-Database variant of the MUMV mode.

You must unmount a mount point using the FUSE executable file, `fusermount`. The following code snippet shows how to drop a DBFS mount point:

```
% fusermount -u /mnt/mp1
```

17.3.3.4 Configuration Parameters of DBFS Client

All configuration parameters of DBFS client in Single User Mount Version (SUMV) mode can also be used with the DBFS client in Multi User Mount Version (MUMV) mode at the time of start up.

All the command-line options passed to the DBFS client in the MUMV mode are inherited by all the DBFS mount points that may be added later. For example, for the following `dbfs_client` command, the DBFS mounted at the `/mnt/mp1` mount point automatically inherits the `spool_max` value as 32 and the `max_threads value` as 16:

```
% dbfs_client -o mfs_mount=/mnt/mfs -o spool_max=32 -o max_threads=16
% setfattr -n mount -v "inst1 /mnt/mp1" /mnt/mfs
```

If you want to configure a mount point differently than the DBFS client, then use the `setfattr` command in the following way:

```
% sefattr -n mount -v "inst2 /mnt/mp2 -o trace_file=/tmp/
clnt.trc,trace_level=1" /mnt/mfs
```

The preceding command enables only the trace for the DBFS client at the `/mnt/mp2` mount point, but does not inherit the `spool_max` and `max_threads` arguments that were specified at the time of start up. The values specified with the `setfattr` command overwrite the values specified during start up.

17.3.3.5 Diagnosability of DBFS Client

Starting from Oracle Database Release 21c, the DBFS Client writes an alert file in the client trace directory of the configured Automatic Diagnostic Repository (ADR) base.

The alert files are generated for every instance of the DBFS client and can be found under the `clients/DBFS/DBFS/trace` directory of the ADR base. The file name is of the format `dbfs_alert_<client_pid>.trc`.

The alert file is different from the trace file. It is always enabled and only important activities of the DBFS clients are written to the alert file.

17.3.4 DBFS Client Command-Line Interface Operations

The DBFS client command-line interface allows you to directly access files stored in DBFS.

- **About the DBFS Client Command-Line Interface**
  The DBFS client command-line interface allows you to perform many pre-defined commands, such as copy files in and out of the DBFS filesystem from any host on the network.

- **Listing a Directory**
  You can use the `ls` command to list the contents of a directory.

- **Copying Files and Directories**
  You can use the `cp` command to copy files or directories from the source location to the destination location.

- **Removing Files and Directories**
  You can use the command `rm` to delete a file or directory.

17.3.4.1 About the DBFS Client Command-Line Interface

The DBFS client command-line interface allows you to perform many pre-defined commands, such as copy files in and out of the DBFS filesystem from any host on the network.

The command-line interface has slightly better performance than the DBFS client mount interface because it does not mount the file system, thus bypassing the user space file system. However, it is not transparent to applications.

The DBFS client mount interface allows DBFS to be mounted through a file system mount point thus providing transparent access to files stored in DBFS with generic file system operations.

To run DBFS commands, specify `--command` to the DBFS client.

All DBFS content store paths , in command-line interface ,must be preceded by `dbfs:` .This is an example: `dbfs:/staging_area/file1`. All database path names specified must be absolute paths.

```
dbfs_client db_user@db_server--command command [switches] [arguments]
```

where:

- `command` is the executable command, such as `ls, cp, mkdir,` or `rm`.
- `switches` are specific for each command.
- `arguments` are file names or directory names, and are specific for each command.

Note that dbfs_client returns a nonzero value in case of failure.

17.3.4.2 Listing a Directory

You can use the `ls` command to list the contents of a directory.

Use this syntax:

```
dbfs_client db_user@db_server --command ls [switches] target
```

where

- *target* is the listed directory.
- *switches* is any combination of the following:
  - *-a* shows all files, including '.' and '..'.
  - *-l* shows the long listing format: name of each file, the file type, permissions, and size.
  - *-R* lists subdirectories recursively.

For example:

```
$ dbfs_client ETLUser@DBConnectString --command  ls dbfs:/staging_area/dir1
```

or

```
$ dbfs_client ETLUser@DBConnectString --command  ls -l -a -R dbfs:/staging_area/dir1
```

17.3.4.3 Copying Files and Directories

You can use the cp command to copy files or directories from the source location to the destination location.

The cp command also supports recursive copy of directories.

```
dbfs_client db_user@db_server --command cp [switches] source destination
```

where:

- *source* is the source location.
- *destination* is the destination location.
- *switches* is either -R or -r, the options to recursively copy all source contents into the destination directory.

The following example copies the contents of the local directory, 01-01-10-dump recursively into a directory in DBFS:

```
$ dbfs_client ETLUser@DBConnectString --command cp -R  01-01-10-dump dbfs:/staging_area/
```

The following example copies the file hello.txt from DBFS to a local file Hi.txt:

```
$ dbfs_client ETLUser@DBConnectString --command cp dbfs:/staging_area/hello.txt Hi.txt
```

17.3.4.4 Removing Files and Directories

You can use the command rm to delete a file or directory.

The command rm also supports recursive delete of directories.

```
dbfs_client db_user@db_server --command rm [switches] target
```

where:

- *target* is the listed directory.
- *switches* is either -R or -r, the options to recursively delete all contents.

For example:

```
$ dbfs_client ETLUser@DBConnectString --command rm  dbfs:/staging_area/srcdir/hello.txt
```

or

```
$ dbfs_client ETLUser@DBConnectString --command rm -R  dbfs:/staging_area/dir1
```

17.3.5 DBFS Mounting Interface (Linux and Solaris Only)

You can mount DBFS using the `dbfs_client` in Linux and Solaris only.

The instructions indicate the different requirements for the Linux and Solaris platforms.

- Installing FUSE on Solaris 11 SRU7 and Later
  You can use `dbfs_client` as a mount client in Solaris 11 SRU7 and later, if you install `FUSE`

- Solaris-Specific Privileges
  On Solaris, the user must have the Solaris privilege `PRIV_SYS_MOUNT` to perform mount and unmount operations on DBFS filesystems.

- About the Mount Command for Solaris and Linux
  The `dbfs_client` mount command for Solaris and Linux uses specific syntax.

- Mounting a File System with a Wallet
  You can mount a file system with a wallet after configuring various environment variables.

- Mounting a File System with Password at Command Prompt
  You must enter a password at the command prompt to mount a file system using `dbfs_client`.

- Unmounting a File System
  In Linux, you can run `fusermount` to unmount file systems.

- Mounting DBFS Through fstab Utility for Linux
  In Linux, you can configure `fstab` utility to use `dbfs_client` to mount a DBFS filesystem.

- Mounting DBFS Through the vfstab Utility for Solaris
  On Solaris, file systems are commonly configured using the `vfstab` utility.

- Restrictions on Mounted File Systems
  DBFS supports most file system operations with exceptions.

- Restrictions on Types of Files Stored at DBFS Mount Points
  DBFS should be avoided in scenarios that can cause a file operation on the DBFS files resulting in more data to be written back to the DBFS.

17.3.5.1 Installing FUSE on Solaris 11 SRU7 and Later

You can use `dbfs_client` as a mount client in Solaris 11 SRU7 and later, if you install `FUSE`

Install `FUSE` to use `dbfs_client` as a mount client in Solaris 11 SRU7 and later.

- Run the following package as `root`.

  ```
  pkg install libfuse
  ```

17.3.5.2 Solaris-Specific Privileges

On Solaris, the user must have the Solaris privilege `PRIV_SYS_MOUNT` to perform mount and unmount operations on DBFS filesystems.

Give the user the Solaris privilege `PRIV_SYS_MOUNT` .

1. Edit `/etc/user_attr`.

2. Add or modify the user entry (assuming the user is Oracle) as follows:

ORACLE

```
oracle::::type=normal;project=group.dba;defaultpriv=basic,priv_sys_mount;;auth
s=solaris.smf.*
```

17.3.5.3 About the Mount Command for Solaris and Linux

The `dbfs_client` mount command for Solaris and Linux uses specific syntax.

Syntax:

`dbfs_client` *db_user*@*db_server* *[*-o *option_1* -o *option_2* ...] mount_point*

where the mandatory parameters are:

- *db_user* is the name of the database user who owns the DBFS content store file system.

- *db_server* is a valid connect string to the Oracle Database server, such as `hrdb_host:1521/hrservice` or an alias specified in the `tnsnames.ora`.

- *mount_point* is the path where the Database File System is mounted. Note that all file systems owned by the database user are visible at the mount point.

The options are:

- `direct_io`: To bypass the OS page cache and provide improved performance for large files. Programs in the file system cannot be executed with this option. Oracle recommends this option when DBFS is used as an ETL staging area.

- `wallet`: To run the DBFS client in the background. The Wallet must be configured to get its credentials.

- `failover`: To fail over the DBFS client to surviving database instances without data loss. Expect some performance cost on writes, especially for small files.

- `allow_root`: To allow the root user to access the filesystem. You must set the `user_allow_other` parameter in the `/etc/fuse.conf` configuration file.

- `allow_other`: To allow other users to access the filesystem. You must set the `user_allow_other` parameter in the `/etc/fuse.conf` configuration file.

- `rw`: To mount the filesystem as read-write. This is the default setting.

- `ro`: To mount the filesystem as read-only. Files cannot be modified.

- `trace_level`=*n* sets the trace level. Trace levels are:

  - 1 `DEBUG`

  - 2 `INFO`

  - 3 `WARNING`

  - 4 `ERROR`: The default tracing level. It outputs diagnostic information only when an error happens. It is recommended that this tracing level is always enabled.

  - 5 `CRITICAL`

- `trace_file`=STR: Specifies the tracing log file, where `STR` can be either a *file_name* or `syslog`.

- `trace_size`=*trcfile_size*: Specifies size of the trace file in MB. By default, `dbfs_client` rotates tracing output between two 10MB files. Specifying `0` for `trace_size` sets the maximum size of the trace file to unlimited.

17.3.5.4 Mounting a File System with a Wallet

You can mount a file system with a wallet after configuring various environment variables.

You must first configure the `LD_LIBRARY_PATH`, `ORACLE_HOME` environment variables and `sqlnet.ora` correctly before mounting a file system with a wallet.

1. Login as admin user.

2. Mount the DBFS store. (Oracle recommends that you do not perform this step as root user.)

   ```
   % dbfs_client @/dbfsdb -o wallet,rw,user,direct_io /mnt/dbfs
   ```

3. [Optional] To test if the previous step was successful, as admin user, list the `dbfs` directory.

   ```
   $ ls /mnt/tdbfs
   ```

   Using the wallet option runs the `dbfs_client` in the background

   > ✎ **See Also:**
   >
   > Using Oracle Wallet with DBFS Client

17.3.5.5 Mounting a File System with Password at Command Prompt

You must enter a password at the command prompt to mount a file system using `dbfs_client`.

- Execute the following command at the command prompt and provide the password:

   ```
   $ dbfs_client ETLUser@DBConnectString /mnt/dbfs
     password: xxxxxxx
   ```

   The `dbfs_client` runs in the foreground after the password is provided at the command prompt.

17.3.5.6 Unmounting a File System

In Linux, you can run `fusermount` to unmount file systems.

- Linux
- Solaris

Linux

To run `fusermount` in Linux, do the following:

- Run the following:

   ```
   $ fusermount -u <mount point>
   ```

Solaris

In Solaris, you can run `umount` to unmount file systems.

- Run the following:

  ```
  $ umount -u <mount point>
  ```

17.3.5.7 Mounting DBFS Through fstab Utility for Linux

In Linux, you can configure `fstab` utility to use `dbfs_client` to mount a DBFS filesystem.

To mount DBFS through `/etc/fstab`, you must use Oracle Wallet for authentication.

1. Login as `root` user.

2. Change the user and group of `dbfs_client` to user `root` and group `fuse`.

   ```
   # chown root.fuse $ORACLE_HOME/bin/dbfs_client
   ```

3. Set the `setuid` bit on `dbfs_client` and restrict `execute` privileges to the user and group only.

   ```
   # chmod u+rwxs,g+rx-w,o-rwx dbfs_client
   ```

4. Create a symbolic link to `dbfs_client` in `/sbin` as "`mount.dbfs`".

   ```
   $ ln -s $ORACLE_HOME/bin/dbfs_client /sbin/mount.dbfs
   ```

5. Create a new Linux group called "`fuse`".

6. Add the Linux user that is running the DBFS Client to the `fuse` group.

7. Add the following line to `/etc/fstab`:

   ```
   /sbin/mount.dbfs#db_user@db_server mount_point fuse rw,user,noauto 0 0
   ```

   For example:

   ```
   /sbin/mount.dbfs#/@DBConnectString /mnt/dbfs fuse rw,user,noauto 0 0
   ```

8. The Linux user can mount the DBFS file system using the standard Linux `mount` command. For example:

   ```
   $ mount /mnt/dbfs
   ```

   Note that `FUSE` does not currently support `automount`.

17.3.5.8 Mounting DBFS Through the vfstab Utility for Solaris

On Solaris, file systems are commonly configured using the `vfstab` utility.

1. Create a mount shell script `mount_dbfs.sh` to use to start `dbfs_client`. All the environment variables that are required for Oracle RDBMS must be exported. These environment variables include `TNS_ADMIN`, `ORACLE_HOME`, and `LD_LIBRARY_PATH`. For example:

   ```
   #!/bin/ksh
   export TNS_ADMIN=/export/home/oracle/dbfs/tnsadmin
   export ORACLE_HOME=/export/home/oracle/11.2.0/dbhome_1
   export DBFS_USER=dbfs_user
   export DBFS_PASSWD=/tmp/passwd.f
   ```

```
export DBFS_DB_CONN=dbfs_db
export O=$ORACLE_HOME
export LD_LIBRARY_PATH=$O/lib:$O/rdbms/lib:/usr/lib:/lib:$LD_LIBRARY_PATH
export NOHUP_LOG=/tmp/dbfs.nohup

(nohup $ORACLE_HOME/bin/dbfs_client $DBFS_USER@$DBFS_DB_CONN < $DBFS_PASSWD
        2>&1 & ) &
```

2. Add an entry for DBFS to `/etc/vfstab`. Specify the `mount_dbfs.sh` script for the `device_to_mount`. Specify `uvfs` for the `FS_type`. Specify no `formount_at_boot`. Specify mount options as needed. For example:

```
/usr/local/bin/mount_dbfs.sh - /mnt/dbfs uvfs - no rw,allow_other
```

3. User can mount the DBFS file system using the standard Solaris mount command. For example:

```
$ mount /mnt/dbfs
```

4. User can unmount the DBFS file system using the standard Solaris umount command. For example:

```
$ umount /mnt/dbfs
```

17.3.5.9 Restrictions on Mounted File Systems

DBFS supports most file system operations with exceptions.

The exceptions are:

- `ioctl`
- range locking (file locking is supported)
- asynchronous I/O through `libaio`
- `O_DIRECT` file opens
- hard links
- other special file modes

Memory-mapped files are supported except in shared-writable mode. For performance reasons, DBFS does not update the file access time every time file data or the file data attributes are read.

You cannot run programs which user Memory mapped files from a DBFS-mounted file system if the `direct_io` option is specified.

Oracle does not support exporting DBFS file systems using NFS or Samba.

17.3.5.10 Restrictions on Types of Files Stored at DBFS Mount Points

DBFS should be avoided in scenarios that can cause a file operation on the DBFS files resulting in more data to be written back to the DBFS.

The following scenarios are not exhaustive but provide examples of operations that can make the DBFS and the database interdependent and hence should be avoided:

- **Sample Scenario 1:** DBFS is the destination for the trace files generated by the same database that is hosting the DBFS.
  For example: The act of writing the trace file into the DBFS could generate more trace data to be written back into DBFS.

- **Sample Scenario 2:** The trail file of a database replication is in a DBFS and the DBFS is in the SAME database that is being replicated.
  For example: The act of writing into the trail by the replication process generates redo. This redo could feed back into the replication.

- **Sample Scenario 3:** DBFS is the destination of any database files of the same database.
  For example: The data files, control files, redo log files could make the DBFS and the database inter dependent.

17.3.6 File System Security Model

The database manages security in DBFS. It does not use the operating system security model.

- About the File System Security Model
  DBFS operates under a security model where all file systems created by a user are private to that user, by default.

- Enabling Shared Root Access
  As an operating system user who mounts the file system, you can allow root access to the file system by specifying the `allow_root` option.

- About DBFS Access Among Multiple Database Users
  DBFS allows multiple users to share a subset of the filesystem state.

- Establishing DBFS Access Sharing Across Multiple Database Users
  Learn about sharing access of DBFS to multiple database users in this section.

17.3.6.1 About the File System Security Model

DBFS operates under a security model where all file systems created by a user are private to that user, by default.

Oracle recommends maintaining this model. Because operating system users and Oracle Database users are different, it is possible to allow multiple operating system users to mount a single DBFS filesystem. These mounts may potentially have different mount options and permissions. For example, OS `user1` may mount a DBFS filesystem as `READ ONLY`, and OS `user2` may mount it as `READ WRITE`. However, Oracle Database views both users as having the same privileges because they would be accessing the filesystem as the same database user.

Access to a database file system requires a database login as a database user with privileges on the tables that underlie the file system.The database administrator grants access to a file system to database users, and different database users may have different `READ` or `UPDATE` privileges to the file system. The database administrator has access to all files stored in the DBFS file system.

On each client computer, access to a DBFS mount point is limited to the operating system user that mounts the file system. This, however, does not limit the number of users who can access the DBFS file system, because many users may separately mount the same DBFS file system.

DBFS only performs database privilege checking. Linux performs operating system file-level permission checking when a DBFS file system is mounted. DBFS does not perform this check either when using the command interface or when using the PL/SQL interface directly.

17.3.6.2 Enabling Shared Root Access

As an operating system user who mounts the file system, you can allow root access to the file system by specifying the `allow_root` option.

This option requires that the `/etc/fuse.conf` file contain the `user_allow_other` field, as demonstrated in Example 17-1.

Example 17-1   Enabling Root Access for Other Users

```
# Allow users to specify the 'allow_root' mount option.
user_allow_other
```

17.3.6.3 About DBFS Access Among Multiple Database Users

DBFS allows multiple users to share a subset of the filesystem state.

A Single filesystem may be accessed by multiple database users. For example, the database user that owns the filesystem may be a privileged user and sharing its user credentials may pose a security risk. To mitigate this, DBFS allows multiple database users to share a subset of the filesystem state.

While DBFS registrations and mounts made through the DBFS Content API are private to each user, the underlying filesystem and the tables on which they rely may be shared across users. After this is done, the individual filesystems may be independently mounted and used by different database users, either through SQL/PLSQL, or through `dbfs_client`.

17.3.6.4 Establishing DBFS Access Sharing Across Multiple Database Users

Learn about sharing access of DBFS to multiple database users in this section.

In the following example, user `user1` is able to modify the filesystem, and user `user2` can see these changes. Here, `user1` is the database user that creates a filesystem, and `user2` is the database user that eventually uses `dbfs_client` to mount and access the filesystem. Both `user1` and `user2` must have the `DBFS_ROLE` privilege.

1. Connect as the user who creates the filesystem.

   ```
   sys@tank as sysdba> connect user1
   Connected.
   ```

2. Create the filesystem `user1_FS`, register the store, and mount it as `user1_mt`.

   ```
   user1@tank> exec dbms_dbfs_sfs.createFilesystem('user1_FS');
   user1@tank> exec dbms_dbfs_content.registerStore('user1_FS', 'posix',
   'DBMS_DBFS_SFS');
   user1@tank> exec dbms_dbfs_content.mountStore('user1_FS', 'user1_mnt');
   user1@tank> commit;
   ```

3. [Optional] You may check that the previous step has completed successfully by viewing all mounts.

   ```
   user1@tank> select * from table(dbms_dbfs_content.listMounts);

   STORE_NAME          |    STORE_ID|PROVIDER_NAME

```

4. [Optional] Connect as the user who will use the `dbfs_client`.

```
user1@tank> connect user2
Connected.
```

5. [Optional] Note that `user2` cannot see `user1`'s DBFS state, as he has no mounts.

```
user2@tank> select * from table(dbms_dbfs_content.listMounts);
```

6. While connected as `user1`, export filesystem `user1_FS` for access to any user with `DBFS_ROLE` privilege.

```
user1@tank> exec dbms_dbfs_sfs.exportFilesystem('user1_FS');
user1@tank> commit;
```

7. Connect as the user who will use the `dbfs_client`.

```
user1@tank> connect user2
Connected.
```

8. As `user2`, view all available tables.

```
user2@tank> select * from table(dbms_dbfs_sfs.listTables);

  DBMS_DBFS_CONTENT_PROPERTY_T('owner', (null), 9),
  DBMS_DBFS_CONTENT_PROPERTY_T('acl', (null), 9),
  DBMS_DBFS_CONTENT_PROPERTY_T('asof', (null), 187),
  DBMS_DBFS_CONTENT_PROPERTY_T('read_only', '0', 2))
```

11. [Optional] List path names for `user2` and `user1`. Note that another mount, `user2_mnt`, for store `user2_FS`, is available for `user2`. However, the underlying filesystem data is the same for `user2` as for `user1`.

```
user2@tank> select pathname from dbfs_content;

PATHNAME
--------------------------------------------------------------------------------
/user2_mnt
/user2_mnt/.sfs/tools
/user2_mnt/.sfs/snapshots
/user2_mnt/.sfs/content
/user2_mnt/.sfs/attributes
/user2_mnt/.sfs/RECYCLE
/user2_mnt/.sfs

user2@tank> connect user1
Connected.

user1@tank> select pathname from dbfs_content;

PATHNAME
--------------------
/user1_mnt
/user1_mnt/.sfs/tools
/user1_mnt/.sfs/snapshots
/user1_mnt/.sfs/content
/user1_mnt/.sfs/attributes
/user1_mnt/.sfs/RECYCLE
/user1_mnt/.sfs
```

12. In filesystem `user1_FS`, `user1` creates file *xxx*.

```
user1@tank> declare
                data blob;
                properties dbms_dbfs_content.properties_t;
            begin
                properties('posix:mode') :=
dbms_dbfs_content.propNumber(33188);
                dbms_dbfs_content.createFile('/user1_mnt/xxx', properties
=> properties, content => data);
            end;
            /
```

13. [Optional] Write to file *xxx*, created in the previous step.

```
user1@tank> var buf varchar2(100);
user1@tank> exec :buf := 'hello world';
user1@tank> exec dbms_lob.writeappend(:data, length(:buf),
utl_raw.cast_to_raw(:buf));
user1@tank> commit;
```

14. [Optional] Show that file *xxx* exists, and contains the appended data.

```
user1@tank> select pathname, utl_raw.cast_to_varchar2(filedata)
  from dbfs_content where filedata is not null;

PATHNAME
--------------------------------------------------------------------------------
UTL_RAW.CAST_TO_VARCHAR2(FILEDATA)
--------------------------------------------------------------------------------
/user1_mnt/xxx
hello world
```

15. User `user2` sees the same file in their own DBFS-specific path name and mount prefix.

```
user1@tank> connect user2
Connected.

user2@tank> select pathname, utl_raw.cast_to_varchar2(filedata) from
  dbfs_content where filedata is not null;

PATHNAME
--------------------------------------------------------------------------------
UTL_RAW.CAST_TO_VARCHAR2(FILEDATA)
--------------------------------------------------------------------------------
/user2_mnt/xxx
hello world
```

After the export and register pairing completes, both users behave as equals with regard to their usage of the underlying tables. The `exportFilesystem()` procedure manages the necessary grants for access to the same data, which is shared between schemas. After `user1` calls `exportFilesystem()`, filesystem access may be granted to any user with `DBFS_ROLE`. Note that a different role can be specified to `exportFilesystem`.

Subsequently, `user2` may create a new DBFS filesystem that shares the same underlying storage as the `user1_FS` filesystem, by invoking `dbms_dbfs_sfs.registerFilesystem()`, `dbms_dbfs_sfs.registerStore()`, and `dmbs_dbfs_sfs.mountStore()` procedure calls.

When multiple database users share a filesystem, they must ensure that all database users unregister their interest in the filesystem before the owner (here, `user1`) drops the filesystem.

Oracle does not recommend that you run the DBFS as `root`.

17.3.7 HTTP, WebDAV, and FTP Access to DBFS

Components that enable HTTP, WebDAV, and FTP access to DBFS over the Internet use various XML DB server protocols.

- Internet Access to DBFS Through XDB
  To provide database users who have DBFS authentication with a hierarchical file system-like view of registered and mounted DBFS stores, stores are displayed under the path `/dbfs`.

- Web Distributed Authoring and Versioning (WebDAV) Access
  WebDAV is an IETF standard protocol that provides users with a file-system-like interface to a repository over the Internet.

- FTP Access to DBFS
  FTP access to DBFS uses the standard FTP clients found on most Unix-based distributions. FTP is a file transfer mechanism built on client-server architecture with separate control and data connections.

- HTTP Access to DBFS
  Users have read-only access through HTTP/HTTPS protocols.

17.3.7.1 Internet Access to DBFS Through XDB

To provide database users who have DBFS authentication with a hierarchical file system-like view of registered and mounted DBFS stores, stores are displayed under the path `/dbfs`.

The `/dbfs` folder is a virtual folder because the resources in its subtree are stored in DBFS stores, not the XDB repository. XDB issues a `dbms_dbfs_content.list()` command for the root path name "/" (with invoker rights) and receives a list of store access points as subfolders in the `/dbfs` folder. The list is comparable to `store_mount` parameters passed to `dbms_dbfs_content.mountStore()`. FTP and WebDAV users can navigate to these stores, while HTTP and HTTPS users access URLs from browsers.

Note that features implemented by the XDB repository, such as repository events, resource configurations, and ACLs, are not available for the `/dbfs` folder.

DBFS Content API for guidelines on DBFS store creation, registration, deregistration, mount, unmount and deletion

17.3.7.2 Web Distributed Authoring and Versioning (WebDAV) Access

WebDAV is an IETF standard protocol that provides users with a file-system-like interface to a repository over the Internet.

WebDAV server folders are typically accessed through Web Folders on Microsoft Windows (2000/NT/XP/Vista/7, and so on). You can access a resource using its fully qualified name, for example, `/dbfs/sfs1/dir1/file1.txt`, where `sfs1` is the name of a DBFS store.

You need to set up WebDAV on Windows to access the DBFS filesystem.

> **See Also:**
>
> *Oracle XML DB Developer's Guide*

The user authentication required to access the DBFS virtual folder is the same as for the XDB repository.

When a WebDAV client connects to a WebDAV server for the first time, the user is typically prompted for a username and password, which the client uses for all subsequent requests. From a protocol point-of-view, every request contains authentication information, which XDB uses to authenticate the user as a valid database user. If the user does not exist, the client does not get access to the DBFS store or the XDB repository. Upon successful authentication, the database user becomes the current user in the session.

XDB supports both basic authentication and digest authentication. For security reasons, it is highly recommended that HTTPS transport be used if basic authentication is enabled.

17.3.7.3 FTP Access to DBFS

FTP access to DBFS uses the standard FTP clients found on most Unix-based distributions. FTP is a file transfer mechanism built on client-server architecture with separate control and data connections.

FTP users are authenticated as database users. The protocol, as outlined in RFC 959, uses clear text user name and password for authentication. Therefore, FTP is not a secure protocol.

The following commands are supported for DBFS:

- `USER`: Authentication username
- `PASS`: Authentication password
- `CWD`: Change working directory
- `CDUP`: Change to Parent directory
- `QUIT`: Disconnect
- `PORT`: Specifies an address and port to which the server should connect
- `PASV`: Enter passive mode
- `TYPE`: Sets the transfer mode, such as, ASCII or Binary
- `RETR`: Transfer a copy of the file
- `STOR`: Accept the data and store the data as a file at the server site
- `RNFR`: Rename From
- `RNTO`: Rename To
- `DELE`: Delete file
- `RMD`: Remove directory
- `MKD`: Make a directory
- `PWD`: Print working directory
- `LIST`: Listing of a file or directory. Default is current directory.

- `NLST`: Returns file names in a directory

- `HELP`: Usage document

- `SYST`: Return system type

- `FEAT`: Gets the feature list implemented by the server

- `NOOP`: No operation (used for keep-alives)

- `EPRT`: Extended address (IPv6) and port to which the server should connect

- `EPSV`: Enter extended passive mode (IPv6)

17.3.7.4 HTTP Access to DBFS

Users have read-only access through HTTP/HTTPS protocols.

Users point their browsers to a DBFS store using the XDB HTTP server with a URL such as `https://hostname:port/dbfs/sfs1` where `sfs1` is a DBFS store name.

17.4 Maintaining DBFS

DBFS administration includes tools that perform diagnostics, manage failover, perform backup, and so on.

- Using Oracle Wallet with DBFS Client
  Learn about using Oracle Wallet in this section.

- DBFS Diagnostics
  The `dbfs_client` program supports multiple levels of tracing to help diagnose problems.

- Preventing Data Loss During Failover Events
  The `dbfs_client` program can failover to one of the other existing database instances if one of the database instances in an Oracle RAC cluster fails.

- Bypassing Client-Side Write Caching
  The sharing and caching semantics for `dbfs_client` are similar to NFS in using the *close-to-open cache consistency* behavior.

- Backing up DBFS
  You have two alternatives for backing up DBFS.

- Small File Performance of DBFS
  Like any shared file system, the performance of DBFS for small files lags the performance of a local file system.

17.4.1 Using Oracle Wallet with DBFS Client

Learn about using Oracle Wallet in this section.

An Oracle Wallet allows the DBFS client to mount a DBFS store without requiring the user to enter a password.

> ✏️ **See Also:**
>
> *Oracle Database Enterprise User Security Administrator's Guide* for more information about creation and management of wallets

1. Create a directory for the wallet. For example:

   ```
   mkdir $ORACLE_HOME/oracle/wallet
   ```

2. Create an auto-login wallet.

   ```
   mkstore -wrl $ORACLE_HOME/oracle/wallet -create
   ```

3. Add the wallet location in the client's `sqlnet.ora` file:

   ```
   WALLET_LOCATION = (SOURCE = (METHOD = FILE) (METHOD_DATA = (DIRECTORY =
    $ORACLE_HOME/oracle/wallet) ) )
   ```

4. Add the following parameter in the client's `sqlnet.ora` file:

   ```
   SQLNET.WALLET_OVERRIDE = TRUE
   ```

5. Create credentials:

   ```
   mkstore -wrl wallet_location -createCredential db_connect_string username password
   ```

   For example:

   ```
   mkstore -wrl $ORACLE_HOME/oracle/wallet -createCredential DBConnectString scott
   password
   ```

6. Add the connection alias to your `tnsnames.ora` file.

7. Use `dbfs_client` with Oracle Wallet.

   For example:

   ```
   $ dbfs_client -o wallet /@DBConnectString /mnt/dbfs
   ```

17.4.2 DBFS Diagnostics

The `dbfs_client` program supports multiple levels of tracing to help diagnose problems.

The `dbfs_client` can either output traces to a file or to `/var/log/messages` using the `syslog` daemon on Linux.

When you trace to a file, the `dbfs_client` program keeps two trace files on disk. `dbfs_client`, rotates the trace files automatically, and limits disk usage to 10 MB.

By default, tracing is turned off except for critical messages which are always logged to `/var/log/messages`.

If `dbfs_client` cannot connect to the Oracle Database, enable tracing using the `trace_level` and `trace_file` options. Tracing prints additional messages to log file for easier debugging.

DBFS uses Oracle Database for storing files. Sometimes Oracle server issues are propagated to `dbfs_client` as errors. If there is a `dbfs_client` error, please view the Oracle server logs to see if that is the root cause.

17.4.3 Preventing Data Loss During Failover Events

The `dbfs_client` program can failover to one of the other existing database instances if one of the database instances in an Oracle RAC cluster fails.

For `dbfs_client` failover to work correctly, you must modify the Oracle database service and specify failover parameters. Run the `DBMS_SERVICE.MODIFY_SERVICE` procedure to modify the service as shown Example 17-2

Example 17-2   Enabling DBFS Client Failover Events

```
exec DBMS_SERVICE.MODIFY_SERVICE(service_name => 'service_name',
               aq_ha_notifications => true,
               failover_method => 'BASIC',
               failover_type => 'SELECT',
               failover_retries => 180,
               failover_delay => 1);
```

Once you have completed the prerequisite, you can prevent data loss during a failover of the DBFS connection after a failure of the back-end Oracle database instance. In this case, cached *writes* may be lost if the client loses the connection. However, back-end failover to other Oracle RAC instances or standby databases does not cause lost writes.

* Specify the `-o failover` mount option:

    ```
    $ dbfs_client database_user@database_server -o failover /mnt/dbfs
    ```

17.4.4 Bypassing Client-Side Write Caching

The sharing and caching semantics for `dbfs_client` are similar to NFS in using the *close-to-open cache consistency* behavior.

This allows multiple copies of `dbfs_client` to access the same shared file system. The default mode caches writes on the client and flushes them after a timeout or after the user closes the file. Also, writes to a file only appear to clients that open the file after the writer closed the file.

You can bypass client-side write caching.

* Specify `O_SYNC` when the file is opened.

    To force writes in the cache to disk call `fsync`.

17.4.5 Backing up DBFS

You have two alternatives for backing up DBFS.

You can back up the tables that underlie the file system at the database level or use a file system backup utility, such as Oracle Secure Backup, through a mount point.

Topics:

* DBFS Backup at the Database Level
    An advantage of backing up the tables at the database level is that the files in the file system are always consistent with the relational data in the database.

* DBFS Backup Through a File System Utility
    The advantage of backing up the file system using a file system backup utility is that individual files can be restored from backup more easily.

17.4.5.1 DBFS Backup at the Database Level

An advantage of backing up the tables at the database level is that the files in the file system are always consistent with the relational data in the database.

A full restore and recover of the database also fully restores and recovers the file system with no data loss. During a point-in-time recovery of the database, the files are recovered to the specified time. As usual with database backup, modifications that occur during the backup do not affect the consistency of a restore. The entire restored file system is always consistent with respect to a specified time stamp.

17.4.5.2 DBFS Backup Through a File System Utility

The advantage of backing up the file system using a file system backup utility is that individual files can be restored from backup more easily.

Any changes made to the restored files after the last backup are lost.

Specify the `allow_root` mount option if backups are scheduled using the Oracle Secure Backup Administrative Server.

17.4.6 Small File Performance of DBFS

Like any shared file system, the performance of DBFS for small files lags the performance of a local file system.

Each file data or metadata operation in DBFS must go through the `FUSE` user mode file system and then be forwarded across the network to the database. Therefore, each operation that is not cached on the client takes a few milliseconds to run in DBFS.

For operations that involve an input/output (IO) to disk, the time delay overhead is masked by the wait for the disk IO. Naturally, larger IOs have a lower percentage overhead than smaller IOs. The network overhead is more noticeable for operations that do not issue a disk IO.

When you compare the operations on a few small files with a local file system, the overhead is not noticeable, but operations that affect thousands of small files incur a much more noticeable overhead. For example, listing a single directory or looking at a single file produce near instantaneous response, while searching across a directory tree with many thousands of files results in a larger relative overhead. Oracle recommends `direct_io` option in `dbfs_client` for optimal performance for reads and writes.

17.5 Shrinking and Reorganizing DBFS Filesystems

DBFS uses Online File system Reorganization to shrink itself, enabling the release of allocated space back to the containing tablespace.

- **About Changing DBFS File Systems**
  DBFS file systems, like other database segments, grow dynamically with the addition or enlargement of files and directories.

- **Advantages of Online Filesystem Reorganization**
  DBFS Online Filesystem Reorganization is a powerful data movement facility with these certain advantages.

- **Determining Availability of Online Filesystem Reorganization**
  DBFS for Oracle Database 12*c* and later supports online filesystem reorganization. Some earlier versions also support the facility.

- **Required Permissions for Online Filesystem Reorganization**
  Database users must have the following set of privileges for Online Filesystem Reorganizaton.

- **Invoking Online Filesystem Reorganization**
  You can perform an Online Filesystem Reorganization by creating a temporary DBFS filesystem.

17.5.1 About Changing DBFS File Systems

DBFS file systems, like other database segments, grow dynamically with the addition or enlargement of files and directories.

Growth occurs with the allocation of space from the tablespace that holds the DBFS file system to the various segments that make up the file system.

However, even if files and directories in the DBFS file system are deleted, the allocated space is not released back to the containing tablespace, but continues to exist and be available for other DBFS entities. A process called Online Filesystem Reorganization solves this problem by shrinking the DBFS Filesystem.

The DBFS Online Filesystem Reorganization utility internally uses the Oracle Database online redefinition facility, with the original file system and a temporary placeholder corresponding to the base and interim objects in the online redefinition model.

> ✎ **See Also:**
>
> *Oracle Database Administrator's Guide* for further information about online redefinition

17.5.2 Advantages of Online Filesystem Reorganization

DBFS Online Filesystem Reorganization is a powerful data movement facility with these certain advantages.

These are:

- **It is online:** When reorganization is taking place, the filesystem remains fully available for read and write operations for all applications.

- **It can reorganize the structure:** The underlying physical structure and organization of the DBFS filesystem can be changed in many ways, such as:

  - A non-partitioned filesystem can be converted to a partitioned filesystem and vice-versa.

  - Special SecureFiles LOB properties can be selectively enabled or disabled in any combination, including the compression, encryption, and deduplication properties.

  - The data in the filesystem can be moved across tablespaces or within the same tablespace.

- **It can reorganize multiple filesystems concurrently:** Multiple different filesystems can be reorganized at the same time, if no temporary filesystems have the same name and the tablespaces have enough free space, typically, twice the space requirement for each filesystem being reorganized.

17.5.3 Determining Availability of Online Filesystem Reorganization

DBFS for Oracle Database 12*c* and later supports online filesystem reorganization. Some earlier versions also support the facility.

To determine if your version does, query for a specific function in the DBFS PL/SQL packages, as shown below:

- Query for a specific function in the DBFS PL/SQL packages.

```
$ sqlplus / as sysdba
SELECT * FROM dba_procedures
WHERE   owner = 'SYS'
    and object_name = 'DBMS_DBFS_SFS'
    and procedure_name = 'REORGANIZEFS';
```

If this query returns a single row similar to the one in this output, the DBFS installation supports Online Filesystem Reorganization. If the query does not return any rows, then the DBFS installation should either be upgraded or requires a patch for bug-10051996.

```
OWNER
--------------------------------------------------------------------------------
OBJECT_NAME
--------------------------------------------------------------------------------
PROCEDURE_NAME
--------------------------------------------------------------------------------
OBJECT_ID|SUBPROGRAM_ID|OVERLOAD                             |OBJECT_TYPE  |AGG|PIP
----------|-------------|----------------------------------|-------------|---|---
IMPLTYPEOWNER
--------------------------------------------------------------------------------

(null)
(null)
NO |NO |NO |CURRENT_USER
```

17.5.4 Required Permissions for Online Filesystem Reorganization

Database users must have the following set of privileges for Online Filesystem Reorganizaton.

Users must have these privileges:

- `ALTER ANY TABLE`

- `DROP ANY TABLE`

- `LOCK ANY TABLE`

- `CREATE ANY TABLE`

- `SELECT ANY TABLE`

- `REDEFINE ANY TABLE`

- `CREATE ANY TRIGGER`

- CREATE ANY INDEX

- CREATE TABLE

- CREATE MATERIALIZED VIEW

- CREATE TRIGGER

17.5.5 Invoking Online Filesystem Reorganization

You can perform an Online Filesystem Reorganization by creating a temporary DBFS filesystem.

> **Note:**
>
> Ensure that you don't create the temporary DBFS filesystem in the SYS schema. DBFS Online Filesystem Reorganization will not work if you create the temporary DBFS filesystem in the SYS schema.

1. Create a temporary DBFS filesystem with the desired new organization and structure: including the desired target tablespace (which may be the same tablespace as the filesystem being reorganized), desired target SecureFiles LOB storage properties (compression, encryption, or deduplication), and so on.

2. Invoke the PL/SQL procedure to reorganize the DBFS filesystem using the newly-created temporary filesystem for data movement.

3. Once the reorganization procedure completes, drop the temporary filesystem.

The example below reorganizes DBFS filesystem FS1 in tablespace TS1 into a new tablespace TS2, using a temporary filesystem named TMP_FS, where all filesystems belong to database user dbfs_user:

```
$ cd $ORACLE_HOME/rdbms/admin
$ sqlplus dbfs_user/***

@dbfs_create_filesystem TS2 TMP_FS
EXEC DBMS_DBFS_SFS.REORGANIZEFS('FS1', 'TMP_FS');
@dbfs_drop_filesystem TMP_FS
QUIT;
```

where:

- TMP_FS can have any valid name. It is intended as a temporary placeholder and can be dropped (as shown in the example above) or retained as a fully materialized point-in-time snapshot of the original filesystem.

- FS1 is the original filesystem and is unaffected by the attempted reorganization. It remains usable for all DBFS operations, including SQL, PL/SQL, and dbfs_client mounts and commandline, during the reorganization. At the end of the reorganization, FS1 has the new structure and organization used to create TMP_FS and vice versa (TMP_FS will have the structure and organization originally used for FS1). If the reorganization fails for any reason, DBFS attempts to clean up the internal state of FS1.

- TS2 needs enough space to accommodate all active (non-deleted) files and directories in FS1.

- TS1 needs at least twice the amount of space being used by FS1 if the filesystem is moved within the same tablespace as part of a shrink.

18

DBFS Hierarchical Store

The DBFS Hierarchical Store and related store wallet management work together to store less frequently used data.

- **About the Hierarchical Store Package DBMS_DBFS_HS**
  The Oracle DBFS Hierarchical Store package (`DBMS_DBFS_HS`) is a store provider for `DBMS_DBFS_CONTENT` that supports hierarchical storage for DBFS content.

- **Setting up the Store**
  You can create, register, and mount a hierarchical Store.

- **Using the Hierarchical Store**
  You can use the Hierarchical Store as an independent file system or as an archive solution for SecureFile LOBs.

- **The DBMS_DBFS_HS Package**
  The `DBMS_DBFS_HS` package is a service provider that enables use of tape or Amazon S3 Web service as storage for data.

- **Views for DBFS Hierarchical Store**
  The DBFS Hierarchical Stores have several types of views.

18.1 About the Hierarchical Store Package DBMS_DBFS_HS

The Oracle DBFS Hierarchical Store package (`DBMS_DBFS_HS`) is a store provider for `DBMS_DBFS_CONTENT` that supports hierarchical storage for DBFS content.

The package stores content in external storage devices like tape and Amazon S3 web service, and associated metadata (or properties) in the database. The DBFS HS may cache frequently accessed content in database tables to improve performance.

The `DBMS_DBFS_HS` package provides you the ability to use tape as a storage tier when implementing Information Lifecycle Management (ILM) for database tables or content. The data on tape or Amazon S3 is part of the Oracle Database and all standard APIs can access it, but only through the database.

`DBMS_DBFS_HS` has additional interfaces needed to manage the external storage device and the cache associated with each store.

To use the package `DBMS_DBFS_HS`, you must be granted the `DBFS_ROLE` role.

18.2 Setting up the Store

You can create, register, and mount a hierarchical Store.

- **Creating, Registering, and Mounting the Store**
  Setting up a hierarchical file system store requires creating, registering, and mounting the store.

18.2.1 Creating, Registering, and Mounting the Store

Setting up a hierarchical file system store requires creating, registering, and mounting the store.

Creating, registering, and mounting the store.

1. Call `CREATESTORE`.

> **See Also:**
>
> CREATESTORE Procedure for more information on `CREATESTORE` procedure.

> **Note:**
>
> You create a wallet with the credentials of the Amazon S3 accounts if Amazon S3 is used as the external storage.

2. Set mandatory and optional properties using `DBMS_DBFS_HS.SETSTOREPROPERTY`.

> **See Also:**
>
> SETSTOREPROPERTY Procedure for more information on `SETSTOREPROPERTY` procedure.

3. Register the store using `DBMS_DBFS_CONTENT.REGISTERSTORE`.

> **See Also:**
>
> REGISTERSTORE Procedure for more information on `REGISTERSTORE` procedure.

4. Mount the store using `DBMS_DBFS_CONTENT.MOUNTSTORE`.

> **See Also:**
>
> MOUNTSTORE Procedure for more information on `MOUNTSTORE` procedure.

18.3 Using the Hierarchical Store

You can use the Hierarchical Store as an independent file system or as an archive solution for SecureFile LOBs.

- Using Hierarchical Store as a File System
  Use the `DBMS_DBFS_CONTENT` package to create, update, read, and delete file system entries in the store.

- Using Hierarchical Store as an Archive Solution For SecureFiles LOBs
  Use the `DBMS_LOB` package to archive SecureFiles LOBs in a tape or an S3 store.

- Dropping a Hierarchical Store
  You can drop a hierarchical store.

- Compression to Use with the Hierarchical Store
  The DBFS hierarchical store can store its files in compressed forms.

- Program Example Using Tape
  This example program configures and uses a tape store.

- Program Example Using Amazon S3
  This example program configures and uses an Amazon S3 store.

18.3.1 Using Hierarchical Store as a File System

Use the `DBMS_DBFS_CONTENT` package to create, update, read, and delete file system entries in the store.

> **See Also:**
>
> DBFS Content API

18.3.2 Using Hierarchical Store as an Archive Solution For SecureFiles LOBs

Use the `DBMS_LOB` package to archive SecureFiles LOBs in a tape or an S3 store.

The `DBMS_LOB` package archives SecureFiles LOBs in a tape or an S3 store. Use the following method to free space in the cache or to force cache resident contents to be written to an external storage device:

```
DBMS_DBFS_HS.storePush(store_name);
```

18.3.3 Dropping a Hierarchical Store

You can drop a hierarchical store.

To drop a hierarchical store, call:

```
DBMS_DBFS_HS.dropStore(store_name, opt_flags);
```

18.3.4 Compression to Use with the Hierarchical Store

The DBFS hierarchical store can store its files in compressed forms.

The DBFS hierarchical store has the ability to store its files in compressed form using the `SETPROPERTY` method and the property `PROPNAME_COMPRESSLVL` to specify the compression level.

Valid values are:

- `PROPVAL_COMPLVL_NONE`: No compression

- `PROPVAL_COMPLVL_LOW`: `LOW` compression

- `PROPVAL_COMPLVL_MEDIUM`: `MEDIUM` compression

- `PROPVAL_COMPLVL_HIGH`: `HIGH` compression

Generally, the compression level `LOW` performs best and still provides a good compression ratio. Compression levels `MEDIUM` and `HIGH` provide significantly better compression ratios, but compression times can be correspondingly longer. Oracle recommends using `NONE` or `LOW` when write performance is critical, such as when files in the DBFS HS store are updated frequently. If space is critical and the best possible compression ratio is desired, use `MEDIUM` or `HIGH`.

Files are compressed as they are paged out of the cache into the staging area (before they are subsequently pushed into the back end tape or S3 storage). Therefore, compression also benefits by storing smaller files in the staging area and effectively increasing the total available capacity of the staging area.

18.3.5 Program Example Using Tape

This example program configures and uses a tape store.

In the example, you must substitute valid values in some places, as indicated by <...>, for the program to run successfully.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* `DBMS_DBFS_HS` documentation for complete details about the methods and their parameters

```
Rem Example to configure and use a Tape store.
Rem
Rem hsuser should be a valid database user who has been granted
Rem the role dbfs_role.

connect hsuser/hsuser

Rem The following block sets up a STORETYPE_TAPE store with
Rem DBMS_DBFS_HS acting as the store provider.

declare
storename varchar2(32) ;
tblname varchar2(30) ;
tbsname varchar2(30) ;
lob_cache_quota number := 0.8 ;
cachesz number ;
ots number ;
begin
cachesz := 50 * 1048576 ;
ots := 1048576 ;
storename := 'tapestore10' ;
tblname := 'tapetbl10' ;
tbsname := '<TBS_3>' ; -- Substitute a valid tablespace name

-- Create the store.
-- Here tbsname is the tablespace used for the store,
-- tblname is the table holding all the store entities,
```

```
-- cachesz is the space used by the store to cache content
--   in the tablespace,
-- lob_cache_quota is the fraction of cachesz allocated
--   to level-1 cache and
-- ots is minimum amount of content that is accumulated
--   in level-2 cache before being stored on tape
dbms_dbfs_hs.createStore(
  storename,
  dbms_dbfs_hs.STORETYPE_TAPE,
  tblname, tbsname, cachesz,
  lob_cache_quota, ots) ;

dbms_dbfs_hs.setstoreproperty(
  storename,
  dbms_dbfs_hs.PROPNAME_SBTLIBRARY,
  '<ORACLE_HOME/work/libobkuniq.so>') ;
  -- Substitute your ORACLE_HOME path

dbms_dbfs_hs.setstoreproperty(
  storename,
  dbms_dbfs_hs.PROPNAME_MEDIAPOOL,
  '<0>') ;  -- Substitute valid value

dbms_dbfs_hs.setstoreproperty(
  storename,
  dbms_dbfs_hs.PROPNAME_COMPRESSLEVEL,
  'NONE') ;

-- Please refer to DBMS_DBFS_CONTENT documentation
-- for details about this method
dbms_dbfs_content.registerstore(
  storename,
  'tapeprvder10',
  'dbms_dbfs_hs') ;

-- Please refer to DBMS_DBFS_CONTENT documentation
-- for details about this method
dbms_dbfs_content.mountstore(storename, 'tapemnt10') ;
end ;

Table 18-1   Methods of the DBMS_DBFS_HS PL/SQL Packages

Method	Description
`CLEANUPUNUSEDBACKUPFILES`	Removes files that are created on the external storage device if they have no current content.
	Oracle Database PL/SQL Packages and Types Reference
`CREATEBUCKET`	Creates an AWS bucket, for use with the `STORETYPE_AMAZON3` store.
	Oracle Database PL/SQL Packages and Types Reference
`CREATESTORE`	Creates a DBFS HS store.
	Oracle Database PL/SQL Packages and Types Reference
`DEREGSTORECOMMAND`	Removes a command (message) that was associated with a store.
	Oracle Database PL/SQL Packages and Types Reference
`DROPSTORE`	Deletes a previously created DBFS HS store.
	Oracle Database PL/SQL Packages and Types Reference

ORACLE®

Table 18-1   (Cont.) Methods of the DBMS_DBFS_HS PL/SQL Packages

Method	Description
FLUSHCACHE	Flushes out level 1 cache to level 2 cache, increasing space in level 1.
	Oracle Database PL/SQL Packages and Types Reference
GETSTOREPROPERTY	Retrieves the values of a property of a store in the database.
	Oracle Database PL/SQL Packages and Types Reference
RECONFIGCACHE	Reconfigures the parameters of the database cache used by the store.
	Oracle Database PL/SQL Packages and Types Reference
REGISTERSTORECOMMAND	Registers commands (messages) for a store so they are sent to the Media Manager of an external storage device.
	Oracle Database PL/SQL Packages and Types Reference .
SENDCOMMAND	Sends a command (message) to the Media Manager of an external storage device.
	Oracle Database PL/SQL Packages and Types Reference
SETSTOREPROPERTY	Associates name/value properties with a registered Hierarchical Store.
	Oracle Database PL/SQL Packages and Types Reference
STOREPUSH	Pushes locally cached data to an archive store.
	Oracle Database PL/SQL Packages and Types Reference

18.5 Views for DBFS Hierarchical Store

The DBFS Hierarchical Stores have several types of views.

- DBA Views
  There are several views available for DBFS Hierarchical Store.

- User Views
  There are several views available for the DBFS Hierarchical Store.

> ✎ **See Also:**
>
> *Oracle Database Reference* for the columns and data types of these views

18.5.1 DBA Views

There are several views available for DBFS Hierarchical Store.

Following are the views available for DBFS Hierarchical Store:

- DBA_DBFS_HS

  This view shows all Database File System (DBFS) hierarchical stores

- DBA_DBFS_HS_PROPERTIES

  This view shows modifiable properties of all Database File System (DBFS) hierarchical stores.

- DBA_DBFS_HS_FIXED_PROPERTIES

This view shows non-modifiable properties of all Database File System (DBFS) hierarchical stores.

- `DBA_DBFS_HS_COMMANDS`

  This view shows all the registered store commands for all Database File System (DBFS) hierarchical stores.

18.5.2 User Views

There are several views available for the DBFS Hierarchical Store.

- `USER_DBFS_HS`

  This view shows all Database File System (DBFS) hierarchical stores owned by the current user.

- `USER_DBFS_HS_PROPERTIES`

  This view shows modifiable properties of all Database File System (DBFS) hierarchical stores owned by current user.

- `USER_DBFS_HS_FIXED_PROPERTIES`

  This view shows non-modifiable properties of all Database File System (DBFS) hierarchical stores owned by current user.

- `USER_DBFS_HS_COMMANDS`

  This view shows all the registered store commands for all Database File system (DBFS) hierarchical stores owned by current user.

- `USER_DBFS_HS_FILES`

  This view shows files in the Database File System (DBFS) hierarchical store owned by the current user and their location on the backend device.

19

Database File System Links

Database File System Links enable storing SecureFiles LOBs in a different location than usual.

- **About Database File System Links**
  DBFS Links allows storing SecureFiles LOBs transparently in a location separate from the segment where the LOB is normally stored. Instead, you store a link to the LOB in the segment.

- **Ways to Create Database File System Links**
  Database File System Links require the creation of a Database File System through the use of the DBFS Content package, `DBMS_DBFS_CONTENT`.

- **Database File System Links Copy**
  The API `DBMS_LOB.COPY_DBFS_LINK(DSTLOB, SRCLOB, FLAGS)` provides the ability to copy a linked SecureFiles LOB.

- **The DBMS_LOB Package Used with DBFS**
  The `DBMS_LOB` package provides subprograms to operate on, or access and manipulate specific parts of a LOB or complete LOBs.

- **DBMS_LOB Constants Used with DBFS**
  Certain constants support DBFS link interfaces.

- **DBMS_LOB Subprograms Used with DBFS**
  You should note that some changes have been made to the `DBMS_LOB` subprograms over time.

- **Copying a Linked LOB Between Tables**
  You can copy DBFS links from source tables to destination tables.

- **Online Redefinition and DBFS Links**
  Online redefinition copies any DBFS Links that are stored in any SecureFiles LOBs in the table being redefined.

- **Transparent Read**
  DBFS Links can read from a linked SecureFiles LOB even if the data is not cached in the database.

19.1 About Database File System Links

DBFS Links allows storing SecureFiles LOBs transparently in a location separate from the segment where the LOB is normally stored. Instead, you store a link to the LOB in the segment.

The link in the segment must reference a path that uses DBFS Content API to locate the LOB when accessed. This means that the LOB could be stored on another file system, on a tape system, in the cloud, or any other location that can be accessed using DBFS Content API.

When a user or application tries to access a SecureFiles LOB that has been stored outside the segment using a DBFS Link, the behavior can vary depending on the attempted operation and the characteristics of the DBFS store that holds the LOB:

- Read:

If the LOB is not already cached in a local area in the database, then it can be read directly from the DBFS content store that holds it, if the content store allows streaming access based on the setting of the PROPNAME_STREAMABLE parameter. If the content store does not allow streaming access, then the entire LOB will first be read into a local area in the database, where it will be stored for a period of time for future access.

- Write:

  If the LOB is not already cached in a local area in the database, then it will first be read into the database, modified as needed, and then written back to the DBFS content store defined in the DBFS Link for the LOB in question.

- Delete:

  When a SecureFiles LOB that is stored through a DBFS Link is deleted, the DBFS Link is deleted from the table, but the LOB itself is NOT deleted from the DBFS content store. Or it is more complex, based on the characteristics/settings, of the DBFS content store in question.

DBFS Links enable the use of SecureFiles LOBs to implement Hierarchical Storage Management (HSM) in conjunction with the DBFS Hierarchical Store (DBFS HS). HSM is a process by which the database moves rarely used or unused data from faster, more expensive, and smaller storage to slower, cheaper, and higher capacity storage.

Figure 19-1   Database File System Link
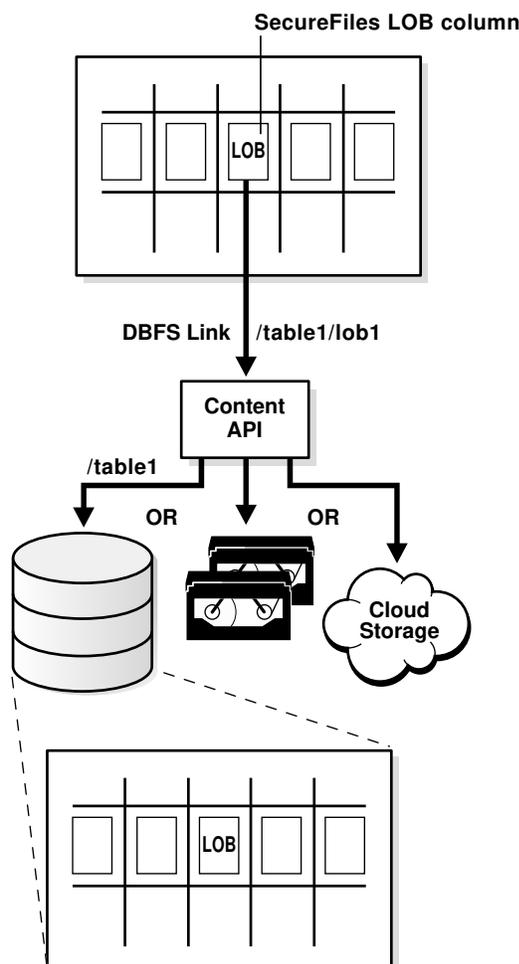

19.2 Ways to Create Database File System Links

Database File System Links require the creation of a Database File System through the use of the DBFS Content package, `DBMS_DBFS_CONTENT`.

Oracle provides several methods for creating a DBFS Link:

- Move SecureFiles LOB data into a specified DBFS pathname and store the reference to the new location in the LOB.

  Call `DBMS_LOB.MOVE_TO_DBFS_LINK()` with LOB and DBFS path name arguments, and the system creates the specified DBFS HSM Store if it does not exist, copies data from the SecureFiles LOB into the specified DBFS HSM Store, removes data from the SecureFiles LOB, and stores the file path name for subsequent access through this LOB.

- Copy or create a reference to an existing file.

  Call `DBMS_LOB.COPY_DBFS_LINK()` to copy a link from an existing DBFS Link. If there is any data in the destination SecureFiles LOB, the system removes this data and stores a copy of the reference to the link in the destination SecureFiles LOB.

- Call `DBMS_LOB.SET_DBFS_LINK()`, which assumes that the data for the link is stored in the specified DBFS path name.

  The system removes data in the specified SecureFiles LOB and stores the link to the DBFS path name.

Creating a DBFS Link impacts which operations may be performed and how. Any `DBMS_LOB` operations that modify the contents of a LOB will throw an exception if the underlying LOB has been moved into a DBFS Link. The application must explicitly replace the DBFS Link with a LOB by calling `DBMS_LOB.COPY_FROM_LINK()` before making these calls.

When it is completed, the application can move the updated LOB back to DBFS using `DBMS_LOB.MOVE_TO_DBFS_LINK()`, if needed. Other `DBMS_LOB` operations that existed before Oracle Database 11*g* Release 2 work transparently if the DBFS Link is in a file system that supports streaming. Note that these operations fail if streaming is either not supported or disabled.

If the DBFS Link file is modified through DBFS interfaces directly, the change is reflected in subsequent reads of the SecureFiles LOB. If the file is deleted through DBFS interfaces, then an exception occurs on subsequent reads.

For the database, it is also possible that a DBA may not want to store all of the data stored in a SecureFiles LOB HSM during export and import. Oracle has the ability to export and import only the Database File System Links. The links are fully qualified identifiers that provide access to the stored data, when entered into a SecureFiles LOB or registered on a SecureFiles LOB in a different database. This ability to export and import a link is similar to the common file system functionality of symbolic links.

The newly imported link is only available as long as the source, the stored data, is available, or until the first retrieval occurs on the imported system. The application is responsible for stored data retention. If the application system removes data from the store that still has a reference to it, the database throws an exception when the referencing SecureFiles LOB(s) attempt to access the data. Oracle also supports continuing to keep the data in the database after migration out to a DBFS store as a cached copy. It is up to the application to purge these copies in compliance with its retention policies.

19.3 Database File System Links Copy

The API `DBMS_LOB.COPY_DBFS_LINK(DSTLOB, SRCLOB, FLAGS)` provides the ability to copy a linked SecureFiles LOB.

sBy default, the LOB is not obtained from the DBFS HSM Store during this operation; this is a copy-by-reference operation that exports the DBFS path name (at source side) and imports it (at destination side). The `flags` argument can dictate that the destination has a local copy in the database and references the LOB data in the DBFS HSM Store.

19.4 The DBMS_LOB Package Used with DBFS

The `DBMS_LOB` package provides subprograms to operate on, or access and manipulate specific parts of a LOB or complete LOBs.

The `DBMS_LOB` package applies to both SecureFiles LOB and BasicFiles LOB.

DBMS_LOB Constants Used with SecureFiles LOBs and DBFS and DBMS_LOB Subprograms Used with SecureFiles LOBs and DBFS describe modifications made to the `DBMS_LOB` constants and subprograms with the addition of SecureFiles LOB and Database File System (DBFS).

> ✏️ **See Also:**
>
> - *Oracle Database PL/SQL Packages and Types Reference* for more information about `DBMS_LOB` package
> - Introducing the Database File System

19.5 DBMS_LOB Constants Used with DBFS

Certain constants support DBFS link interfaces.

Table 19-1 lists constants that support DBFS Link interfaces.

> ✏️ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for complete information about constants used in the PL/SQL `DBMS_LOB` package

Table 19-1   DBMS_LOB Constants That Support DBFS Link Interfaces

Constant	Description
`DBFS_LINK_NEVER`	DBFS link state value
`DBFS_LINK_YES`	DBFS link state value

Table 19-1   (Cont.) DBMS_LOB Constants That Support DBFS Link Interfaces

Constant	Description
`DBFS_LINK_NO`	DBFS link state value
`DBFS_LINK_CACHE`	Flag used by `COPY_DBFS_LINK()` and `MOVE_DBFS_LINK()`.
`DBFS_LINK_NOCACHE`	Flag used by `COPY_DBFS_LINK()` and `MOVE_DBFS_LINK()`.
`DBFS_LINK_PATH_MAX_SIZE`	The maximum length of DBFS path names; `1024`.
`CONTENTTYPE_MAX_SIZE`	The maximum 1-byte ASCII characters for content type; `128`.

19.6 DBMS_LOB Subprograms Used with DBFS

You should note that some changes have been made to the `DBMS_LOB` subprograms over time.

Table 19-2 summarizes changes made to PL/SQL package `DBMS_LOB` subprograms.

Be aware that some of the `DBMS_LOB` operations that existed before Oracle Database 11*g* Release 2 throw an exception error if the LOB is a DBFS link. To remedy this problem, modify your applications to explicitly replace the DBFS link with a LOB by calling the `DBMS_LOB.COPY_FROM_LINK` procedure before they make these calls. When the call completes, then the application can move the updated LOB back to DBFS using the `DBMS_LOB.MOVE_TO_DBFS_LINK` procedure, if necessary.

Other `DBMS_LOB` operations that existed before Oracle Database 11*g* Release 2 work transparently if the DBFS Link is in a file system that supports streaming. Note that these operations fail if streaming is either not supported or disabled.

Table 19-2   DBMS_LOB Subprograms

Subprogram	Description
`COPY_DBFS_LINK`	Copies an existing DBFS link into a new LOB

> ✎ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference*

Table 19-2   (Cont.) DBMS_LOB Subprograms

Subprogram	Description
COPY_FROM_DBFS_LINK	Copies the specified LOB data from DBFS HSM Store into the database **See Also:** *Oracle Database PL/SQL Packages and Types Reference*
DBFS_LINK_GENERATE_PATHNAME	Returns a unique file path name for creating a DBFS Link **See Also:** *Oracle Database PL/SQL Packages and Types Reference*
GET_DBFS_LINK	Returns the DBFS path name for a LOB **See Also:** *Oracle Database PL/SQL Packages and Types Reference*
GET_DBFS_LINK_STATE	Returns the linking state of a LOB **See Also:** *Oracle Database PL/SQL Packages and Types Reference*
MOVE_TO_DBFS_LINK	Moves the specified LOB data from the database into DBFS HSM Store **See Also:** *Oracle Database PL/SQL Packages and Types Reference*

Table 19-2   (Cont.) DBMS_LOB Subprograms

Subprogram	Description
`SET_DBFS_LINK`	Links a LOB with a DBFS path name

> ✎ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference*

19.7 Copying a Linked LOB Between Tables

You can copy DBFS links from source tables to destination tables.

Use the following code to copy any DBFS Links that are stored in any SecureFiles LOBs in the source table to the destination table.

`CREATE TABLE ... AS SELECT (CTAS)` and `INSERT TABLE ... AS SELECT (ITAS)`

19.8 Online Redefinition and DBFS Links

Online redefinition copies any DBFS Links that are stored in any SecureFiles LOBs in the table being redefined.

19.9 Transparent Read

DBFS Links can read from a linked SecureFiles LOB even if the data is not cached in the database.

You can read data from the content store where the data is currently stored and stream that data back to the user application as if it were being read from the SecureFiles LOB segment. This allows seamless access to the DBFS Linked data without the prerequisite first call to `DBMS_LOB.COPY_FROM_DBFS_LINK()`.

Whether or not transparent read is available for a particular SecureFiles LOB is determined by the `DBFS_CONTENT` store where the data resides. This feature is always enabled for `DBFS_SFS` stores, and by default for `DBFS_HS` stores. To disable transparent read for `DBFS_HS` store, set the `PROPNAME_STREAMABLE` parameter to `FALSE`.

20

DBFS Content API

You can enable applications to use the Database File System (DBFS) in several different programming environments.

- **Overview of DBFS Content API**
  You can enable applications to use DBFS using the DBFS Content API (`DBMS_DBFS_CONTENT`), which is a client-side programmatic API package. You can write applications in SQL, PL/SQL, JDBC, OCI, and other programming environments.

- **Stores and DBFS Content API**
  The DBFS Content API aggregates the path namespace of one or more stores into a single unified namespace.

- **Getting Started with DBMS_DBFS_CONTENT Package**
  `DBMS_DBFS_CONTENT` is part of the Oracle Database, starting with Oracle Database 11g Release 2, and does not need to be installed.

- **Administrative and Query APIs**
  Administrative clients and content providers are expected to register content stores with the DBFS Content API. Additionally, administrative clients are expected to mount stores into the top-level namespace of their choice.

- **Querying DBFS Content API Space Usage**
  You can query file system space usage statistics.

- **DBFS Content API Session Defaults**
  Normal client access to the DBFS Content API executes with an implicit context that consists of certain objects.

- **DBFS Content API Interface Versioning**
  To allow for the DBFS Content API itself to evolve, an internal numeric API version increases with each change to the public API.

- **DBFS Content API Creation Operations**
  You must implement the provider SPI so that when clients invoke the DBFS Content API, it causes the SPI to create directory, file, link, and reference elements (subject to store feature support).

- **DBFS Content API Deletion Operations**
  You must implement the provider SPI so that when clients invoke the DBFS Content API, it causes the SPI to delete directory, file, link, and reference elements (subject to store feature support).

- **DBFS Content API Path Get and Put Operations**
  You can query existing path items or update them using simple `GETXXX()` and `PUTXXX()` methods.

- **DBFS Content API Rename and Move Operations**
  You can rename or move path names, possibly across directory hierarchies and mount points, but only within the same store.

- **Directory Listings**
  Directory listings are handled several different ways.

- DBFS Content API Directory Navigation and Search
  Clients of the DBFS Content API can list or search the contents of directory path names, with optional modes.

- DBFS Content API Locking Operations
  DBFS Content API clients can apply user-level locks,depending on certain criteria.

- DBFS Content API Access Checks
  The DBFS Content API checks the access of specific path names by operations.

- DBFS Content API Abstract Operations
  All of the operations in the DBFS Content API are represented as abstract `opcodes`.

- DBFS Content API Path Normalization
  There is a process for performing API path normalization.

- DBFS Content API Statistics Support
  DBFS provides support to reduce the expense of collecting DBFS Content API statistics.

- DBFS Content API Tracing Support
  Any DBFS Content API user (both clients and providers) can use DBFS Content API tracing, a generic tracing facility.

- Resource and Property Views
  You can see descriptions of Content API structure and properties in certain views.

20.1 Overview of DBFS Content API

You can enable applications to use DBFS using the DBFS Content API (`DBMS_DBFS_CONTENT`), which is a client-side programmatic API package. You can write applications in SQL, PL/SQL, JDBC, OCI, and other programming environments.

The DBFS Content API is a collection of methods that provide a file system-like abstraction. It is backed by one or more DBFS Store Providers. The *Content* in the DBFS Content interface refers to a file, including metadata, and it can either map to a SecureFiles `LOB` (and other columns) in a table or be dynamically created by user-written plug-ins in Java or PL/SQL that run inside the database. The plug-in form is referred to as a *provider*.

> **Note:**
>
> The DBFS Content API includes the SecureFiles Store Provider, `DBMS_DBFS_SFS`, a default implementation that enables applications that already use LOBs as columns in their schema, to access the `LOB` columns as files.

> **See Also:**
>
> DBFS SecureFiles Store

Examples of possible providers include:

- Packaged applications that want to expose data through files.

- Custom applications developers use to leverage the file system interface, such as an application that stores medical images.

20.2 Stores and DBFS Content API

The DBFS Content API aggregates the path namespace of one or more stores into a single unified namespace.

The first component of the path name is used to disambiguate the namespace and then present it to client applications. This allows clients to access the underlying documents using either a full absolute path name represented by a single string, as shown in the following code snippet:

```
/store-name/store-specific-path-name
```

The DBFS Content API then takes care of correctly dispatching various operations on path names to the appropriate store provider .

Store providers must conform to the store provider interface (SPI) as declared by the package `DBMS_DBFS_CONTENT_SPI`.

- [Creating Your Own DBFS Store](#)
- *Oracle Database PL/SQL Packages and Types Reference* for `DBMS_DBFS_CONTENT` package syntax reference

20.3 Getting Started with DBMS_DBFS_CONTENT Package

`DBMS_DBFS_CONTENT` is part of the Oracle Database, starting with Oracle Database 11g Release 2, and does not need to be installed.

- [DBFS Content API Role](#)
  Access to the content operational and administrative API (packages, types, tables, and so on) is available through `DBFS_ROLE`.

- [Path Name Constants and Types](#)
  Path name constants are modeled after their SecureFiles LOBs store counterparts.

- [Path Properties](#)
  Every path name in a store is associated with a set of properties.

- [Content IDs](#)
  Content IDs are unique identifiers that represent a path in the store.

- [Path Name Types](#)
  Stores can store and provide access to eight types of entities.

- [Store Features](#)
  In order to provide a common programmatic interface to as many different types of stores as possible, the DBFS Content API leaves some of the behavior of various operations to individual store providers to define and implement.

- [Lock Types](#)
  Stores that support locking should implement three types of locks.

- [Standard Properties](#)
  Standard properties are well-defined, mandatory properties associated with all content path names, which all stores must support, in the manner described by the DBFS Content API.

- **Optional Properties**
  Optional properties are well-defined but non-mandatory properties associated with all content path names that all stores are free to support (but only in the manner described by the DBFS Content API).

- **User-Defined Properties**
  You can define your own properties for use in your application.

- **Property Access Flags**
  DBFS Content API methods to get and set properties can use combinations of property access flags to fetch properties from different namespaces in a single API call.

- **Exceptions**
  DBFS Content API operations can raise any one of the top-level exceptions.

- **Property Bundles**
  Property bundles are discussed as `property_t` record type and `properties_t`.

- **Store Descriptors**
  Store descriptors are discussed as `store_t` and `mount_t` records.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for more information

20.3.1 DBFS Content API Role

Access to the content operational and administrative API (packages, types, tables, and so on) is available through `DBFS_ROLE`.

The `DBFS_ROLE` can be granted to all users as needed.

20.3.2 Path Name Constants and Types

Path name constants are modeled after their SecureFiles LOBs store counterparts.

> **See Also:**
>
> DBMS_DBFS_CONTENT Constants for path name constants and their types

20.3.3 Path Properties

Every path name in a store is associated with a set of properties.

For simplicity and generality, each property is identified by a string name, has a string value (possibly `null` if not set or undefined or unsupported by a specific store implementation), and a value typecode, a numeric discriminant for the actual type of value held in the value string.

Coercing property values to strings has the advantage of making the various interfaces uniform and compact (and can even simplify implementation of the underlying stores), but has the potential for information loss during conversions to and from strings.

It is expected that clients and stores use well-defined database conventions for these conversions and use the `typecode` field as appropriate.

PL/SQL types `path_t` and `name_t` are portable aliases for strings that can represent pathnames and component names,

A typecode is a numeric value representing the true type of a string-coerced property value. Simple scalar types (numbers, dates, timestamps, etc.) can be depended on by clients and must be implemented by stores.

Since standard RDBMS typecodes are positive integers, the `DBMS_DBFS_CONTENT` interface allows negative integers to represent client-defined types by negative typecodes. These typecodes do not conflict with standard typecodes, are maintained persistently and returned to the client as needed, but need not be interpreted by the DBFS content API or any particular store. Portable client applications should not use user-defined typecodes as a back door way of passing information to specific stores.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT` constants and properties and the `DBMS_DBFS_CONTENT_PROPERTY_T` package

20.3.4 Content IDs

Content IDs are unique identifiers that represent a path in the store.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT` Content ID constants and properties

20.3.5 Path Name Types

Stores can store and provide access to eight types of entities.

The entities are:

- `type_file`
- `type_directory`
- `type_link`
- `type_reference`
- `type_scoket`
- `type_character`
- `type_block`
- `type_fifo`

Not all stores must implement all directories, links, or references.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the
> `DBMS_DBFS_CONTENT` constants and path name types

20.3.6 Store Features

In order to provide a common programmatic interface to as many different types of stores as possible, the DBFS Content API leaves some of the behavior of various operations to individual store providers to define and implement.

The DBFS Content API remains rich and conducive to portable applications by allowing different store providers (and different stores) to describe themselves as a feature set. A feature set is a bit mask indicating the supported features and the ones that are not supported.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the store
> features and constants

20.3.7 Lock Types

Stores that support locking should implement three types of locks.

The three types of locks are: `lock_read_only`, `lock_write_only`, `lock_read_write`.

User locks (any of these types) can be associated with user-supplied `lock_data`. The store does not interpret the data, but client applications can use it for their own purposes (for example, the user data could indicate the time at which the lock was placed, and the client application might use this later to control its actions.

In the simplest locking model, a `lock_read_only` prevents all explicit modifications to a path name (but allows implicit modifications and changes to parent/child path names). A `lock_write_only` prevents all explicit reads to the path name, but allows implicit reads and reads to parent/child path names. A `lock_read_write` allows both.

All locks are associated with a principal user who performs the locking operation; stores that support locking are expected to preserve this information and use it to perform read/write lock checking (see `opt_locker`).

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the lock
> types and constants.

20.3.8 Standard Properties

Standard properties are well-defined, mandatory properties associated with all content path names, which all stores must support, in the manner described by the DBFS Content API.

Stores created against tables with a fixed schema may choose reasonable defaults for as many of these properties as needed, and so on.

All standard properties informally use the `std` namespace. Clients and stores should avoid using this namespace to define their own properties to prevent conflicts in the future.

> ✎ **See Also:**
>
> See *Oracle Database PL/SQL Packages and Types Reference* for details of the standard properties and constants

20.3.9 Optional Properties

Optional properties are well-defined but non-mandatory properties associated with all content path names that all stores are free to support (but only in the manner described by the DBFS Content API).

Clients should be prepared to deal with stores that support none of the optional properties.

All optional properties informally use the `opt` namespace. Clients and stores must avoid using this namespace to define their own properties to prevent conflicts in the future.

> ✎ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the optional properties and constants

20.3.10 User-Defined Properties

You can define your own properties for use in your application.

Ensure that the namespace prefixes do not conflict with each other or with the DBFS standard or optional properties.

20.3.11 Property Access Flags

DBFS Content API methods to get and set properties can use combinations of property access flags to fetch properties from different namespaces in a single API call.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the property access flags and constants

20.3.12 Exceptions

DBFS Content API operations can raise any one of the top-level exceptions.

Clients can program against these specific exceptions in their error handlers without worrying about the specific store implementations of the underlying error signalling code.

Store service providers, should try to trap and wrap any internal exceptions into one of the exception types, as appropriate.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the Exceptions

20.3.13 Property Bundles

Property bundles are discussed as `property_t` record type and `properties_t`.

- The `property_t` record type describes a single (value, typecode) property value tuple; the property name is implied.

- `properties_t` is a name-indexed hash table of property tuples. The implicit hash-table association between the index and the value allows the client to build up the full `dbms_dbfs_content_property_t` tuples for a `properties_t`.

There is an approximate correspondence between `dbms_dbfs_content_property_t` and `property_t`. The former is a SQL object type that describes the full property tuple, while the latter is a PL/SQL record type that describes only the property value component.

There is an approximate correspondence between `dbms_dbfs_content_properties_t` and `properties_t`. The former is a SQL nested table type, while the latter is a PL/SQL hash table type.

Dynamic SQL calling conventions force the use of SQL types, but PL/SQL code may be implemented more conveniently in terms of the hash-table types.

DBFS Content API provides convenient utility functions to convert between `dbms_dbfs_content_properties_t` and `properties_t`.

The function `DBMS_DBFS_CONTENT.PROPERTIEST2H` converts a `DBMS_DBFS_CONTENT_PROPERTIES_T` value to an equivalent `properties_t` value, and the function `DBMS_DBFS_CONTENT.PROPERTIESH2T` converts a `properties_t` value to an equivalent `DBMS_DBFS_CONTENT_PROPERTIES_T` value.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `PROPERTY_T` record type

20.3.14 Store Descriptors

Store descriptors are discussed as `store_t` and `mount_t` records.

- A `store_t` is a record that describes a store registered with, and managed by the DBFS Content API .

- A `mount_t` is a record that describes a store mount point and its properties.

Clients can query the DBFS Content API for the list of available stores, determine which store handles accesses to a given path name, and determine the feature set for the store.

> **See Also:**
>
> - Administrative and Query APIs
> - *Oracle Database PL/SQL Packages and Types Reference* for details of the `STORE_T` record type

20.4 Administrative and Query APIs

Administrative clients and content providers are expected to register content stores with the DBFS Content API. Additionally, administrative clients are expected to mount stores into the top-level namespace of their choice.

The registration and unregistration of a store is separated from the mount and unmount of a store because it is possible for the same store to be mounted multiple times at different mount points (and this is under client control).

- Registering a Content Store
  You can register a new store that is backed by a provider that uses the `provider_package` procedure as the store service provider.

- Unregistering a Content Store
  You can unregister a previously registered store, which invalidates all mount points associated with it.

- Mounting a Registered Store
  You can mount a registered store and bind it to the mount point.

- Unmounting a Previously Mounted Store
  You can unmount a previously mounted store, either by name or by mount point.

- Listing all Available Stores and Their Features
  You can list all the available stores.

- Listing all Available Mount Points
  You can list all available mount points, their backing stores, and the store features.

- Looking Up Specific Stores and Their Features
  You can look up the path name, store name, or mount point of a store.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for the summary of `DBMS_DBFS_CONTENT` package methods

20.4.1 Registering a Content Store

You can register a new store that is backed by a provider that uses the `provider_package` procedure as the store service provider.

The method of registration conforms to the `DBMS_DBFS_CONTENT_SPI` package signature.

- Use the `REGISTERSTORE()` procedure.

This method is designed for use by service providers after they have created a new store. Store names must be unique.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `REGISTERSTORE()` method

20.4.2 Unregistering a Content Store

You can unregister a previously registered store, which invalidates all mount points associated with it.

Once the store is unregistered, access to the store and its mount points is no longer guaranteed, although a consistent read may provide a temporary illusion of continued access.

- Use the `UNREGISTERSTORE()` procedure.

If the `ignore_unknown` argument is `true`, attempts to unregister unknown stores do not raise an exception.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `UNREGISTERSTORE()` method

20.4.3 Mounting a Registered Store

You can mount a registered store and bind it to the mount point.

- Use the `MOUNTSTORE()` procedure.

After you mount the store, access to the path names in the form /*store_mount*/xyz is redirected to *store_name* and its content provider.

Store mount points must be unique, and a syntactically valid path name component (that is, a name_t with no embedded /).

If you do not specify a mount point and therefore, it is null, the DBFS Content API attempts to use the store name itself as the mount point name (subject to the uniqueness and syntactic constraints).

The same store can be mounted multiple times, obviously at different mount points.

You can use mount properties to specify the DBFS Content API execution environment, that is, the default values of the principal, owner, ACL, and asof, for a particular mount point. You can also use mount properties to specify a read-only store.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the MOUNTSTORE() method

20.4.4 Unmounting a Previously Mounted Store

You can unmount a previously mounted store, either by name or by mount point.

Attempting to unmount a store by name unmounts all mount points associated with the store.

- Use the UNMOUNTSTORE() procedure.

Once unmounted, access to the store or mount-point is no longer guaranteed to work although a consistent read may provide a temporary illusion of continued access. If the ignore_unknown argument is true, attempts to unmount unknown stores does not raise an exception.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the UNMOUNTSTORE method

20.4.5 Listing all Available Stores and Their Features

You can list all the available stores.

The store_mount field of the returned records is set to null because mount points are separate from stores themselves.

- Use the LISTSTORES() function.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `LISTSTORES` Function

20.4.6 Listing all Available Mount Points

You can list all available mount points, their backing stores, and the store features.

A single mount returns a single row, with the `store_mount` field set to `null`.

- Use the `LISTMOUNTS()` function.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `LISTMOUNTS()` method

20.4.7 Looking Up Specific Stores and Their Features

You can look up the path name, store name, or mount point of a store.

- Use `GETSTOREBYXXX()` or `GETFEATUREBYXXX()` functions.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT` methods

20.5 Querying DBFS Content API Space Usage

You can query file system space usage statistics.

Providers are expected to support this method for their stores and to make a best effort determination of space usage, especially if the store consists of multiple tables, indexes, LOBs, and so on.

- Use the `SPACEUSAGE()` method

where:

- `blksize` is the natural tablespace block size that holds the store; if multiple tablespaces with different block sizes are used, any valid block size is acceptable.

- `tbytes` is the total size of the store in bytes, and `fbytes` is the free or unused size of the store in bytes. These values are computed over all segments that comprise the store.

- `nfile`, `ndir`, `nlink`, and `nref` count the number of currently available files, directories, links, and references in the store.

Database objects can grow dynamically, so it is not easy to estimate the division between free space and used space.

A space usage query on the top level root directory returns a combined summary of the space usage of all available distinct stores under it. If the same store is mounted multiple times, it is counted only once.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `SPACEUSAGE()` method

20.6 DBFS Content API Session Defaults

Normal client access to the DBFS Content API executes with an implicit context that consists of certain objects.

- The `principal` invoking the current operation.
- The `owner` for all new elements created (implicitly or explicitly) by the current operation.
- The `ACL` for all new elements created (implicitly or explicitly) by the current operation.
- The `ASOF` timestamp at which the underlying read-only operation (or its read-only sub-components) execute.

All of this information can be passed in explicitly through arguments to the various DBFS Content API method calls, allowing the client fine-grained control over individual operations.

The DBFS Content API also allows clients to set session duration defaults for the context that are automatically inherited by all operations for which the defaults are not explicitly overridden.

All of the context defaults start out as `null` and can be cleared by setting them to `null`.

> **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT` methods

20.7 DBFS Content API Interface Versioning

To allow for the DBFS Content API itself to evolve, an internal numeric API version increases with each change to the public API.

> **✎ See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the
> `GETVERSION()` method

20.8 DBFS Content API Creation Operations

You must implement the provider SPI so that when clients invoke the DBFS Content API, it causes the SPI to create directory, file, link, and reference elements (subject to store feature support).

All of the creation methods require a valid path name and can optionally specify properties to be associated with the path name as it is created. It is also possible for clients to fetch back item properties after the creation completes, so that automatically generated properties, such as `std_creation_time`, are immediately available to clients. The exact set of properties fetched back is controlled by the various `prop_xxx` bit masks in `prop_flags`.

Links and references require an additional path name associated with the primary path name. File path names can optionally specify a `BLOB` value to initially populate the underlying file content, and the provided `BLOB` may be any valid LOB, either temporary or permanent. On creation, the underlying `LOB` is returned to the client if `prop_data` is specified in `prop_flags`.

Non-directory path names require that their parent directory be created first. Directory path names themselves can be recursively created. This means that the path name hierarchy leading up to a directory can be created in one call.

Attempts to create paths that already exist produce an error, except for path names that are soft-deleted. In these cases, the soft-deleted item is implicitly purged, and the new item creation is attempted.

Stores and their providers that support contentID-based access accept an explicit store name and a `NULL` path to create a new content element. The contentID generated for this element is available by means of the `OPT_CONTENT_ID` property. The `PROP_OPT` property in the `prop_flags` parameter automatically implies contentID-based creation.

The newly created element may also have an internally generated path name if the `FEATURE_LAZY_PATH` property is not supported and this path is available by way of the `STD_CANONICAL_PATH` property.

Only file elements are candidates for contentID-based access.

> **✎ See Also:**
>
> - *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT()` methods, `DBMS_DBFS_CONTENT()` Constants - Optional Properties, and `DBMS_DBFS_CONTENT` Constants - Standard Properties

20.9 DBFS Content API Deletion Operations

You must implement the provider SPI so that when clients invoke the DBFS Content API, it causes the SPI to delete directory, file, link, and reference elements (subject to store feature support).

By default, the deletions are permanent, and remove successfully deleted items on transaction commit. However, repositories may also support soft-delete features. If requested by the client, soft-deleted items are retained by the store. They are not, however, typically visible in normal listings or searches. Soft-deleted items may be restored or explicitly purged.

Directory path names may be recursively deleted; the path name hierarchy below a directory may be deleted in one call. Non-recursive deletions can be performed only on empty directories. Recursive soft-deletions apply the soft-delete to all of the items being deleted.

Individual path names or all soft-deleted path names under a directory may be restored or purged using the `RESTOREXXX()` and `PURGEXXX()` methods.

Providers that support filtering can use the provider filter to identify subsets of items to delete; this makes most sense for bulk operations such as `deleteDirectory()`, `RESTOREALL()`, and `PURGEALL()`, but all of the deletion-related operations accept a filter argument.

Stores and their providers that support contentID-based access can also allow deleting file items by specifying their contentID.

> ✏️ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT()` methods

20.10 DBFS Content API Path Get and Put Operations

You can query existing path items or update them using simple `GETXXX()` and `PUTXXX()` methods.

All path names allow their metadata to be read and modified. On completion of the call, the client can request that specific properties be fetched through `prop_flags`.

File path names allow their data to be read and modified. On completion of the call, the client can request a new `BLOB` locator through the `prop_data` bit masks in `prop_flags`; these may be used to continue data access.

Files can also be read and written without using `BLOB` locators, by explicitly specifying logical offsets, buffer amounts, and a suitably sized buffer.

Update accesses must specify the `forUpdate` flag. Access to link path names may be implicitly and internally dereferenced by stores, subject to feature support, if the `deref` flag is specified. Oracle does not recommend this practice because symbolic links are not guaranteed to resolve.

The read method `GETPATH()` where `forUpdate` is `false` accepts a valid `asof` timestamp parameter that can be used by stores to implement flashback-style queries.

Mutating versions of the `GETPATH()` and the `PUTPATH()` methods do not support `asof` modes of operation.

The DBFS Content API does not have an explicit `COPY()` operation because a copy is easily implemented as a combination of a `GETPATH()` followed by a `CREATE`*`XXX`*`()` with appropriate data or metadata transfer across the calls. This allows copies across stores, while an internalized copy operation cannot provide this facility.

> ✏️ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT` methods

20.11 DBFS Content API Rename and Move Operations

You can rename or move path names, possibly across directory hierarchies and mount points, but only within the same store.

Non-directory path names previously accessible by `oldPath` can be renamed as a single item subsequently accessible by `newPath`, assuming that `newPath` does not exist.

If `newPath` exists and is not a directory, the rename implicitly deletes the existing item before renaming `oldPath`. If `newPath` exists and is a directory, `oldPath` is moved into the target directory.

Directory path names previously accessible by `oldPath` can be renamed by moving the directory and all of its children to `newPath` (if it does not exist) or as children of `newPath` (if it exists and is a directory).

Because the semantics of rename and move is complex with respect to non-existent or existent and non-directory or directory targets, clients may choose to implement complex rename and move operations as sequences of simpler moves or copies.

Stores and their providers that support contentID-based access and lazy path name binding also support the *Oracle Database PL/SQL Packages and Types Reference* `SETPATH` procedure that associates an existing contentID with a new "path".

> ✏️ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT.RENAMEPATH()` methods

20.12 Directory Listings

Directory listings are handled several different ways.

- A `list_item_t` is a tuple of path name, component name, and type representing a single element in a directory listing.

- A `path_item_t` is a tuple describing a store, mount qualified path in a content store, with all standard and optional properties associated with it.
- A `prop_item_t` is a tuple describing a store, mount qualified path in a content store, with all user-defined properties associated with it, expanded out into individual tuples of name, value, and type.

> ✎ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of data structures

20.13 DBFS Content API Directory Navigation and Search

Clients of the DBFS Content API can list or search the contents of directory path names, with optional modes.

Optional Modes:

- searching recursively in sub-directories
- seeing soft-deleted items
- using flashback `asof` a provided timestamp
- filtering items in and out within the store based on list or search predicates.

The DBFS Content API currently only returns list items; clients explicitly use one of the `getPath()` methods to access the properties or content associated with an item, as appropriate.

> ✎ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT` methods

20.14 DBFS Content API Locking Operations

DBFS Content API clients can apply user-level locks,depending on certain criteria.

Clients of the DBFS Content API can apply user-level locks to any valid path name, subject to store feature support, associate the lock with user data, and subsequently unlock these path names. The status of locked items is available through various optional properties.

If a store supports user-defined lock checking, it is responsible for ensuring that lock and unlock operations are performed in a consistent manner.

> ✎ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the
> `DBMS_DBFS_CONTENT` methods

20.15 DBFS Content API Access Checks

The DBFS Content API checks the access of specific path names by operations.

Function `CHECKACCESS()` checks if a given path name (`path`, `pathtype`, `store_name`) can be manipulated by an operation, such as the various `op_xxx` opcodes) by `principal`, as described in "DBFS Content API Locking Operations"

This is a convenience function for the client; a store that supports access control still internally performs these checks to guarantee security.

> ✎ **See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for details of the
> `DBMS_DBFS_CONTENT` methods

20.16 DBFS Content API Abstract Operations

All of the operations in the DBFS Content API are represented as abstract `opcodes`.

Clients can use `opcodes` to directly and explicitly invoke the `CHECKACCESS()` method which verifies if a particular operation can be invoked by a given principal on a particular path name.

An `op_acl()` is an implicit operation invoked during an `op_create()` or `op_put()` call, which specifies a `std_acl` property. The operation tests to see if the principal is allowed to set or change the `ACL` of a store item.

`op_delete()` represents the soft-deletion, purge, and restore operations.

The source and destination operations of a rename or move operation are separated, although stores are free to unify these `opcode`s and to also treat a rename as a combination of delete and create.

`op_store` is a catch-all category for miscellaneous store operations that do not fall under any of the other operational APIs.

> ✎ **See Also:**
>

20.17 DBFS Content API Path Normalization

There is a process for performing API path normalization.

Function `NORMALIZEPATH()` performs the following steps:

1. Verifies that the path name is absolute (starts with a `/`).

2. Collapses multiple consecutive `/`s into a single `/`.

3. Strips trailing `/`s.

4. Breaks store-specific normalized path names into two components: the parent path name and the trailing component name.

5. Breaks fully qualified normalized path names into three components: store name, parent path name, and trailing component name.

Note that the root path `/` is special: its parent path name is also `/`, and its component name is `null`. In fully qualified mode, it has a `null` store name unless a singleton mount has been created, in which case the appropriate store name is returned.

The return value is always the completely normalized store-specific or fully qualified path name.

20.18 DBFS Content API Statistics Support

DBFS provides support to reduce the expense of collecting DBFS Content API statistics.

DBFS Content API statistics are expensive to collect and maintain persistently. DBFS has support for buffering statistics in memory for a maximum of `flush_time` centiseconds or a maximum of `flush_count` operations, whichever limit is reached first), at which time the buffers are implicitly flushed to disk.

Clients can also explicitly invoke a flush using `flushStats`. An implicit flush also occurs when statistics collection is disabled.

`setStats` is used to enable and disable statistics collection; the client can optionally control the flush settings by specifying non-`null` values for the time and count parameters.

20.19 DBFS Content API Tracing Support

Any DBFS Content API user (both clients and providers) can use DBFS Content API tracing, a generic tracing facility.

The DBFS Content API dispatcher itself uses the tracing facility.

Trace information is written to the foreground trace file, with varying levels of detail as specified by the trace level arguments. The global trace level consists of two components: `severity` and `detail`. These can be thought of as additive bit masks.

The `severity` component allows the separation of top-level as compared to low-level tracing of different components, and allows the amount of tracing to be increased as needed. There are no semantics associated with different levels, and users are free to set the trace level at any severity they choose, although a good rule of thumb would be to use severity 1 for top-level API entry and exit traces, severity 2 for internal operations, and severity 3 or greater for very low-level traces.

The `detail` component controls how much additional information the trace reports with each trace record: timestamps, short-stack, and so on.

> ✎ **See Also:**

> - Example 20-1 for more information about how to enable tracing using the DBFS Content APIs.
> - *Oracle Database PL/SQL Packages and Types Reference* for details of the `DBMS_DBFS_CONTENT` methods

Example 20-1   DBFS Content Tracing

```
function    getTrace
        return  integer;
    procedure   setTrace(
        trclvl      in              integer);
    function    traceEnabled(
        sev         in              integer)
        return  integer;
    procedure   trace(
        sev         in              integer,
        msg0        in              varchar2,
        msg1        in              varchar     default '',
        msg2        in              varchar     default '',
        msg3        in              varchar     default '',
        msg4        in              varchar     default '',
        msg5        in              varchar     default '',
        msg6        in              varchar     default '',
        msg7        in              varchar     default '',
        msg8        in              varchar     default '',
        msg9        in              varchar     default '',
        msg10       in              varchar     default '');
```

20.20 Resource and Property Views

You can see descriptions of Content API structure and properties in certain views.

Certain views describe the structure and properties of Content API.

Creating Your Own DBFS Store

You can create your own DBFS Store using DBFS Content Store Provider Interface (`DBMS_DBFS_CONTENT_SPI`).

- Overview of DBFS Store Creation and Use
  In order to customize a DBFS store, you must implement the DBFS Content SPI (`DBMS_DBFS_CONTENT_SPI`). It is the basis for existing stores such as the DBFS SecureFiles Store and the DBFS Hierarchical Store, as well as any user-defined DBFS stores that you create.

- DBFS Content Store Provider Interface (DBFS Content SPI)
  The DBFS Content SPI (Store Provider Interface) is a specification only and has no package body.

- Creating a Custom Store Provider
  You can use this example store provider for DBFS, TaBleFileSystem Store Provider ("tbfs"), as a skeleton for custom providers or as a learning tool, to become familiar with the DBFS and its SPI.

21.1 Overview of DBFS Store Creation and Use

In order to customize a DBFS store, you must implement the DBFS Content SPI (`DBMS_DBFS_CONTENT_SPI`). It is the basis for existing stores such as the DBFS SecureFiles Store and the DBFS Hierarchical Store, as well as any user-defined DBFS stores that you create.

Client-side applications, such the PL/SQL interface, invoke functions and procedures in the DBFS Content API. The DBFS Content API then invokes corresponding subprograms in the DBFS Content SPI to create stores and perform other related functions.

Once you create your DBFS store, you use it much the same way that you would a SecureFiles Store.

> ✏️ **See Also:**
>
> - DBFS Content API
> - DBFS SecureFiles Store

Figure 21-1   Database File System (DBFS)
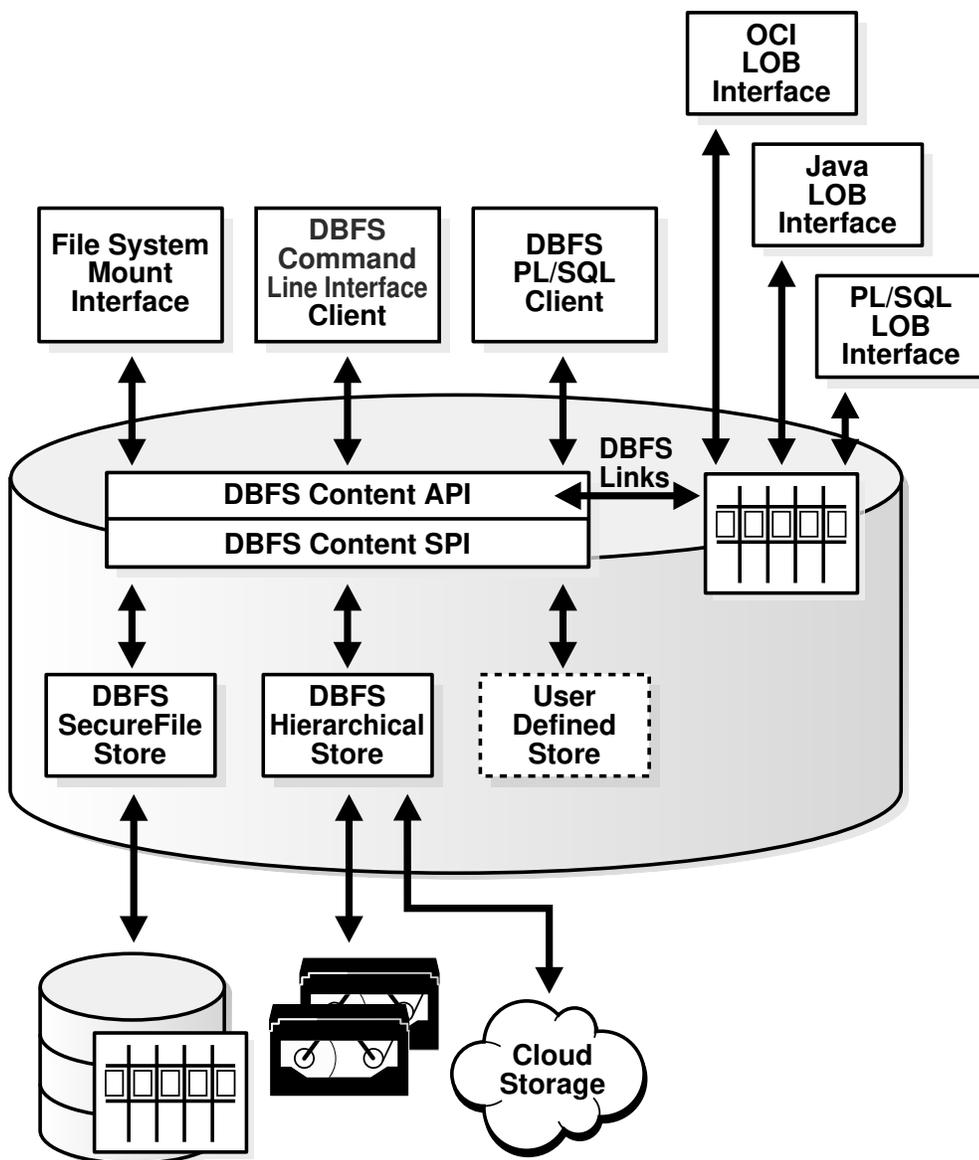

21.2 DBFS Content Store Provider Interface (DBFS Content SPI)

The DBFS Content SPI (Store Provider Interface) is a specification only and has no package body.

You must implement the package body in order to respond to calls from the DBFS Content API. In other words, DBFS Content SPI is a collection of required program specifications which you must implement using the method signatures and semantics indicated.

You may add additional functions and procedures to the DBFS Content SPI package body as needed. Your implementation may implement other methods and expose other interfaces, but the DBFS Content API will not use these interfaces.

The DBFS Content SPI references various elements such as constants, types, and exceptions defined by the DBFS Content API (package `DBMS_DBFS_CONTENT`).

Note that all path name references must be store-qualified, that is, the notion of mount points and full absolute path names has been normalized and converted to store-qualified path names by the DBFS Content API before it invokes any of the Provider SPI methods.

Because the DBFS Content API and SPI implementation is a one-to-many pluggable architecture, the DBFS Content API uses dynamic SQL to invoke methods in the SPI implementation; this may lead to run time errors if your SPI implementation does not follow the specification of SPI implementation given in this document.

There are no explicit initial or final methods to indicate when the DBFS Content API plugs and unplugs a particular SPI implementation. SPI implementations must be able to auto-initialize themselves at any SPI entry point.

> - *Oracle Database PL/SQL Packages and Types Reference* for syntax of the `DBMS_DBFS_CONTENT_SPI` package
> - See the file `$ORACLE_HOME/rdbms/admin/dbmscapi.sql` for more information

21.3 Creating a Custom Store Provider

You can use this example store provider for DBFS, TaBleFileSystem Store Provider ("tbfs"), as a skeleton for custom providers or as a learning tool, to become familiar with the DBFS and its SPI.

This example store provider for DBFS, exposes a relational table containing a `BLOB` column as a flat, non-hierarchical filesystem, that is, a collection of named files.

To use this example, it is assumed that you have installed the Oracle Database 12*c* and are familiar with DBFS concepts, and have installed and used `dbfs_client` and `FUSE` to mount and access filesystems backed by the standard SFS store provider.

The TaBleFileSystem Store Provider ("tbfs") does not aim to be feature-rich or even complete, it does however provide a sufficient demonstration of what it takes for users of DBFS to write their own custom providers that expose their table(s) through `dbfs_client` to traditional filesystem programs.

- Installation and Setup
  You will need certain files for installation and setup of the DBFS TaBleFileSystem Store Provider ("tbfs").

- TBFS Use
  Once the example store provider for DBFS, TaBleFileSystem Store Provider ("tbfs") is installed, files can be added or removed in several different ways and other changes can be made to the TBFS.

- TBFS Internals
  The TBFS is simple because its primary purpose is to serve as a teaching and learning example.

- Example Scripts
  This section describes some example SQL scripts.

21.3.1 Installation and Setup

You will need certain files for installation and setup of the DBFS TaBleFileSystem Store Provider ("tbfs").

The TBFS consists of the following SQL files:

`tbfs.sql`   top-level driver script

`tbl.sql`   script to create a test user, tablespace, the table backing the filesystem, and so on.

`spec.sql`   the SPI specification of the tbfs

`body.sql`   the SPI implementation of the tbfs

`capi.sql`   DBFS register/mount script

To install the TBFS, just run `tbfs.sql` as `SYSDBA`, in the directory that contains all of the above files. `tbfs.sql` will load the other SQL files in the proper sequence.

Ignoring any name conflicts, all of the SQL files should load without any compilation errors. All SQL files should also load without any run time errors, depending on the value of the "plsql_warnings" init.ora parameter, you may see various innocuous warnings.

If there are any name conflicts (tablespace name TBFS, datafile name"tbfs.f", user name TBFS, package name TBFS), the appropriate references in the various SQL files must be changed consistently.

21.3.2 TBFS Use

Once the example store provider for DBFS, TaBleFileSystem Store Provider ("tbfs") is installed, files can be added or removed in several different ways and other changes can be made to the TBFS.

A `dbfs_client` connected as user TBFS will see a simple, non-hierarchical, filesystem backed by an RDBMS table (TBFS.TBFST).

Files can be added or removed from this filesystem through SQL (that is, through DML on the underlying table), through Unix utilities (mediated by `dbfs_client`), or through PL/SQL (using the DBFS APIs).

Changes to the filesystem made through any of the access methods will be visible, in a transactionally consistent manner (that is, at commit/rollback boundaries) to all of the other access methods.

21.3.3 TBFS Internals

The TBFS is simple because its primary purpose is to serve as a teaching and learning example.

However, the implementation shows the path towards a robust, production-quality custom SPI that can plug into the DBFS, and expose existing relational data as Unix filesystems.

The TBFS makes various simplifications in order to remain concise (however, these should not be taken as inviolable limitations of DBFS or the SPI):

ORACLE

- The TBFS SPI package handles only a single table with a hard-coded name (TBFS.TBFST). It is possible to use dynamic SQL and additional configuration information to have a single SPI package support multiple tables, each as a separate filesystem (or even to unify data in multiple tables into a single filesystem).

- The TBFS does not support filesystem hierarchies; it imposes a flat namespace: a collection of files, identified by a simple item name, under a virtual "/" root directory. Implementing directory hierarchies is significantly more complex because it requires the store provider to manage parent/child relationships in a consistent manner.

  Moreover, existing relational data (the kind of data that TBFS is attempting to expose as a filesystem) does not typically have inter-row relationships that form a natural directory/file hierarchy.

- Because the TBFS supports only a flat namespace, most methods in the SPI are unimplemented, and the method bodies raise a `dbms_dbfs_content.unsupported_operation` exception. This exception is also a good starting point for you to write your own custom SPI. You can start with a simple SPI skeleton cloned from the `DBMS_DBFS_CONTENT_SPI` package, default all method bodies to ones that raise this exception, and subsequently fill in more realistic implementations incrementally.

- The table underlying the TBFS is close to being the simplest possible structure (a key/name column and a LOB column). This means that various properties used or expected by DBFS and `dbfs_client` must be generated dynamically (the TBFS implementation shows how this is done for the `std:guid` property).

  Other properties (such as Unix-style timestamps) are not implemented at all. This still allows a surprisingly functional filesystem to be implemented, but when you write your own custom SPIs, you can easily incorporate support for additional DBFS properties by expanding the structure of their underlying table(s) to include additional columns as needed, or by using existing columns in their existing tables to provide the values for these DBFS properties.

- The TBFS does not implement a rename/move method; adding support for this (a suitable `UPDATE` statement in the `renamePath` method) is left as an exercise for the user.

- The TBFS example uses the string "tbfs" in multiple places (tablespace, datafile, user, package, and even filesystem name). All these uses of "tbfs" belong in different namespaces—identifying which namespace corresponds to a specific occurrence of the string. "tbfs" in these examples is also a good learning exercise to make sure that the DBFS concepts are clear in your mind.

21.3.4 Example Scripts

This section describes some example SQL scripts.

- Driver Script
  The TBFS.SQL script is the top level driver script.
- Creating a Test User, Tablespace and Table to Backup Filesystem
  The TBL.SQL script creates a test user, a tablespace, the table that backs the filesystem and so on.
- Providing SPI Specification
  The `spec.sql` script provide the SPI specification of the tbfs.
- SPI Implementation of tbfs
  The `body.sql` script provides the SPI implementation of the tbfs.

- [Registering and Mounting the DBFS](#)
  The `capi.sql` script registers and mounts the DBFS.

21.3.4.1 Driver Script

The TBFS.SQL script is the top level driver script.

The TBFS.SQL script:

```
set echo on;

@tbl
@spec
@body
@capi

quit;
```

21.3.4.2 Creating a Test User, Tablespace and Table to Backup Filesystem

The TBL.SQL script creates a test user, a tablespace, the table that backs the filesystem and so on.

The TBL.SQL script :

```
connect / as sysdba

create tablespace tbfs datafile 'tbfs.f' size 100m
    reuse autoextend on
    extent management local
    segment space management auto;

create user tbfs identified by tbfs;
alter user tbfs default tablespace tbfs;
grant connect, resource, dbfs_role to tbfs;

connect tbfs/tbfs;

drop table tbfst;
purge recyclebin;

create table tbfst(
    key     varchar2(256)
            primary key
            check           (instr(key, '/') = 0),
    data    blob)
        tablespace tbfs
    lob(data)
        store as securefile
            (tablespace tbfs);

grant select on tbfst to dbfs_role;
grant insert on tbfst to dbfs_role;
grant delete on tbfst to dbfs_role;
grant update on tbfst to dbfs_role;
```

21.3.4.3 Providing SPI Specification

The `spec.sql` script provide the SPI specification of the tbfs.

The `spec.sql` script:

```
connect / as sysdba;

create or replace package tbfs
    authid current_user
as

    /*
     * Lookup store features (see dbms_dbfs_content.feature_XXX). Lookup
     * store id.
     *
     * A store ID identifies a provider-specific store, across
     * registrations and mounts, but independent of changes to the store
     * contents.
     *
     * I.e. changes to the store table(s) should be reflected in the
     * store ID, but re-initialization of the same store table(s) should
     * preserve the store ID.
     *
     * Providers should also return a "version" (either specific to a
     * provider package, or to an individual store) based on a standard
     * <a.b.c> naming convention (for <major>, <minor>, and <patch>
     * components).
     *
     */

    function    getFeatures(
        store_name          in      varchar2)
            return  integer;

    function    getStoreId(
        store_name          in      varchar2)
            return  number;

    function    getVersion(
        store_name          in      varchar2)
            return  varchar2;

    /*
     * Lookup pathnames by (store_name, std_guid) or (store_mount,
     * std_guid) tuples.
     *
     * If the underlying "std_guid" is found in the underlying store,
     * this function returns the store-qualified pathname.
     *
     * If the "std_guid" is unknown, a "null" value is returned. Clients
     * are expected to handle this as appropriate.
     *
     */

    function    getPathByStoreId(
        store_name          in      varchar2,
        guid                in      integer)
            return  varchar2;
```

```
/*
 * DBFS SPI: space usage.
 *
 * Clients can query filesystem space usage statistics via the
 * "spaceUsage()" method. Providers are expected to support this
 * method for their stores (and to make a best effort determination
 * of space usage---esp. if the store consists of multiple
 * tables/indexes/lobs, etc.).
 *
 * "blksize" is the natural tablespace blocksize that holds the
 * store---if multiple tablespaces with different blocksizes are
 * used, any valid blocksize is acceptable.
 *
 * "tbytes" is the total size of the store in bytes, and "fbytes" is
 * the free/unused size of the store in bytes. These values are
 * computed over all segments that comprise the store.
 *
 * "nfile", "ndir", "nlink", and "nref" count the number of
 * currently available files, directories, links, and references in
 * the store.
 *
 * Since database objects are dynamically growable, it is not easy
 * to estimate the division between "free" space and "used" space.
 *
 */

procedure    spaceUsage(
    store_name  in                varchar2,
    blksize     out               integer,
    tbytes      out               integer,
    fbytes      out               integer,
    nfile       out               integer,
    ndir        out               integer,
    nlink       out               integer,
    nref        out               integer);

/*
 * DBFS SPI: notes on pathnames.
 *
 * All pathnames used in the SPI are store-qualified, i.e. a 2-tuple
 * of the form (store_name, pathname) (where the pathname is rooted
 * within the store namespace).
 *
 *
 * Stores/providers that support contentID-based access (see
 * "feature_content_id") also support a form of addressing that is
 * not based on pathnames. Items are identified by an explicit store
 * name, a "null" pathname, and possibly a contentID specified as a
 * parameter or via the "opt_content_id" property.
 *
 * Not all operations are supported with contentID-based access, and
 * applications should depend only on the simplest create/delete
 * functionality being available.
 *
 */

/*
 * DBFS SPI: creation operations
```

```
 *
 * The SPI must allow the DBFS API to create directory, file, link,
 * and reference elements (subject to store feature support).
 *
 *
 * All of the creation methods require a valid pathname (see the
 * special exemption for contentID-based access below), and can
 * optionally specify properties to be associated with the pathname
 * as it is created. It is also possible for clients to fetch-back
 * item properties after the creation completes (so that
 * automatically generated properties (e.g. "std_creation_time") are
 * immediately available to clients (the exact set of properties
 * fetched back is controlled by the various "prop_xxx" bitmasks in
 * "prop_flags").
 *
 *
 * Links and references require an additional pathname to associate
 * with the primary pathname.
 *
 * File pathnames can optionally specify a BLOB value to use to
 * initially populate the underlying file content (the provided BLOB
 * may be any valid lob: temporary or permanent). On creation, the
 * underlying lob is returned to the client (if "prop_data" is
 * specified in "prop_flags").
 *
 * Non-directory pathnames require that their parent directory be
 * created first. Directory pathnames themselves can be recursively
 * created (i.e. the pathname hierarchy leading up to a directory
 * can be created in one call).
 *
 *
 * Attempts to create paths that already exist is an error; the one
 * exception is pathnames that are "soft-deleted" (see below for
 * delete operations)---in these cases, the soft-deleted item is
 * implicitly purged, and the new item creation is attempted.
 *
 *
 * Stores/providers that support contentID-based access accept an
 * explicit store name and a "null" path to create a new element.
 * The contentID generated for this element is available via the
 * "opt_content_id" property (contentID-based creation automatically
 * implies "prop_opt" in "prop_flags").
 *
 * The newly created element may also have an internally generated
 * pathname (if "feature_lazy_path" is not supported) and this path
 * is available via the "std_canonical_path" property.
 *
 * Only file elements are candidates for contentID-based access.
 *
 */

procedure   createFile(

/*
 * DBFS SPI: deletion operations
 *
 * The SPI must allow the DBFS API to delete directory, file, link,
 * and reference elements (subject to store feature support).
 *
 *
 * By default, the deletions are "permanent" (get rid of the
 * successfully deleted items on transaction commit), but stores may
 * also support "soft-delete" features. If requested by the client,
 * soft-deleted items are retained by the store (but not typically
 * visible in normal listings or searches).
 *
 * Soft-deleted items can be "restore"d, or explicitly purged.
 *
 *
 * Directory pathnames can be recursively deleted (i.e. the pathname
 * hierarchy below a directory can be deleted in one call).
 * Non-recursive deletions can be performed only on empty
 * directories. Recursive soft-deletions apply the soft-delete to
 * all of the items being deleted.
 *
 *
 * Individual pathnames (or all soft-deleted pathnames under a
 * directory) can be restored or purged via the restore and purge
 * methods.
 *
 *
 * Providers that support filtering can use the provider "filter" to
 * identify subsets of items to delete---this makes most sense for
 * bulk operations (deleteDirectory, restoreAll, purgeAll), but all
 * of the deletion-related operations accept a "filter" argument.
 *
 *
 * Stores/providers that support contentID-based access can also
 * allow file items to be deleted by specifying their contentID.
 *
 */
```

```
procedure   deleteFile(

/*
 * DBFS SPI: path get/put operations.
 *
 * Existing path items can be accessed (for query or for update) and
 * modified via simple get/put methods.
 *
 * All pathnames allow their metadata (i.e. properties) to be
 * read/modified. On completion of the call, the client can request
 * (via "prop_flags") specific properties to be fetched as well.
 *
 * File pathnames allow their data (i.e. content) to be
 * read/modified. On completion of the call, the client can request
 * (via the "prop_data" bitmaks in "prop_flags") a new BLOB locator
 * that can be used to continue data access.
```

```
 *
 * Files can also be read/written without using BLOB locators, by
 * explicitly specifying logical offsets/buffer-amounts and a
 * suitably sized buffer.
 *
 *
 * Update accesses must specify the "forUpdate" flag. Access to link
 * pathnames can be implicitly and internally deferenced by stores
 * (subject to feature support) if the "deref" flag is
 * specified---however, this is dangerous since symbolic links are
 * not always resolvable.
 *
 *
 * The read methods (i.e. "getPath" where "forUpdate" is "false"
 * also accepts a valid "asof" timestamp parameter that can be used
 * by stores to implement "as of" style flashback queries. Mutating
 * versions of the "getPath" and the "putPath" methods do not
 * support as-of modes of operation.
 *
 *
 * "getPathNowait" implies a "forUpdate", and, if implemented (see
 * "feature_nowait"), allows providers to return an exception
 * (ORA-54) rather than wait for row locks.
 *
 */

/*
 * DBFS SPI: notes on pathnames.
```

```
 *
 * All pathnames used in the SPI are store-qualified, i.e. a 2-tuple
 * of the form (store_name, pathname) (where the pathname is rooted
 * within the store namespace).
 *
 *
 * Stores/providers that support contentID-based access (see
 * "feature_content_id") also support a form of addressing that is
 * not based on pathnames. Items are identified by an explicit store
 * name, a "null" pathname, and possibly a contentID specified as a
 * parameter or via the "opt_content_id" property.
 *
 * Not all operations are supported with contentID-based access, and
 * applications should depend only on the simplest create/delete
 * functionality being available.
 *
 */

/*
 * DBFS SPI: creation operations
 *
 * The SPI must allow the DBFS API to create directory, file, link,
 * and reference elements (subject to store feature support).
 *
 *
 * All of the creation methods require a valid pathname (see the
 * special exemption for contentID-based access below), and can
 * optionally specify properties to be associated with the pathname
 * as it is created. It is also possible for clients to fetch-back
 * item properties after the creation completes (so that
 * automatically generated properties (e.g. "std_creation_time") are
 * immediately available to clients (the exact set of properties
 * fetched back is controlled by the various "prop_xxx" bitmasks in
 * "prop_flags").
 *
 *
 * Links and references require an additional pathname to associate
 * with the primary pathname.
 *
 * File pathnames can optionally specify a BLOB value to use to
 * initially populate the underlying file content (the provided BLOB
 * may be any valid lob: temporary or permanent). On creation, the
 * underlying lob is returned to the client (if "prop_data" is
 * specified in "prop_flags").
 *
 * Non-directory pathnames require that their parent directory be
 * created first. Directory pathnames themselves can be recursively
 * created (i.e. the pathname hierarchy leading up to a directory
 * can be created in one call).
 *
 *
 * Attempts to create paths that already exist is an error; the one
 * exception is pathnames that are "soft-deleted" (see below for
 * delete operations)---in these cases, the soft-deleted item is
 * implicitly purged, and the new item creation is attempted.
 *
 *
 * Stores/providers that support contentID-based access accept an
 * explicit store name and a "null" path to create a new element.
 * The contentID generated for this element is available via the
```

```
 * "opt_content_id" property (contentID-based creation automatically
 * implies "prop_opt" in "prop_flags").
 *
 * The newly created element may also have an internally generated
 * pathname (if "feature_lazy_path" is not supported) and this path
 * is available via the "std_canonical_path" property.
 *
 * Only file elements are candidates for contentID-based access.
 *

 *
 * The SPI must allow the DBFS API to delete directory, file, link,
 * and reference elements (subject to store feature support).
 *
 *
 * By default, the deletions are "permanent" (get rid of the
 * successfully deleted items on transaction commit), but stores may
 * also support "soft-delete" features. If requested by the client,
 * soft-deleted items are retained by the store (but not typically
 * visible in normal listings or searches).
 *
 * Soft-deleted items can be "restore"d, or explicitly purged.
 *
 *
 * Directory pathnames can be recursively deleted (i.e. the pathname
 * hierarchy below a directory can be deleted in one call).
 * Non-recursive deletions can be performed only on empty
 * directories. Recursive soft-deletions apply the soft-delete to
 * all of the items being deleted.
 *
 *
 * Individual pathnames (or all soft-deleted pathnames under a
 * directory) can be restored or purged via the restore and purge
 * methods.
 *
 *
 * Providers that support filtering can use the provider "filter" to
 * identify subsets of items to delete---this makes most sense for
 * bulk operations (deleteDirectory, restoreAll, purgeAll), but all
 * of the deletion-related operations accept a "filter" argument.
 *
 *
 * Stores/providers that support contentID-based access can also
 * allow file items to be deleted by specifying their contentID.
```

```

/*
 * DBFS SPI: path get/put operations.
 *
 * Existing path items can be accessed (for query or for update) and
 * modified via simple get/put methods.
 *
 * All pathnames allow their metadata (i.e. properties) to be
 * read/modified. On completion of the call, the client can request
 * (via "prop_flags") specific properties to be fetched as well.
 *
 * File pathnames allow their data (i.e. content) to be
 * read/modified. On completion of the call, the client can request
 * (via the "prop_data" bitmaks in "prop_flags") a new BLOB locator
 * that can be used to continue data access.
 *
 * Files can also be read/written without using BLOB locators, by
 * explicitly specifying logical offsets/buffer-amounts and a
 * suitably sized buffer.
 *
 *
 * Update accesses must specify the "forUpdate" flag. Access to link
 * pathnames can be implicitly and internally defereced by stores
 * (subject to feature support) if the "deref" flag is
 * specified---however, this is dangerous since symbolic links are
 * not always resolvable.
 *
 *
 * The read methods (i.e. "getPath" where "forUpdate" is "false"
 * also accepts a valid "asof" timestamp parameter that can be used
 * by stores to implement "as of" style flashback queries. Mutating
 * versions of the "getPath" and the "putPath" methods do not
```

```
 * support as-of modes of operation.
 *
 *
 * "getPathNowait" implies a "forUpdate", and, if implemented (see
 * "feature_nowait"), allows providers to return an exception
 * (ORA-54) rather than wait for row locks.
 *

show errors;
```

21.3.4.5 Registering and Mounting the DBFS

The `capi.sql` script registers and mounts the DBFS.

The `capi.sql` script:

```
connect tbfs/tbfs;

exec dbms_dbfs_content.registerStore('MY_TBFS', 'table', 'TBFS');
exec dbms_dbfs_content.mountStore('MY_TBFS', singleton => true);
commit;
```

22

DBFS Access Using OFS

You can access Database File System (DBFS) using the Oracle File Server (OFS) process.

This chapter provides details about how OFS uses OFSD, a dedicated background process, to manage DBFS. It also provides details about how you can access and manage DBFS.

To access a newly created DBFS across multiple nodes where there are no Oracle Client installations, use OFS to NFS mount the file system. In the absence of an Oracle Client installation, use OFS to mount the newly created DBFS to NFS and use it across multiple nodes. All file system requests are served by threads in the OFS background process.

- **About OFS**
  Oracle File Server (OFS) addresses the need to store PDB specific scripts, logs, trace files and other files produced by running an application in the database.

- **About Oracle File Server Process**
  OFS manages the database file system using a non-fatal and dedicated background process called Oracle File Server Deamon (OFSD).

- **OFS Configuration Parameters**
  The following table specifies all the parameters that enable NFS access in the database.

- **OFS Client Interface**
  The OFS interface includes views and procedures that support OFS operations.

- **Managing DBFS Locally Using FUSE**
  Understand how you can manage DBFS using Filesystem in User Space (FUSE).

- **Accessing DBFS and OFS with an NFS Account**
  NFS is a widely used protocol to access any local file system across network. OFS makes use of this protocol and enables access to any DBFS file system that is mounted on the compute node.

22.1 About OFS

Oracle File Server (OFS) addresses the need to store PDB specific scripts, logs, trace files and other files produced by running an application in the database.

Additionally, you can use OFS for the following tasks:

- As a staging area where you can host the source data before it is loaded into database tables.

- To store import or export files from Oracle Data Pump process.

Ensure that you do not place core database files such as data, redo, archive log files, and database trace file on OFS as this can produce a dependency cycle and cause the system to hang. Similarly, the `diagnostic_dest` initialization parameter that sets the location of the automatic diagnostic repository should not point to a directory inside OFS.

OFS provides methods and procedures to allow you to create a Database file system using storage that is part of the PDB. You can mount the created file system, unmount it like any other Unix file system using PL/SQL procedures, and destroy the file system when it is no

longer in use. When the PDB is destroyed, the file system is also destroyed, which frees up the underlying storage space.

22.2 About Oracle File Server Process

OFS manages the database file system using a non-fatal and dedicated background process called Oracle File Server Deamon (OFSD).

For more information about background process, see Background Processes in the *Database Reference* guide.

When an instance starts, the OFSD process gets spawned on operating system platforms, such as Linux, where OFS is supported. OFSD is multi-threaded and non-fatal. It serves both file system management requests and file requests from each mounted file system.

The centralized server background process model of OFS allows multiple file systems to be mounted and accessed using a limited set of server threads. It allows better resource sharing and a linear scalability with new file server threads created on demand. Both memory and CPU used by these threads are controlled through system wide parameters set in the RDBMS instance.

OFSD process starts two types of threads: receiver thread and worker thread. The receiver thread receives requests from the mounted file system. The name of this thread name is similar to `of01`. The requests received by this thread are placed in a submit queue which is served by different worker threads. The submit queue is hash partitioned to efficiently distribute the incoming requests across all the worker threads. By default, OFSD starts 3 worker threads. You can update the value of the `OFS_THREADS` parameter to increase the number of worker thread.
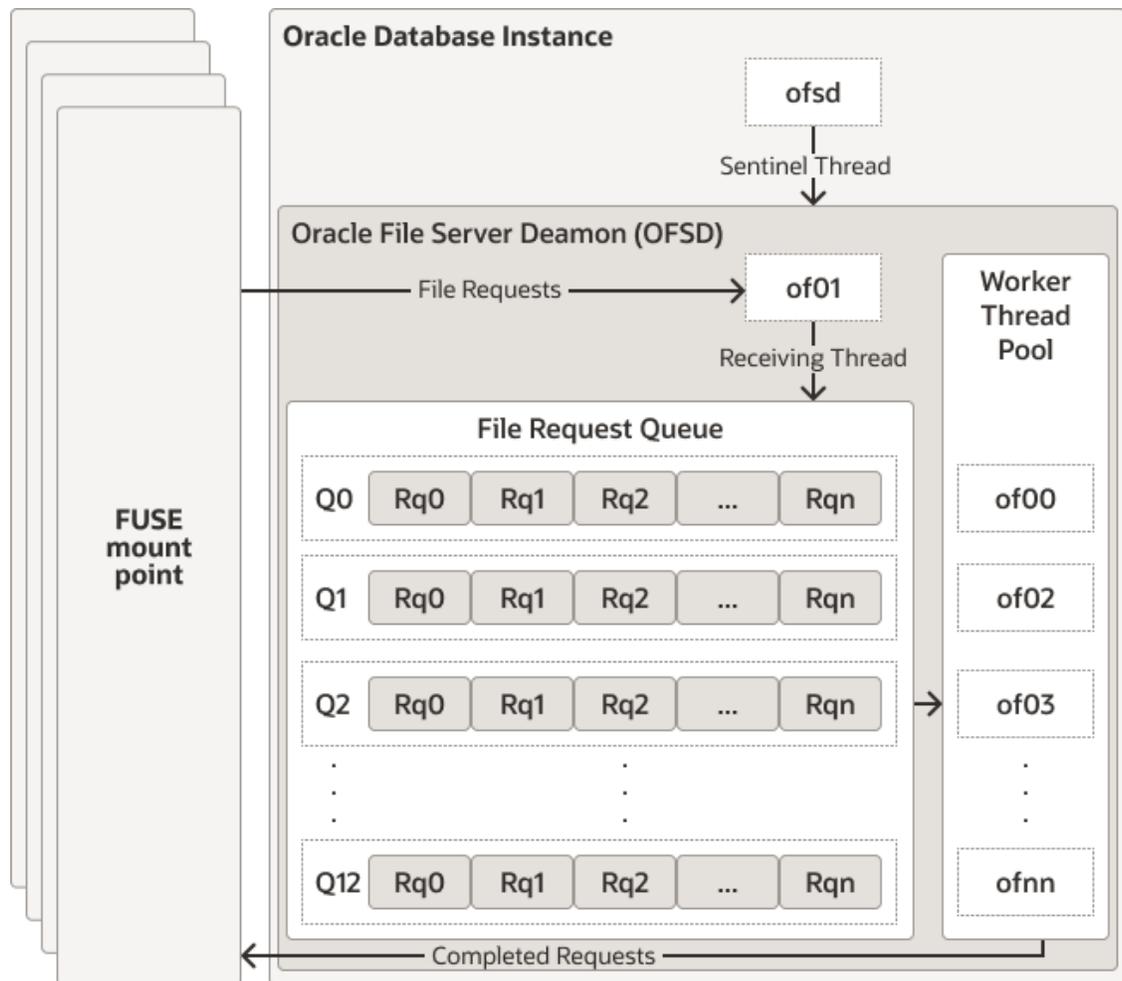

OFSD supports these 2 types of file systems: DBFS and OFS.

Use the `DBMS_FS` PL/SQL procedures to create, mount, and work with the file systems managed by the OFSD process.

OFSD uses a pool of worker threads to serve requests from multiple file systems that are mounted on the instance. Use `V$OFSMOUNT` to query the mounted file systems. The response that is returned is specific to each PDB. It lists only the file systems that are mounted in the specified PDB.

22.4 OFS Client Interface

The OFS interface includes views and procedures that support OFS operations.

- DBMS_FS Package
  The `DBMS_FS` package enables users to perform operations on Oracle file system (make, mount, unmount and destroy) in the Oracle database.
- Views for OFS
  The views that support OFS operations start with `V$OFS` .

22.4.1 DBMS_FS Package

The `DBMS_FS` package enables users to perform operations on Oracle file system (make, mount, unmount and destroy) in the Oracle database.

> **✎ See Also:**
>
> *Oracle Database PL/SQL Packages and Types Reference* for more information about Oracle OFS procedures.

The following example illustrates the use of `DBMS_FS` package.

```
BEGIN
 DBMS_FS.MAKE_ORACLE_FS (
   fstype           => 'dbfs',
   fsname           => 'dbfs_fs1',
   mount_options    => 'TABLESPACE=dbfs_fs1_tbspc');
END;
/
BEGIN
 DBMS_FS.MOUNT_ORACLE_FS (
   fstype           => 'dbfs',
   fsname           => 'dbfs_fs1',
   mount_point      => '/oracle/dbfs/testfs',
   mount_options    => 'default_permissions, allow_other, persist');
END;
/
/************** Now you can access the file system. All the FS operations go
here ***************/

BEGIN
 DBMS_FS.UNMOUNT_ORACLE_FS (
   fsname           => 'dbfs_fs1',
   mount_point      => '/oracle/dbfs/testfs',
   mount_options    => 'force');
END;
/
BEGIN
 DBMS_FS.DESTROY_ORACLE_FS (
   fstype           => 'dbfs',
   fsname           => 'dbfs_fs1');
END;
/
```

22.4.2 Views for OFS

The views that support OFS operations start with `V$OFS` .

> **✎ See Also:**
>
> *Oracle Database Reference* for the columns and data types of these views.

ORACLE

22.5 Managing DBFS Locally Using FUSE

Understand how you can manage DBFS using Filesystem in User Space (FUSE).

The FUSE interface in the Linux kernel makes the file systems available to the operating system processes. After mounting the file system, you can export it, and then NFS mount it on other nodes where client applications can access this file system.

- Configuring FUSE
  OFSD exposes the database file system through FUSE. Before using OFSD to mount the database file systems, you must install and configure the FUSE module.

- Accessing OFS in Cloud
  To access files from an OFS mounted on any Cloud environment, you must perform additional steps to configure the environment.

22.5.1 Configuring FUSE

OFSD exposes the database file system through FUSE. Before using OFSD to mount the database file systems, you must install and configure the FUSE module.

If you are running your database instance in a Compute node, configure the FUSE module in that node. The file system gets mounted and is visible through a mounted path on the compute node. In a RAC configuration, configure FUSE in each node, so that the OFS file systems can be mounted independently in each node.

To configure the FUSE module in Cloud or on-premises environment, where the database instance is running:

1. Set read and execute permissions for an Oracle user to use the FUSE executable file, `fusermount`.

   ```
   sudo chmod o+rx /usr/bin/fusermount
   ```

   Use the `fusermount` file to mount and unmount the FUSE user mode file systems.

2. Set the `setuid` bit on the `fusermount` file to permit an Oracle user to mount file systems.

   ```
   sudo chmod u+s /usr/bin/fusermount
   ```

3. Permit other users to access the mounted file system.

   ```
   sudo sh -c ''echo user_allow_other >> /etc/fuse.conf''
   ```

4. Optional. By default, the maximum number of file systems that you can mount using FUSE is 1000. If you are running a large number of PDBs and need to configure a separate file system for each PDB, then run the following command to increase the number of file systems that can be mounted using FUSE. The following command increases the number of file systems that can be mounted using FUSE to 4000.

   ```
   sudo sh -c ''echo mount_max=4000 >> /etc/fuse.conf''
   ```

5. Allow all users to read the `fuse.conf` file, so that the Oracle process can read this file at run time.

```
sudo chmod a+r /etc/fuse.conf
```

22.5.2 Accessing OFS in Cloud

To access files from an OFS mounted on any Cloud environment, you must perform additional steps to configure the environment.

To access files in an OFS mount in the Cloud environment, you may need to perform additional configuration. It may not be possible to export the OFS mount point from database node to client node due to security reasons. This may hinder client applications from accessing the OFS files through operating system commands and utilities and the OFS mount path may not be available to access using system calls. In such situations, Oracle recommends that you use the `utl_file` package to access files in the OFS mount. For information about UTL file package, see Summary of UTL_FILE Subprograms in *PL/SQL Packages and Types Reference*.

To configure the environment so that client applications in Cloud can access files in an OFS:

1. Create a directory object using the OFS mount path.

   The following sample code displays how you can create a directory object called `pdb1_ofsdir` when `/u03/dbfs/<pdbid>/data` is the OFS mount directory on the db node.

   ```
   CREATE DIRECTORY pdb1_ofsdir AS '/u03/dbfs/<pdbid>/data/';
   ```

2. Grant access to the user to access the directory object.

   For more information on creating a directory object and setting access permissions on it, see CREATE DIRECTORY in *PL/SQL Packages and Types Reference*.

Do not access the OFS files by directly querying or modifying the DBFS tables. Do not use `dbfs_client` when the DBFS file system is mounted through OFS or else it could lead to metadata and data inconsistency. To access the OFS files, use the `UTL_FILE` package in addition to the procedures listed in the `DBMS_FS` package. See FS_EXISTS and LIST_FILES in *PL/SQL Packages and Types Reference*.

22.3 OFS Configuration Parameters

The following table specifies all the parameters that enable NFS access in the database.

Table 22-1   OFS Configuration Parameters

Parameter Name	Description
OFS_THREADS	This parameter is used to set the number of OFS worker threads to handle OFS requests. Possible values: • An integer value in the range of 2–128 • Default value is 4

22.6 Accessing DBFS and OFS with an NFS Account

NFS is a widely used protocol to access any local file system across network. OFS makes use of this protocol and enables access to any DBFS file system that is mounted on the compute node.

NFS enables the compute node to be accessible across all nodes that are authorized to access the file system.

- **Accessing OFS with an NFS Account**
  You can export an OFS mount to a specified list of nodes and NFS mount it on them. This allows users to access the contents of an OFS mount point from a node where the database is not running. The NFS exports may not work in cloud environments due to security reasons, but you can use it in on-premise environments.

- **Prerequisites to Access Storage Through NFS Server**
  Learn about the prerequisites to access storage through NFS server.

- **NFS Security**
  OFS uses the OS authentication model to authorize NFS client users. If the user is accessing a local node (where the Oracle instance is running), the access to each file in the file system is controlled through **Unix Access Control List** set for each object.

22.6.1 Accessing OFS with an NFS Account

You can export an OFS mount to a specified list of nodes and NFS mount it on them. This allows users to access the contents of an OFS mount point from a node where the database is not running. The NFS exports may not work in cloud environments due to security reasons, but you can use it in on-premise environments.

NFS v3 is a stateless protocol because of which it encapsulates each `readdir` request between `opendir` and `releasedir` calls. This may lead to poor performance when you want to list directories that have a large number of files. Therefore, OFS maintains a directory cache which persists across the `opendir` and `releasedir` calls. Do not use the `no_rbt_cache` mount option to avoid inconsistent directory cache listing and to utilize the benefits of directory cache.

22.6.2 Prerequisites to Access Storage Through NFS Server

Learn about the prerequisites to access storage through NFS server.

Following are the prerequisites:

- DBFS file system must be created before using OFS.

- You should be able to mount the file systems exported by the database.

- NFS server must be configured with `KERNEL` module.

> **✒ Note:**
>
> The `KERNEL` module is supported through `FUSE` driver for Linux.

22.6.3 NFS Security

OFS uses the OS authentication model to authorize NFS client users. If the user is accessing a local node (where the Oracle instance is running), the access to each file in the file system is controlled through **Unix Access Control List** set for each object.

On Linux, OFS uses FUSE to receive file system requests from the OS kernel or NFS client. This requires `user_allow_other` parameter to be set in `/etc/fuse.conf` configuration file if an OS user other than the `root` user and oracle user need to access the file system.

> **Note:**
>
> Users can also be configured with an Oracle password to log into Oracle client tools like `SQL* Plus` to execute SQL statements.

If the network is not secure, the customer is advised to setup Kerberos to authenticate the user using OS NFS.

> **Note:**
>
> - The Kerberos authentication is available from NFS version 4 onwards. If the OFS is exported via NFS version 3, then the authentication is performed using `AUTH_SYS`.
>
> - For local node, the authentication is performed using `AUTH_SYS` irrespective of how the OFS is exported (NFS version 3 or NFS version 4).

- About Kerberos
  Kerberos uses encryption technology, Key Distribution Center (KDC), and an arbitrator to perform secure authentication on open networks.
- Configuring Kerberos Server
  To configure a Kerberos Server in a Linux system:

22.6.3.1 About Kerberos

Kerberos uses encryption technology, Key Distribution Center (KDC), and an arbitrator to perform secure authentication on open networks.

Kerberos is the widely used security mechanism that provides all three flavors of security:

- Authentication
- Integrity check
- Privacy

Kerberos Infrastructure consists of Kerberos software, secured authentication servers, centralized account and password store, and systems configured to authenticate through the Kerberos protocol. The OS NFS server handles the complete authentication and integrity checks by using kerberos principal name as the user name. Once the authentication is

performed, the requests passed to the Oracle kernel are handled based on the user name passed through the **VFS I/O** request.

22.6.3.2 Configuring Kerberos Server

To configure a Kerberos Server in a Linux system:

1. Install Kerberos software in the Linux system.

2. Check if the daemons are running using the following commands.

   ```
   # /sbin/chkconfig krb5kdc on
   # /sbin/chkconfig kadmin on
   ```

3. If the daemons are not running use the following commands to start the daemons manually:

   ```
   # /etc/rc.d/init.d/krb5kdc start
   # /etc/rc.d/init.d/kadmin start
   ```

4. Add user principal using the `kadmin.local` command.

   Example:

   ```
   kadmin.local: addprinc <scott>
   ```

A

Comparing the LOB Interfaces

The following tables compare the eight LOB programmatic interfaces by listing their functions and methods used to operate on LOBs. The tables are split in two only to accommodate all eight interfaces.

APIs for BLOBs and CLOBs

Table A-1   APIs for BLOBs and CLOBs (PL/SQL, JDBC, OCI, OCCI)

PL/SQL: DBMS_LOB (dbmslob.sql)	JDBC (Java) interfaces java.sql.Clob and java.sql.Blob	OCI (C/ocip.h)	OCCI (C++/occiData.h) classes: Clob and Blob
		`OCILobLocatorIsInit()`	`isInitialized()`
`ISSECUREFILE`	`isSecureFile()`		
`OPEN`	`open()`	`OCILobOpen()`	`Open()`
`ISOPEN`	`isOpen()`	`OCILobIsOpen()`	`isOpen()`
`CLOSE`	`close()`	`OCILobClose()`	`Close()`
`CREATETEMPORARY`	`createTemporary`	`OCILobCreateTemporary()`	
`FREETEMPORARY`	`freeTemporary`	`OCILobFreeTemporary()`	
`ISTEMPORARY`	`isTemporary`	`OCILobIsTemporary()`	
`GETLENGTH`	`length()`	`OCIGetLobLength2()`	`length()`
