This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software," "commercial computer software documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

## Changes in This Release for Oracle Data Provider for .NET

---

|                                                                    |        |
|--------------------------------------------------------------------|--------|
| Changes in Oracle Data Provider for .NET Release 23.26.0           | ii     |
| Changes in Oracle Data Provider for .NET Release 23.9              | iii    |
| Changes in Oracle Data Provider for .NET Release 23.8              | vi     |
| Changes in Oracle Data Provider for .NET Release 23.7              | viii   |
| Changes in Oracle Data Provider for .NET Release 23.6.1            | x      |
| Changes in Oracle Data Provider for .NET Release 23.6              | xi     |
| Changes in Oracle Data Provider for .NET Release 23.5.1            | xiii   |
| Changes in Oracle Data Provider for .NET Release 23.5              | xiv    |
| Changes in Oracle Data Provider for .NET Release 23.3              | xvi    |
| Changes in Oracle Data Provider for .NET Release 21c (21.12)       | xxiv   |
| Changes in Oracle Data Provider for .NET Release 21c (21.8)        | xxiv   |
| Changes in Oracle Data Provider for .NET Release 21c (21.7)        | xxiv   |
| Changes in Oracle Data Provider for .NET Release 21c (21.6.1)      | xxv    |
| Changes in Oracle Data Provider for .NET Release 21c (21.5)        | xxvi   |
| Changes in Oracle Data Provider for .NET Release 21c (21.4.1)      | xxvi   |
| Changes in Oracle Data Provider for .NET Release 21c (21.4)        | xxvii  |
| Changes in Oracle Data Provider for .NET Release 21c (21.3)        | xxvii  |
| Changes in Oracle Data Provider for .NET (21.1)                    | xxix   |
| Changes in Oracle Data Provider for .NET (19.16)                   | xxx    |
| Changes in Oracle Data Provider for .NET (19.15.1)                 | xxxi   |
| Changes in Oracle Data Provider for .NET (19.10)                   | xxxi   |
| Changes in Oracle Data Provider for .NET (19.9)                    | xxxiii |
| Changes in Oracle Data Provider for .NET ODAC Release 19c (19.3.2) | xxxiii |
| Changes in Oracle Data Provider for .NET (19.7)                    | xxxiv  |
| Changes in Oracle Data Provider for .NET (19.6)                    | xxxiv  |

|                                                                     |       |
|---------------------------------------------------------------------|-------|
| Changes in Oracle Data Provider for .NET (19.5)                     | xxxv  |
| Changes in Oracle Data Provider for .NET in ODAC Release 19c (19.3) | xxxv  |
| Changes in Oracle Data Provider for .NET Release 19c (19.3)         | xxxvi |

## 1 Introducing Oracle Data Provider for .NET

---

|                                                                           |    |

### 3 Features of Oracle Data Provider for .NET

---

|                                                                                              |    |
|----------------------------------------------------------------------------------------------|----|
| Base Classes, Provider Factory Classes, and DbDataSource                                     | 2  |
| Code Access Security                                                                         | 6  |
| Configuring OraclePermission                                                                 | 7  |
| Configuring OraclePermission for Web Applications with High or Medium Trust Levels           | 8  |
| Configuring OraclePermission for Windows Applications Running in a Partial Trust Environment | 8  |
| Connecting to Oracle Database                                                                | 8  |
| Connecting to Oracle Autonomous Database                                                     | 9  |
| Using Oracle Identity and Access Management                                                  | 11 |
| Configuring a Client Connection Using an IAM Database Password Verifier                      | 11 |
| Configuring a Client Connection Using Token                                                  | 12 |
| Configuring Client Connection to use Token File                                              | 12 |
| Use of ODP.NET API to pass the Token                                                         | 13 |
| IAM Token Functionality Requirements                                                         | 15 |
| Sample Code                                                                                  | 15 |
| Configuring a Client Connection Using Database Alternate Password for Token Authentication   | 16 |
| Comparing IAM Token Authentication Methods                                                   | 16 |
| IAM Single Sign-On                                                                           | 18 |
| Using Microsoft Entra ID                                                                     | 21 |
| Connection String Attributes and URLs                                                        | 27 |
| Connection String Builder                                                                    | 30 |
| Specifying the Data Source Attribute                                                         | 30 |
| Using the TNS Alias                                                                          | 31 |
| Using the Connect Descriptor                                                                 | 31 |
| Easy Connect and Easy Connect Plus Naming Methods                                            | 31 |
| Using LDAP                                                                                   | 32 |
| LDAP URL Naming                                                                              | 33 |
| LDAPS Configuration without Wallets                                                          | 33 |
| Data Source Enumerator                                                                       | 34 |

| Identifier Name Length and Uniqueness                                                                   | 29 |
| Using Large Character or Binary Data Types                                                              | 30 |
| Performance Considerations                                                                              | 30 |
| Artificial Intelligence Vector Data Types                                                               | 31 |

## 6 Oracle Data Provider for .NET Classes

---

|                                         |    |
|-----------------------------------------|----|
| OracleAccessToken Class                 | 2  |
| OracleAccessToken Members               | 3  |
| OracleAccessToken Constructors          | 4  |
| OracleAccessToken(char)                 | 4  |
| OracleAccessToken(char, char)           | 5  |
| RefreshAccessToken Event                | 5  |
| OracleClientFactory Class               | 6  |
| OracleClientFactory Members             | 7  |
| OracleClientFactory Field               | 9  |
| Instance                                | 9  |
| OracleClientFactory Constructor         | 10 |
| OracleClientFactory Public Properties   | 10 |
| CanCreateDataSourceEnumerator           | 10 |
| OracleClientFactory Public Methods      | 11 |
| CreateCommand                           | 12 |
| CreateCommandBuilder                    | 12 |
| CreateConnection                        | 13 |
| CreateConnectionStringBuilder           | 13 |
| CreateDataAdapter                       | 13 |
| CreateDataSource                        | 14 |
| CreateDataSourceEnumerator              | 14 |
| CreateParameter                         | 15 |
| CreatePermission                        | 15 |
| OracleCommand Class                     | 16 |
| OracleCommand Members                   | 18 |
| OracleCommand Constructors              | 21 |
| OracleCommand()                         | 22 |
| OracleCommand(string)                   | 22 |
| OracleCommand(string, OracleConnection) | 23 |
| OracleCommand Static Methods            | 23 |
| OracleCommand Properties                | 23 |
| AddRowid                                | 25 |
| AddToStatementCache                     | 26 |
| ArrayBindCount                          | 27 |
| ArrayBindRowsAffected                   | 28 |
| BindByName                              | 29 |
| CommandText                             | 30 |
| CommandTimeout                          | 31 |

|                                                                                 |    |
|---------------------------------------------------------------------------------|----|
| CommandType                                                                     | 32 |
| Connection                                                                      | 32 |
| DesignTimeVisible                                                               | 33 |
| FetchSize                                                                       | 33 |
| FetchSqlId                                                                      | 34 |
| ImplicitRefCursors                                                              | 35 |
| InitialLOBFetchSize                                                             | 36 |
| InitialLONGFetchSize                                                            | 36 |
| Notification                                                                    | 37 |
| NotificationAutoEnlist                                                          | 38 |
| Parameters                                                                      | 39 |
| RowSize                                                                         | 40 |

## 8 Oracle Data Provider for .NET HA Event Classes

---

|                              |   |
|------------------------------|---|
| OracleHAEventArgs Class      | 1 |
| OracleHAEventArgs Members    | 2 |
| OracleHAEventArgs Properties | 3 |
| DatabaseDomainName           | 3 |
| DatabaseName                 | 4 |
| DrainTimeout                 | 4 |

|                                 |    |
|---------------------------------|----|
| HostName                        | 5  |
| InstanceName                    | 5  |
| Reason                          | 6  |
| ServiceName                     | 6  |
| Source                          | 7  |
| Status                          | 7  |
| Time                            | 8  |
| OracleHAEventHandler Delegate   | 8  |
| OracleHAEventSource Enumeration | 9  |
| OracleHAEventStatus Enumeration | 10 |

## 9 Continuous Query Notification Classes

---

|                                                  |    |
|--------------------------------------------------|----|
| OracleDependency Class                           | 1  |
| OracleDependency Members                         | 2  |
| OracleDependency Constructors                    | 4  |
| OracleDependency ( )                             | 5  |
| OracleDependency(OracleCommand)                  | 5  |

## 10 Oracle Data Provider for .NET Globalization Classes

---

|                                    |    |
|------------------------------------|----|
| OracleGlobalization Class          | 1  |
| OracleGlobalization Members        | 2  |
| OracleGlobalization Static Methods | 4  |
| GetClientInfo                      | 4  |
| GetClientInfo()                    | 5  |
| GetClientInfo(OracleGlobalization) | 6  |
| GetThreadInfo                      | 7  |
| GetThreadInfo()                    | 7  |
| GetThreadInfo(OracleGlobalization) | 8  |
| SetThreadInfo                      | 9  |
| OracleGlobalization Properties     | 10 |
| Calendar                           | 11 |
| ClientCharacterSet                 | 12 |
| Comparison                         | 12 |
| Currency                           | 13 |

|                                    |    |
|------------------------------------|----|
| DateFormat                         | 13 |
| DateLanguage                       | 14 |
| DualCurrency                       | 14 |
| ISOCurrency                        | 15 |
| Language                           | 16 |
| LengthSemantics                    | 16 |
| NCharConversionException           | 17 |
| NumericCharacters                  | 18 |
| Sort                               | 18 |
| Territory                          | 19 |
| TimeStampFormat                    | 19 |
| TimeStampTZFormat                  | 20 |
| TimeZone                           | 20 |
| OracleGlobalization Public Methods | 21 |
| Clone                              | 22 |
| Dispose                            | 22 |
| OracleDatabaseCharset Enumeration  | 23 |
| OracleDatabaseNCharset Enumeration | 29 |

## 11 Oracle Data Provider for .NET Transparent Application Failover Classes

---

|                                        |    |
|----------------------------------------|----|
| OracleFailoverEventArgs Class          | 1  |
| OracleFailoverEventArgs Members        | 3  |
| OracleFailoverEventArgs Static Methods | 4  |
| OracleFailoverEventArgs Properties     | 5  |
| FailoverEvent                          | 5  |
| FailoverType                           | 6  |
| OracleFailoverEvent                    | 6  |
| OracleFailoverType                     | 7  |
| OracleFailoverEventArgs Public Methods | 7  |
| OracleTAFMode Class                    | 8  |
| OracleTAFMode Constructors             | 8  |
| OracleFailoverEventHandler Delegate    | 9  |
| FailoverEvent Enumeration              | 10 |
| FailoverReturnCode Enumeration         | 12 |
| FailoverType Enumeration               | 12 |
| OracleFailoverEvent Enumeration        | 13 |
| OracleFailoverRestore Enumeration      | 14 |
| OracleFailoverReturnCode Enumeration   | 16 |
| OracleFailoverType Enumeration         | 17 |

## 12 Oracle Database Advanced Queuing and Transactional Event Queues Classes

---

|                                       |    |
|---------------------------------------|----|
| OracleAQAgent Class                   | 1  |
| OracleAQAgent Members                 | 2  |
| OracleAQAgent Constructors            | 3  |
| OracleAQAgent (string)                | 3  |
| OracleAQAgent (string, string)        | 4  |
| OracleAQAgent Properties              | 5  |

# Preface

This document is your primary source of introductory, installation, postinstallation configuration, and usage information for Oracle Data Provider for .NET.

Oracle Data Provider for .NET is an implementation of the Microsoft ADO.NET interface.

This Preface contains these topics:

- [Audience](#)
- [Documentation Accessibility](#)
- [Related Documents](#)
- [Passwords in Code Examples](#)
- [Conventions](#)

## Audience

*Oracle Data Provider for .NET Developer's Guide* is intended for programmers who are developing applications to access an Oracle database using Oracle Data Provider for .NET. This documentation is also valuable to systems analysts, project managers, and others interested in the development of database applications.

To use this document, you must be familiar with Microsoft .NET Framework classes and ADO.NET and have a working knowledge of application programming using Microsoft C#, Visual Basic .NET, or another .NET language.

Although the examples in the documentation and the samples in the sample directory are written in C#, developers can use these examples as models for writing code in other .NET languages.

Users should also be familiar with the use of Structured Query Language (SQL) to access information in relational database systems.

## Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

### Access to Oracle Support

Oracle customer access to and use of Oracle support services will be pursuant to the terms and conditions specified in their Oracle order for the applicable services.

## Related Documents

To download free release notes, installation documentation, white papers, or other collateral, please visit the Oracle Technology Network (OTN). You must register online before using OTN; registration is free and can be done at

<http://www.oracle.com/technetwork/index.html>

For additional information, see:

<https://learn.microsoft.com/en-us/docs/>

## Passwords in Code Examples

For simplicity in demonstrating this product, code examples do not perform the password management techniques that a deployed system normally uses. In a production environment, follow the Oracle Database password management guidelines, and disable any sample accounts. See *Oracle Database Security Guide* for password management guidelines and other security recommendations.

## Conventions

The following text conventions are used in this document:

| Convention      | Meaning                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>boldface</b> | Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.         |
| <i>italic</i>   | Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.                          |
| monospace       | Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter. |

# Changes in This Release for Oracle Data Provider for .NET

This section describes new features added for each ODP.NET release. A summary of these new features by release are also available on [Oracle's Web site](#).

# Changes in Oracle Data Provider for .NET Release 23.26.0

The following are the changes in Oracle Data Provider for .NET for Release 23.26.0.

## New Features

The following features are new in this release:

- Managed ODP.NET and ODP.NET Core – Upgrading ODP.NET Time Zone File

ODP.NET now allows an app to specify a newer time zone file if the ODP.NET default uses an older version. This feature eliminates errors from using outdated time zone files.

### See Also

OracleConfiguration.[TimeZoneFileLocation](#)

OracleConnection.[DatabaseTimeZoneFileVersion](#)

OracleConnection.[ClientTimeZoneFileVersion](#)

- Managed ODP.NET and ODP.NET Core – OpenTelemetry Rows Fetched per Round Trip

ODP.NET OpenTelemetry now returns the number of rows returned per database roundtrip for ODP.NET SELECT statements in a new `db.response.returned_rows` tag.

This tag enhances visibility into ODP.NET activity and performance.

### See Also

[OpenTelemetry](#)

- Managed ODP.NET and ODP.NET Core – Application Continuity Maximum Calls Per Request Boundary

In Application Continuity, ODP.NET stores all the driver calls that occur between request boundaries, generally when connections are checked out and in. Having this call record is what makes session restoration possible after a failover. For long-running connections, more calls to restore mean more memory is necessary to retain all the changes between request boundaries. ODP.NET allows you to disable session replay when this memory usage becomes too high by setting a maximum number of calls to retain between request boundaries.

If you have long-running connections using Application Continuity that consume too much memory for replay, you can free memory from the connections with the most calls by setting the `OracleConfiguration.MaxCallsPerRequestBoundary` property to a lower value.

### See Also

OracleConfiguration [MaxCallsPerRequestBoundary](#) property

- Raft Replication

All ODP.NET provider types now support Oracle Globally Distributed Database Raft replication for fault-tolerant replication with transactional support.

ODP.NET apps will then have automatic failover with no data loss while using distributed databases and Oracle Data Guard. No ODP.NET code changes are necessary to use Raft replication.

#### ① See Also

ODP.NET [Oracle Globally Distributed Database](#)

Using Raft Replication in Oracle Globally Distributed Database

## Changes in Oracle Data Provider for .NET Release 23.9

The following are the changes in Oracle Data Provider for .NET for Release 23.9.

### New Features

The following features are new in this release:

- ODP.NET Core – Distributed Transactions on Windows

With a fully managed System.Transactions library now available, ODP.NET Core now supports distributed transactions on Windows. In-doubt transaction recovery occurs via the Oracle Services for MTS recovery service.

Distributed transactions apps running in .NET Framework can be ported to .NET runtime. New .NET distributed transaction apps can be developed with .NET 8 and higher.

#### ① See Also

[Distributed Transactions](#)

- Managed ODP.NET and ODP.NET Core – Binary Sparse Vector Data Types for AI Apps

ODP.NET enhances its sparse vector data type support by adding binary numeric format. ODP.NET sparse vectors can now be represented in all four numeric formats: BINARY, FLOAT32, FLOAT64, and INT8.

The BINARY format advantages are:

- Its vector storage footprint can be reduced by a factor of 32 compared to FLOAT32.
- Distance computations between two vectors are up to 40 times faster.

Its disadvantage is possible accuracy loss, though that loss is often not substantial.

#### ① See Also

[Artificial Intelligence Vectors and Semantic Search](#)

- Managed ODP.NET and ODP.NET Core – Bulk Copy Vector Data Types

ODP.NET now supports bulk copying vector data types into the database.

Apps can now efficiently load AI and vector data sets for use in Oracle database.

**See Also**

[Bulk Copy](#)

- Managed ODP.NET and ODP.NET Core – ODP.NET OpenTelemetry Round Trip Count and Duration Activity Tags

ODP.NET OpenTelemetry now returns the total roundtrips and the duration of individual ODP.NET method calls.

These tags enhance visibility into ODP.NET activity and performance.

**See Also**

[OpenTelemetry](#)

- ODP.NET Core – PEM Files for Securing ODP.NET Apps

ODP.NET now supports PEM files for storing client security certificates.

This feature gives apps another option to store credentials and certificates.

**See Also**

[Mutual TLS/SSL Certificate Selection](#)

- Managed ODP.NET – Kerberos.NET

Managed ODP.NET has the option to utilize the Kerberos.NET library for Kerberos authentication. ODP.NET Core already uses Kerberos.NET.

Developers can now standardize on Kerberos.NET for both their ODP.NET managed and core apps. Managed ODP.NET programmers can choose between MIT Kerberos or Kerberos.NET. Oracle recommends customers select Kerberos.NET as it is a fully managed solution built specifically for .NET.

**See Also**

[Using Kerberos](#)

- SHA2-based Thumbprint for Certificate Selection

ODP.NET can now select certificates via thumbprint using SHA2 algorithms in addition to existing SHA1 support.

SHA2 is generally considered more secure than SHA1 and provides another security option for ODP.NET apps.

**① See Also**

OracleConfiguration.[SSLCertificateThumbprint](#)

OracleConnection.[SSLCertificateThumbprint](#)

- Easier TLS Version Configuration

ODP.NET can specify a minimum TLS version by appending the plus (+) sign to the property version value, such as 1.2+ or TLSv1.2+. ODP.NET will automatically use the highest TLS version the Oracle database server supports. This property can be set in the TLSVersion or SSLVersion properties.

To exclude specific higher TLS versions from use, developers set the TLSExcludeVersion property to identify the excluded versions.

These new capabilities make it easier to upgrade and specify newer TLS versions when they become available on the database server.

**① See Also**

[OracleConfiguration Secure Connection Properties](#)

[OracleConnection Properties](#)

- ODP.NET Core – More OracleDataSource and OracleDataSourceBuilder Properties

OracleDataSource and OracleDataSourceBuilder classes support the new properties, RetryCount and RetryDelay.

In addition, OracleDataSource supports the DatabaseCharset, DatabaseNCharset, and MaxIdentifierLength properties.

**① See Also**

[OracleDataSource Properties](#)

OracleDataSourceBuilder [Methods, Properties, and Events in Common with OracleConnection or OracleDataSource](#)

- Managed ODP.NET and ODP.NET Core – Configurable Connection String URL Expiration Grace Period

Applications set the time to keep connection string URLs cached. Once they expire, ODP.NET attempts to refresh the connection string values. If it can not, then it continues to use the old connection string URL to open new connections. The length of this time can now be set using the config\_time\_to\_live\_grace\_period property.

Apps can determine the grace period expired connection string URLs can continue to be used.

**① See Also**

[Connection URL Caching](#)

# Changes in Oracle Data Provider for .NET Release 23.8

The following are the changes in Oracle Data Provider for .NET for Release 23.8.

## New Features

The following features are new in this release:

- ODP.NET Core – `OracleDataSource` and `OracleDataSourceBuilder`

With the new `OracleDataSource` and `OracleDataSourceBuilder` classes, ODP.NET Core supports ADO.NET `DbDataSource` from which apps can retrieve connections and execute commands directly. The class encapsulates all Oracle database connection configuration.

`OracleDataSource` is portable and can be registered in dependency injection as a connection factory. It can be used in provider agnostic code to connect to Oracle databases.

`OracleDataSourceBuilder` instantiates an immutable `OracleDataSource` class.

### See Also

[DbDataSource](#)

- Managed ODP.NET and ODP.NET Core – Sparse and Dense Vector Data Types for AI Apps

ODP.NET now supports new vector data types for storing sparse and dense data sets. Sparse vectors typically have a large number of dimensions and few non-zero dimension values. Dense vectors are better suited when nearly every dimension stores a non-zero value.

Because sparse vectors only store non-zero values, they are more storage and memory efficient and ODP.NET can process them faster than dense vectors when there are few non-zero dimensions. That makes them better for some AI applications, such as text retrieval systems in which an inputted phrase identifies relevant matching documents.

Dense vectors are better for semantic search when the word meaning nuances are important to identify matches.

ODP.NET EF Core 9 and higher now support sparse vectors in addition to its existing support of dense vectors.

### See Also

[Artificial Intelligence Vectors and Semantic Search](#)

- EF Core – Scaffolding Data Type Mapping Customization Templates

Oracle EF Core scaffolding of entity properties from database columns can now be customized using custom reverse engineering templates when developers prefer an alternative set of .NET data type mappings than the default.

Developers can flexibly choose a more complementary set of .NET data type mappings for their database columns, including CLR types that store all possible values of the mapped Oracle Database data types.

**① See Also**

[Scaffolding Or Reverse Engineering](#)

- Managed ODP.NET and ODP.NET Core – PKCS #12 Wallet Files and Secure External Password Store

ODP.NET now supports using PKCS #12 wallet files and Secure External Password Store. PKCS #12 is a popular file format that stores security credentials and certificates. These files typically use the .p12 file extension.

This feature gives ODP.NET apps another option for storing credential and certificate file storage.

- Managed ODP.NET and ODP.NET Core – Protect ODP.NET Code from SQL Injection Attacks

ODP.NET developers write secure code using bind variables to limit SQL injection attacks. However, it's not always possible to use bind variables. ODP.NET adds new methods to sanitize the input literal and database identifier values to protect against SQL injection attacks.

Through some simple code modifications, developers can secure their SQL literal and identifier usage easily and automatically.

**① See Also**

[Securing Identifiers and Literals from SQL Injection Attacks](#)

[OracleDBMSAssert Class](#)

- Automatic Connection Recovery

ODP.NET can now automatically detect invalid connections resulting from planned or unplanned outages. After detecting an invalid session, ODP.NET fails over by creating a new session to an available database instance. The end user can conduct their work without encountering an error.

This feature makes apps more resilient and highly available without developers have to add or maintain code to do so.

**① See Also**

[Automatic Connection Recovery](#)

- Prevent Application State Leaks Between Database Sessions

When an ODP.NET session returns to the connection pool, the database session state is partially reset preventing much of the state from leaking to the next connection's state. This feature is enabled by setting the RESET\_STATE database service attribute to LEVEL1.

This enhancement ensures all newly dispensed connections have a more consistent session state with fewer artifacts which can occur after a failover event.

**① See Also**

[Reset Session State to Limit Application State Leaks](#)

- **Managed ODP.NET and ODP.NET Core – Bulk Copy Boolean Data Types**  
Managed ODP.NET and ODP.NET Core provider types now support Oracle database Boolean data types with bulk copy.  
Apps can now efficiently load data sets that contain Boolean data.

**① See Also**

[Bulk Copy](#)

- **Managed ODP.NET and ODP.NET Core – Bulk Copy Index Check Enforcement**  
ODP.NET bulk copy can enforce index checks when this option is enabled. When an index-related error occurs, no rows are loaded and indexes remain unchanged.  
Apps can now abort data loads unless constraints are kept in an usable state.

**① See Also**

[OracleBulkCopyOptions Enumeration](#)

## Changes in Oracle Data Provider for .NET Release 23.7

The following are the changes in Oracle Data Provider for .NET for Release 23.7.

### New Features

The following features are new in this release:

- **ODP.NET Core -- Alpine Linux and macOS**  
ODP.NET Core is certified with Alpine Linux and macOS (ARM64).

**① See Also**

[System Requirements](#)

- **Managed ODP.NET and ODP.NET Core – Sessionless Transaction**  
ODP.NET sessionless transactions enable apps to start a transaction, suspend the transaction, and then continue the work in another database session before finally committing.  
With sessionless transactions, transactions can span multiple sessions for more app development flexibility. Programmers have more options available, allowing them to select more efficient, easier to manage, and faster running app implementations.

**① See Also**

[Sessionless Transactions](#)

- Managed ODP.NET and ODP.NET Core – Set Rows to Fetch Per Round Trip

ODP.NET apps can now set the number of rows to fetch per database round trip using the `RowsToFetchPerRoundTrip` property available in the .NET configuration file, `OracleConfiguration`, `OracleConnection`, `OracleCommand`, `OracleDataReader`, and `OracleRefCursor` classes.

This setting is easier for developers to use when they know exactly the number of rows they wish to fetch for each round trip.

**① See Also**

[Controlling the Number of Rows Fetched in One Database Round-Trip](#)

- Managed ODP.NET and ODP.NET Core – Set Database Role on Connections

Database roles are created by users, usually administrators, to group multiple privileges or other roles together. ODP.NET can set database roles programmatically on connections it creates and those retrieved from the connection pool. The connection can then use the role's privileges.

This feature makes assigning database roles to ODP.NET database connections straightforward and simple.

**① See Also**

[OracleRoleCollection Class](#)

`OracleConnection` [Roles](#)

- Managed ODP.NET and ODP.NET Core – Customize Each Connection's Encryption and Data Integrity Settings

ODP.NET can now set encryption and data integrity properties for each connection at the `OracleConnection` level instead of at only the app level with `OracleConfiguration`. App connections may not all use the same security settings. Each connection can have different security settings if needed.

This feature allows apps to customize and individualize their connection security settings when business and technical requirements dictate.

**① See Also**

[OracleConnection Properties](#)

- Managed ODP.NET and ODP.NET Core – Server Name Indication

Server Name Indication (SNI) is a TLS extension normally used to send the hostname in the client hello message. ODP.NET now supports SNI.

SNI is used by Oracle to pass the relevant connect\_data information, such as the service name, clients send when connecting to the database server. On the listener side, the requested connect data is obtained without performing TLS negotiation and consuming the client hello packet. With this information, an appropriate handler is selected. The listener can proceed with spawning dedicated server process.

SNI improves resource usage, scalability, security, and ease of management.

#### ① See Also

OracleConnection [UseSNI](#)

OracleConfiguration [UseSNI](#)

- Managed ODP.NET and ODP.NET Core – Enhanced Password Security with OracleOpaqueString

.NET SecureString class is more secure than the String class, but still has some security weaknesses. OracleOpaqueString class securely obfuscates string data, such as passwords, without SecureString's limitations. ODP.NET APIs that use SecureString now have the same APIs that use OracleOpaqueString.

Oracle recommends using OracleOpaqueString for more robust security instead of SecureString.

#### ① See Also

[Securing Passwords with OracleOpaqueString](#)

- Managed ODP.NET and ODP.NET Core - Sharding Split Partitionset

ODP.NET supports sharding split partitionset events in core and managed drivers. A split partitionset is an operation on the sharding database performed when moving data within a specified super sharding key to a different shardspace.

ODP.NET connection pools receive database events about data in a chunk being split and moved across these partition sets. The provider updates its sharding topology appropriately and transparently so that end users are dispensed the correct connection to use.

#### ① See Also

[Sharding Split Partitionset](#)

## Changes in Oracle Data Provider for .NET Release 23.6.1

The following are the changes in Oracle Data Provider for .NET for Release 23.6.1.

### New Features

The following feature is new in this release:

- .NET 9 Runtime

ODP.NET Core is certified for .NET 9.

**See Also**

[System Requirements](#)

- Managed ODP.NET and ODP.NET Core – Connection Configuration Restriction

ODP.NET can now be configured to restrict connection string Data Source attribute settings at a global level when using full connect descriptors, Easy Connect (Plus), or TNS net service names.

Independent software vendors and application administrators have an easy way to control which connection settings and options are allowed. This capability makes securing application connectivity simpler.

**See Also**

[Connection Configuration Restriction](#)

## Changes in Oracle Data Provider for .NET Release 23.6

The following are the changes in Oracle Data Provider for .NET for Release 23.6.

### New Features

The following features are new in this release:

- Entity Framework Core 9

ODP.NET Entity Framework (EF) Core now supports Entity Framework Core 9 with Oracle databases. ODP.NET EF Core NuGet package 9.23.60 or higher is required.

**See Also**

[Oracle Entity Framework Core 9 Features](#)

- ODP.NET Core -- Kerberos

ODP.NET Core now supports Kerberos, a network authentication service for security in distributed environments. ODP.NET applications can use Kerberos for single sign-on and centralized user authentication.

**See Also**

[Using Kerberos](#)

- Managed ODP.NET and ODP.NET Core – OpenTelemetry enhancements

OpenTelemetry has been enhanced to publish the ODP.NET NuGet version as the activity source version, ODP.NET executed statement texts, and to redact traced command text to hide literal values for security reasons.

These new features provide more trace options and capabilities for ODP.NET OpenTelemetry.

**See Also**

[OpenTelemetry](#)

- Managed ODP.NET and ODP.NET Core – Vector BINARY Numeric Format

ODP.NET developers can use the BINARY dimension format for vectors.

The BINARY numeric format is 32 times smaller than the FLOAT32 format and distance computations between two vectors are up to 40 times faster.

There is a potential loss of accuracy with format; however, the loss is often not substantial.

**See Also**

[Artificial Intelligence Vectors and Semantic Search](#)

- Managed ODP.NET and ODP.NET Core – Easier proxy server setup for cloud deployments

More ODP.NET apps are being deployed with cloud databases that are behind firewalls. This setup requires using web proxy servers in the Oracle database connection address. New `OracleConnection` properties (`AutoProxy`, `HttpsProxy`, `HttpsProxyPort`, `SSLServerDNMatch`, `SSLServerCertDN`, and `SSLVersion`) have been introduced to make it easier to use web proxy servers.

These interfaces allow ODP.NET to detect or set the proxy so that proxy setup is simpler.

**See Also**

[OracleConnection Class](#)

- Managed ODP.NET and ODP.NET Core – IsFloatingPointNumber Schema Table Column

This new column in the ADO.NET `SchemaTable` indicates whether the result set column data type is a floating-point number or not.

It allows apps to easily distinguish whether a column stores floating-point numbers or some other type, such as fixed-point numbers.

**See Also**

`OracleDataReader` [GetSchemaTable](#)

- Managed ODP.NET and ODP.NET Core – Disallow UNC Paths

Apps can disallow ODP.NET access to configuration files with Universal Naming Convention (UNC) location paths.

Server Message Block coercion attacks use UNC paths to have a target machine authenticate an attacker's computer. If successful, then the attacker copies that authentication to gain access to another system. Disabling UNC paths protects ODP.NET apps from this attack.

**See Also**

OracleConfiguration [AllowUncPaths](#)

- Managed ODP.NET and ODP.NET Core – User-Created Wallet Stored Client Secret for Azure Service Principal Authentication

ODP.NET now allows Azure Service Principal authentication flows using a client secret stored in a user-created wallet in addition to the existing methods of providing the client secret directly and client certificate.

This new option securely stores the client secret and provides more flexibility when using Azure Service Principal with ODP.NET.

**See Also**

[Azure Centralized Configuration Provider](#)

- Managed ODP.NET and ODP.NET Core – Disable Double Encryption and Double Data Integrity

When TCPS is enabled along with Oracle Native Network Encryption (NNE) and/or data integrity, ODP.NET can be configured to use TCPS only.

This feature allows apps to avoid inadvertently enabling double encryption and double checksumming, which can lower performance.

**See Also**

OracleConfiguration [SqlNetIgnoreANOEncryptionForTCPS](#)

## Changes in Oracle Data Provider for .NET Release 23.5.1

The following are the changes in Oracle Data Provider for .NET for Release 23.5.1.

### New Features

The following feature is new in this release:

- Managed ODP.NET and ODP.NET Core - Eliminate Exception Using Transparent Application Failover SELECT Mode

Managed ODP.NET and ODP.NET Core 23.5.1 introduced TAF session mode support. TAF SELECT mode is not yet supported.

ODP.NET 23.5.1 has been enhanced so that no error occurs when TAF SELECT mode is configured. ODP.NET will use TAF session mode instead.

# Changes in Oracle Data Provider for .NET Release 23.5

The following are the changes in Oracle Data Provider for .NET for Release 23.5.

## New Features

The following features are new in this release:

- Managed ODP.NET and ODP.NET Core - REF CURSOR column type

ODP.NET can now return REF CURSOR type column in a select list to an `OracleDataReader`, `OracleRefCursor`, or as JSON-formatted .NET string or `OracleString` result set.

This feature improves flexibility and adds another way to consume Oracle result sets.

### ① See Also

`OracleDataReader`.[GetOracleDataReader](#)

`OracleDataReader`.[GetOracleRefCursor](#)

- Managed ODP.NET and ODP.NET Core – Globally Suppress GetDecimal Invalid Cast Exception

The `SuppressGetDecimalInvalidCastException` property has been added to `OracleConfiguration` and `OracleConnection` classes. Previously, they were available to only to `OracleDataReader` and `OracleDataAdapter` classes. When enabled and `GetDecimal` is called, ODP.NET suppresses the `InvalidCastException` and returns a rounded-off 28 or 29 precision .NET decimal value, that represents the Oracle NUMBER.

This feature allows the exception suppression to be set at either the application level (`OracleConfiguration`) or connection level (`OracleConnection`), which improves ease of use. All of the settings also enable suppressing the exception when UDTs and `OracleParameters` retrieve large numbers.

### ① See Also

`OracleConfiguration`.[SuppressGetDecimalInvalidCastException](#)

`OracleConnection`.[SuppressGetDecimalInvalidCastException](#)

- Managed ODP.NET and ODP.NET Core – ODP.NET Product Information and Application Metadata

ODP.NET adds new properties that indicate the provider type (core or managed), NuGet version, and allow applications to assign a program name to identify the client app in the database's PROGRAM column in V\$SESSION.

These new properties provide a systematic way for database administrators and application support personnel to identify the ODP.NET provider type, version, and application name.

### ① See Also

OracleConnection.[ProviderName](#)

OracleConnection.[ProviderNuGetVersion](#)

OracleConfiguration.[Program](#)

- Managed ODP.NET and ODP.NET Core – OCI Object Storage Change Notification for Connection Information

Since connection information retrieval takes longer from a cloud resource than local disk, ODP.NET caches connection information. If that information is updated, cache updates can occur using a pull model (polling) or automated push model (change notification). Change notification for ODP.NET connection attributes stored in Azure was previously introduced. This new release introduces the same capability for Oracle Cloud Infrastructure Object Storage.

Change notification provides an automated way to get fast updates to connection properties changes without having to sacrifice the performance of storing the information locally.

### ① See Also

[Connection URL Caching](#)

- Managed ODP.NET and ODP.NET Core – Bulk Copy Notification After All Rows Processed

ODP.NET bulk copy can now send a notification after all rows have been processed when the bulk copy operation has completed. This feature is enabled using `OracleBulkCopyOptions.NotifyAllRowsProcessed`. The number of rows is returned via the `OracleRowsCopiedEventArgs.RowsCopied` property in the notification.

By using this property, applications can now determine the total number of rows processed when their bulk copy operations complete.

### ① See Also

[OracleBulkCopyOptions Enumeration](#)

OracleRowsCopiedEventArgs.[RowsCopied](#)

- Managed ODP.NET and ODP.NET Core – Easy Connect Plus Address Lists

ODP.NET incorporates address list support in Easy Connect Plus configurations.

With address lists, multiple lists of addresses, each with its own characteristics can be configured for ODP.NET connections.

### ① See Also

[Easy Connect and Easy Connect Plus Naming Methods](#)

- Managed ODP.NET and ODP.NET Core – Microsoft identity platform tokens v2.0 enhancement

ODP.NET supports Microsoft identity platform tokens v1.0 for Microsoft Entra ID-only applications and v2.0 for applications that support consumer accounts. ODP.NET 23.5 and higher check the roles (roles) and user principal name (UPN) claims in v2.0 tokens to verify at least one is present. If both claims are missing, then the provider will report an error.

**See Also**

[Vault Wallets and Tokens](#)

- Managed ODP.NET and ODP.NET Core – OpenTelemetry Activity Tag for rows affected by SQL

ODP.NET OpenTelemetry now returns the row count affected by SQL DML (INSERT, UPDATE, and DELETE only) when using `ExecuteNonQuery*`, `ExecuteReader*`, or `ExecuteScalar*` methods.

**See Also**

[OpenTelemetry](#)

- Unmanaged ODP.NET – Dynamic loading of `System.Text.Json` DLL and its dependencies

Unmanaged ODP.NET adds support for dynamic loading of the `System.Text.Json.dll` and its dependencies if they are not loaded by the application or a different version is loaded. This enhancement is for unmanaged ODP.NET's token-based authentication feature used by the applications, such as Power BI.

## Changes in Oracle Data Provider for .NET Release 23.3

The following are the changes in Oracle Data Provider for .NET for Release 23.3.

### New Features

The following features are new in this release:

- ODP.NET: AI Vector Search

You can now leverage semantic search capabilities using Artificial Intelligence (AI) Vector Search. These capabilities include a new vector data type, vector indexes, and vector search SQL operators that allow the database to store semantic document content, images, and other unstructured data as vectors and then run fast performing similarity queries. This allows the database to better understand user intent and the search context to find similar matches, rather than only find exact matches.

AI Vector Search provides your business with the capability to leverage Generative AI constructs, specifically Retrieval Augmented Generation (RAG), for responding to natural language questions. RAG effectively merges large language models (LLMs) with your private business data, preserving data privacy while enhancing response accuracy. This functionality allows you to unlock new opportunities for growth with AI.

**See Also**

[Artificial Intelligence Vectors and Semantic Search](#)

- Managed ODP.NET and ODP.NET Core - Asynchronous Programming

ODP.NET supports the .NET Task Asynchronous Programming (TAP) model with the core and managed drivers. With support for TAP and the `async` and `await` keywords, ODP.NET data access operations are more responsive and easier to develop for asynchronicity. This feature includes support for Entity Framework Core and Entity Framework asynchronous query and save.

**See Also**

[Asynchronous Programming and Pipelining](#)

- Managed ODP.NET and ODP.NET Core - Pipelining

ODP.NET core and managed drivers support pipelining for its database communication. It allows subsequent database requests to be sent and queued transparently even while ODP.NET awaits a database response. Pipelining improves overall app performance and allows database resources to be used more effectively. ODP.NET does not need to wait for the database to respond from previous requests before submitting subsequent requests.

**See Also**

[Asynchronous Programming and Pipelining](#)

- Managed ODP.NET and ODP.NET Core – OpenTelemetry

OpenTelemetry is a popular open-source observability framework for instrumenting, generating, collecting, and exporting telemetry data. It provides a common specification and protocol so that multiple services can furnish a unified version of traces, metrics, and logs.

Numerous managed ODP.NET and ODP.NET Core APIs have been instrumented to support OpenTelemetry observability and standards. Developers and operators can customize the ODP.NET metrics collected with OpenTelemetry. ODP.NET OpenTelemetry includes support for automatic, dynamic, and manual instrumentation.

With OpenTelemetry support, monitoring, tracking, and analyzing how ODP.NET operations interact in cloud computing, microservices and distributed systems becomes easier using this industry standard.

**See Also**

[OpenTelemetry](#)

- Managed ODP.NET and ODP.NET Core - .NET Metrics

.NET Metrics are application numerical measurements collected at regular time intervals for the purposes of monitoring and alerting about application health. In an ODP.NET

setting, metrics can monitor connection statistics, such as number of ODP.NET hard connections to the database, number of active connections, or number of free connections.

ODP.NET Core and managed ODP.NET support .NET Metrics. ODP.NET metrics can be published to and analyzed by the rich and expansive toolsets integrated with OpenTelemetry and .NET Metrics, such as Grafana and Prometheus.

**See Also**

[.NET Metrics](#)

- Managed ODP.NET and ODP.NET Core - Advanced Queuing and Transactional Event Queues

ODP.NET Core and managed ODP.NET now support Advanced Queuing (AQ) and Transactional Event Queues (TxEventQ) application programming interfaces (APIs) that can be used in modern applications, such as microservices. TxEventQ's highly optimized and partitioned implementation leverages the functions of Oracle AI Database so that producers and consumers can exchange messages at high throughput, by storing messages persistently, and propagate messages between queues on different databases. TxEventQ are a high performance partitioned implementation with multiple event streams per queue, while AQ is a disk-based implementation for simpler workflow use cases.

ODP.NET developers can leverage the same APIs no matter if they use TxEventQ or AQ. The APIs provide access to a robust and feature-rich message queuing systems integrated with Oracle AI Database. It can be used with web, mobile, IoT, and other data-driven and event-driven applications to stream events or communicate with each other as part of a workflow.

**See Also**

[Advanced Queuing and Transactional Event Queues](#)

- Managed ODP.NET and ODP.NET Core - Application Continuity and Transparent Application Continuity

ODP.NET Core and managed drivers now support Application Continuity (AC) and Transparent Application Continuity (TAC). AC and TAC mask outages from end users and applications by recovering the in-flight database sessions following recoverable outages, including transactions. The recovery is transparent such that the end user merely experiences a slightly delayed execution, but no perceptible outage nor error.

AC and TAC improve the user experience for both unplanned outages and planned maintenance. They enhance the fault tolerance of systems and .NET applications that use an Oracle AI Database. Developers can use AC and TAC with existing .NET apps without making any code changes.

**See Also**

[ODP.NET and Application Continuity](#)

- Managed ODP.NET and ODP.NET Core - Transparent Application Failover

Oracle Transparent Application Failover (TAF) is a high availability feature that enables client apps to automatically reconnect to a secondary database instance if the connected

primary instance fails or shuts down. ODP.NET Core and managed ODP.NET now support connection and basic session state TAF.

ODP.NET TAF enables apps to recover and continue operating when database downtime occurs. It requires no changes to .NET application code to use.

**See Also**

[Transparent Application Failover](#)

- **JSON Relational Duality**

JSON Relational Duality manifests as fully updatable JSON views over relational data. Data remains stored in relational tables in a highly efficient normalized format but can be accessed by .NET applications in the form of JSON documents. All ODP.NET provider types, core, managed, and unmanaged, support using JSON Relational Duality.

Duality views provide game-changing flexibility and simplicity by overcoming the historical challenges .NET developers have faced when building applications using relational or document models.

**See Also**

[Native JSON Support](#)

- **Oracle Client Driver Support for SQL BOOLEAN Data Type**

Oracle client drivers support fetching and binding the new `BOOLEAN` database column. Applications can use the native database `BOOLEAN` column data type with a native driver `BOOLEAN` data type. This enhancement makes working with `BOOLEAN` data types easier for developers.

- **True Cache**

Oracle True Cache is a read-only, in-memory, high performance SQL and key-value cache that is automatically managed and consistent. It improves application response time while reducing the load on the database server. Automatic management and consistency simplify application development; reducing developer effort and cost.

All ODP.NET provider types can transparently use Oracle True Cache without needing any code changes.

- **Faster Connection Establishment**

ODP.NET connection establishment has been optimized to reduce the number of database round trips required when connecting with Oracle AI Database 26ai and higher. Applications that upgrade experience this performance improvement transparently.

- **Managed ODP.NET and ODP.NET Core - Centralized Configuration Providers**

Managed ODP.NET and ODP.NET Core can store and retrieve application configuration data from a centralized on-premises, cloud infrastructure, Oracle Cloud Infrastructure (OCI), or Azure store using centralized configuration providers. This store contains connection information, such as connect descriptors and tuning parameters. Secrets, such as passwords and wallets, can be stored in OCI Vault or Azure Key Vault with the same providers.

Centralized application configuration makes client configuration and secrets management across multiple deployments simpler, especially for modern architectures, such as microservices, cloud application services, and serverless apps.

**See Also**

[Centralized Configuration Providers for Deployments](#)

- Managed ODP.NET and ODP.NET Core - Azure Active Directory Single Sign-On

ODP.NET can now request the Microsoft Entra ID (Azure AD) OAuth2 access token directly from the Entra ID endpoint in addition to the prior methods of receiving the token through a file location or the .ODP.NET API. This simplifies the use of the OAuth2 tokens since applications don't need to be modified or a separate helper utility isn't needed to get the token.

Users can sign-on once with Microsoft Entra ID, acquire the token, and access their on-premises and cloud-based Oracle AI Databases. This feature is available in ODP.NET Core and managed ODP.NET. This multicloud capability eases authentication and authorization between Microsoft Entra ID and Oracle AI Databases by simplifying user access and management.

**See Also**

[Using Microsoft Entra ID](#)

- Managed ODP.NET and ODP.NET Core – Oracle IAM SSO token

ODP.NET can now request the OCI IAM access token directly from IAM in addition to the prior methods of receiving the token through a file location or the .ODP.NET API. This simplifies the use of the IAM tokens since applications do not need to be modified or a separate helper utility is not needed to get the token.

Users can sign-on once with OCI IAM, acquire the token, and access their OCI DBaaS Oracle AI Databases. This feature is available in ODP.NET Core and managed ODP.NET.

**See Also**

[Connecting to Oracle Database](#)

- Managed ODP.NET and ODP.NET Core - TLS/SSL Certificate Selection

Managed ODP.NET and ODP.NET Core allow selecting a specific TLS/SSL certificate stored in the Microsoft Certificate Store wallet location via a graphical user interface or thumbprint. The selected key is cached so that it doesn't have to be re-selected on subsequent connection attempts.

The graphical interface selection is enabled by setting the `OracleConnection.AllowCertificateSelectionUI` property to true. Thumbprint selection is enabled by populating the `SSLCertificateThumbprint` property with the thumbprint value.

This feature was backported to the latest ODP.NET 19c and 21c release updates.

- Managed ODP.NET and ODP.NET Core – Enhanced Transaction Management Options

By default, ODP.NET auto-commits after every SQL operation execution outside of a transaction. Managed ODP.NET and ODP.NET Core now allow disabling auto-commit so that SQL statements can be executed after an explicit commit without requiring a transaction.

The `OracleConnection` class adds new APIs to manage local transactions.

These new capabilities provide ODP.NET developers flexible and simpler transaction management options.

**See Also**

[Command Auto-Commit](#)

- **Data Use Case Domain Name and Schema**

A Data Use Case Domain is a dictionary object that belongs to a schema and encapsulates a set of optional properties and constraints for common values, such as credit card numbers or email addresses. After you define a Data Use Case Domain, you can define table columns to be associated with that domain, thereby explicitly applying the domain's optional properties and constraints to those columns.

With Data Use Case Domains, you can define how you intend to use data centrally. They make it easier to ensure you handle values consistently across applications and improve data quality.

All ODP.NET provider types support using Data Use Case Domains, as well as retrieving Data Use Case Domain schema and name information

**See Also**

[Data Use Case Domains](#)

- **Annotations**

Oracle AI Database annotations enable storing and retrieving metadata about database objects. These are either name-value pairs or only a name. These are free-form text fields that applications can use to customize business logic or user interfaces. All ODP.NET provider types support Oracle AI Database annotations.

Annotations help you to use database objects in the same way, across all applications. This simplifies development and improves data quality.

**See Also**

[Annotations](#)

- **Increased Database Password Length**

Starting with this release, Oracle AI Database and client drivers including ODP.NET managed, unmanaged, and core drivers support passwords up to 1024 bytes in length.

- **Transport Layer Security 1.3**

ODP.NET supports Transport Layer version 1.3 for the core, managed, and unmanaged providers. TLS is used to encrypt data and authenticate connections. TLS 1.3 offers better security and performance over TLS 1.2.

**① See Also**

[Using Transport Layer Security and Secure Sockets Layer](#)

- Managed ODP.NET and ODP.NET Core - Programmatic Database Startup and Shutdown Operations

Users with database administrator privileges can use the `OracleDatabase` class to startup or shutdown a database instance with managed ODP.NET and ODP.NET Core.

**① See Also**

[OracleDatabase Class](#)

- Allowed Logon Version Client Support

This feature enables applications to specify the minimum authentication protocol that is to be used for a given application and/or a given `OracleConnection` object when authenticating against an Oracle AI Database.

**① See Also**

[Allowed Logon Version Client Support](#)

- Managed ODP.NET - Public `OracleMigrationSqlGenerator` class

For Entity Framework 6 apps, the `OracleMigrationSqlGenerator` class is now public to allow developers to override the default SQL generation if they want to customize it.

**① See Also**

[Unsupported Entity Framework Features](#)

- HTTPS Proxy for Cloud Connections

ODP.NET supports HTTPS proxy of the database connection. The feature enables tunneling of that connection over a forward HTTP proxy using the HTTP CONNECT method.

It can be enabled in the connect address, such as

```
(description=(address=(https_proxy=www-proxy.example.com)(https_proxy_port=80)
(protocol=tcps)(port=1522)(host=dbhost.example.com))
(connect_data=(service_name=svc.example.com)) )
```

HTTPS proxy improves public cloud database service access as it eliminates requiring the client side firewall to open an outbound port.

## Deprecated Features

The following features are deprecated in Oracle Data Provider for .NET for Release 26ai:

- Oracle Data Provider for .NET, Unmanaged Driver

Oracle Data Provider for .NET (ODP.NET), Unmanaged Driver is deprecated in Oracle AI Database 26ai, and can be desupported in a future release. Oracle recommends existing unmanaged ODP.NET applications migrate to ODP.NET, Managed Driver.

ODP.NET provides ADO.NET-based data access to Oracle databases. There are two primary Oracle data access drivers for Microsoft .NET Framework: ODP.NET, Managed Driver and ODP.NET, Unmanaged Driver.

In Oracle AI Database 26ai, ODP.NET, Managed Driver supports all major features available in ODP.NET, Unmanaged Driver with the same application programming interfaces and configuration settings. Code migration from unmanaged ODP.NET to managed ODP.NET is straightforward for the vast majority of existing .NET applications. ODP.NET, Managed Driver is a more compact and simpler install that can be consumed via NuGet packaging. Unmanaged ODP.NET is not available as a NuGet package. It is easier to manage multiple managed ODP.NET deployments on the same machine than multiple unmanaged ODP.NET deployments. These advantages make managed ODP.NET preferable for customer use over unmanaged ODP.NET.

As unmanaged ODP.NET no longer has any advantages over managed ODP.NET, Oracle has chosen to deprecate unmanaged ODP.NET.

- The mkstore wallet management command line tool

The mkstore command-line utility is being deprecated in favor of orakpi.

- MY\_WALLET\_DIRECTORY

#### See Also

- *Oracle AI Database Upgrade Guide* for a complete list of deprecated features.

## Desupported Features

Some features previously described in this document are desupported in Oracle AI Database 26ai. See *Oracle AI Database Upgrade Guide* for a complete list of desupported features.

The following features are no longer supported by Oracle:

- Oracle Database Extensions for .NET

Oracle Database Extensions for .NET is desupported. Oracle recommends that you either place .NET code in the middle tier, or use the External Procedures feature, or rewrite the code using PL/SQL or Java.

Oracle Database Extensions for .NET is a feature of Oracle Database on Microsoft Windows that enables you to use stored procedures and functions written in a language managed by .NET, such as C#.

Oracle Database hosts the Microsoft Common Language Runtime (CLR) in an external process, outside of the Oracle Database process. Application developers can write stored procedures and functions using any .NET compliant language, such as C# and VB.NET, and use these .NET stored procedures in the database, in the same manner as other PL/SQL or Java stored procedures. .NET stored procedures can be called from PL/SQL packages, procedures, functions, and triggers; from SQL statements; or from anywhere a PL/SQL procedure or function can be called.

Migration options include:

- Moving the .NET code (assemblies) into a middle tier

- Using the External Procedures feature to have the external process load and execute the .NET assembly
  - Rewriting the stored procedures using PL/SQL or Java
- Oracle Wallet Manager (OWM)
- `OracleConfiguration.DirectoryType` Property

## Changes in Oracle Data Provider for .NET Release 21c (21.12)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.12).

### New Features

The following features are new in this release:

- .NET 8 Runtime  
ODP.NET Core is certified for .NET 8.
- Entity Framework Core 8  
ODP.NET Entity Framework (EF) Core now supports Entity Framework Core 8 with Oracle databases. ODP.NET EF Core 21.12.1 or higher is required.

## Changes in Oracle Data Provider for .NET Release 21c (21.8)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.8).

### New Features

The following features are new in this release:

- .NET 7 Runtime  
ODP.NET Core is certified for .NET 7.
- Entity Framework Core 7  
ODP.NET Entity Framework (EF) Core now supports Entity Framework Core 7 with Oracle databases. Entity Framework Core is a cross-platform Microsoft object-relational mapper that enables .NET developers to work with relational databases using .NET objects.

## Changes in Oracle Data Provider for .NET Release 21c (21.7)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.7).

### New Features

The following feature is new in this release:

- Managed ODP.NET and ODP.NET Core -- Microsoft Entra ID  
Managed ODP.NET and ODP.NET Core 21.7 support Microsoft Entra ID, earlier known as Azure Active Directory authentication when connecting to Oracle Database. ODP.NET will then use an access token to authenticate instead of an username and password.

This feature benefits applications and services that use Microsoft Entra ID for centralized user authentication with Oracle database. Those services can include Azure and Microsoft 365-based cloud services, such as Microsoft Power BI service, that rely on Microsoft Entra ID for user management.

Using token-based authentication is more secure and simpler for the end user. It becomes unnecessary to specify credentials each time the user accesses a resource. Moreover, the resource never needs to handle and manage individual user credentials.

**See Also**

[Using Microsoft Entra ID](#)

- Managed ODP.NET and ODP.NET Core -- Transport Layer Security 1.3

Managed ODP.NET and ODP.NET Core have added support for version 1.3 of Transport Layer Security (TLS) protocol. TLS allows applications to communicate securely with the database in a way that prevents message eavesdropping, tampering, and forgery.

**See Also**

[Using Transport Layer Security and Secure Sockets Layer](#)

## Changes in Oracle Data Provider for .NET Release 21c (21.6.1)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.6.1).

### New Features

The following feature is new in this release:

- Managed ODP.NET and ODP.NET Core - Oracle Identity and Access Management Cloud Service Enhancements

ODP.NET adds more support for Oracle Identity and Access Management (IAM) cloud service for unified identity across Oracle cloud services for the managed and core drivers. ODP.NET can use the same Oracle IAM credentials for authentication and authorization.

This capability allows single sign-on and for identity to be propagated to all services Oracle IAM supports. A unified identity makes user management and account management easier for administrators and end users.

Managed ODP.NET adds support for IAM database password verifier, token, and database alternate password for token authentication.

ODP.NET Core already has support for IAM database password verifier and token. This new version adds database alternate password for token authentication in ODP.NET Core.

**See Also**

[Connecting to Oracle Autonomous Database](#)

- ODP.NET Core - Multi-Platform Secure External Password Store

The Secure External Password Store (SEPS) is the use of a client-side wallet for securely storing the password credentials. ODP.NET Core can now be configured to use the external password store on any operating system it supports beyond just Windows.

An Oracle wallet is a container that securely stores authentication and signing credentials. Wallets can simplify large-scale deployments that rely on password credentials for database connections. Applications no longer need embedded user names and passwords, which reduces security risk.

**See Also**

[Using Secure External Password Store](#)

## Changes in Oracle Data Provider for .NET Release 21c (21.5)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.5).

### New Features

The following feature is new in this release:

- Unmanaged ODP.NET – One-way TLS/SSL with Built-in Truspoints (Walletless)

Unmanaged ODP.NET now supports one-way Transport Layer Security/Secure Sockets Layer without wallets. Not having to provide a wallet can simplify database connectivity, such as with Oracle Autonomous Database.

## Changes in Oracle Data Provider for .NET Release 21c (21.4.1)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.4.1).

### New Features

The following features are new in this release:

- .NET 6 Runtime Certification

ODP.NET Core is certified for .NET 6.

- Entity Framework Core 6

ODP.NET Entity Framework (EF) Core now supports Entity Framework Core 6 with Oracle databases. Entity Framework Core is a cross-platform Microsoft object-relational mapper that enables .NET developers to work with relational databases using .NET objects.

- ODP.NET Core - Oracle Identity and Access Management Cloud Service

ODP.NET supports Oracle Identity and Access Management (IAM) cloud service for unified identity across Oracle cloud services, including Oracle Cloud Database Services, with the core driver. ODP.NET can use the same Oracle IAM credentials for authentication and authorization.

This capability allows single sign-on and for identity to be propagated to all services Oracle IAM supports. A unified identity makes user management and account management easier for administrators and end users.

**① See Also**

[Connecting to Oracle Autonomous Database](#)

## Changes in Oracle Data Provider for .NET Release 21c (21.4)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.4).

### New Features

The following features are new in this release:

- Managed ODP.NET and ODP.NET Core – One-way TLS/SSL with Built-in Truspoints (Walletless)

ODP.NET core and managed now support one-way Transport Layer Security/Secure Sockets Layer without wallets. Not having to provide a wallet can simplify database connectivity, such as with Oracle Autonomous Database.

- ODP.NET Core -- Ubuntu and Debian Linux

ODP.NET Core add certification for additional Linux distributions: Ubuntu and Debian.

**① See Also**

[System Requirements](#)

## Changes in Oracle Data Provider for .NET Release 21c (21.3)

The following are the changes in Oracle Data Provider for .NET for Release 21c (21.3).

### New Features

The following feature is new in this release:

- Managed ODP.NET and ODP.NET Core – User-Defined Types

ODP.NET Core and managed providers now support user-defined types (UDT), including Oracle Collections (VARRAY and nested tables), Oracle Objects, and references (REF) to object types. These new features provide near-parity functionality with existing ODP.NET, Unmanaged Driver UDT functionality. This new enhancement allows the vast majority of unmanaged ODP.NET applications to migrate to managed ODP.NET or ODP.NET Core easily with minimal code changes necessary.

**① See Also**

[Oracle User-Defined Types \(UDTs\) and .NET Custom Types](#)

- OracleConfiguration SqlNetURI Setting

ODP.NET OracleConfiguration SqlNetURI property is being renamed to SqlNetURI. This setting specifies the WebSocket universal resource identifier. The change reflects improved adherence to .NET's PascalCasing capitalization convention. If you currently use the property, then please modify your code accordingly.

## Deprecated Features

The following property and setting are deprecated in Oracle Data Provider for .NET for Release 21c:

- OracleConfiguration DirectoryType property
- Configuration file DIRECTORY\_TYPE setting

The OracleConfiguration DirectoryServerType property replaces the DirectoryType property. The .NET configuration file DIRECTORY\_SERVER\_TYPE setting replaces the DIRECTORY\_TYPE setting. All these properties have identical functionality. Oracle recommends developers to use and migrate to the new properties. The DirectoryServerType and DIRECTORY\_SERVER\_TYPE names better align with the ldap.ora parameter DIRECTORY\_SERVER\_TYPE, which provides equivalent functionality.

- [Deprecation of Oracle Database Extensions for .NET](#)

### ① See Also

- *Oracle Database Upgrade Guide* for a complete list of deprecated features.

## Deprecation of Oracle Database Extensions for .NET

Oracle Database Extensions for .NET is deprecated in Oracle Database 21c. Oracle recommends that you either place .NET code in the middle tier, or use the External Procedures feature, or rewrite the code using PL/SQL or Java.

**Date: September 2021**

Oracle Database Extensions for .NET is a feature of Oracle Database on Microsoft Windows that enables you to use stored procedures and functions written in a language managed by .NET, such as C#.

Oracle Database hosts the Microsoft Common Language Runtime (CLR) in an external process, outside of the Oracle Database process. Application developers can write stored procedures and functions using any .NET compliant language, such as C# and VB.NET, and use these .NET stored procedures in the database, in the same manner as other PL/SQL or Java stored procedures. .NET stored procedures can be called from PL/SQL packages, procedures, functions, and triggers; from SQL statements; or from anywhere a PL/SQL procedure or function can be called.

Migration options include:

- Moving the .NET code (assemblies) into a middle tier
- Using the External Procedures feature to have the external process load and execute the .NET assembly
- Rewriting the stored procedures using PL/SQL or Java

# Changes in Oracle Data Provider for .NET (21.1)

The following are the changes in Oracle Data Provider for .NET (21.1).

## New Features

The following features are new in this release:

- Entity Framework Core 5

ODP.NET Entity Framework (EF) Core now supports Entity Framework Core 5 with Oracle databases. Entity Framework Core is a cross-platform Microsoft object-relational mapper that enables .NET developers to work with relational databases using .NET objects.

### ① See Also

[Oracle Data Provider for .NET Entity Framework Core](#)

- Oracle Database JSON Data Type

ODP.NET supports the native JavaScript Object Notation (JSON) data type in Oracle Database. The new JSON data type is optimized for query and DML processing, yielding database performance improvements processing JSON.

When using a .NET string or `OracleString`, JSON data can be bound as a parameter using the `OracleDbType.Json` enumeration value. ODP.NET Core, managed, and unmanaged all support these new JSON features.

- Client Initiated Continuous Query Notification

Client Initiated Continuous Query Notification (CICQN) is similar to the traditional Continuous Query Notification (CQN) feature available in ODP.NET. In CQN, applications receive client-side notifications when server side change occurs that would affect the client's query result set, the underlying schema objects, or the database state. This notification is out of process, occurring without an existing ODP.NET connection.

CICQN uses in-process notifications. ODP.NET creates one separate connection per pool for receiving notifications. The database server uses this specific connection to send change notifications to ODP.NET. CICQN is useful when out of process communications is not available between client and database server, such as in cloud deployments.

### ① See Also

[Client Initiated Continuous Query Notifications](#)

- Managed ODP.NET and ODP.NET Core – Oracle Globally Distributed Database

ODP.NET Core and managed providers now support sharding. Oracle Globally Distributed Database provides the ability to horizontally partition the data across multiple independent Oracle databases (shards). Based on a key specified in the connect string, ODP.NET can route the database requests to a particular shard. Oracle Globally Distributed Database is a shared-nothing architecture that allows near-linear scaling of the database across low-cost commodity database servers located in one or more local or global data centers. Other key benefits include global data distribution (store particular data close to consumers) and fault containment (failure of one shard does not affect the availability of

other shards). Global Data Services manages the location of data among the shards and allows ODP.NET client requests to be routed to the appropriate shard in this distributed database system.

In addition to the same sharding functionality that unmanaged ODP.NET supports, ODP.NET managed and core also support pausing connection requests during chunk migrations. Users will not experience a timeout without giving the chunk migration sufficient times to move across shards.

**See Also**

[Oracle Globally Distributed Database](#)

- **New Administrative Privileges**

ODP.NET now supports assignment of task-specific and least-privileged administrative privileges to enable database administrative duty separation. The newly added privileges include SYSBACKUP for backup and recovery, SYSDBG for Oracle Data Guard, SYSKM for encryption key management, and SYSRAC for Oracle Real Applications Clusters operations. Core, managed, and unmanaged ODP.NET support all these administrative privileges.

**See Also**

[OracleDBAPrivilege Enumeration](#)

- **Managed ODP.NET and ODP.NET Core-- Debug Tracing Redaction**

Managed ODP.NET and ODP.NET Core has introduced a new trace level, that can exclude SQL statements and network packet contents from being included in the trace file.

**See Also**

[Debug Tracing](#)

## Changes in Oracle Data Provider for .NET (19.16)

The following are the changes in Oracle Data Provider for .NET (19.16).

### New Features

The following features are new in this release:

- **Managed ODP.NET and ODP.NET Core -- Transport Layer Security 1.3**

Managed ODP.NET and ODP.NET Core have added support for version 1.3 of Transport Layer Security (TLS) protocol. TLS allows applications to communicate securely with the database in a way that prevents message eavesdropping, tampering, and forgery.

**① See Also**

[Using Transport Layer Security and Secure Sockets Layer](#)

## Changes in Oracle Data Provider for .NET (19.15.1)

The following are the changes in Oracle Data Provider for .NET (19.15.1).

### New Features

The following feature is new in this release:

- Microsoft Entra ID

Starting with ODP.NET 21.7 and 19.15.1, ODP.NET supports Microsoft Entra ID, earlier known as Azure Active Directory authentication when connecting to Oracle Database. ODP.NET will then use an access token to authenticate instead of a username and password.

This feature benefits applications and services that use Microsoft Entra ID for centralized user authentication with Oracle database. Those services can include Azure and Microsoft 365-based cloud services, such as Microsoft Power BI service, that rely on Microsoft Entra ID for user management.

Using token-based authentication is more secure and simpler for the end user. It becomes unnecessary to specify credentials each time the user accesses a resource. Moreover, the resource never needs to handle and manage individual user credentials.

**① See Also**

[Using Microsoft Entra ID.](#)

## Changes in Oracle Data Provider for .NET (19.10)

The following are the changes in Oracle Data Provider for .NET (19.10).

### New Features

The following features are new in this release:

- .NET 5 Runtime Certification

ODP.NET Core is certified for .NET 5.

- Managed ODP.NET and ODP.NET Core -- Bulk Copy

ODP.NET Bulk Copy enables applications to efficiently load large amounts of data from a table in one database to another table in a different database. Managed ODP.NET and ODP.NET Core now support Bulk Copy and all its APIs.

ODP.NET Bulk Copy is the most optimized .NET solution when a large data set needs to be loaded into a table or between database tables in different databases.

**See Also**[Bulk Copy](#)

- Oracle Provider Types Deserialization into DataSet and DataTable

Due to a change in all .NET versions to enhance application security, the allowed DataSet and DataTable data types that can be deserialized are now restricted. This change applies to .NET 5, .NET Core, and .NET Framework with new updates. If application DataSets and DataTables use ODP.NET data types with one of these newer .NET versions, then they may encounter an ODP.NET type initializer exception. To avoid this exception, developers can add ODP.NET-specific data types to the “allow” list to permit deserialization into DataSet or DataTable.

To do this, call the `OracleConfiguration.AddOracleTypesDeserialization` method or add the types individually via a .NET configuration file.

**See Also**[Deserializing ODP.NET Types into DataSet and DataTable](#)

- ODP.NET Core -- KeepAlive on non-Windows platforms

KeepAlive is supported on non-Windows operating systems, such as Oracle Linux. In previous releases, ODP.NET Core supported these KeepAlive properties for Windows platforms only. The properties include `KeepAlive`, `KeepAliveInterval`, and `KeepAliveTime`.

KeepAlive is used to prevent idle TCP connections from being closed, such as by a firewall or load balancer. In some cloud deployments, this idle TCP connection timeout cannot be changed. KeepAlive will keep the connection alive by periodically sending a probe packet with no data in it and the ACK flag turned on.

**See Also**[OracleConnection Properties](#)

- Suppress GetDecimal Invalid Cast Exception

The `SuppressGetDecimalInvalidCastException` property has been added to the `OracleDataReader` and `OracleDataAdapter` classes. When enabled and `GetDecimal` is called on the `OracleDataReader` object explicitly by the application or implicitly through the `Fill()` method on the `OracleDataAdapter` object, for example, it suppresses the `InvalidCastException` and returns a rounded-off 28 or 29 precision .NET decimal value, that represents the Oracle NUMBER.

**See Also**[SuppressGetDecimalInvalidCastException](#)

- ODP.NET Core -- LDAP for Non-Windows Platforms

ODP.NET Core now supports connecting with net service names mapped to connect descriptors in an LDAP-compliant directory server from all non-Windows operating systems the provider supports, such as Oracle Linux and Red Hat Enterprise Linux. Now ODP.NET Core apps on all platforms can use LDAP authentication to connect to Oracle Database.

## Changes in Oracle Data Provider for .NET (19.9)

The following are the changes in Oracle Data Provider for .NET (19.9).

### New Features

The following feature is new in this release:

- In-Band Fast Application Notification

In some scenarios, such as cloud deployments and when firewalls block notification messages between the database and client, out of band messages and using Oracle Notification Service may not be possible. ODP.NET can use in-band FAN notifications instead in these scenarios. In-band notifications rely on existing ODP.NET connections to communicate messages. ODP.NET will check for notifications every time a connection makes a database round trip, is checked in, or checked out. When a DOWN notification is received, ODP.NET will scan the pool for affected connections and close them.

This feature was introduced with managed ODP.NET and ODP.NET Core in 19.9. It was introduced in unmanaged ODP.NET in 19.10.

#### ① See Also

[In-Band Fast Application Notification](#)

## Changes in Oracle Data Provider for .NET ODAC Release 19c (19.3.2)

The following are the changes in Oracle Data Provider for .NET for ODAC Release 19c (19.3.2).

### New Features

The following features are new in this release:

- Entity Framework Core 3.1

ODP.NET Entity Framework (EF) Core now supports Entity Framework Core 3.1 with Oracle databases. Entity Framework Core is a cross-platform Microsoft object-relational mapper that enables .NET developers to work with relational databases using .NET objects. This ODP.NET EF Core release adds support for relational views and materialized views. These views can be read-only or updatable.

Oracle EF Core 3.1 developers can now create and migrate data models in the Oracle Database. They can scaffold EF Core classes based on an Oracle Database schema objects. They can migrate and scaffold with Oracle views. Oracle EF Core is integrated with popular EF Core tools, such as the EF Core Package Manager Tools.

**① See Also**

[Oracle Data Provider for .NET Entity Framework Core](#)

## Changes in Oracle Data Provider for .NET (19.7)

The following are the changes in Oracle Data Provider for .NET (19.7).

### New Features

The following features are new in this release:

- Managed ODP.NET and ODP.NET Core -- Administer Storage using SYSASM Privilege

Oracle Automatic Storage Management (Oracle ASM) is a volume manager and a file system for Oracle database files. SYSASM is a system privilege that enables administrators to manage ASM instances. Managed ODP.NET and ODP.NET Core can now connect using the SYSASM administrative privilege to perform storage management of the Oracle Database.

ODP.NET can now perform database ASM administration when connecting with a SYSASM privileged connection.

**① See Also**

[OracleDBAPrivilege Enumeration](#)

- WebSocket and WebSocket with SSL/TLS

WebSocket is a protocol that offers full-duplex communication channels over a single TCP connection. WebSocket with SSL/TLS offers a secure WebSocket connection. WebSocket is an extension to HTTP and is able to work with HTTP proxies and intermediaries. ODP.NET Core, managed, and unmanaged providers all support WebSocket and secure WebSocket protocols.

**① See Also**

[Using WebSocket](#)

## Changes in Oracle Data Provider for .NET (19.6)

The following are the changes in Oracle Data Provider for .NET (19.6).

### New Features

The following features are new in this release:

- .NET Core 3.1 Certification

ODP.NET Core is certified for .NET Core 3.1.

- Linux 8 Certification  
ODP.NET Core is certified on Oracle Linux 8 and Red Hat Enterprise Linux 8.
- Entity Framework 6.4 Certification  
Managed and unmanaged ODP.NET Entity Framework is certified for Entity Framework 6.4.

## Changes in Oracle Data Provider for .NET (19.5)

The following are the changes in Oracle Data Provider for .NET (19.5).

### New Features

The following features are new in this release:

- .NET Core 3 Certification  
ODP.NET Core is certified for .NET Core 3.
- Entity Framework Core 2.1 Certification  
ODP.NET Entity Framework Core is certified for EF Core 2.1.

## Changes in Oracle Data Provider for .NET in ODAC Release 19c (19.3)

The following are the changes in Oracle Data Provider for .NET for ODAC Release 19c (19.3).

### New Features

The following features are new in this release:

- Entity Framework Core  
ODP.NET Entity Framework (EF) Core is a database provider that allows Entity Framework Core to be used with Oracle databases. Entity Framework Core is a cross-platform Microsoft object-relational mapper that enables .NET developers to work with relational databases using .NET objects.

Oracle EF Core developers can now create and migrate data models in the Oracle Database. They can reverse engineer/scaffold EF Core classes based on an Oracle Database schema. Oracle EF Core is integrated with popular EF Core tools, such as the EF Core Package Manager Tools.

#### See Also

[Oracle Data Provider for .NET Entity Framework Core](#)

- Managed ODP.NET and ODP.NET Core -- More Configuration Options with New OracleConnection Properties

OracleConnection class introduces additional properties to configure ODP.NET connections. The new properties are:

- `KeepAlive`, `KeepAliveInterval`, and `KeepAliveTime` - specifies whether and the conditions under which to keep idle connections alive
- `TnsAdmin` - specifies the `tnsnames.ora` and `sqlnet.ora` directory
- `WalletLocation` - specifies the wallet directory location

**Note**

[OracleConnection Class](#)

- Unmanaged ODP.NET -- Administer Storage using SYSASM Privilege

Oracle Automatic Storage Management (Oracle ASM) is a volume manager and a file system for Oracle database files. SYSASM is a system privilege that enables administrators to manage ASM instances. Unmanaged ODP.NET can now connect using the SYSASM administrative privilege to perform storage management of the Oracle Database.

ODP.NET can now perform database ASM administration when connecting with a SYSASM privileged connection.

**Note**

[OracleDBAPrivilege Enumeration](#)

- Dynamically Enabled Tracing and Size Limits

To improve diagnostics ease of use and productivity, ODP.NET trace output can now be enabled and disabled at runtime using the `OracleConfiguration.TraceLevel` property. To keep trace files down to a manageable size, the `TraceFileMaxSize` property can be set.

Administrators can isolate tracing to only known times or events when problems occur. This feature helps keep trace files down to the minimum size needed to investigate issues. If a trace file does become large, ODP.NET will write to a new trace file once the maximum file limit that is set in `TraceFileMaxSize` is reached. These features are available with core, managed, and unmanaged providers.

**See Also**

- [Debug Tracing](#)
- [OracleConfiguration Diagnostics and Tracing Properties](#)

## Changes in Oracle Data Provider for .NET Release 19c (19.3)

The following are the changes in Oracle Data Provider for .NET for Release 19c (19.3).

### New Features

The following features are new in this release:

- .NET Framework 4.8 Certification

ODP.NET Core, Managed, and Unmanaged Drivers are certified with .NET Framework 4.8.

- ODP.NET, Managed Driver -- Configuration as Code

Managed ODP.NET now supports `OracleConfiguration`, `OracleDataSourceCollection`, and `OracleOnsServerCollection` classes.

These classes allow developers to configure managed ODP.NET within source code in lieu of .NET configuration and Oracle configuration files.

- ODP.NET Core -- Lightweight Directory Access Protocol (LDAP)

ODP.NET Core can use connect identifiers mapped to connect descriptors in an LDAP-compliant directory server, such as Oracle Internet Directory and Microsoft Active Directory. The provider supports the same LDAP features and settings as managed ODP.NET.

ODP.NET Core LDAP support is available on Windows operating systems only.

**See Also**

[OracleConfiguration Directories Properties](#)

- ODP.NET Core -- Performance Counters

ODP.NET Core can publish key runtime connection counters to Windows Performance Monitor or a file. The provider supports the same counters, setup process, and settings as managed and unmanaged ODP.NET.

ODP.NET Core performance counters are available on Windows operating systems only. They require `System.Diagnostics` namespace in using performance counters programmatically.

**See Also**

[Connection Performance Counters](#)

- Easy Connect Plus

Oracle Easy Connect Plus provides a simple way to configure TCP/IP connections to the Oracle Database without having to use parameter files, such as `tnsnames.ora`, nor environment variables. Easy Connect Plus includes support for:

- TCP/IP with SSL/TLS
- Any SQL\*Net description level parameter can be used
- Multiple hosts and ports
- A straightforward name-value pair format

Easy Connect Plus supports more configurations and a wider breadth of ODP.NET applications than traditional Easy Connect, including clustered or cloud databases.

**See Also**

[Easy Connect and Easy Connect Plus Naming Methods](#)

- More Secure Oracle Notification Service Connections

ODP.NET now enables Oracle Notification Service (ONS) communications to occur over TCP/IP with SSL/TLS (TCPS), which is more secure than just TCP/IP. As TCPS requires using a wallet for storing keys and certificates, ODP.NET can use one wallet for both ONS and ODP.NET connections or have separate wallets for each.

TCPS provides more secure ONS communication, gives administrators flexibility in how to configure their wallets, and enables cloud database connections.

# Introducing Oracle Data Provider for .NET

This chapter introduces Oracle Data Provider for .NET (ODP.NET), an implementation of a .NET data provider for Oracle Database.

This chapter contains these topics:

- [.NET Data Access in Oracle: Products and Documentation](#)
- [Overview of Oracle Data Provider for .NET \(ODP.NET\)](#)
- [Oracle Data Provider for .NET Assemblies](#)
- [Differences between the ODP.NET Drivers](#)
- [Getting Started With Developing ODP.NET Applications](#)

## .NET Data Access in Oracle: Products and Documentation

This section discusses Oracle Data Provider for .NET and Oracle Database components that use Oracle Data Provider for .NET for data access. It briefly describes what each component does and where to find additional documentation.

These Oracle products provide .NET integration on the Windows operating system:

## Oracle Data Provider for .NET (ODP.NET)

Oracle Data Provider for .NET provides fast data access from .NET clients to Oracle databases. ODP.NET enables .NET applications to take advantage of Oracle advanced features, such as Oracle Real Application Clusters (Oracle RAC) and XML DB. It is accessible through any .NET language, including C#, Visual Basic .NET, and C++ .NET.

ODP.NET consists of three drivers: ODP.NET, Managed Driver, ODP.NET, Unmanaged and ODP.NET Core. ODP.NET, Managed Driver is a fully managed ADO.NET provider, consisting of fewer DLLs and smaller install size than ODP.NET, Unmanaged Driver. The managed driver has the same exact application programming interfaces (APIs) as ODP.NET, Unmanaged Driver. However, the managed driver's APIs are a subset of the Unmanaged Driver's APIs.

ODP.NET Core is a multi-platform provider for Microsoft .NET Core. In functionality, it is very similar to ODP.NET, Managed Driver. However, ODP.NET Core has a subset of managed ODP.NET's APIs.

This guide describes Oracle Data Provider for .NET features, their use, installation, requirements, and classes. The guide distinguishes which classes and APIs are supported for the managed driver, unmanaged driver, and .NET clients.

Additionally, Oracle Data Provider for .NET Dynamic Help, which is context-sensitive online help, contains the same reference sections available in *Oracle Data Provider for .NET Developer's Guide for Microsoft Windows*, this guide.

Oracle Data Provider for .NET Dynamic Help is integrated with Visual Studio Dynamic Help. With Dynamic Help, you can access Oracle Data Provider for .NET documentation within Visual Studio by placing the cursor on an Oracle Data Provider for .NET keyword and pressing the F1 function key.

## Oracle Developer Tools for Visual Studio

Oracle Developer Tools is an add-in to Visual Studio that provides graphical user interface (GUI) access to Oracle functionality. It provides improved developer productivity and ease of use.

Oracle Developer Tools for Visual Studio Help describes Oracle Developer Tools. This help is in the form of dynamic help, which installs as part of the product.

Additionally, the Oracle Developer Tools for Visual Studio Help includes the following documentation:

- *Oracle AI Database PL/SQL Language Reference*
- *Oracle AI Database SQL Language Reference*
- *Oracle AI Database Error Messages Reference*
- Access to Oracle Data Provider for .NET Dynamic Help
- Access to Oracle Providers for ASP.NET Dynamic Help

## Oracle Providers for ASP.NET

Oracle Providers for ASP.NET offer ASP.NET developers an easy to use method to store state common to web applications within an Oracle database. These providers are modeled on existing Microsoft ASP.NET providers, sharing similar schema and programming interfaces to provide .NET developers a familiar interface. Oracle supports the following providers:

- Cache Dependency Provider
- Membership Provider
- Profile Provider
- Role Provider
- Session State Provider
- Site Map Provider
- Web Events Provider
- Web Parts Personalization Provider

Oracle Providers for ASP.NET classes, their use, installation, and requirements are described in *Oracle Providers for ASP.NET Developer's Guide for Microsoft Windows*, which is also provided as dynamic help.

## Oracle Services for Microsoft Transaction Server

Oracle Services for Microsoft Transaction Server (OraMTS) permit Oracle databases to be used as resource managers in Microsoft application coordinated transactions. OraMTS acts as a proxy for the Oracle database to the Microsoft Distributed Transaction Coordinator (MSDTC). As a result, OraMTS provides client-side connection pooling and allows client components that leverage Oracle to participate in promotable and distributed transactions. In addition, OraMTS can operate with Oracle databases running on any operating system, given that the services themselves are run on Windows.

**① See Also**

*Oracle Services for Microsoft Transaction Server Developer's Guide for Microsoft Windows* for description about OraMTS, which allows Oracle databases to be used as resource managers in distributed transactions.

## Oracle TimesTen In-Memory Database

ODP.NET support for Oracle TimesTen In-Memory Database (TimesTen) provides fast and efficient ADO.NET data access for applications that require the highest performance.

You can use ODP.NET with any of the following TimesTen installations:

- TimesTen Data Manager only (for direct connections)
- TimesTen Client only (for client/server connections, assuming a TimesTen Data Manager instance and TimesTen Server instance are accessible elsewhere)
- TimesTen Data Manager with TimesTen Server

For more information on ODP.NET features specific to a TimesTen environment, refer to the *Oracle Data Provider for .NET Oracle TimesTen In-Memory Database Support User's Guide*.

**① Note**

TimesTen does not support ODP.NET, Managed Driver and ODP.NET Core.

## Overview of Oracle Data Provider for .NET (ODP.NET)

Oracle Data Provider for .NET (ODP.NET) is an implementation of a .NET data provider for Oracle Database, using and inheriting from classes and interfaces available in the [Microsoft .NET Framework Class Library](#).

Following the .NET Framework, ODP.NET uses the ADO.NET model, which allows native providers to expose provider-specific features and data types. This is similar to Oracle Provider for OLE DB, where ADO (ActiveX Data Objects) provides an automation layer that exposes an easy programming model. ADO.NET provides a similar programming model, but without the automation layer, for better performance.

Oracle Data Provider for .NET uses Oracle native APIs to offer fast and reliable access to Oracle data and features from any .NET application. ODP.NET consists of three drivers: ODP.NET, Managed Driver, ODP.NET, Unmanaged Driver, and ODP.NET Core. ODP.NET, Managed Driver is a fully managed ADO.NET provider, consisting of fewer DLLs and smaller install size than ODP.NET, Unmanaged Driver. The managed driver has the same exact application programming interfaces (APIs) as ODP.NET, Unmanaged Driver. However, the managed driver's APIs are a subset of the Unmanaged Driver's APIs.

ODP.NET Core employs the same namespaces and application programming interfaces (APIs) as ODP.NET, Managed Driver. This parallel eases migration and developer learning curve from managed ODP.NET to ODP.NET Core. It does not support all managed ODP.NET functionality. ODP.NET Core supports a subset of managed ODP.NET APIs. These differences are listed later on in this documentation.

The ODP.NET classes described in this guide are contained in the `Oracle.DataAccess.dll` and `Oracle.ManagedDataAccess.dll` assembly.

- Client Applications: All ODP.NET classes are available for use in client applications.

As ODP.NET, Managed Driver does not support all classes and members in the ODP.NET, Unmanaged Driver, the unsupported managed driver classes and members will be labeled *Not Supported in ODP.NET, Managed Driver*.

ODP.NET Core does not support all classes and members in the ODP.NET, Managed Driver. The unsupported managed driver classes and members will be labeled *Not Supported in ODP.NET Core*.

## Oracle Data Provider for .NET Assemblies

This section contains the following topics:

- [Oracle Data Provider for .NET, Unmanaged Driver Assemblies](#)
- [Oracle Data Provider for .NET, Managed Driver and ODP.NET Core Assemblies](#)
- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)

## Oracle Data Provider for .NET, Unmanaged Driver Assemblies

The `Oracle.DataAccess.dll` [assembly](#) provides two namespaces:

- The `Oracle.DataAccess.Client` namespace contains ODP.NET classes and enumerations for the client-side provider.
- The `Oracle.DataAccess.Types` namespace contains the Oracle Data Provider for .NET data types (ODP.NET Types).

To use Code First or Entity Framework 6 or higher with ODP.NET, Unmanaged Driver, add `Oracle.DataAccess.EntityFramework.dll` as a project assembly reference. It contains the namespace `Oracle.DataAccess.EntityFramework`.

## Oracle Data Provider for .NET, Managed Driver and ODP.NET Core Assemblies

The `Oracle.ManagedDataAccess.dll` [assembly](#) provides two namespaces:

- The `Oracle.ManagedDataAccess.Client` namespace contains ODP.NET classes and enumerations for the client-side provider.
- The `Oracle.ManagedDataAccess.Types` namespace contains the Oracle Data Provider for .NET data types (ODP.NET Types).

ODP.NET, Managed Driver contains additional assemblies. These assemblies are optional to install if not using the specific functionality.

Applications do not need to explicitly add these assemblies to their project. ODP.NET, Managed Driver will access these assemblies by default if installed.

The one exception is `Oracle.ManagedDataAccess.EntityFramework.dll`. That DLL must be explicitly added to a project for its functionality to be used.

- `Oracle.ManagedDataAccess.EntityFramework.dll` - Only required when using Code First or Entity Framework 6 or higher. It contains the `Oracle.ManagedDataAccess.EntityFramework` namespace.
- `Oracle.ManagedDataAccessIOP.dll` - Only required when using MIT Kerberos. The assembly makes calls to unmanaged assemblies. Applications do not need to explicitly add this assembly to their project as ODP.NET is already configured to access this assembly by default.

## Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces

The `Oracle.DataAccess.Client` and `Oracle.ManagedDataAccess.Client` namespaces contains implementations of core ADO.NET classes and enumerations for ODP.NET, as well as ODP.NET specific classes.

The following tables list ODP.NET classes, enumerations, and types that are supported by the `Oracle.DataAccess.Client` and `Oracle.ManagedDataAccess.Client` namespaces. The tables indicate which of them are not supported by ODP.NET, Managed Driver and/or ODP.NET Core. All are supported by ODP.NET, Unmanaged Driver unless noted as not supported in the description field.

## Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client

[Table 1-1](#) lists the `Oracle.DataAccess.Client` and `Oracle.ManagedDataAccess.Client` classes and delegates.

**Table 1-1 Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client**

| Class or Delegate                             | Supported in the ODP.NET, Managed Driver | Supported in the ODP.NET Core | Description                                                                                                                                        |
|-----------------------------------------------|------------------------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OnChangeEventHandler Delegate</a> | -                                        | -                             | The <code>OnChangeEventHandler</code> event delegate represents the signature of the method that handles the notification.                         |
| <a href="#">OracleAQAgent Class</a>           | -                                        | -                             | The <code>OracleAQAgent</code> class represents agents that may be senders or recipients of a message.                                             |
| <a href="#">OracleAQDequeueOptions Class</a>  | -                                        | -                             | An <code>OracleAQDequeueOptions</code> object represents the options available when dequeuing a message from an <code>OracleAQQueue</code> object. |

Table 1-1 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client

| Class or Delegate                                             | Supported in the ODP.NET,<br>Managed Driver | Supported in the ODP.NET<br>Core | Description                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------|---------------------------------------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleAQEnqueueOptions Class</a>                  | -                                           | -                                | The <code>OracleAQEnqueueOptions</code> class represents the options available when enqueueing a message to an <code>OracleAQQueue</code> .                                                                                                                                        |
| <a href="#">OracleAQMessage Class</a>                         | -                                           | -                                | An <code>OracleAQMessage</code> object represents a message to be enqueued and dequeued.                                                                                                                                                                                           |
| <a href="#">OracleAQMessageAvailableEventArgs Class</a>       | -                                           | -                                | The <code>OracleAQMessageAvailableEventArgs</code> class provides event data for the <code>OracleAQQueue.MessageAvailable</code> event.                                                                                                                                            |
| <a href="#">OracleAQMessageAvailableEventHandler Delegate</a> | -                                           | -                                | The <code>OracleAQMessageAvailableEventHandler</code> delegate represents the signature of the method that handles the <code>OracleAQQueue.MessageAvailable</code> event.                                                                                                          |
| <a href="#">OracleAQQueue Class</a>                           | -                                           | -                                | An <code>OracleAQQueue</code> object represents a queue.                                                                                                                                                                                                                           |
| <a href="#">OracleBulkCopy Class</a>                          | -                                           | -                                | An <code>OracleBulkCopy</code> object efficiently bulk loads or copies data into an Oracle table from another data source.                                                                                                                                                         |
| <a href="#">OracleBulkCopyOptions Enumeration</a>             | -                                           | -                                | The <code>OracleBulkCopyOptions</code> enumeration specifies the values that can be combined with an instance of the <code>OracleBulkCopy</code> class and used as options to determine its behavior and the behavior of the <code>WriteToServer</code> methods for that instance. |
| <a href="#">OracleBulkCopyColumnMapping Class</a>             | -                                           | -                                | The <code>OracleBulkCopyColumnMapping</code> class defines the mapping between a column in the data source and a column in the destination database table.                                                                                                                         |

**Table 1-1 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client**

| Class or Delegate                                           | Supported in the ODP.NET,<br>Managed Driver | Supported in the ODP.NET<br>Core | Description                                                                                                                                                                                                                 |
|-------------------------------------------------------------|---------------------------------------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleBulkCopyColumnMappingCollection Class</a> | -                                           | -                                | The <code>OracleBulkCopyColumnMappingCollection</code> class represents a collection of <code>OracleBulkCopyColumnMapping</code> objects that are used to map columns in the data source to columns in a destination table. |
| <a href="#">OracleClientFactory Class</a>                   | -                                           | No                               | An <code>OracleClientFactory</code> object allows applications to instantiate ODP.NET classes in a generic way.                                                                                                             |
| <a href="#">OracleCommand Class</a>                         | -                                           | -                                | An <code>OracleCommand</code> object represents a SQL command, a stored procedure or function, or a table name.                                                                                                             |
| <a href="#">OracleCommandBuilder Class</a>                  | -                                           | -                                | An <code>OracleCommandBuilder</code> object provides automatic SQL generation for the <code>OracleDataAdapter</code> when the database is updated.                                                                          |
| <a href="#">OracleConfiguration Class</a>                   | -                                           | -                                | An <code>OracleConfiguration</code> is a static class for setting ODP.NET Core configuration data using a single programming interface.                                                                                     |
| <a href="#">OracleConnection Class</a>                      | -                                           | -                                | An <code>OracleConnection</code> object represents a connection to Oracle Database.                                                                                                                                         |
| <a href="#">OracleConnectionOpenEventArgs Class</a>         | -                                           | -                                | An <code>OracleConnectionOpenEventArgs</code> object provides connection information for the <code>OracleConnection.Open()</code> method.                                                                                   |
| <a href="#">OracleConnectionOpenEventHandler Delegate</a>   | -                                           | -                                | The <code>OracleConnectionOpenEventHandler</code> delegate represents the signature of the method that handles <code>OracleConnection.ConnectionOpen</code> event.                                                          |
| <a href="#">OracleConnectionStringBuilder Class</a>         | -                                           | -                                | An <code>OracleConnectionStringBuilder</code> object allows applications to create or modify connection strings.                                                                                                            |

**Table 1-1 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client**

| Class or Delegate                                | Supported in the ODP.NET,<br>Managed Driver | Supported in the ODP.NET<br>Core | Description                                                                                                                                  |
|--------------------------------------------------|---------------------------------------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleCredential Class</a>           | -                                           | -                                | OracleCredential class provides a secure way to provide password while opening connection with Oracle Database using the ODP.NET driver      |
| <a href="#">OracleDataAdapter Class</a>          | -                                           | -                                | An OracleDataAdapter object represents a data provider object that communicates with the DataSet.                                            |
| <a href="#">OracleDatabase Class</a>             | -                                           | -                                | An OracleDatabase object represents an Oracle Database instance.                                                                             |
| <a href="#">OracleDataReader Class</a>           | -                                           | -                                | An OracleDataReader object represents a forward-only, read-only, in-memory result set.                                                       |
| <a href="#">OracleDataSource Class</a>           | No                                          | -                                | An OracleDataSource object represents an Oracle database from which to open connections to or execute commands directly against.             |
| <a href="#">OracleDataSourceCollection Class</a> | -                                           | -                                | An OracleDataSourceCollection object supports adding and deleting network service name (i.e. TNS) entries in the OracleDataSourceCollection. |
| <a href="#">OracleDataSourceEnumerator Class</a> | -                                           | -                                | An OracleDataSourceEnumerator object allows applications to generically obtain a collection of data sources to connect to.                   |
| <a href="#">OracleDependency Class</a>           | -                                           | -                                | An OracleDependency class represents a dependency between an application and an Oracle database.                                             |
| <a href="#">OracleError Class</a>                | -                                           | -                                | The OracleError object represents an error reported by an Oracle database.                                                                   |
| <a href="#">OracleErrorCollection Class</a>      | -                                           | -                                | An OracleErrorCollection object represents a collection of OracleErrors.                                                                     |

**Table 1-1 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client**

| Class or Delegate                                      | Supported in the ODP.NET,<br>Managed Driver | Supported in the ODP.NET<br>Core | Description                                                                                                                                                      |
|--------------------------------------------------------|---------------------------------------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleException Class</a>                  | -                                           | -                                | The <code>OracleException</code> object represents an exception that is thrown when Oracle Data Provider for .NET encounters an error.                           |
| <a href="#">OracleFailoverEventArgs Class</a>          | -                                           | -                                | The <code>OracleFailoverEventArgs</code> class provides event data for the <code>OracleConnection.Failover</code> event.                                         |
| <a href="#">OracleFailoverEventHandler Delegate</a>    | -                                           | -                                | The <code>OracleFailoverEventHandler</code> represents the signature of the method that handles the <code>OracleConnection.Failover</code> event.                |
| <a href="#">OracleGlobalization Class</a>              | -                                           | -                                | The <code>OracleGlobalization</code> class is used to obtain and set the Oracle globalization settings of the session, thread, and local computer (read-only).   |
| <a href="#">OracleHAEEventArgs Class</a>               | -                                           | -                                | The <code>OracleHAEEventArgs</code> class provides event data for the <code>OracleConnection.HAEvent</code> event.                                               |
| <a href="#">OracleHAEEventHandler Delegate</a>         | -                                           | -                                | The <code>OracleHAEEventHandler</code> delegate represents the signature of the method that handles the <code>OracleConnection.HAEvent</code> event.             |
| <a href="#">OracleInfoMessageEventArgs Class</a>       | -                                           | -                                | The <code>OracleInfoMessageEventArgs</code> object provides event data for the <code>OracleConnection.InfoMessage</code> event.                                  |
| <a href="#">OracleInfoMessageEventHandler Delegate</a> | -                                           | -                                | The <code>OracleInfoMessageEventHandler</code> delegate represents the signature of the method that handles the <code>OracleConnection.InfoMessage</code> event. |

**Table 1-1 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client**

| Class or Delegate                                     | Supported in the ODP.NET,<br>Managed Driver | Supported in the ODP.NET<br>Core | Description                                                                                                                                                                                                                                           |
|-------------------------------------------------------|---------------------------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleLogicalTransaction Class</a>        | -                                           | -                                | The <code>OracleLogicalTransaction</code> class provides detailed information about the logical transaction status.                                                                                                                                   |
| <a href="#">OracleNotificationEventArgs Class</a>     | -                                           | -                                | The <code>OracleNotificationEventArgs</code> class provides event data for a notification.                                                                                                                                                            |
| <a href="#">OracleNotificationRequest Class</a>       | -                                           | -                                | An <code>OracleNotificationRequest</code> class represents a notification request to be subscribed in the database.                                                                                                                                   |
| <a href="#">OracleOnsServerCollection Class</a>       | -                                           | -                                | The <code>OracleOnsServerCollection</code> class supports adding to and deleting from a collection of logical servers with their corresponding list of nodes where the Oracle Notification Service (ONS) daemons are talking to their remote clients. |
| <a href="#">OracleParameter Class</a>                 | -                                           | -                                | An <code>OracleParameter</code> object represents a parameter for an <code>OracleCommand</code> .                                                                                                                                                     |
| <a href="#">OracleParameterCollection Class</a>       | -                                           | -                                | An <code>OracleParameterCollection</code> object represents a collection of <code>OracleParameters</code> .                                                                                                                                           |
| <a href="#">OraclePermission Class</a>                | -                                           | No                               | An <code>OraclePermission</code> object enables ODP.NET to enforce imperative security and helps ensure that a user has a security level adequate for accessing data.                                                                                 |
| <a href="#">OraclePermissionAttribute Class</a>       | -                                           | No                               | An <code>OraclePermissionAttribute</code> object enables ODP.NET to enforce declarative security and helps ensure that a user has a security level adequate for accessing data.                                                                       |
| <a href="#">OracleRowsCopiedEventHandler Delegate</a> | -                                           | -                                | The <code>OracleRowsCopiedEventHandler</code> delegate represents the method that handles the <code>OracleRowsCopied</code> event of an <code>OracleBulkCopy</code> object.                                                                           |

Table 1-1 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client

| Class or Delegate                                      | Supported in the ODP.NET,<br>Managed Driver | Supported in the ODP.NET<br>Core | Description                                                                                                                                                               |

| <a href="#">OracleRowUpdatingEventArgs Class</a>       | -                                           | -                                | The <code>OracleRowUpdatingEventArgs</code> object provides event data for the <code>OracleDataAdapter.RowUpdating</code> event.                                          |
| <a href="#">OracleRowUpdatingEventHandler Delegate</a> | -                                           | -                                | The <code>OracleRowUpdatingEventHandler</code> delegate represents the signature of the method that handles the <code>OracleDataAdapter.RowUpdating</code> event.         |
| <a href="#">OracleShardingKey Class</a>                | -                                           | -                                | An <code>OracleShardingKey</code> object can represent either a sharding key or a super sharding key.                                                                     |
| <a href="#">OracleTAFMode Class</a>                    | -                                           | -                                | The <code>OracleTAFMode</code> object sets the Oracle Transparent Application Failover parameters for the connection.<br><br><i>Not supported with unmanaged ODP.NET.</i> |
| <a href="#">OracleTransaction Class</a>                | -                                           | -                                | An <code>OracleTransaction</code> object represents a local transaction.                                                                                                  |

**Table 1-1 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client**

| Class or Delegate                              | Supported in the ODP.NET, Managed Driver | Supported in the ODP.NET Core | Description                                                                                                                                                                                                                                     |
|------------------------------------------------|------------------------------------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleXmlQueryProperties Class</a> | -                                        | -                             | An <code>OracleXmlQueryProperties</code> object represents the XML properties used by the <code>OracleCommand</code> class when the <code>XmlCommandType</code> property is <code>Query</code> .                                                |
| <a href="#">OracleXmlSaveProperties Class</a>  | -                                        | -                             | An <code>OracleXmlSaveProperties</code> object represents the XML properties used by the <code>OracleCommand</code> class when the <code>XmlCommandType</code> property is <code>Insert</code> , <code>Update</code> , or <code>Delete</code> . |

## Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Enumerations

[Table 1-2](#) lists the client enumerations.

**Table 1-2 Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Enumerations**

| Enumeration                                             | Supported in the ODP.NET, Managed Driver and ODP.NET Core | Description                                                                                                                                                                                                   |
|---------------------------------------------------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">FailoverEvent Enumeration</a>               | No                                                        | <code>FailoverEvent</code> enumerated values are used to specify the state of the failover.                                                                                                                   |
| <a href="#">FailoverReturnCode Enumeration</a>          | No                                                        | <code>FailoverReturnCode</code> enumerated values are passed back by the application to the ODP.NET provider to request a retry in case of a failover error, or to continue in case of a successful failover. |
| <a href="#">FailoverType Enumeration</a>                | No                                                        | <code>FailoverType</code> enumerated values are used to indicate the type of failover event that was raised.                                                                                                  |
| <a href="#">OracleAQDequeueMode Enumeration</a>         | -                                                         | The <code>OracleAQDequeueMode</code> enumeration type specifies the dequeue mode.                                                                                                                             |
| <a href="#">OracleAQMessageDeliveryMode Enumeration</a> | -                                                         | The <code>OracleAQMessageDeliveryMode</code> enumeration type specifies the delivery mode of the message.                                                                                                     |
| <a href="#">OracleAQMessageState Enumeration</a>        | -                                                         | The <code>OracleAQMessageState</code> enumeration type identifies the state of the message at the time of dequeue.                                                                                            |
| <a href="#">OracleAQMessageType Enumeration</a>         | -                                                         | The <code>OracleAQMessageType</code> enumeration type specifies the message payload type.                                                                                                                     |

**Table 1-2 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Enumerations**

| Enumeration                                                  | Supported in the ODP.NET, Managed Driver and ODP.NET Core | Description                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleAQNavigationMode Enumeration</a>           | -                                                         | The <code>OracleAQNavigationMode</code> enumeration type specifies the navigation mode.                                                                                                                                                                                            |
| <a href="#">OracleAQNotificationGroupingType Enumeration</a> | -                                                         | The <code>OracleAQNotificationGroupingType</code> enumeration type specifies the notification grouping type.                                                                                                                                                                       |
| <a href="#">OracleAQNotificationType Enumeration</a>         | -                                                         | The <code>OracleAQNotificationType</code> enumeration type specifies the notification type of the received notification.                                                                                                                                                           |
| <a href="#">OracleAQVisibilityMode Enumeration</a>           | -                                                         | The <code>OracleAQVisibilityMode</code> enumeration type specifies whether the enqueue or dequeue operation is part of the current transaction.                                                                                                                                    |
| <a href="#">OracleBulkCopyOptions Enumeration</a>            | No                                                        | The <code>OracleBulkCopyOptions</code> enumeration specifies the values that can be combined with an instance of the <code>OracleBulkCopy</code> class and used as options to determine its behavior and the behavior of the <code>WriteToServer</code> methods for that instance. |
| <a href="#">OracleCollectionType Enumeration</a>             | -                                                         | <code>OracleCollectionType</code> enumerated values specify whether or not the <code>OracleParameter</code> object represents a collection, and if so, specifies the collection type.                                                                                              |
| <a href="#">OracleConnectionType Enumeration</a>             | No                                                        | <code>OracleConnectionType</code> enumerated values specify whether a particular connection object is associated with an Oracle database connection, a TimesTen database connection, or no physical connection at all.                                                             |
| <a href="#">OracleDBShutdownMode Enumeration</a>             | -                                                         | <code>OracleDBShutdownMode</code> enumerated values specify the database shutdown options.                                                                                                                                                                                         |
| <a href="#">OracleDBStartupMode Enumeration</a>              | -                                                         | <code>OracleDBStartupMode</code> enumerated values specify the database startup options.                                                                                                                                                                                           |
| <a href="#">OracleDbType Enumeration</a>                     | -                                                         | <code>OracleDbType</code> enumerated values are used to explicitly specify the <code>OracleDbType</code> of an <code>OracleParameter</code> .                                                                                                                                      |
| <a href="#">OracleDRCPYPurity Enumeration</a>                | -                                                         | <code>OracleDRCPYPurity</code> enumerated values specify the session purity.                                                                                                                                                                                                       |
| <a href="#">OracleFailoverEvent Enumeration</a>              | -                                                         | <code>OracleFailoverEvent</code> enumerated values are used to specify the state of the failover.<br><i>Not supported with unmanaged ODP.NET.</i>                                                                                                                                  |

Table 1-2 (Cont.) Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Enumerations

| Enumeration                                          | Supported in the ODP.NET, Managed Driver and ODP.NET Core | Description                                                                                                                                                                                                                                            |
|------------------------------------------------------|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleFailoverRestore Enumeration</a>    | -                                                         | OracleFailoverRestore enumerated values indicate whether ODP.NET must restore session state after failover.<br><i>Not supported with unmanaged ODP.NET.</i>                                                                                            |
| <a href="#">OracleFailoverReturnCode Enumeration</a> | -                                                         | OracleFailoverReturnCode enumerated values are passed back by the application to the ODP.NET provider to request a retry in case of a failover error, or to continue in case of a successful failover.<br><i>Not supported with unmanaged ODP.NET.</i> |
| <a href="#">OracleFailoverType Enumeration</a>       | -                                                         | OracleFailoverType enumerated values are used to indicate the type of failover event that was raised.<br><i>Not supported with unmanaged ODP.NET.</i>                                                                                                  |
| <a href="#">OracleHAEventSource Enumeration</a>      | -                                                         | The OracleHAEventSource enumeration indicates the source of the HA event.                                                                                                                                                                              |
| <a href="#">OracleHAEventStatus Enumeration</a>      | -                                                         | The OracleHAEventStatus enumeration indicates the status of the HA event source.                                                                                                                                                                       |
| <a href="#">OracleIdentityType Enumeration</a>       | -                                                         | The OracleIdentityType enumeration specifies how Oracle identity column values are generated.                                                                                                                                                          |
| <a href="#">OracleNotificationInfo Enumeration</a>   | -                                                         | OracleNotificationInfo enumerated values specify the database event that causes the notification.                                                                                                                                                      |
| <a href="#">OracleNotificationSource Enumeration</a> | -                                                         | OracleNotificationSource enumerated values specify the different sources that cause notification.                                                                                                                                                      |
| <a href="#">OracleNotificationType Enumeration</a>   | -                                                         | OracleNotificationType enumerated values specify the different types that cause the notification.                                                                                                                                                      |
| <a href="#">OracleParameterStatus Enumeration</a>    | -                                                         | The OracleParameterStatus enumeration type indicates whether a NULL value is fetched from a column, or truncation has occurred during the fetch, or a NULL value is to be inserted into a database column.                                             |
| <a href="#">OracleRowidInfo Enumeration</a>          | -                                                         | The OracleRowidInfo enumeration values specify whether ROWID information is included as part of the ChangeNotificationEventArgs or not                                                                                                                 |
| <a href="#">OracleXmlCommandType Enumeration</a>     | -                                                         | The OracleXmlCommandType enumeration specifies the values that are allowed for the OracleXmlCommandType property of the OracleCommand class.                                                                                                           |

## Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces

The `Oracle.DataAccess.Types` and `Oracle.ManagedDataAccess.Types` namespaces provides classes, structures, and exceptions for Oracle native types that can be used with Oracle Data Provider for .NET.

## Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Structures

[Table 1-3](#) lists the type structures.

**Table 1-3 Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Structures**

| Structure                                    | Description                                                                                                       |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleBinary Structure</a>       | The <code>OracleBinary</code> structure represents a variable-length stream of binary data.                       |
| <a href="#">OracleBoolean Structure</a>      | The <code>OracleBoolean</code> structure represents a logical value that is either TRUE or FALSE.                 |
| <a href="#">OracleDate Structure</a>         | The <code>OracleDate</code> structure represents the Oracle DATE data type.                                       |
| <a href="#">OracleDecimal Structure</a>      | The <code>OracleDecimal</code> structure represents an Oracle NUMBER in the database or any Oracle numeric value. |
| <a href="#">OracleIntervalDS Structure</a>   | The <code>OracleIntervalDS</code> structure represents the Oracle INTERVAL DAY TO SECOND data type.               |
| <a href="#">OracleIntervalYM Structure</a>   | The <code>OracleIntervalYM</code> structure represents the Oracle INTERVAL YEAR TO MONTH data type.               |
| <a href="#">OracleString Structure</a>       | The <code>OracleString</code> structure represents a variable-length stream of characters.                        |
| <a href="#">OracleTimeStamp Structure</a>    | The <code>OracleTimeStamp</code> structure represents the Oracle TIMESTAMP data type.                             |
| <a href="#">OracleTimeStampLTZ Structure</a> | The <code>OracleTimeStampLTZ</code> structure represents the Oracle TIMESTAMP WITH LOCAL TIME ZONE data type.     |
| <a href="#">OracleTimeStampTZ Structure</a>  | The <code>OracleTimeStampTZ</code> structure represents the Oracle TIMESTAMP WITH TIME ZONE data type.            |

## Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Exceptions

Type Exceptions are thrown only by ODP.NET type structures. [Table 1-4](#) lists the type exceptions.

**Table 1-4 Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Exceptions**

| Exception                                      | Description                                                                                                                                     |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleTypeException Class</a>      | The <code>OracleTypeException</code> object is the base exception class for handling exceptions that occur in the ODP.NET Types classes.        |
| <a href="#">OracleNullValueException Class</a> | The <code>OracleNullValueException</code> represents an exception that is thrown when trying to access an ODP.NET Types structure that is null. |

**Table 1-4 (Cont.) Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Exceptions**

| Exception                                     | Description                                                                                                                             |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleTruncateException Class</a> | The <code>OracleTruncateException</code> class represents an exception that is thrown when truncation in an ODP.NET Types class occurs. |

## Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Classes

[Table 1-5](#) lists the type classes.

**Table 1-5 Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Classes**

| Class                                                  | Description                                                                                                                                                                                                   |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleArrayMappingAttribute Class</a>      | The <code>OracleArrayMappingAttribute</code> class is required to mark a custom class field or property with information that ODP.NET uses when a custom type represents an Oracle Collection type.           |
| <a href="#">OracleBFile Class</a>                      | An <code>OracleBFile</code> is an object that has a reference to BFILE data. It provides methods for performing operations on BFILE objects.                                                                  |
| <a href="#">OracleBlob Class</a>                       | An <code>OracleBlob</code> object is an object that has a reference to BLOB data. It provides methods for performing operations on BLOB objects.                                                              |
| <a href="#">OracleClob Class</a>                       | An <code>OracleClob</code> is an object that has a reference to CLOB data. It provides methods for performing operations on CLOB objects.                                                                     |
| <a href="#">OracleCustomTypeMappingAttribute Class</a> | The <code>OracleCustomTypeMappingAttribute</code> class is used to mark a custom type factory class or struct with information that is used by ODP.NET when a custom type is used to represent an Oracle UDT. |

**Table 1-5 (Cont.) Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Classes**

| Class                                              | Description                                                                                                                                                                                                                       |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleObjectMappingAttribute Class</a> | The OracleObjectMappingAttribute class marks custom class fields or properties with information that ODP.NET uses when a custom type represents an Oracle Object type.                                                            |
| <a href="#">OracleRef Class</a>                    | An OracleRef instance represents an Oracle REF, which references a persistent, standalone, referenceable object that resides in the database. The OracleRef object provides methods to insert, update, and delete the Oracle REF. |
| <a href="#">OracleRefCursor Class</a>              | An OracleRefCursor object represents an Oracle REF CURSOR.                                                                                                                                                                        |
| <a href="#">OracleUdt Class</a>                    | The OracleUdt class defines static methods that are used when converting between Custom Types and Oracle UDTs and vice-versa.                                                                                                     |
| <a href="#">OracleXmlStream Class</a>              | An OracleXmlStream object represents a sequential read-only stream of XML data stored in an OracleXmlType object.                                                                                                                 |
| <a href="#">OracleXmlType Class</a>                | An OracleXmlType object represents an Oracle XmlType instance.                                                                                                                                                                    |

## Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Interfaces

[Table 1-6](#) lists the type interfaces.

**Table 1-6 Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Interfaces**

| Interface                                         | Description                                                                                                  |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">IOracleArrayTypeFactory Interface</a> | The IOracleArrayTypeFactory interface is used by ODP.NET to create arrays that represent Oracle Collections. |

**Table 1-6 (Cont.) Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Interfaces**

| Interface                                          | Description                                                                                                                      |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">IOracleCustomType Interface</a>        | IOracleCustomType is an interface for converting between a Custom Type and an Oracle Object or Collection Type.                  |
| <a href="#">IOracleCustomTypeFactory Interface</a> | The IOracleCustomTypeFactory interface is used by ODP.NET to create custom objects that represent Oracle Objects or Collections. |
| <a href="#">INullable Interface</a>                | The INullable interface is used to determine whether or not an ODP.NET type has a NULL value.                                    |

## Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Enumerations

[Table 1-7](#) lists the type enumerations.

**Table 1-7 Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Enumerations**

| Enumeration                                      | Description                                                                                                                                                                           |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleUdtFetchOption Enumeration</a> | OracleUdtFetchOption enumeration values specify how to retrieve a copy of the referenceable object.                                                                                   |
| <a href="#">OracleUdtStatus Enumeration</a>      | OracleUdtStatus enumeration values specify the status of an object attribute or collection element. An object attribute or a collection element can be a valid value or a null value. |

## Differences between the ODP.NET Drivers

ODP.NET, Managed Driver, ODP.NET, Unmanaged Driver, and ODP.NET Core have a number of configuration setting differences.

**Table 1-8 Application Programming Interfaces not supported in ODP.NET, Managed Driver and ODP.NET Core**

| Namespace                       | Class/Enumeration/Interface                | Unsupported Method/Property/Event |
|---------------------------------|--------------------------------------------|-----------------------------------|
| Oracle.ManagedDataAccess.Client | FailoverEvent enumeration                  | All                               |
| Oracle.ManagedDataAccess.Client | FailoverReturnCode enumeration             | All                               |
| Oracle.ManagedDataAccess.Client | FailoverType enumeration                   | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQAgent class                        | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQDequeueMode enumeration            | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQDequeueOptions class               | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQEnqueueOptions class               | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQMessage class                      | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQMessageAvailableEventArgs class    | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQMessageAvailableEventHandler class | All                               |
| Oracle.ManagedDataAccess.Client | OracleAQMessageDeliveryMode enumeration    | All                               |

**Table 1-8 (Cont.) Application Programming Interfaces not supported in ODP.NET, Managed Driver and ODP.NET Core**

| Namespace                       | Class/Enumeration/Interface                  | Unsupported Method/Property/Event                                                                                                                                                                                                                                                                                       |
|---------------------------------|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Oracle.ManagedDataAccess.Client | OracleAQMessageState enumeration             | All                                                                                                                                                                                                                                                                                                                     |
| Oracle.ManagedDataAccess.Client | OracleAQMessageType enumeration              | All                                                                                                                                                                                                                                                                                                                     |
| Oracle.ManagedDataAccess.Client | OracleAQNavigationMode enumeration           | All                                                                                                                                                                                                                                                                                                                     |
| Oracle.ManagedDataAccess.Client | OracleAQNotificationGroupingType enumeration | All                                                                                                                                                                                                                                                                                                                     |
| Oracle.ManagedDataAccess.Client | OracleAQNotificationType enumeration         | All                                                                                                                                                                                                                                                                                                                     |
| Oracle.ManagedDataAccess.Client | OracleAQQueue class                          | All                                                                                                                                                                                                                                                                                                                     |
| Oracle.ManagedDataAccess.Client | OracleAQVisibilityMode enumeration           | All                                                                                                                                                                                                                                                                                                                     |
| Oracle.ManagedDataAccess.Client | OracleClientFactory class                    | <i>Not supported in ODP.NET Core only</i>                                                                                                                                                                                                                                                                               |

## System Requirements

Oracle Data Provider for .NET, Unmanaged Driver requires the following:

- Windows operating system
  - 64-bit: Windows 10 x64 (Pro, Enterprise, and Education Editions), Windows 11 x64 (Pro, Enterprise, and Education Editions), Windows Server 2016 x64 (Standard, Datacenter, and Essentials Editions), Windows Server 2019 (Standard, Datacenter, and Essentials Editions), Windows Server 2022 x64 (Standard, Datacenter, and Essentials Editions), or Windows Server 2025 x64 (Standard, Datacenter, and Essentials Editions).

Oracle supports 64-bit ODP.NET for Windows x64 on these operating systems.

- Microsoft .NET
  - ODP.NET for .NET Framework 4 is only supported with Microsoft .NET Framework 4.7.2 and higher.
- Access to Oracle Database 19c or later
- Oracle Client release 26ai

This is automatically installed as part of the ODP.NET installation.

Promotable and distributed transactions may require Oracle Services for Microsoft Transaction Server in whole or in part. Refer to the [Distributed Transactions](#) section for more information.

Oracle Data Provider for .NET, Managed Driver requires the following:

- Same Windows operating system support as ODP.NET, Unmanaged Driver.  
ODP.NET, Managed Driver only runs on 64-bit .NET Framework and 64-bit (x64) Windows.
- Microsoft .NET Framework 4.7.2 and higher.
- Access to Oracle Database 19c or later

ODP.NET Core requires the following:

- Operating systems:
  - Same Windows operating system support as managed and unmanaged ODP.NET
  - Oracle Linux 9.2 or higher
  - Oracle Linux 8.6 or higher
  - Red Hat Enterprise Linux 9.2 or higher
  - Red Hat Enterprise Linux 8.6 or higher
  - 64-bit Ubuntu 22.04.1 LTS 5.15.0-1016 or higher
  - 64-bit Debian GNU/Linux 11 (bullseye) 5.10.120-1 or higher
  - Alpine Linux: 3.20.3 or higher
  - macOS (ARM64) 14.7 or higher
- Microsoft .NET
  - ODP.NET Core supports .NET 8.  
ODP.NET Core 23.6.1 and higher supports .NET 9.
- Access to Oracle Database 19c or later

ODP.NET Core is compatible with ASP.NET Core.

ODP.NET Core supports only 64-bit .NET.

## Entity Framework Requirements

This section contains the following topics:

- [Entity Framework Database First and Model First Requirements](#)
- [Entity Framework Code First Requirements](#)

### Entity Framework Database First and Model First Requirements

Oracle's support for Entity Framework Database First and Model First has the following version requirement:

- Microsoft Entity Framework 6.5.1
- Microsoft .NET Framework 4.8.x
- ODP.NET, Managed Driver

If using Visual Studio tools, then install Oracle Developer Tools for Visual Studio.

### Entity Framework Code First Requirements

Oracle's support for Entity Framework Code First has the following version requirements:

- Microsoft Entity Framework 6.5.1
- Microsoft .NET Framework 4.8.x

Projects must set the target framework to a supported .NET Framework version. This can be done by modifying the project's properties in Visual Studio.

- ODP.NET, Managed Driver

## Entity Framework Core System Requirements

ODP.NET Entity Framework Core (EF Core) has the same system requirements as ODP.NET Core. In addition, ODP.NET EF Core has the following dependencies:

- ODP.NET Core
- Entity Framework Core 8 and 9. Oracle Entity Framework Core 23.6 and higher supports Entity Framework 9.
- `Microsoft.EntityFrameworkCore.Relational`

## Oracle Data Provider for .NET Versioning Scheme

Oracle Data Provider for .NET, Unmanaged Driver; ODP.NET, Managed Driver; and ODP.NET Core each ship with their own set of binaries.

For example, 26ai binaries would be the following:

- Unmanaged ODP.NET for .NET Framework 4
  - `Oracle.DataAccess.dll`
    - \* Built with .NET Framework 4
    - \* Assembly version number: 4.122.23.1
  - `OraOps.dll` and Oracle Client
    - \* Used by ODP.NET for .NET Framework
- Managed ODP.NET for .NET Framework 4:
  - `Oracle.ManagedDataAccess.dll`
    - \* Built with .NET Framework 4
    - \* Assembly version number: 4.122.23.1
- ODP.NET Core:
  - `Oracle.ManagedDataAccess.dll`
    - \* Built with .NET (Core) version
    - \* Assembly version number: 23.1.0.0

The convention for managed and unmanaged ODP.NET assembly/DLL product versioning is *n1.o1o2.o3.o4:o5*

where

- *n1* is the most significant .NET Framework version number.
- *o1o2* once represented the first two digits of the ODP.NET 12.2 version number. It remains "122" as modifying this version would not allow in place ODP.NET upgrades without an application rebuild.
- *o3* is the first digit of the ODP.NET product version number.
- *o4* indicates whether the release is a production version (1) or beta/pre-release version (0).
- *o5* is the ODP.NET assembly build date.

For example, if the ODP.NET version number is 23.4, the corresponding managed and unmanaged ODP.NET assembly product version is 4.122.23.1:20240502.

For ODP.NET Core, the assembly product version convention is:

*n1.n2.o1.o2:o3*

- *n1* is the first digit of the ODP.NET product version number.
- *n2* indicates whether the release is a production version (1) or beta/pre-release version (0).
- *o1* is currently unused.
- *o2* is currently unused.

- o3 is the ODP.NET assembly build date.

For example, if the ODP.NET Core version number is 23.4, the corresponding assembly product version is 23.1.0.0.20240502.

The ODP.NET *assembly* version is distinct from the *assembly product* version. The *assembly* version uses four sets of digits and the *assembly product* version uses five sets of digits. For each ODP.NET release, the first four sets of digits of the assembly version and the assembly product version will be the same. For example, if the ODP.NET Core assembly product version is 23.1.0.0.20240502, then its assembly version is 23.1.0.0. In the case of managed and unmanaged ODP.NET 4.122.23.1:20240502, the assembly version is 4.122.23.1.

The assembly product version identifies the precise ODP.NET version used. Since there are multiple updates Oracle ships within a major release family, you would provide the ODP.NET assembly product version in a support context.

The assembly version is used in more .NET-specific contexts. For example, the <version> section of the .NET configuration file uses the four digit assembly version to identify which ODP.NET version to use.

The assembly product version number can be found in the ODP.NET DLL "Product version" property on Windows. The assembly version can be found in the ODP.NET DLL "File version" property on Windows.

Note that the Oracle installer and documentation still refer to the ODP.NET product version number and not the assembly/DLL version number.

Publisher Policy DLL is provided as before so that applications built with older versions of ODP.NET are redirected to the newer ODP.NET assembly, even though the versioning scheme has changed.

### ODP.NET, Managed Driver Versioning

ODP.NET, Managed Driver uses assembly manifest attribute `AssemblyInformationalVersionAttribute` to uniquely identify assemblies with the same `AssemblyVersionAttribute` attribute value. This value can be accessed via .NET code, PowerShell, and other Windows applications to identify ODP.NET, Managed Driver versions uniquely.

`AssemblyInformationalVersionAttribute` is set to the same version as the actual .NET assembly version.

This value is accessible using .NET Framework `System.Diagnostics.FileVersionInfo.ProductVersion` property. The returned value can be used as a `Version` object or as a comparison String using comparison operators or methods. Essentially, among a collection of ODP.NET, Managed Driver assemblies that have the same assembly version, the newest ODP.NET, Managed Driver assembly will have the largest fourth digit `ProductVersion` value than an older assembly.

**PowerShell Example:** In this example, administrators uniquely distinguish the assemblies between ODP.NET, Managed Driver versions from an old version of ODP.NET, Managed Driver in `c:\old` and a more recent one in `c:\new`.

Script:

```
$VC1 = New-Object System.Version((Get-Command
C:\old\Oracle.ManagedDataAccess.dll).FileVersionInfo.ProductVersion)
$VC2 = New-Object System.Version((Get-Command
C:\new\Oracle.ManagedDataAccess.dll).FileVersionInfo.ProductVersion)
"Compare V1 to V2: " + $VC1.CompareTo($VC2)
```

```
"Compare V1 to V1: " + $VC1.CompareTo($VC1)
"Compare V2 to V1: " + $VC2.CompareTo($VC1)
```

Output:

```
Compare V1 to V2: -1
Compare V1 to V1: 0
Compare V2 to V1: 1
```

#### Note

ProductVersion property comparisons will provide correct information on which version is more recent than the other *only* for ODP.NET, Managed Driver.

## Installing Oracle Data Provider for .NET, Unmanaged Driver

Oracle Data Provider for .NET, Unmanaged Driver can be installed through Oracle AI Database software, a Microsoft installer (MSI), or XCopy. One example of an MSI is Oracle Client for Microsoft Tools. Xcopy is a command-line Oracle Data Access Components (ODAC) software installation. Unmanaged ODP.NET software is available from Oracle's website for download. This section provides details on unmanaged ODP.NET installation.

Administrators use XCopy to deploy Oracle Data Provider for .NET to large numbers of computers for production deployments. The XCopy has a smaller installation size and fine-grain control during installation and configuration than Oracle Universal Installer.

#### Note

This section describes non-ODAC installation using the Oracle Universal Installer for database server or client. For installation and configuration using the XCopy install, refer to the README.TXT file that is part of the XCopy installation.

Additionally, Oracle Data Provider for .NET Dynamic Help is registered with Visual Studio, providing context-sensitive online help that is seamlessly integrated with Visual Studio Dynamic Help. With Dynamic Help, the user can access ODP.NET documentation within the Visual Studio IDE by placing the cursor on an ODP.NET keyword and pressing the F1 function key.

## File Locations After Installation

The Oracle.DataAccess.dll assembly is installed to the following location:

.NET Framework 4:

`ORACLE_HOME\odp.net\bin\4` directory

## Search Order for Unmanaged DLLs

Unmanaged ODP.NET consists of managed and unmanaged binaries. Through the use of the `DllPath` configuration parameter, each application can specify the `ORACLE_HOME\bin` location that the dependent unmanaged Oracle Client binaries are loaded from. However, the `ORACLE_HOME` must have the same unmanaged ODP.NET version installed as the version that the application uses. Otherwise, a version mismatch exception is thrown.

The `Oracle.DataAccess.dll` searches for dependent unmanaged DLLs (such as Oracle Client) based on the following order:

1. Directory of the application or executable.
2. `DllPath` setting specified by application config or `web.config`.
3. `DllPath` setting specified by `machine.config`.
4. `DllPath` setting specified by the Windows Registry.  
`HKEY_LOCAL_MACHINE\Software\Oracle\ODP.NET\version\DllPath`
5. Directories specified by the Windows PATH environment variable.

Upon installation of unmanaged ODP.NET, Oracle Universal Installer sets the `DllPath` Windows Registry value to the `ORACLE_HOME\bin` directory where the corresponding dependent DLLs are installed. Developers must provide this configuration information on an application-by-application basis.

### Note

`Oracle.DataAccess.dll` uses the unmanaged DLL, `OraOpsXX.dll`, where the `XX` is replaced by the version number.

## Unmanaged ODP.NET and Dependent Unmanaged DLL Mismatch

To enforce the usage of `Oracle.DataAccess.dll` assembly with the correct version of its unmanaged DLLs, an exception is raised if `Oracle.DataAccess.dll` notices it has loaded a mismatched version of a dependent unmanaged DLL.

## Installing Oracle Data Provider for .NET, Managed Driver

### Getting started with ODP.NET, Managed Driver

Get started with ODP.NET, Managed Driver by either using NuGet or a Windows Installer.

**If you are using NuGet:** Download the ODP.NET NuGet package and use NuGet Package Manager to install.

**If you are using Windows Installer:** Follow the VSIX or Microsoft Windows Installer (MSI) steps to install ODP.NET, Managed Driver.

### ODP.NET, Managed Driver Files

ODP.NET, Managed Driver consists of the following files:

**Table 2-1 ODP.NET, Managed Driver Files with Descriptions**

| File                                                      | Description                                                                                            |
|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Oracle.ManagedDataAccess.dll                              | Platform-independent (AnyCPU), fully-managed ADO.NET provider                                          |
| \Resources\<lang>\Oracle.ManagedDataAccess.resources.dll  | Platform-independent (AnyCPU), fully-managed ADO.NET provider resource DLLs.                           |
| OraProvCfg.exe                                            | Platform-independent (AnyCPU) utility to configure/unconfigure ODP.NET, Managed and Unmanaged Drivers. |
| configure.bat                                             | Batch file to add managed ODP.NET Windows Registry entries.                                            |
| unconfigure.bat                                           | Batch file to remove managed ODP.NET Windows Registry entries.                                         |
| tnsnames.ora                                              | A sample configuration file that defines data source aliases.                                          |
| sqlnet.ora                                                | A sample configuration file that configures network related settings.                                  |
| Oracle.ManagedDataAccess.Client.Configuration.Section.xsd | An XML schema file that defines the configuration section for ODP.NET, Managed Driver.                 |
| Oracle.ManagedDataAccess.EntityFramework.dll              | Platform-independent (AnyCPU), fully-managed assembly for Code First and Entity Framework 6 higher     |
| \x64\Oracle.ManagedDataAccessIOP.dll                      | Platform-dependent (64-bit .NET Framework), Managed Assembly for MIT Kerberos support                  |

The OraProvCfg.exe utility can perform many different configuration tasks, such as GACing ODP.NET or configuring ODP.NET in the machine.config file. To learn about how to use this utility, run oraprovcfg.exe on the command line without any parameters, which will output the documentation.

### See Also

*Oracle AI Database Installation Guide for Microsoft Windows* for installation instructions

## Platform-Dependent Assemblies and Their Search Order

ODP.NET, Managed Driver has one platform-dependent DLL: Oracle.ManagedDataAccessIOP.dll, which is 64-bit. While it consists of 100% managed code, it calls APIs outside of .NET, which is why it is platform dependent.

Oracle.ManagedDataAccessIOP.dll supports MIT Kerberos. The assembly is only needed in your application if you are using MIT Kerberos.

The assembly is not intended to be directly referenced by an application. Rather, it is referenced implicitly. ODP.NET, Managed Driver references the assembly by using the following search order:

1. Global Assembly Cache

2. The web application's bin directory or Windows application's EXE directory
3. The DLL's default install location. Oracle recommends using this method of finding dependent assemblies if your application is AnyCPU.

For example, use the following steps for your application to use `Oracle.ManagedDataAccessIOP.dll`:

1. Right click **Visual Studio project**, select **Add**, and then select **New Folder**.
2. Name the folder `x64`.
3. Right-click the newly created **x64** folder, select **Add**, and then select **Existing Item**.
4. Browse to the folder where the DLL is located, which usually is `ORACLE_HOME\odp.net\managed\x64`, and then select **Oracle.ManagedDataAccessIOP.dll**.
5. Click **Add**.
6. Click the newly added **Oracle.ManagedDataAccessIOP.dll** in the `x64` folder.
7. In the properties window, set **Copy To Output Directory** to **Copy Always**.

For x86 targeted applications, name the folder `x86` and add the assembly from the `x86` directory.

To make your application platform independent even if it depends on `Oracle.ManagedDataAccessIOP.dll` create both `x64` and `x86` folders with the necessary assemblies added to them.

## File Locations After Installation

In an Oracle Universal Installer based install, the `Oracle.ManagedDataAccess.dll` assembly is installed to the following location:

.NET Framework 4:

`ORACLE_HOME\ODP.NET\nuget` directory

Managed ODP.NET is embedded within the `Oracle.ManagedDataAccess.<version>.nupkg` file. This file is a NuGet package. ODP.NET users can install this package using common Microsoft tools, such as NuGet Package Manager and Visual Studio.

When Oracle Developer Tools for Visual Studio is installed, Oracle documentation is installed in Visual Studio itself.

Samples are provided in GitHub:

<https://github.com/oracle/dotnet-db-samples>

## Installing Oracle Data Provider for .NET Core

### Getting started with ODP.NET Core

Get started with ODP.NET Core on Windows by using NuGet, Windows Installer, or Oracle Universal Installer (OUI). Only NuGet can be used to install ODP.NET Core on non-Windows operating systems.

**If you are using NuGet:** Download the ODP.NET Core NuGet package and use NuGet Package Manager to install.

**If you are using Windows Installer:** Follow the Microsoft Windows Installer (MSI) steps. This installer will copy the ODP.NET Core NuGet package to the machine.

**If you are using OUI:** Follow the OUI steps to install ODP.NET Core. OUI will copy the ODP.NET Core NuGet package to the machine.

### ODP.NET Core Files

ODP.NET Core consists of the following files:

**Table 2-2 ODP.NET, Core Files with Descriptions**

| File                                      | Description                                                                                 |
|-------------------------------------------|---------------------------------------------------------------------------------------------|
| <code>Oracle.ManagedDataAccess.dll</code> | Platform-independent (AnyCPU), operating system independent, fully-managed ADO.NET provider |

### File Locations After Installation

In an Oracle Universal Installer based install, the ODP.NET Core package is installed to the following directory:

`%ORACLE_HOME%\ODP.NET\nuget`

ODP.NET Core is embedded within the `Oracle.ManagedDataAccess.Core.<version>.nupkg` file. This file is a NuGet package. ODP.NET users can install this package using common Microsoft tools, such as NuGet Package Manager and Visual Studio."

Samples are provided on our ODP.NET GitHub site:

<https://github.com/oracle/dotnet-db-samples>

## Entity Framework Assemblies and File Location

ODP.NET ships with a separate assembly to support Code First and Entity Framework 6. This model physically separates Entity Framework 6 functionality from ADO.NET functionality.

The managed ODP.NET assembly is `Oracle.ManagedDataAccess.EntityFramework.dll`.

Unmanaged ODP.NET discontinued Entity Framework support starting with ODP.NET 21c. Unmanaged ODP.NET EF apps should migrate to managed ODP.NET.

When installed using the XCopy package, the Oracle Entity Framework assembly is found in the following location after install:

`%ORACLE_HOME%\odp.net4\odp.net\managed\common\EF6`

where `%ORACLE_HOME%` represents the operating system path to the installation directory.

The assembly is fully managed code and is designed to be bin deployable meaning that the assembly should be copied into the application's `bin` directory. As such the assembly is not registered in the Global Assembly Cache (GAC) during installation.

In Oracle Universal Installer, the Oracle Entity Framework (Core) assemblies are now NuGet packages located in:

`%ORACLE_HOME%\ODP.NET\nuget`

In that location, you will find managed ODP.NET Entity Framework 6 and ODP.NET Entity Framework Core NuGet packages. ODP.NET users can install these packages using common Microsoft tools, such as NuGet Package Manager and Visual Studio.

**Note**

If desired the Oracle Entity Framework 6 assemblies may be registered in the GAC manually but Oracle recommends not doing so.

## Configuring Oracle Data Provider for .NET

The settings for specific versions of ODP.NET, can be configured in several ways for specific effects on precedence:

- The Windows registry entries are machine-wide settings for a particular version of ODP.NET.  
Windows registry based configuration is not supported for ODP.NET, Managed Driver nor ODP.NET Core.
- The machine.config settings are .NET framework-wide settings that override the Windows registry values.
- The application or web config file settings are application-specific settings that override the machine.config settings and the Windows registry settings.

**Note**

There is one exception to app/web/config settings overriding machine.config. For `oracle.manageddataaccess.client` and `oracle.unmanageddataaccess.client` sections, a machine.config with a specific ODP.NET version subsection, that is, `<version number="4.121.2.0">`, will override an app/web.config subsection that references all versions generically, that is, `<version number="*">`. To override the machine.config subsection, create a subsection for that version in the app/web/config file, that is, `<version number="4.121.2.0">`.

- Any attribute settings made in the ODP.NET application code override everything else.

The application or web config file can be useful and sometimes essential in scenarios where more than one application on a computer use the same version of ODP.NET, but each application needs a different ODP.NET configuration. The Windows registry value settings for a given version of ODP.NET affect all the applications that use that version of ODP.NET. However, having ODP.NET configuration values in the application or web config file assure that these settings are applied only for that application, thus providing more granularities.

For example, if the application or web.config file has a `StatementCacheSize` configuration setting of 100, this application-specific setting forces the version of ODP.NET that is loaded by that application to use 100 for the `StatementCacheSize` and overrides any setting in the machine.config and in the registry. Note that for any setting that does not exist in a config file (machine.config or application/web config), the value in the registry for a loaded version of ODP.NET is used, as in previous releases.

Note that ODP.NET reads the `machine.config` files from the version of the .NET Framework on which ODP.NET runs, not from the version of ODP.NET.

ODP.NET only reads the Windows Registry and the XML configuration file when it is loaded into memory, thus any configuration changes made after that are not read or used until the application is re-started.

All boolean attributes in ODP.NET .NET configuration settings accept `true`, `false`, `1`, and `0` as valid values. `1` is equivalent to `true` and `0` is equivalent to `false`.

#### ① Note

ODP.NET Core does not support the Windows registry nor .NET configuration files. ODP.NET Core configuration can be set using .NET Configuration API, `sqlnet.ora` file, and `tnsnames.ora` file.

## Oracle Client Configuration File Automated Setup During Installation

When installing Oracle Data Access Components (ODAC) in a new Oracle Home, Oracle Universal Installer (OUI) automatically copies the Oracle local naming (`tnsnames.ora`), profile (`sqlnet.ora`), and directory (`ldap.ora`) parameter files and settings from an existing Oracle home into the newly installed ODAC home, as long as they share the same bitness. That is, they are both 32-bit installations or they are both 64-bit installations.

Alternatively, existing `*.ora` files can be copied over from another existing Oracle home, besides the last active one, to the new ODAC Oracle home. OUI provides location information for these files from up to three other existing Oracle homes if they exist. The `*.ora` files can be customized if the new Oracle home uses a different configuration from the previous Oracle home from which the files were copied over.

If you install into an existing ODAC or RDBMS Oracle home, then no new `*.ora` files is copied or created.

If you install onto a computer without any previous Oracle homes present, then OUI prompts the user for the database connection alias information. OUI then automatically creates the `tnsnames.ora` file. If no alias information is provided, then no `tnsnames.ora` file is created. Even if the user does not have all the database connection information readily available, Oracle recommends inserting placeholder values during the install process, then modifying the `tnsnames.ora` file later with actual values to replace the placeholders.

## Oracle Client Configuration File Settings

ODP.NET configuration file parameter values can be set in .NET configuration, `tnsnames.ora`, `sqlnet.ora`, and `ldap.ora` files. The `*.ora` file location can be a location different from the standard `ORACLE_HOME/network/admin` directory. The `*.ora` settings order of precedence is similar to ODP.NET's settings order of precedence. The main difference is that the `*.ora` files themselves are included in the search order. The ODP.NET connection configuration precedence order is as follows.

Managed ODP.NET:

1. `OracleConfiguration.OracleDataSources`
2. `<dataSources>` in .NET configuration file
3. Directory set in `OracleConnection.TnsAdmin` property

4. Directory set for the Tns\_Admin (connection string attribute) or tns\_admin setting (connection string URL or centralized configuration file connection string).
5. Directory set in OracleConfiguration.TnsAdmin property
6. TNS\_ADMIN directory setting in .NET configuration file
7. Current working directory
8. TNS\_ADMIN directory setting of the Windows environment variable or container environment variable
9. Directory set in the Windows Registry key, HKLM\SOFTWARE\Oracle\ODP.NET.Managed\<version>\TNS\_ADMIN for 64-bit apps

**Note**

32-bit apps use the Registry key  
HKLM\SOFTWARE\Wow6432Node\Oracle\ODP.NET.Managed\<version>\TNS\_ADMIN

10. %ORACLE\_HOME%\network\admin directory

Unmanaged ODP.NET:

1. <dataSources> and <settings> in .NET configuration file
2. Current working directory
3. TNS\_ADMIN directory setting of the Windows environment variable or container environment variable
4. TNS\_ADMIN Windows Registry setting (HKLM\SOFTWARE\ORACLE\KEY\_<Oracle Version>HOME<#>\)
5. %ORACLE\_HOME%\network\admin directory

The managed ODP.NET ldap.ora precedence order is as follows:

1. <LDAPsettings> and <settings> in .NET configuration file
2. Directory set in OracleConnection.TnsAdmin property
3. Directory set for the Tns\_Admin connection string attribute
4. Directory set in OracleConfiguration.TnsAdmin property
5. Directory set in OracleConfiguration.LdapAdmin property
6. TNS\_ADMIN directory setting in .NET configuration file
7. LDAP\_ADMIN directory setting in .NET configuration file
8. Current working directory
9. TNS\_ADMIN directory setting in the Windows environment variable
10. LDAP\_ADMIN directory setting in the Windows environment variable

The unmanaged ODP.NET ldap.ora precedence order is as follows:

1. LDAP\_ADMIN directory setting in the Windows environment variable
2. %ORACLE\_HOME%\ldap\admin directory
3. TNS\_ADMIN directory setting in the Windows environment variable
4. %ORACLE\_HOME%\network\admin directory

Oracle recommends using an `app.config` or `web.config` file to store all these Oracle Client configuration parameter settings.

Once the first `tnsnames.ora`, `sqlnet.ora`, and `ldap.ora` are found and read, no additional `*.ora` file lower in the precedence order is read. That means all Oracle Client configuration settings must be made in the `app.config`, `web.config`, `machine.config`, or the first set of `*.ora` files found. Additional parameter values set in `*.ora` files lower in the precedence order will not be read.

## Configuring .NET Framework to Use ODP.NET

Automatic ODP.NET machine-wide configuration upon installation is no longer available as of ODAC 18c. This change improves compatibility when applications on the same machine use different ODP.NET versions and/or depend on application-specific configuration settings instead of machine-wide assembly registration and configuration.

Nonetheless, administrators can still manually place managed and unmanaged ODP.NET in the Global Assembly Cache (GAC), as well as add configurations for section handler, `DbProviderFactories`, `TNS_ADMIN`, `LDAP_ADMIN`, and assembly redirection (in place of policy DLLs), into `machine.config`, if desired.

Most ODP.NET settings in `machine.config` can be overridden by local settings in `app.config` or `web.config`. However, conflicts between the `machine.config` and, `app.config` or `web.config` can prevent applications from running properly. Care should be taken when configuring ODP.NET at both the `machine.config` level and application level using `app.config` or `web.config`.

To avoid such issues, Oracle recommends ODP.NET application configuration settings reside in the `app.config` or `web.config`. The following sections explore how to set up these ODP.NET configuration sections and provide sample configuration sections and files.

### Configuration Section Handler

In order for the application to read the ODP.NET configuration section, a section handler must be configured. The following entry should be added to the .NET configuration file to enable applications to add an `oracle.manageddataaccess.client` section for ODP.NET, Managed Driver-specific configuration:

```
<configuration>
  <configSections>
    <section name="oracle.manageddataaccess.client"
type="OracleInternal.Common.ODPMSectionHandler, Oracle.ManagedDataAccess,
Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
  </configSections>
</configuration>
```

#### Note

In all the examples in this section, the version of the ODP.NET assembly is understood to be 4.122.19.1. This version number should be modified appropriately if you are using another version.

The unmanaged ODP.NET equivalent section handler is as follows:

```
<configuration>
  <configSections>
```

```

    <section name="oracle.unmanageddataaccess.client"
type="OracleInternal.Common.CustomSectionHandler, Oracle.DataAccess, Version=4.122.19.1,
Culture=neutral, PublicKeyToken=89b483f429c47342" />
  </configSections>
</configuration>

```

One of the configuration entries that either has to match between machine.config and, app.config or web.config, or only exist in the app.config or web.config to avoid any conflict is the configuration for the section handler. For example, if your application is a web application and the above entry was added to a web.config and the same configuration section handler for oracle.manageddataaccess.client also exists in machine.config but the Version attribute values are different, an error message of "There is a duplicate oracle.manageddataaccess.client section defined." may be observed at runtime. To avoid this issue, the configuration section handler entry in the machine.config for oracle.manageddataaccess.client has to be removed from the machine.config or the ODP.NET config section handler entry in machine.config and web.config has to match exactly. If there are other applications on the machine that depend on this entry in the machine.config, then this section handler entry will need to be moved to all local applications' .NET configuration files.

### DbProviderFactories

The following entry should be added in the app.config or web.config for applications that use DbProviderFactories and DbProviderFactory classes. Also, any DbProviderFactories entry for Oracle.ManagedDataAccess.Client in the machine.config will be ignored due to the <remove> entry:

```

<configuration>
  <system.data>
    <DbProviderFactories>
      <remove invariant="Oracle.ManagedDataAccess.Client" />
      <add name="ODP.NET, Managed Driver" invariant="Oracle.ManagedDataAccess.Client"
description="Oracle Data Provider for .NET, Managed Driver"
type="Oracle.ManagedDataAccess.Client.OracleClientFactory, Oracle.ManagedDataAccess,
Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    </DbProviderFactories>
  </system.data>
</configuration>

```

The equivalent for unmanaged ODP.NET is as follows:

```

<configuration>
  <system.data>
    <DbProviderFactories>
      <remove invariant="Oracle.DataAccess.Client" />
      <add name="Oracle Data Provider for .NET" invariant="Oracle.DataAccess.Client"
description="Oracle Data Provider for .NET"
type="Oracle.DataAccess.Client.OracleClientFactory, Oracle.DataAccess,
Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    </DbProviderFactories>
  </system.data>
</configuration>

```

### Dependent Assembly

For users accustomed to the policy DLLs that were registered automatically upon installation, the same can be accomplished through configuration. The following is an example configuration that redirects the application that depends on 4.122 version of ODP.NET and higher to be redirected to use ODP.NET 4.122.19.1. Note that in this example, an entry is added to ignore policy ODP.NET DLLs that are registered in the GAC:

```
<configuration>
  <runtime>
    <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
      <dependentAssembly>
        <publisherPolicy apply="no" />
        <assemblyIdentity name="Oracle.ManagedDataAccess"
publicKeyToken="89b483f429c47342" culture="neutral" />
        <bindingRedirect oldVersion="4.122.0.0 - 4.65535.65535.65535"
newVersion="4.122.19.1" />
      </dependentAssembly>
    </assemblyBinding>
  </runtime>
</configuration>
```

The equivalent for unmanaged ODP.NET is as follows:

```
<configuration>
  <runtime>
    <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
      <dependentAssembly>
        <publisherPolicy apply="no" />
        <assemblyIdentity name="Oracle.DataAccess" publicKeyToken="89b483f429c47342"
culture="neutral" />
        <bindingRedirect oldVersion="4.122.0.0 - 4.65535.65535.65535"
newVersion="4.122.19.1" />
      </dependentAssembly>
    </assemblyBinding>
  </runtime>
</configuration>
```

The final .NET configuration section that includes a configuration section handler, DbProviderFactories, dependent assembly, and provider configuration would look similar to the following example:

```
<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <configSections>
    <section name="oracle.manageddataaccess.client"
      type="OracleInternal.Common.ODPMSectionHandler, Oracle.ManagedDataAccess,
Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342"/>
    </configSections>
  <startup>
    <supportedRuntime version="v4.0" sku=".NETFramework,Version=v4.7.1"/>
  </startup>
  <system.data>
    <DbProviderFactories>
      <remove invariant="Oracle.ManagedDataAccess.Client"/>
      <add name="ODP.NET, Managed Driver"
invariant="Oracle.ManagedDataAccess.Client" description="Oracle Data Provider for .NET,
Managed Driver"
type="Oracle.ManagedDataAccess.Client.OracleClientFactory, Oracle.ManagedDataAccess,
Version=4.122.19.1, Culture=neutral, PublicKeyToken=89b483f429c47342"/>
    </DbProviderFactories>
  </system.data>
  <runtime>
    <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
      <dependentAssembly>
        <publisherPolicy apply="no"/>
        <assemblyIdentity name="Oracle.ManagedDataAccess"
publicKeyToken="89b483f429c47342" culture="neutral"/>
        <bindingRedirect oldVersion="4.121.0.0 - 4.65535.65535.65535"
newVersion="4.122.19.1" />
      </dependentAssembly>
    </assemblyBinding>
  </runtime>
</configuration>
```

```

newVersion="4.122.19.1"/>
    </dependentAssembly>
    </assemblyBinding>
</runtime>
<oracle.manageddataaccess.client>
    <version number="*">
        <dataSources>
            <dataSource alias="SampleDataSource"
descriptor="(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=localhost)(PORT=1521))
(CONNECT_DATA=(SERVICE_NAME=ORCL)))" />
        </dataSources>
    </version>
</oracle.manageddataaccess.client>
</configuration>

```

## ODP.NET Intellisense for .NET Configuration Files

When installing ODP.NET from a non-ODAC release, such as from a database server installation, Intellisense for ODP.NET configuration files is not enabled by default as it is with ODAC-based GUI installations. .xsd files are included in the ORACLE\_HOME\odp.net\managed\common directory to enable developers to modify the .NET configuration file using IntelliSense. For Visual Studio to leverage the supplied .xsd files, do the following:

1. Open the .NET config file (i.e. app.config, web.config, or machine.config) within Visual Studio.
2. Within Visual Studio, navigate to **XML**, and then **Schemas**.
3. Enable the check mark under the **Use** column for:
  - Oracle.ManagedDataAccess.Client.Configuration.Section.xsd for managed ODP.NET and
  - Oracle.UnmanagedDataAccess.Client.Configuration.Section.xsd for unmanaged ODP.NET, respectively.

## Oracle Data Provider for .NET, Unmanaged Driver Configuration

The following sections explain how to configure ODP.NET, Unmanaged Driver.

ODP.NET can be configured using an XML file named web.config, app.config, or machine.config. These config files contain sections specific to ODP.NET configuration.

For unmanaged ODP.NET, developers use either the traditional <oracle.dataaccess.client> section or the newer <oracle.unmanageddataaccess.client> section. Oracle recommends applications use <oracle.unmanageddataaccess.client> when possible. For managed ODP.NET, developers use <oracle.manageddataaccess.client>.

<oracle.unmanageddataaccess.client> is a superset of <oracle.manageddataaccess.client> as unmanaged ODP.NET supports some features not available in the managed driver. For features both providers have in common, they share the same structure, properties, and nearly all values. Programmers will find using either provider interchangeably or migrating between unmanaged and managed ODP.NET is easier with the shared format.

This documentation section covers unmanaged ODP.NET configuration settings in the Windows registry, <oracle.dataaccess.client>, or unique

<oracle.unmanageddataaccess.client> settings. For shared settings with <oracle.manageddataaccess.client>.

**See Also**

[Oracle Data Provider for .NET, Managed Driver Configuration](#)

## Supported Configuration Settings

ODP.NET, Unmanaged Driver supports the configuration of an attribute as follows:

- In the Windows registry.
- In an XML file.
- Through a different mechanism such as a connection string or programmatically through an ODP.NET class, if applicable.

[Table 2-3](#) describes each configurable attribute that is supported by ODP.NET. In the table, the term Configuration Support is followed by the types of configuration support (Windows registry, XML file, and so on) that are available for that attribute.

The table describes valid values as well as the default for each attribute.

**Note**

The default values shown are the values used for an attribute if the registry key does not exist or if it is not configured anywhere.

**Table 2-3 Configuration Attributes**

| Attribute/Setting Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CheckConStatus         | <p>Specifies whether the status of the connection is checked or not before putting the connection back into the connection pool. This registry entry is not created by the installation of ODP.NET. However, the default value 1 is used.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:</p> <p>1: Check the status of the connection.<br/>0: Do not check the status of the connection.</p> <p>Default: 1</p> |

Table 2-3 (Cont.) Configuration Attributes

| Attribute/Setting Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DbNotificationPort     | <p>Specifies the port number which ODP.NET listens to, for all notifications sent by the database for change notification, HA, or RLB features. ODP.NET does not throw any errors if an invalid or used port number is specified. The port can also be set to override the Windows registry and XML configuration file by setting the <code>OracleDependency.Port</code> static field.</p> <p>Configuration Support:<br/>XML file, and ODP.NET class</p> <p>Valid Values:<br/>-1: Open a random unused port to listen to.<br/><math>n \geq 0</math>: Listen on port <math>n</math>.<br/>Default: -1</p> |
| DemandOraclePermission | <p>Specifies whether ODP.NET demands <code>OraclePermission</code> from the .NET application that is trying to access the database using ODP.NET.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:<br/>0: Disables demands for <code>OraclePermission</code>.<br/>1: Enables demands for <code>OraclePermission</code><br/>Default: 0</p>                                                                                                                                                                                                                           |

| LegacyEntireLobFetch             | <p>Returns either <code>OracleBlob</code> and <code>OracleClob</code> types or <code>OracleBinary</code> and <code>OracleString</code> types from Oracle Database BLOB and CLOB columns. This setting only applies when <code>InitialLobFetchSize</code> is set to -1.</p> <p>Valid Values:</p> <p>0: Returns <code>OracleBlob</code> and <code>OracleClob</code></p> <p>1: Returns <code>OracleBinary</code> and <code>OracleString</code></p> <p>Default: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| LegacyTransactionBindingBehavior | <p>Specifies when a database connection detaches from a <code>System.Transactions</code> transaction. By default, connections detach from a transaction only when explicitly unbound as is the case when the connection closes or implicitly unbound when the transaction is disposed. Alternatively, this attribute can be set so that the connection detaches whenever the transaction ends (commits, aborts, or times out), the connection closes, or the transaction is disposed.</p> <p>In ODP.NET 11.2.0.3.20 and earlier releases, the latter was the default behavior. Oracle recommends using the current default behavior.</p> <p>In the earlier default behavior, when the timeout elapses before the transaction completes, the connection unbinds itself from the transaction and all subsequent executions on this connection execute in <code>AutoCommit</code> mode. Any operations prior to the timeout roll back, but operations performed after the timeout commit.</p> <p>In the current default setting, users receive an exception when the transaction times out and additional operations execute on the connection.</p> <p>Configuration Support:</p> <p>Windows Registry and XML file</p> <p>Valid Values:</p> <p>0: Connections detach from transaction when the connection closes or the transaction is disposed.</p> <p>1: Connections detach from transaction when the connection closes, the transaction is disposed, or the transaction completes (commits, rolls back, times out).</p> <p>Default: 0</p> |
| MaxStatementCacheSize            | <p>Specifies the maximum number of statements that can be cached when self-tuning is enabled.</p> <p>Configuration Support:</p> <p>Windows Registry and XML file</p> <p>Valid Values:</p> <p>0 to <code>System.Int32.MaxValue</code>.</p> <p>Default: <code>OPEN_CURSORS</code> setting value of the database</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 2-3 (Cont.) Configuration Attributes

| MetaDataXml            | <p>Specifies the name of the XML file that customizes the queries to obtain the metadata the ADO.NET 2.0 GetSchema method returns. MetaDataXml can only be set in a configuration file.</p> <p>Configuration Support:<br/>XML file only</p> <p>Valid Values:<br/>A complete file name for the XML file.</p> <p>Default: <i>none</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PerformanceCounters    | <p>Enables or disables publishing performance counters for connection pooling. Multiple performance counters can be obtained by adding the valid values.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:<br/>0: Not Enabled</p> <p>1: Number of sessions being established with Oracle Database every second.</p> <p>2: Number of sessions being severed from Oracle Database every second.</p> <p>4: Number of active connections originating from connection pools every second.</p> <p>8: Number of active connections going back to the connection pool every second.</p> <p>16: Total number of active connections.</p> <p>32: Number of inactive connection pools.</p> <p>64: Total number of connections in use.</p> <p>128: Total number of connections available for use in all the connection pools.</p> <p>256: Total number of pooled active and free connections.</p> <p>512: Number of non-pooled active connections</p> <p>1024: Number of connections which were garbage-collected implicitly.</p> <p>2048: Number of connections that will be soon available in the pool. User has closed these connections, but they are currently awaiting actions, such transaction completion, before they can be placed back into the pool as free connections.</p> <p>4095: All the above</p> <p>Default: 0</p> |

Table 2-3 (Cont.) Configuration Attributes

| Attribute/Setting Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SelfTuning             | <p>Specifies whether self-tuning is enabled for an ODP.NET application.</p> <p>Configuration Support:<br/>Windows Registry, XML file, and Self Tuning connection string attribute</p> <p>Valid Values:</p> <p>0: Self Tuning is disabled. Used in the registry or XML file.</p> <p>false: Self Tuning is disabled. Used for the Self Tuning connection string attribute.</p> <p>1: Self Tuning is enabled. Used in the registry or XML file.</p> <p>true: Self Tuning is enabled. Used for the Self Tuning connection string attribute.</p> <p>Default: 1</p>                            |
| StatementCacheSize     | <p>Specifies the number of cursors or statements to be cached on the database for each connection. This setting corresponds to <i>Statement Cache Size</i> attribute in the connection string. A value greater than zero also enables statement caching.</p> <p>Configuration Support:<br/>Windows Registry, XML file, and <i>Statement Cache Size</i> connection string attribute</p> <p>Valid Values:</p> <p>0 &lt;= <i>n</i> &lt;= the value of OPEN_CURSORS parameter set in <code>init.ora</code> database config file.</p> <p><i>n</i> is the number to set.</p> <p>Default: 0</p> |
| StatementCacheWithUdts | <p>Specifies whether or not Oracle UDTs retrieved by executing a SELECT statement are cached along with the statement in the statement cache. This setting affects the memory usage and performance of the application.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:</p> <p>0: Oracle UDTs are not cached with statements.</p> <p>1: Oracle UDTs are cached along with statements.</p> <p>Default: 1</p>                                                                                                                                         |

Table 2-3 (Cont.) Configuration Attributes

| Attribute/Setting Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ThreadPoolMaxSize      | <p>Specifies the default maximum size of worker threads for each available processor in a process. This value may affect the performance of ODP.NET connection creation, command execution timeout, and external procedures (extproc) that use the thread pool. However, unnecessarily increasing thread pool maximum size can also cause performance problems.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:<br/> <math>0 \leq n \leq \text{int.MaxValue}</math>: Allows ODP.NET to reset thread pool maximum size with the value <math>n</math>. The ODP.NET reset operation may be ignored if the value is invalid. For example, if <math>n</math> is less than the number of available processors of the system. In this case, the result is the same as the value -1.<br/>           -1: Leave the thread pool max size as is.</p> <p>Default: -1 (this registry entry is not created by default)</p> |
| TraceFileLocation      | <p>Trace file destination directory, for example, D:\traces.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Default: &lt;windows user temporary folder&gt;\ODP.NET\unmanaged\trace</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TraceFileMaxSize       | <p>Maximum file size of each trace file.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Default: 100. Units are in megabytes (that is, 100 MB).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| TraceFileName          | <p>Specifies the file name to be used for logging trace information.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:<br/>Any valid directory location and file name.</p> <p>Default: c:\odpnet2.trc (for .NET Framework 2.0)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 2-3 (Cont.) Configuration Attributes

| Attribute/Setting Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TraceLevel             | <p>Specifies the level of tracing in ODP.NET. Because tracing all the entry and exit calls for all the objects can be excessive, TraceLevel is provided to limit tracing to certain areas of the provider. Each valid value indicates a possible tracing level. Compounded tracing levels can be obtained by adding the valid values.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:</p> <ul style="list-style-type: none"> <li>0: None</li> <li>1: Entry, exit, and SQL statement information</li> <li>2: Connection pooling statistics</li> <li>4: Distributed transactions (enlistment and delistment)</li> <li>8: User-mode dump creation upon unmanaged exception</li> <li>16: HA Event Information</li> <li>32: Load Balancing Information</li> <li>64: Self Tuning Information</li> <li>127: All the above</li> </ul> <p>Default: 0</p> <p><b>Note:</b> ODP.NET does bit-wise checking on the value. When tracing is enabled, logging to the trace file can affect ODP.NET performance.</p> <p><b>Note:</b> The user-mode dump creation requires dbghelp.dll version 5.1.2600.0 or later.</p> |
| TraceOption            | <p>Specifies whether to log trace information in single or multiple files for different threads. If a single trace file is specified, the file name specified in TraceFileName is used. If the multiple trace files option is requested, a Thread ID is appended to the file name provided to create a trace file for each thread.</p> <p>Configuration Support:<br/>Windows Registry and XML file</p> <p>Valid Values:</p> <ul style="list-style-type: none"> <li>0: Single trace file</li> <li>1: Multiple trace files</li> </ul> <p>Default: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 2-3 (Cont.) Configuration Attributes

| Attribute/Setting Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UdtCacheSize           | Specifies the size of the object cache for each connection in kilobytes (KB) that ODP.NET uses to retrieve and manipulate Oracle UDTs.<br>Configuration Support:<br>Windows Registry and XML file<br>Valid Values:<br>$0 \leq n \leq 4194303$ , $n$ is the number to set.<br>Default: 4096                                                                                                                                                                                 |
| UDT Mapping            | Specifies a mapping between a custom type and an Oracle UDT in the database. The mappings can be specified in configuration files and custom type factories. However, if the mapping is specified in both places, mappings specified in the configuration files takes precedence over mappings specified using custom type factories.<br>Configuration Support:<br>XML file and Custom Type Factory Classes<br>Valid Values:<br>Any valid mapping.<br>Default: <i>none</i> |

## Windows Registry

Upon installation, ODP.NET creates entries for configuration and tracing within the Windows Registry. Configuration and tracing registry values apply across all ODP.NET applications running in that Oracle client installation. Individual ODP.NET applications can override some of these values by configuring them within the ODP.NET application itself (for example, `FetchSize`). Applications can also use the .NET configuration files to override some of the ODP.NET Windows Registry values.

The ODP.NET registry values are located under `HKEY_LOCAL_MACHINE\Software\Oracle\ODP.NET\version\`. There is one key for .NET Framework 3.5, and one key for .NET Framework 4 and later.

### Note

32-bit applications running on an x64-based version of Windows use the registry subkey, `HKEY_LOCAL_MACHINE\Software\Wow6432node` in place of `HKEY_LOCAL_MACHINE\Software`. If such applications use Oracle Data Provider for .NET (32-bit), then the ODP.NET registry values are located under `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Oracle\ODP.NET\version\`.

## Configuration File Support

For customers who have numerous applications on a computer that depends on a single version of ODP.NET, the Windows Registry settings for a given version of ODP.NET may not necessarily be applicable for all applications that use that version of ODP.NET. To provide more

granular control, ODP.NET Configuration File Support allows developers to specify ODP.NET configuration settings in an application config, web.config, or a machine.config file.

If a computer does not require granular control beyond configuration settings at the ODP.NET version level, there is no need to specify ODP.NET configuration settings through configuration files.

The following is an example of a web.config file for .NET Framework:

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="DllPath" value="C:\oracle\bin"/>
      <add name="FetchSize" value="131072"/>
      <add name="StatementCacheSize" value="10"/>
      <add name="TraceFileName" value="D:\odpnet2.trc"/>
      <add name="TraceLevel" value="63"/>
      <add name="TraceOption" value="1"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

The following is an example of app.config for ODP.NET, Unmanaged Driver using .NET Framework, which sets some additional attributes as well as two UDT type mappings:

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="DbNotificationPort" value="-1"/>
      <add name="DllPath" value="C:\app\user\product\21.3.0\client_1\bin"/>
      <add name="DynamicEnlistment" value="0"/>
      <add name="FetchSize" value="131072"/>
      <add name="MetaDataXml" value="CustomMetaData.xml"/>
      <add name="PerformanceCounters" value="4095"/>
      <add name="StatementCacheSize" value="50"/>
      <add name="ThreadPoolMaxSize" value="30"/>
      <add name="TraceFileName" value="D:\odpnet2.trc"/>
      <add name="TraceLevel" value="0"/>
      <add name="TraceOption" value="0"/>
      <add name="Person" value="udtMapping factoryName='PersonFactory, Sample,
        Version=0.0.0.0, Culture=neutral, PublicKeyToken=null' typeName='PERSON'
        schemaName='HR' dataSource='oracle'"/>
      <add name="Student" value="udtMapping factoryName='StudentFactory, Sample,
        Version=0.0.0.0, Culture=neutral, PublicKeyToken=null' typeName='STUDENT'
        schemaName='HR'"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

ODP.NET, Unmanaged Driver now has the option of using the same configuration file format as ODP.NET, Managed Driver. The format simplifies configuration by using a single unified scheme. To utilize this format, the existing unmanaged ODP.NET configuration section should be renamed from `<oracle.dataaccess.client>` to `<oracle.unmanageddataaccess.client>`. The existing unmanaged ODP.NET elements and values are supported within the new section using the same format as with ODP.NET, Managed Driver. To see how to set the elements and values, see ["Oracle Data Provider for .NET, Managed Driver Configuration"](#) for more information.

For example, converting the `FetchSize` element and value from the traditional to the new format would be done as follows:

```
<oracle.dataaccess.client>
  <settings>
    <add name="FetchSize" value="131072" />
  </settings>
</oracle.dataaccess.client>

<oracle.unmanageddataaccess.client>
  <version number="*">
    <settings>
      <setting name="FetchSize" value="131072" />
    </settings>
  </version>
</oracle.unmanageddataaccess.client>
```

The traditional ODP.NET, Unmanaged Driver configuration file format will continue to be supported.

## SQL Translation Framework Configuration

### Configuring the SQL Translation Profile

The default SQL Translation Profile can be set in the .NET config file, either for all connections across the application, or it is also possible to limit the scope of a profile based on optional `dataSource` and `userId` XML attributes. Please note that these `dataSource` and `userId` XML attributes directly correspond to the `Data Source` and `User Id` attributes in the connection string used to open a database connection.

#### Note

SQL Translation Profile settings are only supported in the `<oracle.unmanageddataaccess.client>` section. It is not supported in the `<oracle.dataaccess.client>` section nor the `<oracle.manageddataaccess.client>` section.

This would be used for all connections to the `Data Sources` and `User Ids`.

This would be used for all connections to the specified `Data Source`.

This would be used for all connections to the specified `User Id`.

This would be used for all connections to the specified `Data Source` and `User Id`.

It is possible to configure multiple default profile entries which allow configuring default profiles for different `dataSource` and `userId` attributes, but while selecting a profile, the profile with maximum matching attributes will be selected.

In case there are 2 matching entries, one with `dataSource` only and the other with `userId` only then the entry with matching the `userId` would be given priority over the entry with matching `dataSource`.

With the above configuration, if we try to connect with a connection string which has `stf_ds` for `Data Source` and `stf_user` for `User Id` attributes, then both the entries given above will match

and in such cases, we will give priority to the entry with a matching User Id attribute which means profile\_user will be selected as the default profile.

### Configuring the Error Mapping

Applications can configure the connection related error mapping in their application configuration file. The error mapping can also be scoped based on Data Source name, User Id and the profile name itself.

Here is an example of providing error mapping with all three attributes.

```
<configuration>
  <oracle.unmanageddataaccess.client>
    <version number="*">
      <sqlTranslation>
        <defaultProfiles>
          <defaultProfile dataSource="stf_ds" userId="stf_user" profile=" Profile4"/>
        </defaultProfiles>
        <ErrorMappings>
          <ErrorMapping dataSource="stf_ds" userId="stf_user" profile="Profile4">
            <add oracleErrorNumber="1017" translatedErrorCode="222" />
            <add oracleErrorNumber="1005" translatedErrorCode="888" />
          </ErrorMapping>
        </ErrorMappings>
      </sqlTranslation>
    </version>
  </oracle.unmanageddataaccess.client>
</configuration>
```

Please note that dataSource and userId attributes are optional but can be used to scope the mapping.

It is also possible to provide an error mapping which could be used for all profiles. Here is an example:

```
<ErrorMappings>
  <ErrorMapping profile="*">
    <add oracleErrorNumber="1017" translatedErrorCode="222" />
    <add oracleErrorNumber="1018" translatedErrorCode="888" />
  </ErrorMapping>
</ErrorMappings>
```

### Configuring the Default Error Mapping Profile

The default error mapping profile can be configured through the defaultErrorMappingProfile setting. This is to be used to specify the default error mapping profile, especially in scenarios when the default profile is not specified through the .NET configuration file, but specified on the server side. In this case, if connectivity related errors occur, then ODP.NET will be able to properly use error mappings specified in the .NET configuration file for the profile specified by the defaultErrorMappingProfile setting.

Here is an example to configure the default error mapping profile:

```
<sqlTranslation>
  <settings>
    <add name="defaultErrorMappingProfile" value="error_mapping_profile" />
  </settings>
</sqlTranslation>
```

## Configuring the SQL Translation Framework Statement Cache Size

Client can configure the number of translated statements that ODP.NET can cache internally to avoid translations, which can be an expensive operation.

Here is an example to configure default error mapping profile:

```
<sqlTranslation>
  <settings>
    <add name="translatedStatementCacheSize" value="50" />
  </settings>
</sqlTranslation>
```

## Sample SQL Translation Framework configuration file

Here is a sample configuration file with all possible elements that can be used:

```
<sqlTranslation>
  <settings>
    <add name="translatedStatementCacheSize" value="50" />
    <add name="defaultErrorMappingProfile" value="def_Profile" />
  </settings>
  <defaultProfiles>
    <defaultProfile profile="STF.NO_DS.NO_USERID"/>
    <defaultProfile userId="stf" profile="STF.NO_DS"/>
    <defaultProfile dataSource="stf_inst" profile="STF.NO_USERID"/>
    <defaultProfile dataSource="stf_inst" userId="stf" profile="STF.STF_X"/>
  </defaultProfiles>
  <ErrorMappings>
    <ErrorMapping profile="def_profile">
      <add oracleErrorNumber="1017" translatedErrorCode="444" />
    </ErrorMapping>
    <ErrorMapping dataSource="stf_inst" userId="stf" profile="STF.STF_X">
      <add oracleErrorNumber="1018" translatedErrorCode="88888" />
    </ErrorMapping>
  </ErrorMappings>
</sqlTranslation>
```

### Example 2-1 Setting the profile which could be used for all connections

```
<configuration>
  <oracle.unmanageddataaccess.client>
    <version number="*">
      <sqlTranslation>
        <defaultProfiles>
          <defaultProfile profile="Profile1"/>
        </defaultProfiles>
      </sqlTranslation>
    </version>
  </oracle.unmanageddataaccess.client>
</configuration>
```

### Example 2-2 Setting the Profile for a Specific Data Source

```
<defaultProfiles>
  <defaultProfile dataSource="stf_ds" profile="Profile2"/>
</defaultProfiles>
```

**Example 2-3 Setting the Profile for a Specific User Id**

```
<defaultProfiles>
  <defaultProfile userId="stf_user" profile="Profile3"/>
</defaultProfiles>
```

**Example 2-4 Setting the Profile for a Specific Data Source and User Id'**

```
<defaultProfiles>
  <defaultProfile dataSource="stf_ds" userId="stf_user" profile="Profile4"/>
</defaultProfiles>
```

**Example 2-5 Configuring Multiple Default Profile Entries**

```
<defaultProfiles>
  <defaultProfile dataSource="stf_ds" profile="profile_ds"/>
  <defaultProfile userId="stf_user" profile="profile_user"/>
</defaultProfiles>
```

## Specifying UDT Mappings with Unified Configuration for Unmanaged ODP.NET

As UDT mapping is not currently supported by ODP.NET, Managed Driver, a new section within the <version> section is used to support custom UDT mappings for unmanaged ODP.NET in the unified configuration format. This new section is identified as <udtmappings> and each mapping is identified using a <udtmapping> element. The following attributes may be specified for each udtMapping element:

- typeName (required)
- factoryName (required)
- dataSource (optional)
- schemaName (optional)

These elements retain the same name and meaning as when used with the traditional configuration format.

Example of converting traditional format to unified format:

```
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="Person" value="udtMapping factoryName='PersonFactory, Sample,
Version=0.0.0.0, Culture=neutral, PublicKeyToken=null' typeName='PERSON'
schemaName='SCOTT' dataSource='oracle'" />
    </settings>
  </oracle.dataaccess.client>
</configuration>

<configuration>
  <oracle.unmanageddataaccess.client>
    <udtmappings>
      <udtmapping typename="PERSON" factoryname="PersonFactory, Sample,
Version=0.0.0.0, Culture=neutral, PublicKeyToken=null" schemaname="SCOTT"
datasource="oracle" />
    </udtmappings>
  </oracle.unmanageddataaccess.client>
</configuration>
```

**① See Also**[Oracle User-Defined Types \(UDTs\) and .NET Custom Types](#)

## Oracle Data Provider for .NET, Managed Driver Configuration

ODP.NET, Managed Driver supports .NET configuration file-based settings in `machine.config`, `app.config`, and `web.config`. It does not support Windows registry based configuration. ODP.NET, Managed Driver settings in .NET configuration files are similar to ODP.NET, Unmanaged Driver settings to make porting easier.

The ODP.NET, Managed Driver configuration file section name is `<oracle.manageddataaccess.client>`. The `<oracle.manageddataaccess.client>` settings and values are also supported in unmanaged ODP.NET configuration file: `<oracle.unmanageddataaccess.client>`. While this documentation section discusses managed ODP.NET configuration, it is also applicable to `<oracle.unmanageddataaccess.client>`. The `<oracle.unmanageddataaccess.client>` share numerous common settings with `<oracle.manageddataaccess.client>`. Differences between the two are noted on this page. The `<oracle.unmanageddataaccess.client>` settings not available in managed ODP.NET are documented in "[Oracle Data Provider for .NET, Unmanaged Driver Configuration](#)". A typical .NET config that uses ODP.NET, Managed Driver has some or all of the following subsections nested within a `<version>` subsection under `<oracle.manageddataaccess.client>` section. Note the tag names are case sensitive, while the attribute names are case insensitive.

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <oracle.manageddataaccess.client>
    <version number="*">
      <dataSources>
        ...
      </dataSources>
      <settings>
        ...
      </settings>
      <LDAPsettings>
        ...
      </LDAPsettings>
      <implicitRefCursor>
        ...
      </implicitRefCursor>
      <edmMappings>
        ...
      </edmMappings>
    </version>
    <version number="4.121.2.0">
      <dataSources>
        ...
      </dataSources>
      <settings>
        ...
      </settings>
    </version>
  </oracle.manageddataaccess.client>
</configuration>
```

```

    ...
  </settings>
  <LDAPsettings>
    ...
    ...
  </LDAPsettings>
  <implicitRefCursor>
    ...
    ...
  </implicitRefCursor>
  <edmMappings>
    ...
    ...
  <edmMappings>
</version>
</oracle.manageddataaccess.client>
</configuration>

```

The ODP.NET, Managed Driver configuration and settings are described in the following sections. Many of the attributes are the same as ODP.NET, Unmanaged Driver. See [Table 2-3](#) for detailed attribute descriptions.

## version Section

All the information required by an application should be grouped under the version subsections. Each `<version number="X">` section contains parameters applicable for version X of the ODP.NET, Managed Driver. For example, `<version number="4.121.2.0">` section parameters will be applicable only for those applications using ODP.NET, Managed Driver assembly 4.121.2.0.

Apart from version specific sections, there can also be a generic section `<version number="*">`. This section's parameters are applicable for all ODP.NET, Managed Driver versions. Parameters in the version specific section take precedence over the parameters of the generic section. The following is an example of a version section:

```

<oracle.manageddataaccess.client>
  <version number="*">
    <settings>
      <setting name="TraceOption" value="1"/>
      <setting name="PerformanceCounters" value="0" />
    </settings>
  </version>
  <version number="4.121.2.0">
    <settings>
      <setting name="PerformanceCounters" value="4095" />
    </settings>
  </version>
</oracle.manageddataaccess.client>

```

An application referencing ODP.NET, Managed Driver 4.121.2.0 has the following values set:

- TraceOption = 1
- PerformanceCounters= 4095

## dataSources Section

This section can appear only under a `<version>` section. The mapping between the different data source aliases and corresponding data descriptors should appear in this section. This section is supported by managed ODP.NET only. The following is an example.

```
<dataSources>
  <dataSource alias="inst1" descriptor="(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=sales-
server).....))"/>
  <dataSource alias="inst2" descriptor="(DESCRIPTION= .....))"/>
</dataSources>
```

**Note**

The data source connection string attribute can alternatively be set to a full descriptor or Easy Connect syntax rather than a data source alias.

Requirements for connecting to a local database *without* specifying "data source" connection string attribute:

- The listener must be up and running.
- ORACLE\_SID environment variable must be set appropriately.

**Note**

When data source connection string attribute is not specified, protocol defaults to 'tcp' and port defaults to '1521'.

The ODP.NET managed driver reads and caches all the alias entries from the app.config, web.config, machine.config, and from a tnsnames.ora file that is found at application start-up time. However, aliases that are defined in LDAP servers are resolved and cached on demand. This means for each unique alias that is used by the application, an alias resolution query is executed against an LDAP server and the full descriptor associated with the alias will be cached once it is fetched.

For developers that need to change or add alias settings while developing applications, one may consider using `OracleDataSourceEnumerator.GetDataSources()` rather than restarting the application. Invoking this method will first wipe out existing cache entries that were read from the tnsnames.ora file and all aliases obtained from the LDAP Server. Then, the tnsnames.ora is re-parsed and all its entries will be cached again. Please note that the app.config, web.config, and machine.config entries are read only once at application start-up time and thus their contents are maintained and not re-parsed even if `OracleDataSourceEnumerator.GetDataSources()` is invoked.

The `OracleDataSourceEnumerator.GetDataSources()` method invocation has an impact on the connection pool. This is because a connection pool, which is created for each unique connection string, will cache the resolved full descriptor information after the first connection is created for a given connection pool. After that, the connection pool uses the cached full descriptor information for all subsequent connection creations. Thus, for applications that have their tnsnames.ora or LDAP entries modified during the execution of an application where an alias points to a different database than before, one should call the `OracleDataSourceEnumerator.GetDataSources()` method to remove old cached entries. This should be followed by the invocation of the `ClearPool(OracleConnection)` instance method or the `ClearAllPools()` static method to remove existing connections and also have it obtain a new full descriptor value that was read by the invocation of `OracleDataSourceEnumerator.GetDataSources()`. Following this scheme will assure that *all* the connections in the connection pool uses the new full descriptor that is now associated with the alias and all connections in a connection pool is established to the same database.

The following keywords are supported within the descriptor setting:

- ADDRESS
- ADDRESS\_LIST (Note: only failover supported)  
Oracle recommends using SCAN listener and Runtime Load Balancing to balance the load when connecting to an Oracle RAC database.
- DESCRIPTION
- DESCRIPTION\_LIST (Note: Failover supported; Address\_list load balancing not supported)
- HOST (Note: <hostname>, <IPv6 literal>, and <IPv4 literal> are supported)
- IP (Note: "loopback" is supported)
- PROTOCOL (Note: tcp and tcps are supported. In addition, WS and WSS are also supported.)
- RETRY\_COUNT: Specifies the number of times an ADDRESS list is traversed before the connection attempt is terminated and times out.
- RETRY\_DELAY: Specifies the delay in seconds between subsequent retries for a connection.

RETRY\_COUNT and RETRY\_DELAY are timeout parameters that work at the Oracle networking layer. They are intended to be used in conjunction with each other. When these parameters are used, ODP.NET will attempt to connect with one of the addresses in the ADDRESS\_LIST. If there is no successful connection after going through the entire list, then ODP.NET will wait for the number of seconds specified by RETRY\_DELAY before traversing the address list again. It will repeat this behavior until there is a successful connection or the RETRY\_COUNT limit is hit.

For example, let's assume RETRY\_COUNT=2 and RETRY\_DELAY=4 when ODP.NET cannot successfully connect to any address on the list. The following sequence is triggered:

1. Traverse address list to connect.
2. Wait four seconds for next set of retry attempts.
3. Traverse the address list again. This is first set of retry attempts.
4. Wait four seconds for the next retry attempt.
5. Traverse the address list again. This is the second and final set of retry attempts.
6. Timeout

These timeout parameters function independent of ODP.NET application timeouts, such as the Connection Timeout connection string attribute. If the Connection Timeout is set to a low value, then it may trigger before the RETRY\_COUNT and RETRY\_DELAY attempt cycle completes.

- Session Data Unit size supports from 256 to 2097152 in bytes.
- SECURITY: SSL\_VERSION (Note: overrides sqlnet.ora:ssl\_version)
- TRANSPORT\_CONNECT\_TIMEOUT (Note: overrides tcp.connect\_timeout)

**Note**

- SSL is now supported via method MCS and FILE.
- Both Kerberos5 and NTS authentication are supported. RADIUS is not supported.
- Only Net Services, Easy Connect naming, and LDAP (namely, Active Directory and Oracle Internet Directory) are supported.
- No bequeath (beq) support. Default address is instead TCP loopback with port 1521 and Oracle service name from environment (ORACLE\_SID)

**See Also**

*Oracle Database Net Services Reference* for a detailed description of the attributes.

Though managed ODP.NET does not support TNS descriptor based load balancing, it does support failover through both an ADDRESS\_LIST and DESCRIPTION\_LIST.

Note that you need not specify either the LOAD\_BALANCE or the FAILOVER directive, because only failover is supported. The directives are ignored.

The following examples demonstrate TNS descriptors utilizing failover:

```
(DESCRIPTION=
  (ADDRESS_LIST=
    (ADDRESS=(PROTOCOL=tcp)(HOST=host1)(PORT=1630))
    (ADDRESS=(PROTOCOL=tcp)(HOST=host2)(PORT=1630))
    (ADDRESS=(PROTOCOL=tcp)(HOST=host3)(PORT=1521)))
  (CONNECT_DATA=(SERVICE_NAME=Sales.us.example.com)))

(DESCRIPTION_LIST=
  (DESCRIPTION=
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=tcp)(HOST=sales1a-svr)(PORT=1521))
      (ADDRESS=(PROTOCOL=tcp)(HOST=sales1b-svr)(PORT=1521)))
    (CONNECT_DATA=(SERVICE_NAME=sales1.example.com)))
  (DESCRIPTION=
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=tcp)(HOST=sales2a-svr)(PORT=1521))
      (ADDRESS=(PROTOCOL=tcp)(HOST=sales2b-svr)(PORT=1521)))
    (CONNECT_DATA=(SERVICE_NAME=sales2.us.example.com))))
```

## settings section

This section can appear only under a <version> section. Any ODP.NET, Managed Driver specific settings should appear in this section. The following is an example of a settings section:

```
<settings>
  <setting name="TraceLevel" value="7" />
  <setting name="TraceOption" value="1"/>
  <setting name="TNS_ADMIN" value="C:\oracle\work"/>
</settings>
```

A new default behavior has been introduced for ODP.NET Release 12.1.0.2 and later when `InitialLobFetchSize` is set to -1. The new default value is `LegacyEntireLobFetch = 0`. To use the old behavior, set `LegacyEntireLobFetch = 1` in the ODP.NET configuration. Refer to ["Setting InitialLONGFetchSize to -1"](#) for more information.

ODP.NET, Managed Driver configuration settings that are supported:

- `BindByName`
- `CPVersion`: Determines whether ODP.NET, Unmanaged Driver uses the traditional connection pool implementation (`Default=1.0`) or the more modern connection pool implementation with better high availability support (`2.0`). In addition, the more modern connection pool (`2.0`) is required if the application uses Database Resident Connection Pooling (DRCP), or hosts multiple pluggable databases or editions in the same pool. Possible values: `1.0` or `2.0`.

ODP.NET, Managed Driver only uses the more modern connection pool implementation. This setting can only be used for ODP.NET, Unmanaged Driver for .NET Framework 4 and higher. It cannot be used for earlier versions of unmanaged ODP.NET, which will always use the traditional connection pool implementation.

If `CPVersion` is set explicitly, then that setting will be used across processes for all connection strings.

If `CPVersion` is left unmodified (or contains an invalid value) and an application's first unmanaged ODP.NET established connection for a given connection string uses DRCP, pluggable databases, or editions by modifying one these features' properties or configuration settings, then `CPVersion` will be implicitly modified to use the newer connection pool implementation (`2.0`).

If a `CPVersion 1.0` pool attempts to use DRCP, pluggable database, or edition settings, then ODP.NET will raise an exception when the application attempts to open a connection.

When `CPVersion 2.0` is used explicitly or implicitly and the "proxy user id" is not specified in the connection string, then a proxy connection will not be created, even if "proxy password" is supplied.

When `CPVersion 2.0` is used by ODP.NET, Unmanaged Driver, the connection pool behavior will be the same as the more modern connection pool as implementation that ODP.NET, Managed Driver uses.

- `DbNotificationPort`
- `DemandOraclePermission`
- `Disable_0ob`: Interrupts database query execution via either TCP/IP urgent data or normal TCP/IP data, called out of band data (default) or in band data, respectively. (Default=off).

All Oracle database clients support interrupting database query execution, such as through an ODP.NET command timeout. Windows-based database servers only support in band breaks, whereas all other (predominantly UNIX-based) database servers can support out of band (OOB) or in band breaks. ODP.NET, Managed Driver uses OOB breaks by default with database servers that support it. For certain network topologies, the routers or firewalls involved in the route to the database may have been configured to drop urgent data or in band the data. If the routers or firewalls can not be changed to handle urgent data appropriately, then the ODP.NET, Managed Driver can be configured to utilize in band breaks by setting the .NET configuration parameter `Disable_0ob` to on.

- `DllPath`: (Unmanaged ODP.NET only) Specifies the directory location dependent unmanaged Oracle Client binaries are loaded from.

See [Search Order for Unmanaged DLLs](#) for more information.

- **DRCPConnectionClass**: Specifies a logical name that identifies the DRCP connection pool that the ODP.NET connection will use. It will be used as a default if the **DRCPConnectionClass** property on the **OracleConnection** object is not set. It will be ignored for non-DRCP connections.  
  
Valid Values: the connection class name is string at max 1024 characters. The default is null.
- **FetchSize**
- **GetDecimalRetainTrailingZeros**: (Managed ODP.NET only) Specifies whether to retain trailing zeros from an Oracle NUMBER in a .NET Decimal.  
  
See OracleConfiguration [GetDecimalRetainTrailingZeros](#) for more information.
- **LDAP\_ADMIN**: Specifies the `ldap.ora` location. The **LDAP\_ADMIN** setting works in conjunction with the **TNS\_ADMIN** setting to set `ldap.ora` search order.  
  
See [Oracle Client Configuration File Settings](#) for `ldap.ora` search order.
- **LegacyEntireLOBFetch**
- **MaxStatementCacheSize**
- **MetaDataXml**
- **NAMES.DIRECTORY\_PATH**: The default search order is **TNSNAMES** and **EZCONNECT**. **TNSNAMES**, **LDAP**, and **EZCONNECT** are the only name resolution methods supported, but their order of precedence can be modified.
- **NAMES.LDAP\_AUTHENTICATE\_BIND**
- **NAMES.LDAP\_AUTHENTICATE\_BIND\_METHOD**
- **NAMES.LDAP\_CONN\_TIMEOUT**
- **NODELAY**
- **ORA\_DEBUG\_JDWP**: Allows Oracle PL/SQL Debugger and database to connect automatically without application code changes. Value is set as `host=<IP_address or host_name>;port=<debugging port number>`. Ex. `host=localhost;port=1234`
- **OCI\_COMPARTMENT**
- **OCI\_CONFIG\_FILE**
- **OCI\_DATABASE**
- **OCI\_PROFILE**
- **OpenTelemetryTracing**: Enable (true) or disable (false) ODP.NET OpenTelemetry tracing instrumentation. Default is true. ODP.NET will only read this property during app startup. It cannot be used to change tracing during runtime.
- **ORACLE\_SID**
- **PASSWORD\_AUTH**: Possible values are **OCI\_TOKEN** and **PASSWORD\_VERIFIER** (default).
- **PerformanceCounters**
- **Pipelining**: (Managed ODP.NET only) Specifies whether to enable asynchronous execution on the database server side.
- **RECEIVE\_BUF\_SIZE**: Sets TCP **SO\_RECVBUF**, the total buffer space associated with the local side of a TCP socket
- **RowsToFetchPerRoundTrip**
- **SelfTuning**

- `SEND_BUF_SIZE`: Sets TCP `SO_SENDBUF`, the total buffer space associated with the local side of a TCP socket
- `ServiceRelocationConnectionTimeout`  
In seconds. (Default = 90).

Whenever a database service becomes unavailable, such as due to a service being relocated, an application can encounter numerous connectivity errors during this time. To avoid unnecessary connection attempts to an unavailable service which will result in an error, ODP.NET blocks any connection attempts until the service is up or until this property's specified time limit expires from the time when the service DOWN event was received, whichever comes first. Once the specified time elapses, all the connection attempts to the specific service which is known to be down will no longer be blocked. Those requests will be sent to the server. `ServiceRelocationConnectionTimeout` is only operational in conjunction with Oracle Fast Connection Failover (`HA Events = true`). Once Fast Connection Failover is enabled for the .NET application, Service Relocation Connection Timeout is automatically enabled. It will use its default value if no `ServiceRelocationConnectionTimeout` value has been explicitly set. It works with planned and unplanned outages.

When connecting to Oracle Data Guard in Oracle Database 12c Release 2 or later, database administrators can set their own timeout value, `drain_timeout`, to indicate the number of seconds allowed for resource draining to be completed. This setting can be optionally used by the `ODP.NET ServiceRelocationConnectionTimeout` value as the intent behind `drain_timeout` and `ServiceRelocationConnectionTimeout` are the same.

If `ServiceRelocationConnectionTimeout` and `drain_timeout` are not set, then the default `ServiceRelocationConnectionTimeout` value is used (90 seconds). If only `drain_timeout` is set, then that value will be used for the service relocation connection timeout. If only `drain_timeout` is set and is set to 0, then also default `ServiceRelocationConnectionTimeout` value is used (90 seconds). If both are set, then the value of `ServiceRelocationConnectionTimeout` will override the value of `drain_timeout`.

`ServiceRelocationConnectionTimeout` itself can be set based upon the value of `drain_timeout`. For example, if ODP.NET administrators desire the service relocation connection timeout to be `drain_timeout` plus 50 seconds, then they would set `ServiceRelocationConnectionTimeout` in the following manner:

```
<setting name="ServiceRelocationConnectionTimeout" value="drain_timeout + 50"/>
```

Service Relocation Connection Timeout is not supported in pools that connect to more than one pluggable database.

- `SQLNET.AUTHENTICATION_SERVICES`: Supported values are ALL, Kerberos5, NTS, TCPS, or NONE.

Managed ODP.NET supports NTS, Kerberos5, and TCPS external authentication methods. This setting should be set based on the desired database authentication method. If internal database authentication is desired, then the setting should be set to NONE. Default value is NONE. The value(s) must be enclosed in parentheses. Example settings made in `sqlnet.ora` are:

```
SQLNET.AUTHENTICATION_SERVICES = (TCPS)
SQLNET.AUTHENTICATION_SERVICES = (NTS)
SQLNET.AUTHENTICATION_SERVICES = (Kerberos5, NTS)
SQLNET.AUTHENTICATION_SERVICES = (NONE)
```

**Note**

The NTS external authentication methodology is only supported on a Windows-based client and server.

SQLNET.AUTHENTICATION\_SERVICES default values are different for managed ODP.NET and unmanaged ODP.NET. Managed ODP.NET defaults to NONE and unmanaged defaults to ALL when no value is set.

- SQLNET.CLOUD\_USER
- SQLNET.CRYPTO\_CHECKSUM\_CLIENT: Specifies the desired data integrity behavior when this client connects to a server. Supported values are accepted, rejected, requested, or required. Default = accepted.
- SQLNET.CRYPTO\_CHECKSUM\_TYPES\_CLIENT: Specifies the data integrity algorithms that this client uses. Supported values are SHA512, SHA384, SHA256, and SHA1.
- SQLNET.ENCRYPTION\_CLIENT = Negotiates whether to turn on encryption. Supported values are accepted, rejected, requested, or required.
- SQLNET.ENCRYPTION\_TYPES\_CLIENT = Encryption algorithm(s) to use.

The following table lists the valid encryption algorithms for ODP.NET, Managed Driver.

**Table 2-4 Encryption Algorithms for ODP.NET, Managed Driver**

| Algorithm Name  | Legal Value |
|-----------------|-------------|
| AES 128-bit key | AES128      |
| AES 192-bit key | AES192      |
| AES 256-bit key | AES256      |
| 2-key 3DES      | 3DES112     |
| 3-key 3DES      | 3DES168     |

For more information on data encryption settings, refer to the *Oracle Database Security Guide*.

- SQLNET.EXPIRE\_TIME: Specifies a time interval to send a new set of probes to verify the connection remains active. This setting is equivalent to the `OracleConnection.KeepAliveTime` property. `OracleConnection.KeepAliveInterval` is fixed at 6 seconds for SQLNET.EXPIRE\_TIME. Default is 0 (off). By default the value is specified in minutes. However the value can be specified in seconds (sec) and milliseconds (ms), such as the following example:

```
<setting name=" SQLNET.EXPIRE_TIME" value="30 sec" />
```

- SQLNET.URI
- SQLNET.WALLET\_OVERRIDE
- StatementCacheSize
- SSL\_SERVER\_DN\_MATCH: To enforce the distinguished name (DN) for the database server matches its service name. (Default=no).

If you enforce the match verification, then SSL/TLS ensures that the certificate is from the server. If you select to not enforce the match verification, then SSL/TLS performs the

check but allows the connection, regardless if there is a match. Not enforcing the match allows the server to potentially fake its identify.

Supported values: yes | on | true to enforce a match.

Supported values: no | off | false to not enforce a match.

SSL\_SERVER\_DN\_MATCH is often used together with SSL\_SERVER\_CERT\_DN.

SSL\_SERVER\_CERT\_DN specifies the distinguished name (DN) of the database server. It can be set in the connect descriptor.

```
net_service_name=
  (DESCRIPTION=
    (ADDRESS=(PROTOCOL=tcp)(HOST=sales1-svr)(PORT=1521))
    (ADDRESS=(PROTOCOL=tcp)(HOST=sales2-svr)(PORT=1521))
    (CONNECT_DATA=
      (SERVICE_NAME=sales.us.acme.com))
    (SECURITY=
      (SSL_SERVER_CERT_DN="cn=sales,cn=OracleContext,dc=us,dc=acme,dc=com")))
```

The client uses this information to obtain the list of DNs it expects for each of the servers, enforcing the database server DN to match its service name. Use this parameter with SSL\_SERVER\_DN\_MATCH to enable server DN matching.

- **SSL\_VERSION:** Sets the version of the SSL/TLS connection. By default, all supported versions are enabled, in the order 1.2 and 1.3.

The client and server negotiate to the highest version among the common conversions specified in their configurations. The versions from lowest to highest are: 1.2 and 1.3.

To specify more than one version, enclose the version numbers between parentheses and separate the values with a comma. For example, (1.2,1.3).

- **TimeZoneFileLocation:** Specifies the directory location of the time zone file ODP.NET should use for its time zone settings.
- **TNS\_ADMIN:** Location where either one or more of tnsnames.ora, ldap.ora, and sqlnet.ora are located. Locations can consist of either absolute or relative directory paths.
- **TOKEN\_AUTH:** This attribute specifies the access token authentication type. Possible values are OCI\_API\_KEY, OCI\_INSTANCE\_PRINCIPAL, OCI\_DELEGATION\_TOKEN, OCI\_INTERACTIVE, OCI\_DEFAULT, OCI\_TOKEN, OAUTH, or DISABLED.
- **TOKEN\_LOCATION:** This attribute is the file-based token location. The value can be a directory where a file named "token" is or it can be the file's full path specification.
- **TraceFileLocation:** Trace file destination directory, for example, D:\traces. The default TraceFileLocation is <Windows user temporary folder>\ODP.NET\managed\trace.
- **TraceFileMaxSize:** Maximum file size of each trace file. Default is 100 MB (100,000,000). The default value is 100. The unit of measure is megabytes (i.e. 100 MB).
- **TraceLevel:** 1 = public APIs; 2 = private APIs; 4 = network APIs/data; 8 = disables writing SQL statements and network packet contents. These values can be 0Red. To enable everything, set TraceLevel to 7. Errors will always be traced.
- **TraceOption**
- **TCP.CONNECT\_TIMEOUT**
- **UseClientInitiatedCQN**
- **WALLET\_LOCATION:** Microsoft Certificate Store (MCS) and file system wallets are supported.

## LDAPsettings section

This section can appear only under a <version> section. Any ODP.NET, Managed Driver specific LDAP settings should appear in this section. This section is supported by managed ODP.NET only. The following is an example of a <LDAPsetting> subsection under the <LDAPsettings> section:

```
<LDAPsettings>
  <LDAPsetting name="DIRECTORY_SERVER_TYPE" value="AD" />
  <LDAPsetting name="DEFAULT_ADMIN_CONTEXT" value="dc=Oracle,dc=com"/>
</LDAPsettings>
```

## Lightweight Directory Access Protocol

ODP.NET, Managed Driver supports TNS alias resolution through a LDAP server/service, specifically Microsoft Active Directory and Oracle Internet Directory (OID). TNS alias resolution occurs when using the LDAPsettings section or ldap.ora file settings. The LDAPsettings section settings take precedence over ldap.ora settings.

For Active Directory, only the DIRECTORY\_SERVER\_TYPE and DEFAULT\_ADMIN\_CONTEXT parameters are required in ldap.ora. When the DIRECTORY\_SERVERS parameter is missing or has no value, the default LDAP server for the current domain will be used.

For OID, all ldap.ora parameters must be set with valid values to complete configuration.

ODP.NET, Managed Driver and ODP.NET, Unmanaged Driver support the same level of security when using LDAP for name resolution.

**Table 2-5 Microsoft Active Directory: Encryption Types and Authentication Credentials For Connecting and Binding**

| No Encryption              | SSL Encryption             |
|----------------------------|----------------------------|
| Anonymous authentication   | Anonymous authentication   |
| Domain User authentication | Domain User authentication |

**Table 2-6 Oracle Internet Directory: Encryption Types and Authentication Credentials For Connecting and Binding**

| No Encryption            | SSL Encryption                                                                                           |
|--------------------------|----------------------------------------------------------------------------------------------------------|
| Anonymous authentication | Anonymous authentication                                                                                 |
| -                        | Wallet based authentication                                                                              |
|                          | <i>Note: Wallet based authentication for Oracle Internet Directory is not supported for this release</i> |

## implicitRefCursor section

This section can appear only under a <version> section. Any information about REF CURSOR parameters that need to be bound implicitly should appear in this section. The following is an example of an <implicitRefCursor> section:

```
<implicitRefCursor>
  <storedProcedure schema="USERREFCUR" name="TestProc1">
    <refCursor name="Param3">
      <bindInfo mode="Output"/>
      <metadata columnOrdinal="0" columnName="DEPTNO" baseColumnName="DEPTNO"
baseSchemaName="USERREFCUR" baseTableName="DEPT" nativeDataType="number"
providerType="Int32" dataType="System.Int16" columnSize="2" allowDBNull="true" />
      <metadata columnOrdinal="1" columnName="DNAME" baseColumnName="DNAME"
baseSchemaName="USERREFCUR" baseTableName="DEPT" nativeDataType="varchar2"
providerDbType="String" columnSize="30" />
    </refCursor>
    <refCursor name="param2">
      <bindInfo mode="Output"/>
      <metadata columnOrdinal="0" columnName="EMPNO" baseColumnName="EMPNO"
baseSchemaName="USERREFCUR" baseTableName="EMP" nativeDataType="number"
providerType="Int32" dataType="System.Int16" columnSize="4" allowDBNull="false" />
    </refCursor>
  </storedProcedure>

  <!--Next stored procedure information-->
  <storedProcedure name="TestProc2">
    ...
  </storedProcedure>
</implicitRefCursor>
```

## distributedTransaction section

This section can appear only under a <version> section. Any information about distributed transactions should appear in this section. The following is an example of a distributedTransaction section:

```
<distributedTransaction>
  <setting name="OMTSRECO_IP_ADDRESS" value="my-pc" />
  <setting name="OMTSRECO_PORT" value="2040" />
  <setting name="ORAMTS_SESS_TXNTIMETOLIVE" value="240" />
</distributedTransaction>
```

- OMTSRECO\_IP\_ADDRESS: Specifies the machine name (or IP address) that the OraMTS Recovery service will be running on to resolve database in-doubt transactions. The default is the local machine name.

- OMTSRECO\_PORT: Specifies the port that the OraMTS Recovery service will be listening on to resolve database in-doubt transactions. The default is 2030.
- ORAMTS\_SESS\_TXNTIMETOLIVE : Specifies the time in seconds that the transaction can remain inactive after it has been detached or delisted from the database. Once this time expires, the transaction is automatically terminated by the provider. The default is 120 seconds.
- UseOraMTSManaged: When set to true and using .NET Framework 4.5.2 or higher, ODP.NET uses managed code for distributed transactions. If set to false, ODP.NET uses Oracle Services for Microsoft Transaction Server to support distributed transactions. Boolean (Default = false) for ODP.NET, Unmanaged Driver only.

## connectionPools section

This section can appear only under a <version> section. This section allows setting a string identifier for each set of monitored connection counters. Refer to [Connection Performance Counters](#) documentation section for more details.

## edmMappings section

This section can appear only under a <version> section. Any information related to EDM mappings should appear in this section. Refer to [Oracle Number Default Data Type Mapping and Customization](#) for more examples on edmMappings section.

## onsConfig section

Oracle Notification Service (ONS) can be configured using either local or remote configuration using the <onsConfig> section. The <onsConfig> section is available only for managed ODP.NET. Remote configuration is the preferred configuration for standalone client applications. For releases earlier than Oracle Database 12c, this section is mandatory for ODP.NET to receive ONS notifications. With Oracle Database 12c and later, this section is optional and the information about the ONS daemons is received from the server itself. However, ODP.NET will also listen for events from any <host:port> pairs that is provided by the user in this section in addition to the <host:port> pairs received from the server.

For local configuration, please ensure that ONS is configured and available on the node where ODP.NET is running, so that ODP.NET can receive events directly from the local ONS daemon. The following is a sample format for the local configuration:

```
<onsConfig configFile="C:\temp\test.config" mode="local">
</onsConfig>
```

### ① Note

The configFile specified in .NET config should contain the same localport and remoteport values as specified in the ons.config used by the local ONS daemon. This will enable the application to receive events from the local ONS daemon.

Remote configuration is used in scenarios where the application directly receives ONS events from the ONS daemons running on remote machines. One of the advantages of this configuration is that no ONS daemon is needed on the client end and, therefore, there is no need to manage this process.

The following is a sample format for remote configuration:

```
<onsConfig mode="remote">
  <ons database="db1">
    <add name="nodeList" value="racnode1:4100, racnode2:4200" />
  </ons>
  <ons database="db2">
    <add name="nodeList" value=" racnode3:4100, racnode4:4200" />
  </ons>
</onsConfig>
```

In case of remote configuration, the application has to specify the <host>:<port> values for every potential database that it can connect to. The <host>:<port> value pairs represent the ports on the the different Oracle RAC nodes where the ONS daemons are talking to their remote clients.

### ① See Also

[Client Side ONS Daemon Configuration](#) for information about client side ONS daemon configuration

## ONS TCPS and Wallets

ODP.NET enables ONS communications to occur over TCP/IP with SSL/TLS (TCPS), which is more secure than just TCP/IP. As TCPS requires using a wallet for storing keys and certificates, ODP.NET can use one wallet for both ONS and ODP.NET connections or have separate wallets for each.

TCPS provides more secure ONS communication, gives administrators flexibility in how to configure their wallets, and enables cloud database connections.

oracle.manageddataaccess.client configuration section sample

```
<oracle.manageddataaccess.client>
  <version number="*">
    <onsConfig mode="remote">
      <settings>
        <setting name="Protocol" value="TCPS" />
        <setting name="WALLET_LOCATION" value="D:\user\ONS_SSLWallet" />
      </settings>
      <ons database="acdb183">
        <add name="nodeList" value="slcai611:6205,slcai610:6205,slcai612:6205" />
      </ons>
    </onsConfig>
  </version>
</oracle.manageddataaccess.client>
```

The protocol and wallet location properties are often used together.

If an ONS wallet location is set, ODP.NET will use the wallet for ONS to connect via TCP/IP with SSL/TLS regardless of the protocol setting.

If the protocol is set to "TCPS", ODP.NET first tries to use the wallet in the ONS configuration wallet location to connect via TCP/IP with SSL/TLS. If no wallet is present, ODP.NET next tries to use the wallet from the database wallet location. If no wallet is found, the connection fails.

Administrators can choose between having the ONS connection use its own independent wallet or share the database's wallet for ease of use.

If the protocol is set to "TCP" and no ONS wallet location is set, ODP.NET ONS will connect with TCP/IP.

ODP.NET ONS TCPS works with any Oracle Database version that supports ONS TCPS on the server side.

## Client Side ONS Daemon Configuration

ONS configuration is controlled by the ONS configuration file, `ORACLE_HOME/opmn/conf/ons.config`. This file tells the ONS daemon how it should behave. The `SRVCTL` utility can be used to start and stop the ONS daemon. It is installed on each node by default during server install.

Configuration information within `ons.config` is defined in simple name and value pairs. An example of `ONS.config` is given below

```
# This is an example ons.config file
#
# The first three values are required
localport=4100
remoteport=4200
nodes=racnode1.example.com:4200,racnode2.example.com:4200
```

Some parameters in the `ons.config` file are required and some are optional. [Table 2-7](#) lists the required ONS configuration parameters and [Table 2-8](#) lists the optional ONS configuration parameters.

**Table 2-7 Required ONS Configuration Parameters**

| Parameter  | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| localport  | The port that ONS binds to on the local host interface to talk to local clients.<br>For example, <code>localport=4100</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| remoteport | The port that ONS binds to on all interfaces for talking to other ONS daemons.<br>For example, <code>remoteport=4200</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| nodes      | A list of other ONS daemons to talk to. Node values are given as a comma-delimited list of either host names or IP addresses plus ports. The port value that is given is the remote port that each ONS instance is listening on. In order to maintain an identical file on all nodes, the <code>host:port</code> of the current ONS node can also be listed in the nodes list. It will be ignored when reading the list.<br>For example,<br><code>nodes=myhost.example.com:4200,123.123.123.123:4200</code><br>The nodes listed in the nodes line correspond to the individual nodes in the Oracle RAC instance. Listing the nodes ensures that the middle-tier node can communicate with the Oracle RAC nodes. At least one middle-tier node and one node in the Oracle RAC instance must be configured to see one another. As long as one node on each side is aware of the other, all nodes are visible. You need not list every single cluster and middle-tier node in the ONS configuration file of each Oracle RAC node. In particular, if one ONS configuration file cluster node is aware of the middle tier, then all nodes in the cluster are aware of it. |

**Table 2-8 Optional ONS Configuration Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| loglevel   | The level of messages that should be logged by ONS. This value is an integer that ranges from 1, which indicates least messages logged, to 9, which indicates most messages logged. The default value is 3.<br>For example, loglevel=3                                                                                                                                                                                                                                                                                                                                                       |
| logfile    | A log file that ONS should use for logging messages. The default value for log file is \$ORACLE_HOME/opmn/logs/ons.log.<br>For example,<br>logfile=C:\app\user\product\12.1.0\opmn\logs\myons.log                                                                                                                                                                                                                                                                                                                                                                                            |
| walletfile | The wallet file used by the Oracle Secure Sockets Layer (SSL) to store SSL certificates. If a wallet file is specified to ONS, then it uses SSL when communicating with other ONS instances and require SSL certificate authentication from all ONS instances that try to connect to it. This means that if you want to turn on SSL for one ONS instance, then you must turn it on for all instances that are connected. This value should point to the directory where your ewallet.p12 file is located.<br>For example,<br>walletfile=C:\app\user\product\12.1.0\opmn\conf\ssl.wlt\default |
| useocr     | The value, reserved for use on the server-side, to indicate ONS whether it should store all Oracle RAC nodes and port numbers in Oracle Cluster Registry (OCR) instead of the ONS configuration file or not. A value of useocr=on is used to store all Oracle RAC nodes and port numbers in Oracle Cluster Registry (OCR).<br>Do not use this option on the client-side.                                                                                                                                                                                                                     |

The ons.config file allows blank lines and comments on lines that begin with the number sign (#).

## Relative Windows Path and Windows Environment Variable Configuration Settings

The following managed ODP.NET configuration settings support relative Windows path and environment variables:

- TraceFileLocation
- WALLET\_LOCATION

File locations for the above config parameters can now be set using relative Windows paths. The "." notation informs ODP.NET to use the current working directory. Sub-directories can be added by appending them. For example, .\mydir refers to the sub-directory mydir in the current working directory. To navigate to a parent directory, use the ".." notation.

For web applications, the current working directory is the application directory. For Windows applications, the .EXE location is the current working directory.

Windows paths can also be set using Windows environment variable names within "%" characters.

For example, %tns\_admin%, c:\%dir%\my\_app\_location, c:\%top\_level\_dir%\%bottom\_level\_dir% etc.

#### ① Note

- If the environment variable that is used by the configuration parameter is not set to anything, then an exception will be thrown.
- A directory name cannot partially be using an environment variable. For example, c:\my\_app\_%id%
- Multiple variables can be used in given directory location. For example, c:\%top\_level\_dir%\%bottom\_level\_dir%.

## Oracle Data Provider for .NET Core Configuration

ODP.NET Core developers can assign application settings in .NET Configuration API, `sqlnet.ora` file, and `tnsnames.ora` file.

### .NET Configuration API

.NET Core does not support application configuration via .NET configuration files, that is, `web.config`. Instead, it uses .NET Configuration API in lieu of a configuration file. ODP.NET Core supports Configuration API via the static class, `OracleConfiguration`, for application level provider settings. The `OracleDataSourceCollection` class supports adding and deleting net services names, that is, TNS entries. The `OracleOnsServerCollection` class supports adding to and deleting from a list of nodes where the Oracle Notification Service (ONS) daemons are talking to their remote clients.

All configurations settings through `OracleConfiguration` should be done before opening any connection in the application. Once a connection is opened, any updates to configuration properties will result in `InvalidOperationException`; with only exception of trace settings that are still allowed to change during application runtime.

### Example 2-6 Code Sample

```
using System;
using Oracle.ManagedDataAccess.Client;

namespace ODP_Core_Config_API
```

```

{
    class odp_core_config
    {
        static void Main(string[] args)
        {
            // This sample demonstrates how to use ODP.NET Core Configuration API

            // Add connect descriptors and net service names entries.
            OracleConfiguration.OracleDataSources.Add("orclpdb",
"(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<hostname or IP>)(PORT=1521))
(CONNECT_DATA=(SERVICE_NAME=<service name>)(SERVER=dedicated)))");
            OracleConfiguration.OracleDataSources.Add("orcl",
"(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<hostname or IP>)(PORT=1521))
(CONNECT_DATA=(SERVICE_NAME=<service name>)(SERVER=dedicated)))");

            // Set default statement cache size to be used by all connections.
            OracleConfiguration.StatementCacheSize = 25;

            // Disable self tuning by default.
            OracleConfiguration.SelfTuning = false;

            // Bind all parameters by name.
            OracleConfiguration.BindByName = true;

            // Set default timeout to 60 seconds.
            OracleConfiguration.CommandTimeout = 60;

            // Set default fetch size as 1 MB.
            OracleConfiguration.FetchSize = 1024 * 1024;

            // Set tracing options
            OracleConfiguration.TraceOption = 1;
            OracleConfiguration.TraceFileLocation = @"D:\traces";
            // Uncomment below to generate trace files
            //OracleConfiguration.TraceLevel = 7;

            // Set network properties
            OracleConfiguration.SendBufferSize = 8192;
            OracleConfiguration.ReceiveBufferSize = 8192;
            OracleConfiguration.DisableOOB = true;

            OracleConnection orclCon = null;

            try
            {
                // Open a connection
                orclCon = new OracleConnection("user id=hr; password=<password>; data
source=orclpdb");
                orclCon.Open();

                // Execute simple select statement that returns first 10 names from
EMPLOYEES table
                OracleCommand orclCmd = orclCon.CreateCommand();
                orclCmd.CommandText = "select first_name from employees where rownum <=
10 ";

                OracleDataReader rdr = orclCmd.ExecuteReader();

                while (rdr.Read())
                    Console.WriteLine("Employee Name: " + rdr.GetString(0));

                Console.ReadLine();
            }
        }
    }
}

```

```

        rdr.Dispose();
        orclCmd.Dispose();
    }
    finally
    {
        // Close the connection
        if (null != orclCon)
            orclCon.Close();
    }
}
}
}
}

```

## Oracle Configuration Files

ODP.NET Core supports the `sqlnet.ora` and `tnsnames.ora` parameters below. These settings can be used in conjunction with .NET Configuration API.

- BindByName
- DbNotificationPort
- Disable\_Oob – `sqlnet.ora`
- DRCPCConnectionClass
- FetchSize
- HTTPS\_PROXY - `tnsnames.ora`
- HTTPS\_PROXY\_PORT - `tnsnames.ora`
- MaxStatementCacheSize
- NAMES.DIRECTORY\_PATH – `sqlnet.ora`
- NODELAY – `sqlnet.ora`
- RETRY\_COUNT
- RETRY\_DELAY
- RECEIVE\_BUF\_SIZE – `sqlnet.ora` or `tnsnames.ora`
- SelfTuning
- SEND\_BUF\_SIZE – `sqlnet.ora` or `tnsnames.ora`
- ServiceRelocationConnectionTimeout
- SQLNET.AUTHENTICATION\_SERVICES – `sqlnet.ora`
- SQLNET.CRYPTO\_CHECKSUM\_CLIENT – `sqlnet.ora`
- SQLNET.CRYPTO\_CHECKSUM\_TYPES\_CLIENT – `sqlnet.ora`
- StatementCacheSize
- SSL\_SERVER\_DN\_MATCH – `sqlnet.ora`
- SSL\_VERSION – `sqlnet.ora`
- TNS\_ADMIN
- TOKEN\_AUTH
- TOKEN\_LOCATION
- TraceFileLocation

- `TraceLevel`
- `TraceOption`
- `TCP.CONNECT_TIMEOUT` – `sqlnet.ora`
- `SQLNET.ENCRYPTION_CLIENT` – `sqlnet.ora`
- `SQLNET.ENCRYPTION_TYPES_CLIENT` – `sqlnet.ora`
- `WALLET_LOCATION`

ODP.NET Core will look for its connection configuration settings in the following precedence order:

1. `OracleConfiguration.OracleDataSources`
2. Directory set in `OracleConnection.TnsAdmin` property
3. Directory set for the `Tns_Admin` (connection string attribute) or `tns_admin` setting (connection string URL or centralized configuration file connection string).
4. Directory set in `OracleConfiguration.TnsAdmin` property
5. Current working directory
6. `TNS_ADMIN` directory setting of the Windows environment variable or container environment variable
7. `%ORACLE_HOME%\network\admin` directory

ODP.NET Core will look for `ldap.ora` files in the following precedence order:

1. Directory set in `OracleConnection.TnsAdmin`
2. Directory set for the `Tns_Admin` connection string attribute
3. Directory set in `OracleConfiguration.TnsAdmin` property
4. Directory set in `OracleConfiguration.LdapAdmin` property
5. Current working directory
6. `TNS_ADMIN` directory setting in the environment
7. `LDAP_ADMIN` directory setting in the environment

## Configuration Differences among ODP.NET Drivers

[Table 2-9](#) lists other configuration differences among ODP.NET Core, ODP.NET, Managed Driver and ODP.NET, Unmanaged Driver..

**Table 2-9 Configuration Differences among ODP.NET Core, ODP.NET, Unmanaged Driver and ODP.NET, Managed Driver**

| Feature Category        | Difference compared to ODP.NET, Unmanaged Driver                                                                                                                                                                                           |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configuration           | The older, traditional ODP.NET, Unmanaged Driver configuration file format is different. The new format allows both providers to share the same format. See <a href="#">"Oracle Data Provider for .NET, Managed Driver Configuration."</a> |
| Configuration           | Windows Registry based configuration is not supported                                                                                                                                                                                      |
| Configuration Parameter | Edition is not supported.                                                                                                                                                                                                                  |
| Configuration Parameter | CheckConStatus is not supported.                                                                                                                                                                                                           |
| Configuration Parameter | DllPath is not supported.                                                                                                                                                                                                                  |
| Configuration Parameter | StatementCacheWithUdts is not supported.                                                                                                                                                                                                   |
| Configuration Parameter | ThreadPoolMaxSize is not supported.                                                                                                                                                                                                        |
| Configuration Parameter | TraceFileName is not supported.                                                                                                                                                                                                            |
| Configuration Parameter | UdtCacheSize is not supported.                                                                                                                                                                                                             |
| Configuration Parameter | <i>UDT Mapping</i> is not supported.                                                                                                                                                                                                       |
| Configuration Parameter | UseOraMTSManaged is not supported.                                                                                                                                                                                                         |
| Connection String       | Context Connection is not supported.                                                                                                                                                                                                       |
| Connection String       | LegacyTransactionBindingBehavior setting will be ignored. It will always be set to the default value of 1.                                                                                                                                 |
| Connection String       | Statement Cache Purge is not supported.                                                                                                                                                                                                    |
| Connection String       | Tns_Admin is supported in managed ODP.NET and ODP.NET Core, but not in unmanaged ODP.NET.                                                                                                                                                  |
| Connection String       | Wallet_Location is supported in managed ODP.NET and ODP.NET Core, but not in unmanaged ODP.NET.                                                                                                                                            |
| Connectivity            | Connection to Oracle Times Ten Database is not supported.                                                                                                                                                                                  |
| Performance Monitor     | NumberOfStaticConnections performance counter is not supported.                                                                                                                                                                            |
| Performance Monitor     | Performance monitor category name is "ODP.NET, Managed Driver"                                                                                                                                                                             |
| Provider Types          | Provider Types accept (via constructors) and generate (via ToString() methods) only culture-invariant strings                                                                                                                              |
| Tracing                 | Dynamic tracing is enabled by changing the TraceLevel setting in the app/web/machine.config. NOTE: For ASP.NET applications, doing so will recycle the application domain.                                                                 |

## Centralized Configuration Providers for Deployments

Managed ODP.NET and ODP.NET Core can store and retrieve connection string configuration values securely from a centralized provider. Centralizing ODP.NET connection configuration information makes managing user credentials easier in an app deployment. Ensuring connection strings are stored securely is necessary since they can contain sensitive information, such as passwords.

This configuration provider is available for ODP.NET cloud deployments and on-premises deployments and work with any Oracle database version ODP.NET supports. It can be stored in the following locations:

- Microsoft Azure: Store database connection information in Azure App Configuration and Azure Key Vault.
- Oracle Cloud Infrastructure (OCI): Store database connection information in OCI Object Storage and OCI Vault.
- Local file system: Store database connection information on the local file system for web and desktop apps.

Since centralized configuration providers are often used for cloud deployments, local file system access is disabled by default when the connection string is populated with an URL. To enable local access, set `OracleConnection.RemoteConfigurationFiltering` to `false`.

## Connection String URLs

The connection string URL is different from the traditional ODP.NET connection string format. To access the Azure, OCI, or local file centralized configuration provider, ODP.NET apps specify a URL in the `OracleConnection.ConnectionString` property in place of the traditional ODP.NET connection string. This URL contains the centralized configuration provider type, that is, Azure, and its configuration storage name, as well as authentication and connection configuration parameter values, if applicable. The traditional connection string values, such as `User Id` and `Min Pool Size` are stored within the centralized configuration provider itself.

Nonetheless, it remains simple moving from a traditional ODP.NET connection string to the centralized configuration provider model. The traditional ODP.NET connection string attributes and values are moved over to Azure App Configuration, OCI Object Storage, or local directory. Then, the `ConnectionString` property is set to the connection string URL instead of a traditional ODP.NET connection string.

Sensitive information, such as passwords, can be stored in secure stores, such as Azure Key Vault and OCI Vault, or be encoded. The centralized configuration providers do not support storing plain text passwords in the connection string.

If using pooling, ODP.NET caches the connection string URL. Changing the configuration values in the centralized storage after the pool populates will not change the connection pool properties until the application is restarted.

If pooling is disabled, the connection string URL is not cached. Changes to the connection configuration is then possible for subsequent connection requests without an application restart.

Connection strings begin with the format `config-<provider type>` where the provider type is `azure`, `ociobject`, or `file`, depending on the deployment location.

## Azure Centralized Configuration Provider

The Azure configuration provider can use Azure App Configuration and Azure Key Vault store to store Oracle database connection information. The Azure Centralized Configuration Provider connection string URL syntax is:

```
config-azure://{Config Name}[?  
Key=Prefix&Label=Value&Option1=Value1&Option2=Value2...]
```

- (Required) Config Name: The Azure App Configuration name
- (Optional) Key: a key prefix to identify the connection. Ending the key prefix with a separator, such as `:"`, `/"` or `."`, improves readability, but is not a technical requirement. If a key is not specified, a top-level connection is implied.

- (Optional) Label: The Azure App Configuration label name
- (Optional) Options and Values: The Azure authentication and change notification options and information to use when connecting to the Azure App Configuration service. If no authentication information is provided, ODP.NET uses Azure Default Credential to access the Azure App Configuration. More information about Azure change notification is in the [Connection URL Caching](#) documentation.

### Azure Authentication Options

ODP.NET uses the Azure SDK for .NET credential classes to provide authorization and authentication to Azure App Configuration and Key Vault services. This dependency can be resolved by having your project incorporate the `Oracle.ManagedDataAccess.Azure` package available on NuGet Gallery when Azure authentication is required.

Developers set the Azure authentication option to “Authentication” in the ODP.NET URL connection string. The possible values for this option are listed in the following table.

#### Note

These options and values are case insensitive. The required parameters can be set alternatively as environment variables

**Table 2-10 Azure Authentication Methods and their Values**

| Authentication Method                      | Authentication Option Values  | Required Parameters for This Option Value                           | Optional Parameters for This Option Value           |
|--------------------------------------------|-------------------------------|---------------------------------------------------------------------|-----------------------------------------------------|
| Default Azure Credential                   | AZURE_DEFAULT or Empty String |                                                                     | AZURE_TENANT_ID<br>AZURE_MANAGED_IDENTITY_CLIENT_ID |
| Service Principal with client secret*      | AZURE_SERVICE_PRINCIPAL       | AZURE_CLIENT_ID<br>AZURE_CLIENT_SECRET<br>AZURE_TENANT_ID           |                                                     |
| Service Principal with client certificate* | AZURE_SERVICE_PRINCIPAL       | AZURE_CLIENT_ID<br>AZURE_CLIENT_CERTIFICATE_PATH<br>AZURE_TENANT_ID | AZURE_CLIENT_CERTIFICATE_PASSWORD                   |
| Managed Identity                           | AZURE_MANAGED_IDENTITY        | AZURE_CLIENT_ID - required only if user assigned                    |                                                     |
| Interactive Browser OAuth token flow       | AZURE_INTERACTIVE             | AZURE_CLIENT_ID<br>AZURE_REDIRECT_URL                               |                                                     |

\* The Azure service principal with client secret overrides Azure service principal with client certificate.

ODP.NET supports Azure service principal with a client secret stored in a user created wallet. ODP.NET first attempts to use the ODP.NET Azure token client secret or connection string URL Azure client secret values. If neither contain a value, ODP.NET will then use a client secret stored in the wallet. The wallet path is specified in the `azure_credentials` property. This property can be set in TNS descriptor or `sqlnet.ora`.

When this property is specified, ODP.NET will attempt to authenticate with Azure by utilizing the secret corresponding to the configured wallet entry of the format `oracle.security.azure.credential.{CLIENT_ID}`, where `{CLIENT_ID}` is the Microsoft Entra ID registered Client identifier.

The `azure_credentials` property is ignored if `client_secret` property is specified using the `AzureTokenAuthentication` class.

The ODP.NET connection string URL provides more connection configuration options, including:

- `AZURE_MAX_RETRIES`
- `AZURE_RETRY_TIMEOUT`
- `AZURE_MANAGED_IDENTITY_CLIENT_ID` - only available when using `DefaultAzureCredential` and for user assigned.
- `AZURE_TENANT_ID`
- `AZURE_AUTHORITY_HOST`

The following code sample provides an ODP.NET connection string URL that specifies an Azure App configuration store name called `MyConfig`. The prefix key for the connection in `MyConfig` is `MyConnection` and the Azure App Configuration label name is `production`. The code sample uses Azure Managed Identity authentication to connect and supplies that id value. The code sample then sets the connection string URL using `OracleConnection` constructor. ODP.NET obtains the connection string from the Azure App Configuration store implicitly when opening the connection.

```
{
  // This ODP.NET URL uses Azure Managed Identity authentication
  string connectionString = "config-azure://MyConfig?key=
    MyConnection/&Label=production&Authentication=Azure_Managed_Identity&
    Azure_Managed_Identity_Client_Id=111abccd8-18cc-4fa0-bf7b-d894e5981c67";
  OracleConnection conn = new OracleConnection();
  conn.ConnectionString = connectionString;
  conn.Open();
}
```

#### 📘 See Also

[DefaultAzureCredential Class](#) for more information about Azure identity and authentication.

## OCI Centralized Configuration Provider

The Oracle Cloud Infrastructure configuration provider uses OCI Object Storage and OCI Vault to store database connection information in a JSON configuration file. The connection string URL syntax is:

`config-ociobject://{Object-Url}[?key=name&option1=value1&option2=value2...]`

- (Required) `Object-Url`: The object URL path in OCI Object Storage. This value can be obtained in the OCI Web Console in the Object Details of the Object Storage / Buckets / Object menu. Two examples of Object-Urls are:

```
https://namespace.objectstorage.us-ashburn-1.oci.customer-oci.com/n/
namespace/b/bucket1/o/odp.json
```

and,

```
https://objectstorage.us-ashburn-1.oraclecloud.com/n/namespace/b/bucket1/o/
odp.json.
```

- (Optional) Key: The connection key name identity. If a key is not specified, a top-level connection is implied.
- (Optional) Options: The Oracle Cloud authentication and change notification options and information to use when connecting to OCI Object Storage. If no authentication is provided, then the provider uses OCI API Key-Based Authentication to access OCI Object Storage. More information about Oracle Cloud change notification is in the Connection URL Caching documentation.

### OCI Authentication Options

ODP.NET OCI authentication has a dependency on OCI SDK for authorization and authentication to the OCI Object Storage and Vault services. This dependency can be resolved by having your project incorporate the `Oracle.ManagedDataAccess.Oci` package available on NuGet Gallery when OCI authentication is required.

The authentication parameters are provided via the connection string URL.

Developers set the OCI authentication option to `Authentication` in the ODP.NET URL connection string. The possible values for this option are listed in the following table.

#### Note

These options and values are case insensitive. The required parameters can be set alternatively as environment variables

**Table 2-11 OCI Authentication Methods and their Values**

| Authentication Method             | Authentication Option Values | Optional Configuration                                                        | Optional Parameters                                                                          |
|-----------------------------------|------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| API Key-Based Authentication      | OCI_DEFAULT or Empty String  | (~/oci/config), (~/oraclebmc/config), or environment variable OCI_CONFIG_FILE | OCI_PROFILE<br>OCI_TENANCY<br>OCI_USER<br>OCI_FINGERPRINT<br>OCI_KEY_FILE<br>OCI_PASS_PHRASE |
| Instance Principal Authentication | OCI_INSTANCE_PRINCIPAL       |                                                                               |                                                                                              |
| Resource Principal Authentication | OCI_RESOURCE_PRINCIPAL       |                                                                               |                                                                                              |

The following code sample provides an ODP.NET connection string URL that specifies an OCI Object Store object URL. The connection key name identity is `MyConnection`. The code sample uses OCI's API key-based authentication, `OCI_DEFAULT`, and the optional parameter, `OCI_PROFILE`, to specify the connection profile configuration. The code sample then sets the connection string URL using `OracleConnection.ConnectionString` property. ODP.NET obtains

the connection string from the JSON configuration file stored in OCI Object Storage Service when opening the connection.

```
{
    //This URL will use default OCI authentication, which requires no authentication
    parameters
    string connectionString = "config-ociobject://https://objectstorage.us-ashburn-1.
        oraclecloud.com/n/namespace/b/bucket1/o/odp.json?
key=MyConnection&authentication
    =OCI_DEFAULT&OCI_PROFILE=MyProfile";
    OracleConnection conn = new OracleConnection(connectionString);
    conn.Open();
}
```

### See Also

[OCI SDK Authentication Methods](#) for more information.

## Local File Centralized Configuration Provider

The file config provider stores Oracle database connection information in a JSON configuration file on the local file system. The ODP.NET file connection string URL syntax is:

config-file://{File Path}[?Key=name&tns\_admin=filepath]

- (Required) File Path: JSON config file path and name, which can be an absolute or relative path. For relative paths, ODP.NET will use the TNS\_ADMIN value as the base path.
- (Optional) Key: The connection key name identity. If a key is not specified, a top-level connection is implied.
- (optional) tns\_admin: the filename base path or prefix to locate the JSON config file.

The following code sample provides an ODP.NET connection string URL that specifies a local file, odpconfig.json, and directory location. The connection key name identity is MyConnection. This code sample then sets the connection string URL using OracleConnection constructor. ODP.NET obtains the connection string from the local JSON config file when opening the connection.

```
{
    //This URL will retrieve the c:\configs\odpconfig.json from the file system
    //The connection key is "MyConnection"
    string connectionString = "config-file://c:/configs/odpconfig.json?
key=MyConnection";

    OracleConnection conn = new OracleConnection(connectionString);
    conn.Open();
}
```

The file config provider relies on Oracle.ManagedDataAccess.ConfigFile package available on NuGet Gallery.

### JSON Configuration File Search Order

ODP.NET can use the absolute directory and file name value, that is, c:/configs/myconfig.json, set in the local file centralized configuration provider connection string URL to

locate its JSON configuration file. It can also use a relative directory with a file name. In this case, it will append the relative directory and file to the settings in the following order to locate the JSON file.

1. Current working directory
2. Directory set in `OracleConnection.TnsAdmin` property
3. Directory set for the `Tns_Admin` connection string attribute
4. Directory set in the `tns_admin` attribute of the configuration provider URL
5. Directory set in `OracleConfiguration.TnsAdmin` property
6. `TNS_ADMIN` directory setting in .NET configuration file -- managed ODP.NET only
7. `TNS_ADMIN` directory setting of the Windows environment variable or container environment variable
8. Directory set in the Windows Registry key, `HKLM\SOFTWARE\Oracle\ODP.NET.Managed\<version>\TNS_ADMIN` -- managed ODP.NET only

**Note**

32-bit apps use the Registry key  
`HKLM\SOFTWARE\Wow6432Node\Oracle\ODP.NET.Managed\<version>\TNS_ADMIN`

9. `%ORACLE_HOME%\network\admin` directory

## Vault Providers

Database passwords, proxy passwords, wallets, JSON configuration are sensitive database information that can be stored in Azure Key Vault or OCI Vault services as secret. These vault providers are included with the `Oracle.ManagedDataAccess.Azure` and `Oracle.ManagedDataAccess.Oci` NuGet packages, respectively.

ODP.NET provides a secured way to access this sensitive information from vaults using a predefined URL, secret-URL. The secret-URL must be prefixed with `vault-azure` or `vault-oci` for ODP.NET to access the user provided information in either Azure Key Vault or OCI Vault services, respectively. The user-provided URL must conform to the ODP.NET defined syntax below.

The ODP.NET vault providers support single sign-on (.sso) and PKCS #12 (.p12) wallets in cloud vaults.

### Azure Key Vault

All ODP.NET secrets can be stored as Azure Vault secrets. Use the following URL syntax to access Azure Key Vault secrets:

```
config-azurevault://{Secret Identifier}[?key=name&Option1=Value1&Option2=Value2...]
```

Applications need to provide the following information in the URL:

- (Required) Secret Identifier: The Azure secret identifier obtained from the Azure portal
- (Optional) Key: The connection identifier. If a key is not specified, then it is a top level connection. This option is only used when a JSON configuration file is in Azure Key Vault.

- (Optional) Authentication Options: The Azure Key Vault authentication connection information. If authentication information is not provided, ODP.NET uses Azure Default Credential to access secrets in Azure Key Vault service. The authentication options are the same as the [Azure Authentication Options](#).

### OCI Vault

All ODP.NET secrets can be stored as OCI Vault secrets. Use the following URL syntax to access OCI Vault secrets:

```
config-ocivault://{Secret OCID}[?
VersionNumber=Value1&Stage=Value2&key=name&Option3=Value3&Option4=Value4...]
```

Applications need to provide the following information in the URL:

- (Required) Secret OCID: The OCI secret identifier (OCID) obtained from the OCI portal
- (Optional) VersionNumber: The OCI secret version. If the version is not specified, the latest secret version is retrieved by default.
- (Optional) Stage: The secret's rotation stage. If stage is not specified, the secret's current stage is retrieved by default.
- (Optional) Key: The connection identifier. If a key is not specified, then it is a top level connection. The option is only used when a JSON configuration file is in the OCI Vault.
- (Optional) Options: The OCI Vault authentication connection information. If authentication information is not provided, ODP.NET uses the API Key-Based authentication to access secrets in OCI Vault service. The authentication options are the same as the [OCI Authentication Options](#).

### Vault Connection String URLs

Similarly for centralized configuration providers, vault URLs can be passed as a connection string to the `OracleConnection` class through a constructor connection string property or an `OracleConnection.ConnectionString` property.

Here is an example for Azure Vault:

```
new OracleConnection("config-azurevault://https://vault1.vault.azure.net/secrets/
ODPConnStr/
abc69352e1d040e59wd7b83ffcdaf123");
```

The Vault can contain a standard connection string or a JSON config string.

Standard connection string example:

```
user id = scott; password = tiger; data source = inst1; pooling = false
```

JSON config example:

```
{
  "Connection1": {
    "ODP": {
      "User Id": "scott",
      "Password": "tiger",
      "Data Source": "inst1",
      "Pooling": "false"
    }
  }
}
```

**Note**

The connection/JSON config strings should be uploaded as clear text.

**Vault Passwords**

Instead of storing the entire connection string, developers have the option to store only the password or proxy password in a cloud vault. To do this, the application provides the vault URL value in the password or proxy password connection string attribute value.

For example, the ODP.NET connection string for Azure Vault could be:

```
"User ID = HR; Data Source = mydb;  
password=config-azurevault://https://vault1.vault.azure.net/secrets/ODPConnStr/  
abc69352e1d040e59wd7b83ffcdaf123"
```

**Vault Wallets and Tokens**

An application can store wallets and tokens in cloud vault services securely by providing the vault URL in the ODP.NET wallet and token location properties. The application must store the wallet or token file data in the cloud vault as a base64 string.

**Note**

For OCI vault, although wallet and token have to be converted to base64 string, they must be uploaded to OCI vault as "plain-text" type secret.

ODP.NET connection strings can use the `Wallet_Location` and `Token_Location` properties, respectively, to store wallets and tokens. For example, the ODP.NET connection string for accessing a wallet stored in Azure Vault could be:

```
"User ID = HR; password = <PASSWORD>; Data source = mydb;  
Wallet_Location=config-azurevault://https://vault1.vault.azure.net/secrets/HRWallet/  
abc69352e1d040e59wd7b83ffcdaf123"
```

The `OracleConnection.WalletLocation` and `TokenLocation` properties can be set to a vault URL or file path location. These `OracleConnection` properties have precedence over the wallet and token location attributes in the connection string. Here's sample code to use these properties with Azure Vault:

```
OracleConnection conn = new OracleConnection();  
conn.WalletLocation = "config-azurevault://https://vault1.vault.azure.net/secrets/  
HRWallet/abc693...";  
conn.TokenLocation = "config-azurevault://https://vault1.vault.azure.net/secrets/HRToken/  
abc3ffc...";
```

**Note**

Secure External Password Store is not supported for cloud wallet locations.

ODP.NET supports Microsoft identity platform tokens v1.0 for Microsoft Entra ID-only applications and v2.0 for applications that support consumer accounts. ODP.NET 23.5 and higher check the roles (roles) and user principal name (UPN) claims in v2.0 tokens to verify at least one is present. If both claims are missing, then the provider will report an error.

## Provider Configuration

The local file and OCI centralized configuration providers both use a JSON format to specify connection information. They both use the same JSON configuration.

### Provider Configuration Keys

ODP.NET uses the values in the provider configuration keys to construct a connection string to an Oracle database. Configuration keys generally map to an existing ODP.NET connection string and Oracle connection properties. Some keys are generic to all Oracle data access drivers. Those properties are:

- user: database user/schema name
- password: database password
- connect\_descriptor: ODP.NET data source
- config\_time\_to\_live: cached connection information retention time in seconds
- config\_time\_to\_live\_grace\_period: After config\_time\_to\_live expires, new connections can continue to use the cached credentials for the set grace period.

In Azure App Configuration, the ODP.NET specific configuration keys are prefixed with ODP/ to indicate intent to be used for ODP.NET only. For example, MyConnection/ODP/Pooling key specifies the ODP.NET's Pooling connection string attribute.

For OCI and local file providers, the ODP.NET specific configuration keys are specially identified in the JSON configuration. These keys use the "ODP" key. For example, "ODP": {"Max Pool Size": "500", "Pooling": true } specifies the Max Pool Size and Pooling connection string attributes for MyConnection property in the following example.

```
{
  "MyConnection": {
    "ODP": {"Max Pool Size": "500", "Pooling": true },
    "password":
    {
      "type": "ocivault",
      "value": "ocid1.vaultsecret.oc1.phx.example",
      "authentication":
      {
        "method": "OCI_DEFAULT",
        "OCI_PROFILE": "<PROFILE>"
      }
    }
  },
  "user": "HR",
  "connect_descriptor": "(description= .....)"
}
```

Generally, ODP.NET configuration keys are case insensitive. However, the ODP/ section in Azure App configuration and the ODP section in OCI and local configuration, including the keys and their values, are case-sensitive.

## Connection Attributes

The `ConnectionString` key is an ODP.NET specific key in the configuration provider. It allows defining complete or partial ODP.NET connection strings. ODP.NET apps can continue to use the `OracleConnection.ConnectionString` property and are not required to use the configuration provider's `ConnectionString` key.

All the connection string attributes defined in `OracleConnection.ConnectionString` are supported as is used in the traditional connection string except the following attribute:

- `Tns_Admin`: Not supported.

ODP.NET also supports the following `OracleConnection` properties in the provider configuration:

- `AutoProxy`
- `BindByName`
- `CommandTimeout`
- `ChunkMigrationConnectionTimeout`
- `ConnectionIdPrefix`
- `DatabaseEditionName`
- `DrcpConnectionClass`
- `FetchSize`
- `HttpsProxy`
- `HttpsProxyPort`
- `MaxStatementCacheSize`
- `OciCompartment`
- `OciDatabase`
- `OciIamUrl`
- `OciTenancy`
- `PasswordAuthentication`
- `Pipelining`
- `PoolName`
- `ServiceRelocationConnectionTimeout`
- `SSLVersion`
- `SSLServerCertDN`
- `SSLServerDNMatch`
- `SuppressGetDecimalInvalidCastException`
- `SqlNetEncryptionClient`
- `SqlNetEncryptionTypesClient`
- `SqlNetCryptoChecksumClient`
- `SqlNetCryptoChecksumTypesClient`

- TokenAuthentication
- UseClientInitiatedCQN
- UseSNI
- Wallet\_Location: Wallet that is stored in local system file is not supported. Wallet that is stored as Base64 string in Azure App Configuration, Azure Vault, or OCI Vault is supported for .p12 and .sso files. For JSON configuration, Wallet\_Location must be specified using Password JSON object.
- Wallet\_Password: For encrypted PKCS #12 wallets.
- Token\_Location: Token that is stored in local system file is not supported. Token that is stored as Base64 string in Azure App Configuration, Azure Vault, or OCI vault is supported. For JSON configuration, Token\_Location must be specified using Password JSON object.

If a non-supported attribute is specified in the provider configuration under the ODP JSON property or ODP/ Azure App Configuration section, then ODP.NET throws an exception.

The following example contains three connections: sales\_app, hr\_app, and sh\_app using various configuration key types.

```
{
  "sales_app":
  {
    "connect_descriptor": "(description=(address=(protocol=tcps)(port=1521)
(host=<HOSTNAME>
(connect_data=(service_name=<SERVICE NAME>))(security=(ssl_server_dn_match=yes)))",
    "user": "sales",
    "password": {
      "type": "ocivault",
      "value": "<VAULT LOCATION>",
      "authentication": {
        "method": "OCI_INSTANCE_PRINCIPAL"
      }
    },
    "ODP": {
      "Connection Timeout": 30,
      "pooling": "true",
      "max pool size": 100
    }
  },
  "hr_app":
  {
    "password": {
      "type": "azurevault",
      "value": "<VAULT LOCATION>",
      "authentication": {
        "method": "AZURE_DEFAULT"
      }
    },
    "ODP": {
      "user": "hr",
      "data source": "oracle",
      "max pool size": 100
    }
  },
  "sh_app":
  {
    "ODP": {
      "ConnectionString": "user id = sh; data source = oracle; max pool size = 100",
```

```

        "BindByName": "false"
    }
    "password": {
        "type": "ocivault",
        "value": "<SECRET OCID>",
        "authentication": {
            "method": "OCI_INSTANCE_PRINCIPAL",
            "OCI_PROFILE": "DEFAULT"
        }
    }
}
}
}

```

Within the configuration provider, `ConnectionString` key has precedence over other keys, such as `connect_descriptor`, with the same prefix key. Thus, if the `User Id` attribute is not included in the `ConnectionString`, then ODP.NET uses the user key that has the same prefix key. If the `Data Source` attribute is not included in the `ConnectionString`, then it will use the value of the `connect_descriptor` key that has the same prefix key. Similar behavior applies for all the `ConnectionString` attributes.

The precedence order for constructing the ODP.NET connection string from higher precedence to lower is as follows:

1. ODP.NET `ConnectionString` centralized configuration provider key
2. ODP.NET `OracleConnection` `ConnectionString` attributes, `OracleConnection` properties, provider configuration file, and ODP.NET connection parameters, such as ODP/Pooling, ODP/Connection Timeout, and ODP/OciCompartment. All of these have equal precedence.
3. Oracle common driver attributes in provider configuration file, such as user, password, and `connect_descriptor`.

### Password Connection Attributes

For the OCI and local file providers, passwords, wallet locations, and token locations must be specified as password JSON objects. Password JSON objects are supported with Azure Vault as well, but not Azure App Configuration.

The Oracle user password has the following format and properties in the configuration providers:

| Property       | Required or Optional | Possible Values and Notes                                                                                                                                                                                                                        |
|----------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type           | Required             | <ul style="list-style-type: none"> <li>Base64</li> <li>azurevault</li> <li>ocivault</li> </ul>                                                                                                                                                   |
| value          | Required             | <ul style="list-style-type: none"> <li>Base64 encoded password (base64)</li> <li>Azure Key Vault URI (azurevault)</li> <li>OCID of the secret (ocivault)</li> </ul>                                                                              |
| authentication | Optional             | <ul style="list-style-type: none"> <li>Authentication type</li> <li>Optional parameters</li> </ul> <p>This property has the same possible values and defaults as described in the Azure and OCI Centralized Configuration Provider sections.</p> |

| Property      | Required or Optional | Possible Values and Notes    |
|---------------|----------------------|------------------------------|
| versionNumber | Optional             | Applicable to OCI Vault only |
| stage         | Optional             | Applicable to OCI Vault only |

Sample OCI password configuration:

```
"password": {
  "type": "ocivault",
  "value": "<SECRET OCID>",
  "authentication": {
    "method": "OCI_INSTANCE_PRINCIPAL",
    "OCI_PROFILE": "DEFAULT"
  }
}
```

Sample Azure password configuration:

```
"password": {
  "type": "azurevault",
  "value": "<AZURE KEY VAULT URI>",
  "authentication": {
    "method": "AZURE_SERVICE_PRINCIPAL",
    "AZURE_CLIENT_ID": "<AZURE CLIENT ID>",
    "AZURE_CLIENT_CERTIFICATE_PATH": "<AZURE CLIENT CERTIFICATE PATH>",
    "AZURE_TENANT_ID": "<AZURE TENANT ID>"
  }
}
```

Sample Base64 password configuration

```
{
  "type": "base64",
  "value": "<BASE64 ENCODED PASSWORD>"
}
```

ODP.NET ignores plain text passwords in the OCI Object Store or local file centralized configuration provider file for security reasons. The Azure centralized configuration provider accepts plain text passwords in password keys and the connection string since Azure provides secure means to access the app configuration.

While Base64 format is allowed in the password JSON object, it is not considered secure and should only be used in development environments.

If Persist Security Info is false (default) in the ODP.NET connection string, then the Password value is not returned with the connection string value to protect the sensitive password information. In the Azure case, the following sensitive authentication information is also removed from the connection string:

- AZURE\_CLIENT\_SECRET
- AZURE\_CLIENT\_CERTIFICATE
- AZURE\_CLIENT\_CERTIFICATE\_PASSWORD

In the OCI case, the following sensitive authentication information is also removed from the connection string:

- OCI\_FINGERPRINT
- OCI\_PRIVATE\_KEY
- OCI\_PASS\_PHRASE

### Automatic Password Refresh

Administrators often set up password expiration policies so that the passwords become invalid at a regular cadence and replaced with new ones. For existing connection pools, this can result in ORA-01017 errors (invalid username/password; logon denied) and having to rebuild the connection pool.

ODP.NET supports the ability to automatically refresh the existing connection pool with the new password. This feature eliminates end users experiencing connection errors and forcing apps to rebuild their pool after each password refresh.

Using this feature requires:

- ODP.NET connection with pooling enabled
- An URL connection string stored in a centralized configuration provider
- One of the following locations to specify the password:
  - “ODP/ConnectionString” key
  - “ODP/Password” key
  - “ODP/ProxyPassword” key
  - “Password” key

#### Note

ODP.NET does not currently support password refresh using cloud key vaults.

When ODP.NET encounters an invalid password, it retrieves the latest configuration provider values and checks for the following conditions:

- The new password(s) must use the same key(s) as the expired password(s).
  - If the original configuration used the “ODP/Password” key, but the refreshed configuration uses the “Password” key, the original connection error will be thrown.
  - If the original configuration used the “ODP/Password” and “ODP/ProxyPassword” keys, but the refreshed configuration only uses the “ODP/Password” key, the original connection error will be thrown.
- The password value must be different between the original and updated passwords.
  - If both the password and proxy password are used, then at least one of them must be different.
- All non-password related keys must be identical between the original and updated values.

If any part of this process does not meet the stated conditions, then ODP.NET returns the original connection error.

For end users and administrators, this automated password refresh experience provides a seamless and error free experience.

## Connection URL Caching

Since connection information retrieval takes longer retrieving from a cloud resource than local disk, ODP.NET can cache connection information. Cache updates can occur using a polling or change notification model.

### Connection URL Polling Updates

The polling model uses the `config_time_to_live` key. This property sets the duration in seconds for ODP.NET to keep the connection information cached.

By default, `config_time_to_live` is 86,400 seconds (24 hours). The maximum value is `Int64.MaxValue`. If it is set to a non-positive value, ODP.NET will never expire the cache.

When the cache expires, ODP.NET retrieves the connection information from the configuration provider again. Once retrieved, ODP.NET refreshes the cache and uses the new configuration for the duration of the `config_time_to_live` setting.

#### Note

If pooling is enabled, then only the password and proxy password can be updated. If pooling is disabled, then all the connection information will be refreshed.

When `config_time_to_live` expires, the configuration is considered "softly expired". ODP.NET attempts to refresh the cache with every connection request. If a new configuration cannot be retrieved, then ODP.NET continues to open new connections with the "softly expired" configuration for up to the time set in `config_time_to_live_grace_period`.

By default, `config_time_to_live_grace_period` is 1800 seconds (30 minutes). It is an `Int64`. Any negative value will be treated as a grace period of zero seconds.

If new connection information can not be retrieved during `config_time_to_live_grace_period`, then the configuration fully expires. No new connections can be made with these old credentials. Existing "softly expired" connections will continue to work until closed or disposed.

### Connection URL Change Notification Updates

The change notification model provides real time connection information updates. When data on the cloud is modified, ODP.NET receives the notification almost immediately instead of waiting for `config_time_to_live` to expire. The relevant cache entries are evicted, and the latest values are retrieved the next time they are needed.

Connection URL change notifications are available for Azure App Configuration and OCI Object Storage only at this time.

Similarly to `config_time_to_live`, if connection pooling is disabled, then change notification can monitor and update all connection configuration provider settings. If pooling is enabled, only the password and proxy password are monitored and updated.

Developers register their apps for change notification using the options in the connection string URL.

To unregister from change notification, developers call the `OracleConnection.UnregisterCloudConfigNotification(OracleConnection con)` method. If

pooling is enabled, the method unregisters all connections that reside in the same pool as the connection passed into the method.

Change notification updates do not reset the `config_time_to_live` timer.

### Azure App Configuration Setup for Change Notification

ODP.NET Azure-based change notifications require Azure Event Grid and Azure Service Bus. Azure Event Grid watches the Azure App Configuration for changes. When a change is detected, it sends a notification message to Azure Service Bus. Service Bus forwards the message to the ODP.NET application, prompting the application to refresh the values associated with the update notification upon their next use.

### Azure Service Bus

Azure Service Bus is a fully managed enterprise message broker with message queues and publish-subscribe topics. ODP.NET change notification can use the Service Bus message entities, Queues and Topics. Queues follow a one-to-one model, where one sender delivers messages to one receiver. Topics follow a one-to-many model, where one sender delivers messages to multiple receivers.

Topics are used when multiple ODP.NET applications register for change notification on the same Azure App Configuration. Otherwise, Queues are sufficient. Azure Service Bus pricing varies depending on the usage and feature set the change notification app required.

### Azure Service Bus Setup

1. On the Azure portal, navigate to the Service Bus page.
2. Start a new Service Bus resource setup by selecting a pricing tier appropriate for the intended use and budget.
3. Once the Service Bus resource is created, select it, and go to the Overview tab. Remember the "Host name"

- It will look like: `<Service Bus Name>.servicebus.windows.net`

Next, you will need to set up either Service Bus queue or topic, not both.

### Azure Service Bus Queue Setup

1. On the Azure portal Service Bus page, navigate to the Queues and create a new Queue.
  - The default options can be used or be modified. It will not affect compatibility with ODP.NET change notifications.
2. Name the Queue and remember the Queue name.

### Azure Service Bus Topic Setup

1. On the Azure portal Service Bus page, navigate to the Topics and create a new Topic.
  - The default options can be used or be modified. It will not affect compatibility with ODP.NET change notifications.
2. Name the Topic and remember the Topic name.
3. Navigate to the created topic.
4. Create a new subscription.
  - The default options can be used with ODP.NET change notifications.
5. Name the Subscription and remember the Subscription name.

- Repeat Steps 4 and 5 if there are multiple ODP.NET Applications that will receive change notifications from the same Azure App Configuration. Each application should use a separate subscription.

### Azure Event Grid Setup

To connect the App Configuration to Service Bus, an Event Grid resource is required.

- On the Azure portal, search or navigate to the Event Grid page.
- Go to the "System topics" tab and create a new Event Grid System Topic.
- For "Topic Types", search for and select Microsoft Azure App Configuration
- Have the System Topic point to the App Configuration to be watched.
- Navigate to your new System Topic and create a new subscription.
- For "Event Schema", select "Event Grid Schema" from the drop-down menu.
- For "Filter to Event Types", select both "Key-Value Modified" and "Key-Value Deleted".
- For "Endpoint Type", select "Service Bus Topic" or "Service Bus Queue" depending on whether you are using a topic or queue.
- For the "Endpoint", select the topic or queue created earlier.
  - For the other options, you may use the default values.

### ODP.NET Setup for Azure Change Notifications

To enroll ODP.NET in change notifications, the following options in the URL connection string are required for Service Bus queues:

| Service Bus Option | Description            |
|--------------------|------------------------|
| SERVICE_BUS_HOST   | Service Bus host URL   |
| SERVICE_BUS_QUEUE  | Service Bus queue name |

All options are required values for queues and all are string values.

### URL Connection String format for Azure queues

```
string connStr = "config-azure://myAppConfig?key=test/&SERVICE_BUS_HOST=<Service Bus Host>  
&SERVICE_BUS_QUEUE=<Queue Name>";
```

For Service Bus topics, the following options in the ODP.NET URL connection string are required:

| Service Bus Option       | Description                                    |
|--------------------------|------------------------------------------------|
| SERVICE_BUS_HOST         | Service Bus host URL                           |
| SERVICE_BUS_TOPIC        | Service Bus topic name                         |
| SERVICE_BUS_SUBSCRIPTION | Subscription name within the Service Bus topic |

All options are required values for topics and all are string values.

### URL Connection String format for Azure topics

```
string connStr = "config-azure://myAppConfig?key=test/&SERVICE_BUS_HOST=  
<Service Bus Host>&SERVICE_BUS_TOPIC=<Topic Name>&SERVICE_BUS_SUBSCRIPTION=  
<Subscription Name>";
```

You have now completed change notification setup for Azure App Configuration.

### OCI Object Storage Event Notification for Change Notification

ODP.NET OCI Object Storage-based change notifications require Oracle Cloud Infrastructure Events Service and Notifications service to establish a communication channel that publishes messages using topics and subscriptions. When a change is detected, it sends a notification message to the HTTPS endpoint. The OCI event listener of the ODP.NET application receives the message, prompting the application to refresh the values associated with the update notification upon their next use.

To use OCI Object Storage event notifications, you must configure the OCI Object Storage, OCI Notifications service, event rules, an event listener, and ODP.NET to use OCI event notifications. Let's walk through each of these setup topics.

### OCI Object Storage Setup

The first step is to setup the OCI JSON configuration file in OCI Object Storage and then connect to the Oracle database using the file.

1. Create a bucket in Object Storage and enable "Emit Object Events" for that bucket. Existing buckets can enable "Emit Object Events" in the "Bucket Details" > "Bucket Information" section.
2. Upload your OCI JSON configuration file to this bucket.

### OCI Event Listener Setup

ODP.NET's OCI Event Listener uses HTTPS protocol to receive notification messages, and it has two requirements. First, OCI Notifications service requires a publicly accessible URL with a certificate authority issued certificate. It also must accept POST calls. The OCI API Gateway can be set up to fulfill this requirement through setting up a route. A gateway route is the mapping between a path, one or more methods, and a back-end service.

Second, the host running ODP.NET application must be able to receive the HTTPS message. This usually requires the host to have a port open to the traffic of the notifications service. If your application is running in an OCI Compute Instance and are using OCI API Gateway, you can modify the virtual cloud network's ingress rules security list to permit an open port to OCI API Gateway for the OCI Notifications service. Remember the network path and port you are forwarding into. You will use it in your ODP.NET connection string URL.

### OCI Notifications Service

When the JSON configuration file in the OCI Object Storage bucket is updated, OCI Notifications service can emit an event. The event can publish a notification and use the notification to update to the latest configuration version.

OCI Notifications service supports alarms, event rules, and connectors to emit human-readable messages through supported endpoints, including email, SMS, and Slack messages with an HTTPS payload. Additionally, you can automate tasks through custom HTTPS endpoints and OCI Functions, as well as directly publish messages.

The notifications service can be enabled to set up communication channels for publishing messages using topics and subscriptions. A topic is a communication channel for sending messages to subscriptions. When a message is published to a topic, the notifications service sends the message to all the topic's subscriptions. A subscription is a topic endpoint.

## Setup OCI Notification Topic and Subscription

A notification topic allows creating a set of notification subscriptions that can be tied together by an event. Here's how to setup a topic and subscription.

1. Navigate to your OCI tenancy compartment's Notifications service management web page. The page title should be "Topics in <Compartment Name> Compartment".
2. Click the **Create Topic** button.
3. Give the topic an identifiable name. It can be helpful to include bucket/configuration file name and subscription protocols in the name.
4. Click on the newly created topic name in the list. Now, let's create the subscription.
5. Click the **Create Subscription** button.
6. Select **HTTPS (Custom URL)** as the communication protocol and add the URL for HTTPS.
7. Confirm your subscription. For HTTPS, you will receive a payload like the following:

```
{"ConfirmationURL":"https://cell1.notification.us-phoenix-1.oci.oraclecloud.com/20181201/subscriptions/ocid1.onssubscription.oc1.phx.../confirmation?token=MDA...&protocol=CUSTOM_HTTPS"}
```

After confirming your subscription, its status will change from "Pending" to "Active". You can test your subscription by publishing a test message.

## Setup OCI Notification Event Rules

Rules trigger actions for specified event conditions. Let's create a rule to trigger a notification when the config file is modified.

1. Navigate to your OCI tenancy compartment's event service rules web page. The page title should be "Rules in <Compartment Name> Compartment".
2. Click the **Create Rule** button.
3. Give the rule an identifiable display name.
4. Under the rule conditions section, set the following values:
  - Condition: Event Type
  - Service Name: Object Storage
  - Event Type: Object – Update

These settings indicate whenever there is an Object Storage object update, an action is triggered. Since update can occur for any object in any bucket, let's add more conditions to narrow it down.

5. Click the **Another Condition** button to add more conditions.
  - a. Create a condition with the following attributes:
    - Condition: Attribute
    - Attribute Name: <Bucket Name or ID>
    - Attribute Value: <Configuration File Bucket Name/OCID>
  - b. Create a second condition with the following attributes:
    - Condition: Attribute
    - Attribute Name: <Resource Name or ID>

- Attribute Value: *<Configuration File Name/OCID>*
6. In the Actions section, set the following values:
    - Action Type: Notifications
    - Notifications Compartment: *<Compartment Name of the Notification Topic>*
    - Topic: *<Topic Name>*
  7. Click the **Create Rule** button.
  8. Click the **Validate Rule** button to test whether the rule works. A notification message should be sent.
    - a. In the Example Events section, use a code editor to change the following settings to the matching values you just set for the event rules.
      - *<Compartment Name of the Notification Topic>*
      - *<Resource Name>*
      - *<Bucket Name>*
    - b. Click the **Check If Example Event Matches Rule** button.

That completes the OCI setup. Let's complete the ODP.NET setup for OCI notifications.

### ODP.NET Setup for OCI Notifications

For OCI Object Storage notifications, the ODP.NET connection string URL requires the OCI profile name in the JSON configuration file and the OCI event listener path and port. The connection string URL syntax is:

```
@config-ociobject:{object-url}[?key=name&option1=value1&option2=value2...]
```

To enable OCI change notification, the following options in the URL connection string are required:

| OCI Event Listener Option | Description                                        |
|---------------------------|----------------------------------------------------|
| Event_Listener_Path       | network path listener listens on for notifications |
| Event_Listener_Port       | network port listener listens on for notifications |

In our setup, the connection string URL will also include the `OCI_PROFILE` name that you created earlier for the OCI configuration file. Your ODP.NET connection string will look similar to the following.

**Sample Code:** ODP.NET OCI change notification connection string URL

```
OracleConnection conn = new OracleConnection("@config-ociobject:https://objectstorage.us-ashburn-1.oraclecloud.com/.../Connection.json?KEY=myconn&authentication=OCI_DEFAULT&EVENT_LISTENER_PATH=<HOSTNAME/DIRECTORY>&EVENT_LISTENER_PORT=80")
```

You have now completed change notification setup for OCI Object Storage.

## Connection Configuration Restriction

ODP.NET has many ways to configure and secure connections to the Oracle database. This flexibility provides numerous options for how apps prefer to connect. In some situations, apps

may want to restrict other connection methods that it does not use, have not been tested, and to limit possible unauthorized entry when they get deployed.

ODP.NET connection configuration restriction allows developers to globally set restrictions for how an app can connect. For example, a SaaS app can allow using MY\_WALLET\_LOCATION, WALLET\_LOCATION, and TOKEN\_LOCATION to set a wallet and token directory location. ODP.NET apps would then be allowed to connect with any of these settings in the Data Source connection string value, which is generally either a connect descriptor, Easy Connect string, or TNS alias.

If any other data source parameter is not on the allowed list, the connection request is rejected, and an error is thrown. The error is an "ORA-50122: The following configuration parameters are not allowed to be set:" followed by a parameter name list used but not allowed.

This feature is available in managed ODP.NET and ODP.NET Core only.

Connection configuration uses an allow list, which details to ODP.NET which connection options are allowed. The app can supply the list as a string or file so that code changes are not necessary.

### Connection Configuration Restriction Methods

To use connection configuration restriction, a developer can call the following OracleConfiguration methods to set or unset the restrictions:

- `EnableConnectionStringAllowedProperties(FileInfo, bool)`

This method accepts a file path to an allowed parameter list in a JSON file. The file should be named `ODPConnectionStringAllowedProperties.json`. Developers may configure whether to enforce allowed parameters on the TNS alias by setting the Boolean argument.

- `EnableConnectionStringAllowedProperties(string, bool)`

This method accepts an allowed parameter list in a JSON string format. Developers may configure whether to enforce allowed parameters on the TNS alias by setting the Boolean argument. If both overloaded methods are set, this JSON string method will override using the JSON file.

- `DisableConnectionStringAllowedProperties`

This method disables using any prior list of allowed parameters. Connections are no longer subject to configuration restrictions.

### Data Source Allowed Parameters

The connection configuration JSON format to allow parameters is:

```
{
  "DataSource" : {
    "<property_name1>" : true/false,
    "<property_name2>" : true/false,
    "<property_name3>" : true/false
  }
}
```

This sample JSON file lists all properties that can be disallowed. Each of the properties set to true is allowed. Properties set to false are restricted. Connections using those restricted properties will be rejected.

All properties not set are false by default.

If there are duplicate property names, then the last property name is used.

The JSON strings are case insensitive.

### ODP.NET Connection Configuration JSON Sample

```
{
  "DataSource" : {
    "CLIENT_ID" : true,
    "COLOCATION_TAG" : true,
    "CONNECT_TIMEOUT" : true,
    "CONNECTION_ID_PREFIX" : true,
    "ENABLE" : true,
    "EXPIRE_TIME" : true,
    "FAILOVER" : true,
    "HOST" : true,
    "HTTPS_PROXY" : true,
    "HTTPS_PROXY_PORT" : true,
    "IGNORE_ANO_ENCRYPTION_FOR_TCPS" : true,
    "INSTANCE_NAME" : true,
    "LOAD_BALANCE" : true,
    "PASSWORD_AUTH " : true,
    "POOL_BOUNDARY" : true,
    "POOL_CONNECTION_CLASS" : true,
    "POOL_NAME" : true,
    "POOL_PURITY" : true,
    "PORT" : true,
    "PROTOCOL" : true,
    "RECV_BUF_SIZE" : true,
    "RECV_TIMEOUT" : true,
    "RETRY_COUNT" : true,
    "RETRY_DELAY" : true,
    "SDU" : true,
    "SEND_BUF_SIZE" : true,
    "SERVER" : true,
    "SERVICE_NAME" : true,
    "SHARDING_KEY" : true,
    "SHARDING_KEY_ID" : true,
    "SOURCE_ROUTE" : true,
    "SSL_CERTIFICATE_THUMBPRINT" : true,
    "SSL_SERVER_CERT_DN" : true,
    "SSL_SERVER_DN_MATCH" : true,
    "SSL_VERSION" : true,
    "SUPER_SHARDING_KEY" : true,
    "TRANSPORT_CONNECT_TIMEOUT" : true,
    "BACKUP" : true,
    "TYPE" : true,
    "METHOD" : true,
    "TRANSACTION" : true,
    "RETRIES" : true,
    "DELAY" : true,
    "COMMIT_OUTCOME" = true,
    "MY_WALLET_LOCATION" : false,
    "OCI_COMPARTMENT" : false,
    "OCI_DATABASE" : false,
    "OCI_PROFILE " : false,
    "OCI_TENANCY " : false,
    "TUNNEL_SERVICE_NAME" : false,
    "TENANT_ID" : false,
    "TOKEN_AUTH " : false,
    "TOKEN_LOCATION" : false,
    "WALLET_LOCATION" : false
  }
}
```

## Code Sample

```
using System;
using Oracle.ManagedDataAccess.Client;

class Example
{
    static void Main()
    {

        string allowedParameters = "{
        \"DataSource\" : {
            \"CLIENT_ID\" : true,
            \"COLOCATION_TAG\" : true,
            \"CONNECT_TIMEOUT\" : true,
            \"CONNECTION_ID_PREFIX\" : true,
            \"ENABLE\" : true,
            \"EXPIRE_TIME\" : true,
            \"FAILOVER\" : true,
            \"HOST\" : true,
            \"HTTPS_PROXY\" : true,
            \"HTTPS_PROXY_PORT\" : true,
            \"IGNORE_ANO_ENCRYPTION_FOR_TCPS\" : true,
            \"INSTANCE_NAME\" : true,
            \"LOAD_BALANCE\" : true,
            \"PASSWORD_AUTH \" : true,
            \"POOL_BOUNDARY\" : true,
            \"POOL_CONNECTION_CLASS\" : true,
            \"POOL_NAME\" : true,
            \"POOL_PURITY\" : true,
            \"PORT\" : true,
            \"PROTOCOL\" : true,
            \"RECV_BUF_SIZE\" : true,
            \"RECV_TIMEOUT\" : true,
            \"RETRY_COUNT\" : true,
            \"RETRY_DELAY\" : true,
            \"SDU\" : true,
            \"SEND_BUF_SIZE\" : true,
            \"SERVER\" : true,
            \"SERVICE_NAME\" : true,
            \"SHARDING_KEY\" : true,
            \"SHARDING_KEY_ID\" : true,
            \"SOURCE_ROUTE\" : true,
            \"SSL_CERTIFICATE_THUMBPRINT\" : true,
            \"SSL_SERVER_CERT_DN\" : true,
            \"SSL_SERVER_DN_MATCH\" : true,
            \"SSL_VERSION\" : true,
            \"SUPER_SHARDING_KEY\" : true,
            \"TRANSPORT_CONNECT_TIMEOUT\" : true,
            \"BACKUP\" : true,
            \"TYPE\" : true,
            \"METHOD\" : true,
            \"TRANSACTION\" : true,
            \"RETRIES\" : true,
            \"DELAY\" : true,
            \"COMMIT_OUTCOME\" = true,
            \"MY_WALLET_LOCATION\" : false,
            \"OCI_COMPARTMENT\" : false,
            \"OCI_DATABASE\" : false,
            \"OCI_PROFILE \" : false,
            \"OCI_TENANCY \" : false,
```

```

        "TUNNEL_SERVICE_NAME" : false,
        "TENANT_ID" : false,
        "TOKEN_AUTH " : false,
        "TOKEN_LOCATION" : false,
        "WALLET_LOCATION" : false
    }
}";
OracleConfiguration.EnableConnectionStringAllowedProperties(allowedParameters,
enforceOnAlias: false);
// Supply the connection string and open a connection
OracleConnection con = new OracleConnection(<connection string>);
con.Open();
    }
}

```

### Connection Configuration Usage and Validation

For pooled connections, allowed properties validation occurs only once during each pool's first connection creation. Changing the JSON settings will not change the existing pool settings unless either `ClearPool()` or `ClearAllPools()` is invoked. Then, the next connection open will use the new settings.

Newly created pools use the latest updated JSON settings.

In non-pooled connection scenarios, validation executes for each connection request with the latest supplied allowed properties version.

## Configuring for Entity Framework Code First

Developers must configure applications to use the Oracle Entity Framework functionality. This consists of creating two entries in the `app.config` or `web.config` file and adding an assembly reference:

- Add entries in the .NET config file
  - Connection string
 

A standard ADO.NET connection string is used rather than the Entity Framework connection string used by Database First or Model First paths. The connection string name should match the application context name. The connection string entry is an element of the `connectionStrings` section in the configuration file.
  - Provider registration
 

Entity Framework uses the provider registration to determine the assembly to use for Oracle Entity Framework functionality. The provider registration is an element of the `providers` section within the `entityFramework` section in the application configuration file.
- Add Assembly reference
 

Add Oracle Entity Framework assembly to the project references.

**Note**

When using the official ODP.NET, NuGet installation, these preceding sections are created automatically, if they do not already exist. After the NuGet install, the ODP.NET connection string will need to be customized to the application's specific settings.

When using the Oracle Universal Installer or xcopy install, the preceding sections must all be configured manually.

Examples of connection strings are as follows:

- ODP.NET, Unmanaged Driver

```
<add name="TestContext" providerName="Oracle.DataAccess.Client"
connectionString="User Id=test;Password=testpassword;Data Source=eftest" />
```

- ODP.NET, Managed Driver

```
<add name="TestContext" providerName="Oracle.ManagedDataAccess.Client"
connectionString="User Id=test;Password=testpassword;Data Source=eftest" />
```

Examples of Oracle provider registration are as follows:

- ODP.NET, Unmanaged Driver

```
<provider invariantName="Oracle.DataAccess.Client"
type="Oracle.DataAccess.EntityFramework.EFOracleProviderServices,
Oracle.DataAccess.EntityFramework, Version=6.121.2.0, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
```

- ODP.NET, Managed Driver

```
<provider invariantName="Oracle.ManagedDataAccess.Client"
type="Oracle.ManagedDataAccess.EntityFramework.EFOracleProviderServices,
Oracle.ManagedDataAccess.EntityFramework, Version=6.121.2.0, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
```

## Entity Framework 6 Code-Based Registration

Entity Framework 6 allows an application to register with an Entity Framework provider without using any configuration file. With ODP.NET, Managed Driver, the code will look as follows:

```
// C#
using Oracle.ManagedDataAccess.EntityFramework;
...
public class ModelConfiguration : DbConfiguration
{
    public ModelConfiguration()
    {
        SetProviderServices("Oracle.ManagedDataAccess.Client",
EFOracleProviderServices.Instance);
    }
}
```

For ODP.NET, Unmanaged Driver, replace occurrences of ManagedDataAccess with DataAccess in the preceding code.

If you are using code-based registration, then the configuration file should not include the registration. The configuration file based registration overrides the code-based registration.

# Migrating from ODP.NET, Unmanaged Driver to ODP.NET, Managed Driver or ODP.NET Core

To take advantage of new and better feature sets in managed ODP.NET and ODP.NET Core, developers are migrating their existing unmanaged ODP.NET code to these providers. Migration from unmanaged to either managed or core ODP.NET is often straightforward and simple.

The APIs of ODP.NET, Managed Driver and ODP.NET Core are nearly identical. Those two provider APIs generally match ODP.NET, Unmanaged Driver APIs.

As unmanaged ODP.NET is deprecated, it will see fewer new features in the future. Managed and core providers will continually add new Oracle database, cloud, and .NET feature support.

To migrate from unmanaged ODP.NET to managed ODP.NET or ODP.NET Core, perform the following steps:

1. Add a Reference to `Oracle.ManagedDataAccess.dll` in the .NET project.
2. Change the existing ODP.NET, Unmanaged Driver namespace references to ODP.NET, Managed Driver references.

```
// C#  
using Oracle.ManagedDataAccess.Client;  
using Oracle.ManagedDataAccess.Types;  
  
// VB  
Imports Oracle.ManagedDataAccess.Client  
Imports Oracle.ManagedDataAccess.Types
```

3. Some provider configuration settings may need to be migrated because ODP.NET, Managed Driver supports very few Windows Registry settings and a different .NET configuration setting format. ODP.NET Core does not support Windows Registry settings nor .NET Framework configuration files, that is, `app/machine/web.config`.

## Configuring a Port to Listen for Database Notifications

Oracle Data Provider for .NET opens a port to listen for database notifications when the following features are used:

- HA Events
- Load Balancing
- Continuous Query Notification
- AQ Notifications

All these features share the same port, which can be configured centrally by setting the db notifications port in an application or web configuration file.

If the configuration file does not exist or the db notification port is not specified, ODP.NET uses a valid, random port number. The configuration file may also request for a random port by specifying a db notification port value of -1. To specify a particular port in ODP.NET, Unmanaged Driver, for example, 1200, an application or web configuration file can be used as follows:

```
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="DbNotificationPort" value="1200"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

To specify a particular port in ODP.NET, Managed Driver, an application or web configuration file can be used as follows:

```
<configuration>
  <oracle.manageddataaccess.client>
    <version number="*">
      <settings>
        <setting name="DbNotificationPort" value="1200"/>
      </settings>
    </version>
  </oracle.manageddataaccess.client>
</configuration>
```

The port number should be unique for each process running on a computer. Thus, the port number should be set uniquely for each application either programmatically or through an application config file. Note that if the specified port number is already in use or invalid, ODP.NET does not provide any errors.

When the process using ODP.NET starts, the application reads the db notification port number and listens on that port. Once the port is opened, the port number cannot be changed during the lifetime of the process.

## General .NET Programming Recommendations and Tips for ODP.NET

- `Thread.Abort()` should not be used, as unmanaged resources may remain unreleased, which can potentially cause memory leaks and hangs.
- To optimize resource usage, ODP.NET objects, such as `OracleConnection` and `OracleCommand`, should be explicitly closed or disposed, or both, when they are no longer needed. This should be done rather than relying on the .NET Framework garbage collector

to reclaim resources. Many users have found that under stress conditions, explicit `Close` or `Dispose` calls result in much lower resource usage.

- It is recommended not to proceed with application execution if the application encounters exceptions that are associated with possible memory corruption, such as `System.AccessViolationException` and `System.Runtime.InteropServices.SEHException`.
- If the `HKEY_LOCAL_MACHINE\Software\Oracle\NLS_LANG` registry entry is set to `NA`, ODP.NET encounters `ORA-12705` errors. To eliminate this problem, remove the `HKEY_LOCAL_MACHINE\Software\Oracle\NLS_LANG` registry entry.
- .NET requires certain special characters, such as backslash `\` and double quotation mark `"`, to be escaped when used within a string. In a connection string or a class property, .NET requires using the escape character, backslash, before the special character. To represent a backslash in a string, use a double backslash `\\`. To represent a double quotation mark in a string, use a backslash followed by a double quotation mark `\"`. Alternatively, use the at sign `@` to mark the entire string as a verbatim string literal, in which case .NET ignores special characters.
- If your application does not use LDAP, then it is not necessary to include the `System.DirectoryServices` and `System.DirectoryServices.Protocols` libraries in your application.

## Base Classes, Provider Factory Classes, and DbDataSource

### Base Classes and Provider Factory Classes

With ADO.NET, data classes derive from the base classes defined in the `System.Data.Common` namespace. Developers can create provider-specific instances of these base classes using provider factory classes.

Provider factory classes allow generic data access code to access multiple data sources with a minimum of data source-specific code. This reduces much of the conditional logic currently used by applications accessing multiple data sources.

Using Oracle Data Provider for .NET, the `OracleClientFactory` class can be returned and instantiated, enabling an application to create instances of the following ODP.NET classes that inherit from the base classes:

**Table 3-1 ODP.NET Classes that Inherit from ADO.NET Base Classes**

| ODP.NET Classes                            | Inherited from ADO.NET Base Class      |
|--------------------------------------------|----------------------------------------|
| <code>OracleClientFactory</code>           | <code>DbProviderFactory</code>         |
| <code>OracleCommand</code>                 | <code>DbCommand</code>                 |
| <code>OracleCommandBuilder</code>          | <code>DbCommandBuilder</code>          |
| <code>OracleConnection</code>              | <code>DbConnection</code>              |
| <code>OracleConnectionStringBuilder</code> | <code>DbConnectionStringBuilder</code> |
| <code>OracleDataAdapter</code>             | <code>DbDataAdapter</code>             |
| <code>OracleDataReader</code>              | <code>DbDataReader</code>              |
| <code>OracleDataSourceEnumerator</code>    | <code>DbDataSourceEnumerator</code>    |
| <code>OracleException</code>               | <code>DbException</code>               |
| <code>OracleParameter</code>               | <code>DbParameter</code>               |
| <code>OracleParameterCollection</code>     | <code>DbParameterCollection</code>     |
| <code>OracleTransaction</code>             | <code>DbTransaction</code>             |

In general, applications still require Oracle-specific connection strings, SQL or stored procedure calls, and declare that a factory from ODP.NET is used.

[OracleClientFactory Class](#)

## DbDataSource

ODP.NET Core supports the ADO.NET DbDataSource abstraction through the `OracleDataSource` class. The new `OracleDataSource` class can retrieve connections and execute commands directly as an alternative to using `OracleConnection` and `OracleCommand`.

Since the class encapsulates all Oracle database connection configuration, `OracleDataSource` is portable and can be registered in dependency injection as a connection factory. It is ideal when provider agnostic code is preferred when connecting to Oracle databases.

`OracleDataSource` does not have a constructor; it must be created using the `OracleDataSourceBuilder` class or through the `OracleClientFactory.CreateDataSource(string connectionString)` method.

In ODP.NET, many connection configuration options are not available on the connection string. For those configuration options, developers can use `OracleDataSourceBuilder`, then build an `OracleDataSource` from it.

ODP.NET Core 23.8 began support for `OracleDataSource` and `OracleDataSourceBuilder` with .NET 8 runtime or higher.

[OracleDataSourceCommand Class](#)

## OracleDataSource Connections

`OracleDataSource` can return open or closed connections synchronously or asynchronously. It can also create commands and batch operations that use the connection string.

`OracleDataSource` Code Sample:

```
OracleClientFactory factory = new OracleClientFactory();

// Create OracleDataSource
DbDataSource oraDS = factory.CreateDataSource("user id=hr;password=<PASSWORD>;data
source=oracle");

// Create closed connection, which uses the connection string set on OracleDataSource
DbConnection connection = oraDS.CreateConnection();
connection.Open();

connection.Close();

// An OracleCommand can be created directly from the OracleDataSource, which will be
ready to execute commands
DbCommand cmd = oraDS.CreateCommand("select * from employees");
DbDataReader rdr = cmd.ExecuteReader();
while (rdr.Read())
{
    Console.WriteLine(rdr.GetString(1));
}
rdr.Close();
```

When pooling is enabled, each `OracleDataSource` instance has its own corresponding connection pool, allowing connections to be dispensed faster by skipping the look up process. Because `OracleDataSource` corresponds to a specific connection pool, an `OracleDataSource` is immutable once created. However, `OracleConnections` created from an `OracleDataSource` are mutable.

`OracleDataSource` connections use a different pool from traditional `OracleConnection` pools even when they have the same connection properties. By the same principle, `OracleConnection.ClearAllPools()` does not affect pools maintained by `OracleDataSource` objects. `OracleDataSource` has its own `ClearPool()` method. When an `OracleDataSource` is disposed, its corresponding pool is cleared.

After an `OracleConnection` is created from an `OracleDataSource`, its properties can be changed when the connection is closed. However, some connection properties are used to assign the pool a unique identifier. Modifying one or more of those properties removes the connection from the existing `OracleDataSource` pool and either creates a new pool or uses another existing pool.

Passwords can be updated through the `OracleDataSource.Password` and `OracleDataSource.ProxyPassword` properties. Upon the next connection open, the new password will be used to authenticate the user. These properties do not update the database password. Passwords are the only mutable `OracleDataSource` property.

### **OracleDataSource Performance Counters**

Pool names in ODP.NET performance counters are prefixed with "ODS: " for `OracleDataSource` connections, such as "ODS: user id=HR; data source=oracle".

Two `OracleDataSource` instances with the same connection string will have separate pools. Oracle recommends setting pool name values to distinguish each uniquely. The pool name can be set via `OracleConnection.PoolName` or `OracleDataSourceBuilder.UsePoolName`.

Developers are responsible for ensuring there each pool has a unique pool name.

The pool name must be set before the pool is created. ODP.NET will not use the pool name value after the pool is created nor will it throw an error.

### **OracleDataSource Connection Event Callbacks**

Just like `OracleConnection` properties, `OracleDataSource` and `OracleDataSourceBuilder` can employ event callbacks. Their event behavior is near equivalent to `OracleConnection`'s except for `HAEvent`. `OracleConnection.HAEvent` is static, which means it registers events for all `OracleConnection` instances. `OracleDataSource.HAEvent` is not static; it is instance based like the other events. `HAEvent` registered on the `OracleDataSourceBuilder` only affects connections created from the `OracleDataSource`, not all connections.

This table shows the `OracleConnection`, `OracleDataSource`, and `OracleDataSourceBuilder` event properties and their common or unique behavior.

| OracleConnection Property                    | OracleDataSource Property                    | OracleDataSource Method                                                       | Behavior Description                                                                                                                                                                                                                                             |
|----------------------------------------------|----------------------------------------------|-------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConnectionOpen<br>InfoMessage<br>StateChange | ConnectionOpen<br>InfoMessage<br>StateChange | UseConnectionOpenCallback<br>UseInfoMessageCallback<br>UseStateChangeCallback | Applies event callback to all OracleConnection instances created by OracleDataSource, at which point it behaves identically to setting the event on OracleConnection itself.                                                                                     |
| Failover                                     | Failover                                     | UseFailoverCallback                                                           | Behavior is almost identical, except OracleConnection.Failover can only be set if the OracleConnection is open. OracleDataSourceBuilder.Failover applies the event to all OracleConnections created from the OracleDataSource even if they are initially closed. |
| HAEvent                                      | N/A                                          | N/A                                                                           | Being static, it registers callbacks for all OracleConnection instances.                                                                                                                                                                                         |
| N/A                                          | HAEvent                                      | UseHAEventCallback                                                            | Being instance-based, it only registers callbacks for OracleConnection instances created by OracleDataSource.                                                                                                                                                    |

### OracleDataSource Commands

`OracleDataSource.CreateCommand()` returns a new `OracleDataSourceCommand` class, which is derived from `OracleCommand`. The class functions almost identically to `OracleCommand` with a few differences.

First, the connection object is not accessible to the app. `OracleDataSourceCommand` internally opens a connection before an execution call and closes it after the completing the execution except for `ExecuteReader`. The reader depends on the connection to retrieve results. The connection closes when the reader closes.

Applications typically defer retrieving all their ODP.NET connected types, such as LOB and LONG data, which requires the connection to remain open to be able to fetch data in the future. When using connected types with `OracleDataSourceCommand` and without `ExecuteReader`, set the `InitialLOBFetchSize` or `InitialLONGFetchSize` property to a sufficiently large value to retrieve all the result set LOB and LONG data immediately. If any LOB or LONG data remains and the app attempts to fetch it, an exception is thrown.

**Note**

OracleDataSourceCommand is not compatible with OracleDataAdapter.

OracleDataSourceCommand can only be created through OracleDataSource.CreateCommand().

Since connection objects are not accessible to OracleDataSource, the OracleDataSourceCommand.Connection and OracleDataSourceCommand.Transaction properties throw an InvalidOperationException when accessed.

**ExecuteNonQuery() example**

```
OracleDataSource ds = new OracleDataSourceBuilder("<CONNECTION STRING>").Build();
OracleCommand cmd = ds.CreateCommand("INSERT INTO mytable VALUES(0, 1)");
// ODP.NET internally opens a connection when ExecuteNonQuery is called
OracleDataReader rdr = cmd.ExecuteNonQuery();
// ODP.NET closes the connection after ExecuteNonQuery completes.
```

**ExecuteReader() example**

```
OracleDataSource ds = new OracleDataSourceBuilder("<CONNECTION STRING>").Build();
OracleCommand cmd = ds.CreateCommand("SELECT * FROM mytable");
// ODP.NET internally opens a connection when ExecuteReader is called
OracleDataReader rdr = cmd.ExecuteReader();
while (rdr.Read())
{
    Console.WriteLine(rdr.GetString(0));
}
rdr.Close();
// ODP.NET closes the connection when the reader is closed.
```

## Code Access Security

ODP.NET implements code access security through the OraclePermission class. This ensures that application code trying to access the database has the requisite permission to do so.

When a .NET assembly tries to access Oracle Database through ODP.NET, ODP.NET demands OraclePermission. The .NET runtime security system checks to see whether the calling assembly, and all other assemblies in the call stack, have OraclePermission granted to them. If all assemblies in the call stack have OraclePermission granted to them, then the calling assembly can access the database. If any one of the assemblies in the call stack does not have OraclePermission granted to it, then a security exception is thrown.

**Note**

ODP.NET Core does not support Code Access Security.

## Configuring OraclePermission

The DemandOraclePermission configuration attribute is used to enable or disable OraclePermission demand for an ODP.NET API. The DemandOraclePermission value can be specified in the Windows registry for unmanaged ODP.NET only, or an individual application configuration file for both unmanaged and managed ODP.NET.

The following Windows registry key is used to configure the DemandOraclePermission configuration attribute:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ODP.NET\Assembly_Version\DemandOraclePermission
```

Here *Assembly\_Version* is the full assembly version number of Oracle.DataAccess.dll. The DemandOraclePermission key is of type REG\_SZ. It can be set to either 1 (enabled) or 0 (disabled).

You can also enable OraclePermission demand for an individual application using its application configuration file. The following example enables the DemandOraclePermission property in an application configuration file for ODP.NET, Unmanaged Driver:

```
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="DemandOraclePermission" value="1"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

Similarly, you can use DemandOraclePermission to configure ODP.NET, Managed Driver under the settings section for managed provider configuration. See also "[settings section](#)" for more information.

An application or assembly can successfully access the database if OraclePermission has been added to the permission set associated with the assembly's code group. A system administrator can modify the appropriate permission set manually or by using the Microsoft .NET configuration tool (Mscorcfg.msc).

Administrators may also use an appropriate .NET Framework Tool, such as the Code Access Security Policy Tool (Caspol.exe), to modify security policy at the machine, user, and enterprise levels for including OraclePermission.

OracleConnection makes security demands using the OraclePermission object when OraclePermission demand has been enabled using DemandOraclePermission configuration attribute. Application developers should make sure that their code has sufficient permission before using OracleConnection.

## Configuring OraclePermission for Web Applications with High or Medium Trust Levels

For Web applications operating under high or medium trust, OraclePermission needs to be configured in the appropriate `web_TrustLevel.config` file, so that the application does not encounter any security errors.

OraclePermission can be configured using the OraProvCfg tool. OraProvCfg.exe adds appropriate entries to the `web_hightrust.config` and `web_mediumtrust.config` files associated with the specified .NET framework version. The following example illustrates using the OraProvCfg tool for configuring OraclePermission in a .NET 2.0 Web application:

```
OraProvCfg.exe /action:config /product:odp /component:oraclepermission  
               /frameworkversion:v2.0.50727  
               /providerpath:full_path_of_Oracle.DataAccess.dll
```

On running the preceding command, the following entry is added to the `web_hightrust.config` and `web_mediumtrust.config` files under the ASP.NET permission set:

```
<IPermission class="Oracle.DataAccess.Client.OraclePermission, Oracle.DataAccess,  
Version=2.112.2.0, Culture=neutral, PublicKeyToken=89b483f429c47342" version="1"  
Unrestricted="true" />
```

OraProvCfg can also be used to remove these entries from the .config files when required. The following example illustrates this:

```
OraProvCfg.exe /action:unconfig /product:odp /component:oraclepermission  
               /frameworkversion:v2.0.50727  
               /providerpath:full_path_of_Oracle.DataAccess.dll
```

## Configuring OraclePermission for Windows Applications Running in a Partial Trust Environment

For Windows applications operating in a partial trust environment, the OraclePermission entry should be specified under the appropriate permission set in the `security.config` file. The `security.config` file is available in the `%windir%\Microsoft.NET\Framework\{version}\CONFIG` folder.

The following example specifies the OraclePermission entry for a .NET 2.0 Windows application:

```
<IPermission class="Oracle.DataAccess.Client.OraclePermission, Oracle.DataAccess,  
Version=2.112.2.0, Culture=neutral, PublicKeyToken=89b483f429c47342" version="1"  
Unrestricted="true" />
```

## Connecting to Oracle Database

Oracle Data Provider for .NET can connect to Oracle Database in a number of ways, such as using a user name and password, Windows Native Authentication, Kerberos, and Transport Layer Security/Secure Sockets Layer. This section describes OracleConnection provider-specific features, including:

- [Connecting to Oracle Autonomous Database](#)
- [Using Oracle Identity and Access Management](#)

- [Using Microsoft Entra ID](#)

## Connecting to Oracle Autonomous Database

Oracle Autonomous Database includes several deployment options:

- Oracle Autonomous Database Serverless (ADB-S)
- Oracle Autonomous Database on Dedicated Exadata Infrastructure (ADB-D)
- Oracle Autonomous Database on Exadata Cloud@Customer (ADBC@C)

TLS/SSL must be used to connect to ADB-S. For ADB-D and ADBC@C, use of TLS is optional. Currently, only ADB-S can be used with Oracle Identity and Access Management.

This documentation section focuses on how to connect to ADB-S.

Unmanaged ODP.NET 19.14 and 21.5 and higher supports TLS connections without a wallet.

ODP.NET core and managed drivers 19.13 and 21.4 and higher support TLS connections without a wallet.

ODP.NET Core 19.13.1 or 21.4.1 and higher support token based authentication with Oracle Identity and Access Management (IAM).

Managed ODP.NET 21.6.1 now supports token based authentication with IAM.

Oracle recommends using the latest ODP.NET driver version available on NuGet Gallery or Oracle website when connecting to Oracle ADB-S.

### Connecting with a Wallet

The following quick start link has instructions how to download, install, and configure ODP.NET and Oracle Developer Tools for Visual Studio when using a wallet:

[Quick Start: Developing .NET Applications for Oracle Autonomous Database](#)

### Connecting without a Wallet

When you connect to Oracle ADB-S with ODP.NET, you do not need to deploy the Oracle wallet or the Oracle network configuration files `sqlnet.ora` or `tnsnames.ora` with your application. Instead, you supply the data source attribute, a TLS connection string, with the configuration information in the ODP.NET connection.

To use ODP.NET TLS connections, do the following:

1. Obtain managed ODP.NET or ODP.NET Core versions 19.13 or 21.4 or above. For unmanaged ODP.NET, versions 19.14 and 21.5 can be obtained. Lower level versions do not support TLS connections without wallets.
2. Enable TLS connections on your Autonomous Database instance. See [Update your Autonomous Database Instance to Allow both TLS and mTLS Authentication](#) for details.
3. After you enable TLS connections, supply a TLS connection string in the ODP.NET data source to connect to your Autonomous Database instance. See [View TNS Names and Connection Strings for an Autonomous Database Instance](#) for details on viewing or copying TLS connection strings.

#### Note

Older TNS names use a distinguished name and place quotation marks around it. Newer TNS names do not have it. If you store one of these older TNS names in a .NET string, add a backslash escape sequence before each quotation mark (for example, `\"`). This allows .NET to recognize the quotation mark as part of the TNS name.

## Using Oracle Identity and Access Management

Oracle identity and access management (IAM) solutions provide secure access to enterprise applications for both cloud and on-premises deployments. Oracle IAM cloud service supports a unified identity across Oracle cloud services, including Oracle ADB-S. This capability allows identity to be propagated to all services Oracle IAM supports. A unified identity makes user management and account management easier for administrators and end users.

IAM users can connect to the Oracle Autonomous Database instance by using either an IAM database password verifier, an IAM token, or a database alternate password for token authentication.

Using the IAM database password verifier is similar to the Oracle Database password authentication process. However, instead of the password verifier (encrypted hash of the password) being stored in the Oracle Autonomous Database, the verifier is instead stored as part of the Oracle Cloud Infrastructure (OCI) IAM user attributes. This option is supported by all ODP.NET clients.

The second connection method, the use of an IAM token for the database, is more modern. The use of token-based access is a better fit for Cloud resources such as Oracle Autonomous Database. The token is based on the strength that the IAM endpoint can enforce. This can be multi-factor authentication, which is stronger than the use of passwords alone. Starting with versions 19.13.1 and 21.4.1, ODP.NET Core supports this new connection method. This functionality was added to managed ODP.NET in version 21.6.1. This will utilize native OCI Authentication primitive, specifically OCI supported tokens for authenticating OCI users when they logon to a database. By integrating with OCI IAM for authentication, Oracle databases in OCI will provide seamless identity integration with OCI services.

The third connection method is the database password for IAM token authentication. This method is different from using the IAM database password verifier since it is using a database alternate password for token authentication. This connection method is also called token-based authentication using password. ODP.NET Core and Managed ODP.NET support this feature starting with version 21.6.1.

The fourth connection method is IAM single sign-on token (SSO) authentication. Starting with ODP.NET 23ai, Oracle IAM single sign-on is supported with the managed and core provider types. ODP.NET will automatically handle IAM token retrieval and management. Oracle Database 19c (19.16), Oracle AI Database 26ai, and higher versions support IAM SSO.

See also [Use Identity and Access Management \(IAM\) Authentication with Autonomous Database in Using Oracle Autonomous Database Serverless](#).

## Configuring a Client Connection Using an IAM Database Password Verifier

After you have configured the authorization needed for the IAM user, this user can log in without additional configuration.

The application provides the IAM user name and IAM database password, not the Oracle Cloud Infrastructure (OCI) console password, using any ODP.NET driver type. The only constraint is that the ODP.NET driver must have support for Oracle Database 12c passwords verifiers. Earlier password verifiers are not supported with IAM. No special client or tool

configuration is needed for the IAM user to connect to the Oracle Autonomous Database instance.

## Configuring a Client Connection Using Token

ODP.NET supports the IAM token, which is a Signature token represented in standard JSON Web Token (JWT). Signature Token – also called Proof of Possession (PoP) token – is associated with a private key known to the client. The client sends a signature and token to the protected resource. The protected resource verifies the signature along with the token itself.

For passing IAM token to Oracle Autonomous Database, the following options are supported:

- Use of token file: For existing applications, use Oracle Cloud Infrastructure (OCI) command line interface (CLI) to request and store the database token in the file system, and configure ODP.NET to use the token file.
- Use of API: Modify application to request database token from IAM and pass the database token to the database client through ODP.NET API.

ODP.NET presents the database token when connecting to a database. The database requests the public key from IAM and the database validates the database token. If the token is valid, the database requests the IAM groups that the user is a member. The database reviews the local schema mappings to find which global schema the IAM user will have access to, exclusive or shared. If no schema mapping exists, the user will not be allowed to access the database.

## Configuring Client Connection to use Token File

The OCI CLI is available to request database tokens from IAM. When the OCI CLI tool is used to request tokens, it copies the token and private key to the default directory on the local machine or a custom directory can be specified. On Windows operating systems, the default directory is based on the USERPROFILE environment variable (i.e. `$USERPROFILE/.oci/db-token`). On Linux and macOS operating systems, the default directory is based on the HOME environment variable (i.e. `$HOME/.oci/db-token`).

To use token file for authentication:

1. Set ODP.NET User Id to "/" in the connection string and leave the password empty.
2. Set `TOKEN_AUTH` parameter to `OCI_TOKEN`. This parameter can be configured at various levels like TNS descriptor, EZConnect string, `sqlnet.ora` file or application configuration file. This can also be configured programmatically either at connection level through the `OracleConnection.TokenAuthentication` property or at process level through the `OracleConfiguration.TokenAuthentication` property.
3. If using a non-default token location, set the token file directory. More details on setting a specific token file location is discussed in the "Use of ODP.NET API to pass the Token" section.

When database token usage is enabled, all other external authentication methods, such as Kerberos, Windows authentication, and TLS cannot be used. However, TLS to encrypt the client-server connection can be used – and must be used when using IAM tokens.

- Authenticating and Authorizing IAM Users for Oracle Autonomous Databases for all the steps needed to get the token file.
- [OCI Command Line Interface](#)

## Use of ODP.NET API to pass the Token

Applications can use OCI SDK to get database token for IAM user and pass the database token along with private key to ODP.NET through the API.

The database token has attributes within the token, some of which are worth noting, which will be covered in more detail later:

- exp attribute within the token represents the expiry time of the token.
- sub attribute within the token represents the IAM user of the token.

The `OracleConnection.AccessToken` property can be set to the `OracleAccessToken` object. The `OracleAccessToken` object can be constructed by providing both the signature token and private key, which are required to connect via IAM.

If `OracleConnection.AccessToken` property is not supplied by the application and the `TOKEN_AUTH` parameter is set to `OCI_TOKEN`, then ODP.NET will look for the signature token and private key files in the default directory. Applications can override this default directory by setting the `TOKEN_LOCATION` parameter. This parameter can also be configured at various levels like TNS descriptor, EZConnect string, `sqlnet.ora` file, or application configuration file. This parameter can also be configured programmatically either at the ODP.NET connection level through the `OracleConnection.TokenLocation` property or at process level through the `OracleConfiguration.TokenLocation` property.

The following table shows how ODP.NET will use IAM when a signature token is supplied and when `TOKEN_AUTH` / `TokenAuthentication` property is set.

**Table 3-2 ODP.NET Authentication using IAM and Signature Token**

| Application Supplied<br>Oracle Access Token | TOKEN_AUTH /<br>TokenAuthentication<br>Setting                    | PASSWORD_AUTH /<br>PasswordAuthentatio<br>n Setting                             | ODP.NET<br>Authentication             |
|---------------------------------------------|-------------------------------------------------------------------|---------------------------------------------------------------------------------|---------------------------------------|
| Yes                                         | OCI_TOKEN /<br><code>OracleTokenAuth.Oci<br/>Token</code>         | NOT SET /<br><code>OraclePasswordAuth.<br/>PasswordVerifier</code><br>(Default) | IAM via application<br>SUPPLIED TOKEN |
| Yes                                         | NOT SET /<br><code>OracleTokenAuth.Dis<br/>abled (default)</code> | NOT SET /<br><code>OraclePasswordAuth.<br/>PasswordVerifier</code><br>(default) | IAM via application<br>SUPPLIED TOKEN |
| No (default)                                | OCI_TOKEN /<br><code>OracleTokenAuth.Oci<br/>Token</code>         | NOT SET /<br><code>OraclePasswordAuth.<br/>PasswordVerifier</code><br>(Default) | IAM via file SUPPLIED<br>TOKEN        |

**Table 3-2 (Cont.) ODP.NET Authentication using IAM and Signature Token**

| Application Supplied<br>Oracle Access Token | TOKEN_AUTH /<br>TokenAuthentication<br>Setting      | PASSWORD_AUTH /<br>PasswordAuthentatio<br>n Setting               | ODP.NET<br>Authentication                                                                                                                                              |
|---------------------------------------------|-----------------------------------------------------|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

ODP.NET applications using the API to provide signature token and private key are recommended to register with the RefreshAccessToken event exposed on the OracleAccessToken object to receive a callback when token is about to expire. The .NET event provides a convenient way for applications to “refresh” the signature token and the private key before they expire.

ODP.NET triggers the token refresh callback 60 seconds before it expires. It is the application's responsibility to ensure that ODP.NET always has a valid token for authentication when creating new connections to the database. Please note that the callback will be called only once for an authenticated token.

After the callback provides the refreshed token and private key, all new connections start using the refreshed token for authentication. However, the token expiry has no impact on existing connections checked out from or within the connection pool. If for some reason, applications fail to provide a valid refreshed token and private key through the callback, it can use OracleConnection object's OpenWithNewToken() method to open a connection by passing a new signature token and private key.

It's important to note that already established idle connections will be dispensed even when the token has expired. The newly supplied signature token will be used only to create new connections. If the supplied signature token is invalid or expired, applications will receive an error during the Open() method invocation on the OracleConnection object.

## IAM Token Functionality Requirements

With ODP.NET Core NuGet packages, applications must target .NET 5.0 or higher to use IAM tokens.

Managed ODP.NET does not have any unique .NET assembly version dependencies to use IAM tokens.

## Sample Code

Here is ODP.NET sample code showing how to use `OracleAccessToken` to establish a connection and how to propagate the refreshed token through the `OracleRefreshAccessTokenEventArgs` class. This sample code works with managed ODP.NET and ODP.NET Core.

```
// C#
using System;
using System.IO;
using Oracle.ManagedDataAccess.Client;

class RefreshDbTokenSample
{
    // Update this path based from where token and private key would be read.
    private static string tokenPath = @"C:\token_dir";

    static void Main(string[] args)
    {
        // Create token and private key file path.
        string tokenFile = Path.Combine(tokenPath, "token");
        string privateKeyFile = Path.Combine(tokenPath, "oci_db_key.pem");

        // Read token and private key contents.
        char[] dbToken = File.OpenText(tokenFile).ReadToEnd().ToCharArray();
        char[] privateKey = File.OpenText(privateKeyFile).ReadToEnd().ToCharArray();

        // Create OracleAccessToken
        OracleAccessToken accessToken = new OracleAccessToken(dbToken, privateKey);

        // Set the token refresh call back
        accessToken.RefreshAccessToken += new
        OracleRefreshAccessTokenEventHandler(OnRefreshAccessToken);

        // establish a connection
        string constr = "user id=//;data source=oracle";

        // Create connection object
        OracleConnection con = new OracleConnection(constr);

        // Set accessToken to the connection before opening connection.
        con.AccessToken = accessToken;

        // Open connection now.
        con.Open();

        Console.WriteLine("Connected using DB Token Authentication");

        con.Dispose();
    }
}
```

```

    }

    public static void OnRefreshAccessToken(
        OracleRefreshAccessTokenEventArgs eventArgs)
    {
        // Application code to get Refreshed DB token and private key
        RefreshToken(out char[] refreshedToken, out char[] refreshedPrivateKey);

        // Set the refreshed DB token and private key to eventArgs
        eventArgs.DbToken = refreshedToken;
        eventArgs.PrivateKey = refreshedPrivateKey;
    }

    public static void RefreshToken(out char[] refreshedToken, out char[]
refreshedPrivateKey)
    {
        refreshedToken = null;
        refreshedPrivateKey = null;

        // TODO: Add code to refresh the token.
    }
}

```

## Configuring a Client Connection Using Database Alternate Password for Token Authentication

The database alternate password connection method uses a username and password specific for IAM token-based authentication. This set of credentials is separate from the more common database username and password.

To use this feature, the `PASSWORD_AUTH` parameter must be set to `OCI_TOKEN`.

IAM exposes a REST endpoint for clients to request database bearer tokens. ODP.NET makes calls to request tokens from the endpoint via TLS 1.2 or higher. The driver specifies a username, password, oci iam url, tenant Oracle Cloud Identifier (OCID), a database compartment identifier (optional), and a database identifier (optional) in the request. If a database identifier is specified, then the database compartment identifier becomes mandatory. A bearer token is returned to ODP.NET in the response. The driver then sends the returned bearer token to authenticate with the database.

ODP.NET caches the token for reuse when additional connection requests occur. It holds onto the token until its expiration. The application will need to refresh the token before it expires to be able to make connections.

ODP.NET alternate password credentials can be stored securely in a Secure External Password Store (SEPS) wallet for application use.

## Comparing IAM Token Authentication Methods

The following table identifies the differences and similarities among the IAM token authentication options.

| App provides Database Token and Private Key                                                            | Database Token and Private Key through File                                                                                                                                                                                                                                                                                  | Alternate User Credentials for Token Authentication                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username must be set to "/" in the connection string.                                                  | Username must be set to "/" in the connection string.                                                                                                                                                                                                                                                                        | Username and Password in ODP.NET connection string represent alternate credentials.                                                                                                                                                                                                                                                                                                                                                                            |
| -                                                                                                      | -                                                                                                                                                                                                                                                                                                                            | SEPS can store credentials. When SEPS is enabled, the username and password is retrieved first. Then, the parameter, PASSWORD_AUTH, determines whether database access occurs via username/password or token-based authentication.                                                                                                                                                                                                                             |

| OracleAccessToken must be set on connection with proper database token and private key before opening. | -                                                                                                                                                                                                                                                                                                                            | -                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Database token provided by the application must be Signature token.                                    | Database token read from the file must be Signature token.                                                                                                                                                                                                                                                                   | Database token received from IAM is bearer token.                                                                                                                                                                                                                                                                                                                                                                                                              |

| App provides Database Token and Private Key                                                                                                                                                                                                           | Database Token and Private Key through File                                                                                                                                                                                                                                                                                          | Alternate User Credentials for Token Authentication                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>ODP.NET sends the following information to the database upon opening a connection:</p> <ul style="list-style-type: none"> <li>• database token</li> <li>• header</li> <li>• Signature generated by signing the header using private key</li> </ul> | <p>ODP.NET reads the database token and private key from the files and sends the following information to the database for authentication upon opening a connection;</p> <ul style="list-style-type: none"> <li>• database token</li> <li>• header</li> <li>• Signature generated by signing the header using private key</li> </ul> | <p>Upon opening a connection, ODP.NET uses the username/ password to request the database token from IAM and then sends that token to the database for authentication.</p> |

## IAM Single Sign-On

Managed ODP.NET and ODP.NET Core support Oracle IAM single sign-on (SSO), allowing user identity to be propagated across Oracle databases and cloud services, including federated users. SSO is easier for end users as they only need to log on once to access all the services that use an Oracle IAM identity. It is also easier for .NET developers as ODP.NET performs access token management automatically. The application is freed from dealing with the database token and private key.

When ODP.NET is given the Oracle IAM authentication parameters, it acquires the IAM access token to establish the database connection and all subsequent connection requests. The token is cached on a per connection pool basis. When the token is about to expire, ODP.NET automatically retrieves a new access token.

ODP.NET IAM SSO requires `Oracle.ManagedDataAccess.Oci` package in NuGet Gallery. That package uses the Oracle Cloud Identity Data Plane Service (`OCI.DotNetSDK.Identitydataplane` NuGet package) and Oracle Cloud Identity (`OCI.DotNetSDK.Identity` NuGet package), which is automatically downloaded as a dependency.

To configure IAM SSO, ODP.NET requires IAM credential and connection information. It can use the authentication parameters in the table below to connect.

**Table 3-3 ODP.NET OCI IAM Parameters**

| OCI IAM Parameter    | Description                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| Token authentication | Specifies the authentication flow for retrieving an OCI IAM access token                                                 |
| Configuration file   | Specifies the configuration file location for retrieving OCI IAM authentication values, such as user id and tenancy OCID |
| Profile              | Specifies the profile ODP.NET uses from the configuration file                                                           |
| Compartment          | Specifies the compartment Oracle Cloud ID for the database                                                               |
| Database             | Specifies the database Oracle Cloud ID                                                                                   |

For all OCI IAM authentication flows, only the token authentication parameter is required. All other parameters are either optional or not needed. The table below shows all the IAM authentication flows ODP.NET supports and the parameters available.

**Table 3-4 ODP.NET OCI IAM Authentication Flows**

| OCI IAM Authentication Flows | Required Parameters                                                                                                                                                                                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| API Key                      | <ul style="list-style-type: none"> <li>Token authentication set to <code>OciApiKey</code></li> <li>Configuration file (optional)</li> <li>Profile (optional)</li> <li>Compartment OCID (optional)</li> <li>Database OCID (optional)</li> </ul>                                               |
| Instance Principal           | <ul style="list-style-type: none"> <li>Token authentication set to <code>OciInstancePrincipal</code></li> <li>Compartment OCID (optional)</li> <li>Database OCID (optional)</li> </ul>                                                                                                       |
| Resource Principal           | <ul style="list-style-type: none"> <li>Token authentication set to <code>OciResourcePrincipal</code></li> <li>Compartment OCID (optional)</li> <li>Database OCID (optional)</li> </ul>                                                                                                       |
| Delegation Token             | <ul style="list-style-type: none"> <li>Token authentication set to <code>OciDelegationToken</code></li> <li>Compartment OCID (optional)</li> <li>Database OCID (optional)</li> </ul>                                                                                                         |
| Interactive                  | <ul style="list-style-type: none"> <li>Token authentication set to <code>OciInteractive</code></li> <li>Configuration File (optional)</li> <li>Profile (optional)</li> <li>Compartment OCID (optional)</li> <li>Database OCID (optional)</li> <li>Username (optional placeholder)</li> </ul> |
| Default                      | <ul style="list-style-type: none"> <li>Token authentication set to <code>OciDefault</code></li> </ul>                                                                                                                                                                                        |

ODP.NET can retrieve the OCI IAM parameter values from any of the following configuration locations. The parameter values in the locations higher in the table have precedence over values in locations listed lower.

**Table 3-5 ODP.NET OCI IAM Configuration Locations**

| Configuration Location                            | Available Parameters                                                                            |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------|
| OciTokenAuthentication class via OracleConnection | ConfigurationFile<br>Profile<br>Compartment<br>Database<br>OracleConnection.TokenAuthentication |
| Tnsnames.ora file or Easy Connect Plus            | OCI_CONFIG_FILE<br>OCI_PROFILE<br>OCI_COMPARTMENT<br>OCI_DATABASE<br>TOKEN_AUTH                 |

**Table 3-5 (Cont.) ODP.NET OCI IAM Configuration Locations**

| Configuration Location     | Available Parameters                                                                       |
|----------------------------|--------------------------------------------------------------------------------------------|
| OracleConfiguration class  | OciConfigurationFile<br>OciProfile<br>OciCompartment<br>OciDatabase<br>TokenAuthentication |
| App/Web configuration file | OCI_CONFIG_FILE<br>OCI_PROFILE<br>OCI_COMPARTMENT<br>OCI_DATABASE<br>TOKEN_AUTH            |
| Sqlnet.ora                 | OCI_CONFIG_FILE<br>OCI_PROFILE<br>OCI_COMPARTMENT<br>OCI_DATABASE<br>TOKEN_AUTH            |

ODP.NET OCI IAM SSO can be programmatically configured via the `OciTokenAuthentication` class, `OracleConnection UseOciTokenAuthentication` method, and `OracleConfiguration` class. The provider alters the `OciTokenAuthentication` object to read only after the connection is opened to ensure no OCI token authentication settings are changed for the pool's lifetime. With the settings locked, the token is cached for re-use when new pooled connections are requested.

#### ODP.NET OCI IAM SSO code sample:

```
OracleConnection conn = new OracleConnection(constr);
conn.TokenAuthentication = OracleTokenAuth.OciApiKey;
OciTokenAuthentication tokenconfig = new OciTokenAuthentication
{
    ConfigurationFile = "<CONFIGURATION FILE>",
    Profile = "<PROFILE>",
    Compartment = "<COMPARTMENT OCID>",
    Database = "<DATABASE OCID>"
}
conn.UseOciTokenAuthentication(tokenConfig);
conn.Open();
conn.Close();
```

Alternatively, ODP.NET OCI IAM SSO can be configured without any ODP.NET code changes using `tnsnames.ora`, `Easy Connect Plus`, `sqlnet.ora`, and/or `.NET` configuration files.

#### IAM Interactive Authentication Flows

For interactive authentication flows, when the user and tenancy name values are the same for two different data sources, the user will only need to login once even if the connections belong to different connection pools. The reason why is that the same token is used for all these connections and ODP.NET caches it. The app can direct ODP.NET to clear its cache of all its session tokens so that they aren't used with new connections or new pools. `ClearInteractiveTokenCache` static method will clear access token cached in existing

connection pools, that is, pools which are created with interactive authentication flows. Only existing opened connections will continue to work.

### Code sample: ODP.NET OCI IAM Single Sign-on Connection Using Interactive Authentication Flow

```
string username = "user@company.com";
string constr = $"user id=<USERNAME>; data source = db-descriptor1";
OracleConnection conn = new OracleConnection(constr);
conn.TnsAdmin = @"C:\DB1\TnsAdmin\";
conn.TokenAuthentication = OracleTokenAuth.OciInteractive;
OciTokenAuthentication obj1 = new OciTokenAuthentication()
{
    ConfigurationFile = @"C:\oci_config\config"
};
conn.UseOciTokenAuthentication(obj1);
conn.Open();
Console.WriteLine("Connected to DB 1.");
conn.Close();

string constr2 = $"user id=<USERNAME>; data source = db-descriptor2 ";
OracleConnection conn2 = new OracleConnection(constr2);
conn2.TnsAdmin = @"C:\DB2\TnsAdmin\";

conn2.TokenAuthentication = OracleTokenAuth.OciInteractive;
OciTokenAuthentication obj2 = new OciTokenAuthentication()
{
    ConfigurationFile = @"C:\oci_config\config"
};
conn2.UseOciTokenAuthentication(obj2);
conn2.Open();
Console.WriteLine("Connected to DB 2.");
conn2.Close();
```

## Using Microsoft Entra ID

Starting with ODP.NET 21.7 and 19.15.1, ODP.NET supports Microsoft Entra ID, formerly known as Azure Active Directory, authentication when connecting to Oracle Database. ODP.NET will then use an access token to access the database instead of a username and password.

This feature benefits applications and services that use Microsoft Entra ID for centralized user authentication with Oracle database. Those services can include Azure and Microsoft 365-based cloud services, such as Microsoft Power BI service, that rely on Microsoft Entra ID for user management.

Using token-based authentication is more secure and simpler for the end user. It becomes unnecessary to specify credentials each time the user accesses a resource. Moreover, the resource never needs to handle and manage individual user credentials.

Microsoft Entra ID follows the OAuth 2.0 user authorization standard. OAuth 2.0 provides a means of obtaining an access token, then using that access token for accessing resources, such as Oracle database.

Microsoft Entra ID is supported in the core, managed, and unmanaged ODP.NET drivers. It requires Oracle Autonomous Database or Oracle Database 19.16 or higher.

Managed and unmanaged ODP.NET require NET Framework 4.5.2 or higher for Microsoft Entra ID support. ODP.NET Core does not have a runtime requirement more specific than the general component system requirements to support Microsoft Entra ID.

Starting with ODP.NET version 23 and Oracle AI Database 26ai, Microsoft Entra ID single sign-on is supported with managed ODP.NET and ODP.NET Core. ODP.NET will automatically handle Microsoft Entra ID token retrieval and management.

### Connecting Using Microsoft Entra ID Tokens

For an ODP.NET application using the managed or core provider to authenticate with Microsoft Entra ID using a file-based access token, the `TOKEN_AUTH` parameter or `OracleConfiguration.TokenAuthentication` property must be set to `OAuth`. The token's location is then specified in the `TOKEN_LOCATION` parameter or `TokenLocation` property. The token location must be specified explicitly when using `OAuth`. Otherwise, an error will occur. For `OAuth`, this location can be the directory where the file "token" is, or the full path that includes a file name.

For an ODP.NET application to authenticate with Microsoft Entra ID with an access token, none of these configuration steps is necessary. The access token is provided through ODP.NET APIs.

Developers construct an `OracleAccessToken` object to provide the access token via the `OracleConnection.AccessToken` property. If the application sets up a `RefreshAccessToken` event handler, ODP.NET will invoke it 60 seconds before the access token expires. The `OracleRefreshAccessTokenEventArgs` parameter provides a refreshed access token in the callback method.

The `OracleAccessToken` token can only be updated by calling `OpenWithNewToken` method or by setting the `OracleRefreshAccessTokenEventArgs.Token` property upon a .NET callback invocation.

For ODP.NET connection pooling, the `OracleAccessToken` object will be used to distinguish connection pools, not the actual token as they can expire and be refreshed. Only new connections need to use a refreshed access token. Existing pooled connections do not depend on the access token and will continue to work. Applications should always specify the same `OracleAccessToken` object on `OracleConnection` to ensure the same connection pool is used.

`TOKEN_AUTH` and `TOKEN_LOCATION` can also be set in the `tnsnames.ora` and `sqlnet.ora` files. To use `OAuth` with unmanaged ODP.NET, set your token values in these files as there are no equivalent unmanaged ODP.NET APIs.

Sample Code: Using ODP.NET Microsoft Entra ID Authentication

```
// This is a simple ODP.NET, Core Driver application that connects to an Oracle
Autonomous Database
// using a token obtained from Microsoft Entra ID.

// Azure.Identity can be obtained through NuGet Gallery.
// It will include the Azure.Core and Azure.Identity namespaces.
using System;
using System.Threading;
using Azure.Core;
using Azure.Identity;
using Oracle.ManagedDataAccess.Client;

namespace ConnectToOracleUsingAccessToken
{
    class Program
```

```

{
    static void Main()
    {
        try
        {
            // Retrieve an access token from Microsoft Entra ID.
            string token = GetAccessToken();

            // Create an instance of an OracleAccessToken. The access token needs to
            // be passed to the OracleAccessToken constructor as array of characters.
            var oracleAccessToken = new OracleAccessToken(token.ToCharArray());

            // Create an instance of an OracleConnection object.
            // The developer must provide the appropriate data source setting.
            var connection = new OracleConnection("User Id=;/;Data Source=<oracle>");

            // tnsnames.ora, sqlnet.ora, and cwallet.sso must reside in the same
            // directory as the application executable. These files can be downloaded
            // from Oracle Cloud for the Oracle Autonomous DB instance.
            connection.TnsAdmin = @".\";

            // Assign the OracleAccessToken to the AccessToken property on the
            // OracleConnection object.
            connection.AccessToken = oracleAccessToken;

            // Open the connection.
            connection.Open();

            // If Open() fails, it will throw an exception.
            Console.WriteLine("Open success.");

            // Dispose the OracleConnection object.
            connection.Dispose();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex);
        }
    }
}

// Retrieves an Microsoft Entra ID access token through the
// Service Principal Auth flow using a client secret.
static string GetAccessToken()
{
    // The developer must configure the Microsoft Entra ID parameters below.
    string clientId = "<client Id of app registration in Microsoft Entra ID>";
    string tenantId = "<tenant Id of Microsoft Entra ID>";
    string clientSecret = "<secret value of app registration in Microsoft Entra ID>";
    string scope = "<scope of DB registration in Microsoft Entra ID>";

    // Create a TokenRequestContext object.
    var tokenRequestContext = new TokenRequestContext(new[] { scope });

    // Create a ClientSecretCredential object.
    var credentials = new ClientSecretCredential(tenantId, clientId, clientSecret);

    // Get the access token from Microsoft Entra ID.
    AccessToken accessToken = credentials.GetToken(tokenRequestContext,
    default(CancellationTokens));

    // Return the access token.
    return accessToken.Token;
}

```

```
}  
}  
}
```

## Connecting Using Microsoft Entra ID Single Sign-On

ODP.NET supports Microsoft Entra ID single sign-on (SSO), allowing user identity to be propagated across Oracle databases and cloud services. SSO is easier for end users as they only need to log on once to access all the services that use an Microsoft Entra ID identity. It is also easier for .NET developers as ODP.NET performs access token management automatically.

When ODP.NET is given the Microsoft Entra ID authentication parameters, it acquires the Microsoft Entra ID access token to establish the database connection and all subsequent connection requests. The token is cached on a per connection pool basis. When the token is about to expire, ODP.NET automatically retrieves a new access token.

ODP.NET Microsoft Entra ID SSO requires `Oracle.ManagedDataAccess.Azure` package in NuGet Gallery. That package uses Azure .NET SDK (`Azure.Identity` NuGet package), which is automatically download as a dependency.

To configure Microsoft Entra ID SSO, ODP.NET requires Azure credential and connection information. It uses the parameters in the following table to connect.

| Parameters                  | Description                                                                                                                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authentication method       | This specifies the authentication flow for getting an Microsoft Entra ID bearer access token.                                                                                                                  |
| DB application ID URI       | This specifies the protected resource identifier on Microsoft Entra ID for which client application requests the access token.                                                                                 |
| Tenant ID                   | This specifies tenant identifier under which applications (client app or database) are registered. The tenant is an entity or a logical group of cloud resources assigned to an individual or an organization. |
| Client ID                   | Client ID is the identifier of an application registered on Microsoft Entra ID.                                                                                                                                |
| Client secret               | Client secret is the credential of a resource in Azure cloud. An app registered under Microsoft Entra ID can have a client secret.                                                                             |
| Client certificate          | Client certificate is the digital certificate of an Azure cloud resource. This also can be used instead of client secret.                                                                                      |
| Client certificate password | This specifies the protected client certificate password.                                                                                                                                                      |

| Parameters     | Description                                                                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Redirect URI   | A redirect URI, or reply URL, is the location where the authorization server sends the user once the app has been successfully authorized and granted an authorization code or access token. It is used in interactive authorization flow. |
| Azure username | This is the Azure accounts user's ID. For example: user@organization.onmicrosoft.com                                                                                                                                                       |
| Azure password | This is the Azure account's password.                                                                                                                                                                                                      |

The parameters required to connect depend on Azure authentication method and cloud account configuration. The following table shows all the Microsoft Entra ID authentication methods ODP.NET supports and the parameters each requires or can optionally use.

| Authentication Methods     | Required Parameters                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Principal          | <ul style="list-style-type: none"> <li>Client ID</li> <li>Tenant ID</li> <li>Client secret or client digital certificate path</li> <li>Certificate password (only for protected certificates)</li> <li>DB application ID URI</li> </ul>                                                                                                                                                                        |
| Interactive Authentication | <ul style="list-style-type: none"> <li>Client ID (optional when both client app and database registrations are under the same Azure tenant as the logged in user)</li> <li>Tenant ID (optional when both client app and database registrations are under the same Azure tenant as the logged in user)</li> <li>Redirect URI</li> <li>DB application ID URI</li> <li>Username (optional placeholder)</li> </ul> |
| Managed Identity           | <ul style="list-style-type: none"> <li>DB application ID URI</li> <li>Client ID (only for user-defined managed identity)</li> </ul>                                                                                                                                                                                                                                                                            |
| Default                    | <ul style="list-style-type: none"> <li>DB application ID URI</li> <li>Client ID [OPTIONAL]</li> <li>Tenant ID [OPTIONAL]</li> <li>Client secret [OPTIONAL]</li> <li>Client digital certificate path [OPTIONAL]</li> <li>Certificate password [OPTIONAL]</li> <li>Azure account username [OPTIONAL]</li> <li>Azure account password [OPTIONAL]</li> </ul>                                                       |
| Username and Password      | <ul style="list-style-type: none"> <li>Client ID</li> <li>Tenant ID</li> <li>DB application ID URI</li> <li>Azure account username</li> <li>Azure account password</li> </ul>                                                                                                                                                                                                                                  |

| Authentication Methods | Required Parameters                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------|
| Device Code            | <ul style="list-style-type: none"> <li>Client ID</li> <li>Tenant ID</li> <li>DB application ID URI</li> </ul> |

With Azure Default flow, the client driver evaluates five authentication flows in the sequence: Service Principal (using client secret), Service Principal (using client certificate), Username Auth Flow, Managed Identity, and Visual Studio Auth Flow. It performs the most appropriate flow based on the environment where the application is running.

**Note**

ODP.NET always uses the .default Microsoft Entra ID scope.

ODP.NET can attain these Microsoft Entra ID parameter values from any of the following configuration locations. The locations higher in the table have precedence over later locations listed lower.

| Configuration Location                 | Available Parameters                                                                                                                                                                                                    |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AzureTokenAuthentication class         | <ul style="list-style-type: none"> <li>ClientId</li> <li>TenantId</li> <li>DatabaseApplicationIdUri</li> <li>ClientSecret</li> <li>ClientCertificate</li> <li>ClientCertificatePassword</li> <li>RedirectUri</li> </ul> |
| Tnsnames.ora file or Easy Connect Plus | <ul style="list-style-type: none"> <li>CLIENT_ID</li> <li>TENANT_ID</li> <li>AZURE_DB_APP_ID_URI</li> <li>CLIENT_CERTIFICATE</li> <li>REDIRECT_URI</li> </ul>                                                           |
| OracleCredential class                 | Azure account username and password can be configured as username and password, respectively.                                                                                                                           |
| ODP.NET connection string              | Azure account username and password can be configured as username and password, respectively.                                                                                                                           |
| SEPS wallet                            | <p>Client ID and client secret can be configured as username and password, respectively.</p> <p>Azure account username and password can be configured as username and password, respectively.</p>                       |
| Sqlnet.ora                             | <ul style="list-style-type: none"> <li>CLIENT_ID</li> <li>TENANT_ID</li> <li>AZURE_DB_APP_ID_URI</li> </ul>                                                                                                             |

| Configuration Location               | Available Parameters                                                                                                                                                                                                       |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Azure .NET SDK environment variables | <ul style="list-style-type: none"> <li>• AZURE_CLIENT_ID</li> <li>• AZURE_CLIENT_SECRET</li> <li>• AZURE_CLIENT_CERTIFICATE_PATH</li> <li>• AZURE_TENANT_ID</li> <li>• AZURE_USERNAME</li> <li>• AZURE_PASSWORD</li> </ul> |

ODP.NET Microsoft Entra ID SSO can be programmatically configured using the `OracleConnection UseAzureTokenAuthentication` extension method. The provider alters the `AzureTokenAuthentication` object to read only after the connection is opened to ensure no Azure token authentication settings are changed for the pool's lifetime. With the settings locked, the token is cached for re-use when new pooled connections are requested.

### Azure Interactive Authentication Flows

For interactive authentication flows, when the user, application Id uri, client id, tenant id, and redirect uri values are same for two different connections, the user will only need to login once even if the connections belong to different connection pools. The reason why is that the same token is used for all these connections and ODP.NET caches it. The app can direct ODP.NET to clear its cache of all its access tokens so that they aren't used with new connections or new pools. `ClearInteractiveTokenCache` static method will clear access token cached in existing connection pools, that is, pools which are created with interactive authentication flows. Only existing opened connections will continue to work.

### Code Sample: ODP.NET Microsoft Entra ID Single Sign-on Configuration and Connection

```

        string dbAppIdUri = "<value>";
        string clientId = "<value>";
        string tenantId = "<value>";
        string redirectUri = "<value>";
        var conn = new OracleConnection("User Id=/;Data Source=<value>;Connection
Timeout=900");
        var tokenConfig = new AzureTokenAuthentication
        {
            ClientId = clientId,
            TenantId = tenantId,
            DatabaseApplicationIdUri = dbAppIdUri,
            RedirectUri = redirectUri
        };
        conn.WalletLocation = @".\wallet";
        conn.TnsAdmin = @".\tns";
        conn.TokenAuthentication = OracleTokenAuth.AzureInteractive;
        conn.UseAzureTokenAuthentication(tokenConfig);
        conn.Open();

```

Alternatively, Microsoft Entra ID SSO can be configured without any ODP.NET code changes using `tnsnames.ora`, `Easy Connect Plus`, `sqlnet.ora`, `SEPS wallet`, and/or Azure .NET SDK environment variables.

## Connection String Attributes and URLs

All ODP.NET providers support the connection string attributes in the following table.

Managed ODP.NET and ODP.NET Core can accept connection string URLs in lieu of connection string attributes. These URLs access the Azure, Oracle Cloud Infrastructure, or local file centralized configuration provider in which the ODP.NET connection string values are stored.

[Table 3-6](#) lists the supported connection string attributes.

**Table 3-6 Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                                                                                               | Default Value |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Application Continuity      | Enables database requests to automatically replay transactional or non-transactional operations in a non-disruptive and rapid manner in the event of a severed database session, which results in a recoverable error.                                                                    | true          |
| Connection Lifetime         | Minimum life time (in seconds) of the connection.                                                                                                                                                                                                                                         | 0             |
| Connection Timeout          | The time to wait (in seconds) for a new connection or an idle connection from the connection pool before a connection time out error can occur.                                                                                                                                           | 15            |
| Data Source                 | Oracle Net Services Name, Connect Descriptor, or an easy connect naming that identifies the database to which to connect.                                                                                                                                                                 | empty string  |
| DBA Privilege               | Administrative privileges: SYSDBA, SYSASM, SYSOPER, SYSBACKUP, SYSDG, SYSKM, or SYSRAC.                                                                                                                                                                                                   | empty string  |
| Decr Pool Size              | Number of connections that are closed when an excessive amount of established connections are unused.                                                                                                                                                                                     | 1             |
| Enlist                      | Controls the enlistment behavior and capabilities of a connection in context of COM+ transactions or System.Transactions.                                                                                                                                                                 | true          |
| HA Events                   | Enables ODP.NET connection pool to proactively remove connections from the pool when an Oracle database service, service member, instance, or node goes down. Works with Oracle Global Data Services, including Oracle RAC, Data Guard, GoldenGate, and some single instance deployments. | true          |
| Load Balancing              | Enables ODP.NET connection pool to balance work requests across Oracle database instances based on the load balancing advisory and service goal. Works with Oracle Global Data Services, including Oracle RAC, Active Data Guard, and GoldenGate.                                         | true          |
| Incr Pool Size              | Number of new connections to be created when all connections in the pool are in use.                                                                                                                                                                                                      | 5             |
| Max Pool Size               | Maximum number of connections in a pool.                                                                                                                                                                                                                                                  | 100           |
| Metadata Pooling            | Caches metadata information.                                                                                                                                                                                                                                                              | True          |
| Min Pool Size               | Minimum number of connections in a pool.                                                                                                                                                                                                                                                  | 1             |

**Table 3-6 (Cont.) Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                          | Default Value                                 |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Password                    | Password for the user specified by User Id.                                                                                                                                                                          | empty string                                  |
| Persist Security Info       | Retrieval of the password in the connection string.                                                                                                                                                                  | false                                         |
| Pooling                     | Connection pooling.                                                                                                                                                                                                  | true                                          |
| Proxy User Id               | User name of the proxy user.                                                                                                                                                                                         | empty string                                  |
| Proxy Password              | Password of the proxy user.                                                                                                                                                                                          | empty string                                  |
| Self Tuning                 | Enables or disables self-tuning for a connection.                                                                                                                                                                    | true                                          |
| Statement Cache Purge       | Statement cache purged when the connection goes back to the pool.                                                                                                                                                    | false                                         |
| Statement Cache Size        | Statement cache enabled and cache size, that is, the maximum number of statements that can be cached.                                                                                                                | 0                                             |
| Tns_Admin                   | Directory where ODP.NET can find its sqlnet.ora and tnsnames.ora configuration files.<br><i>Not available in ODP.NET, Unmanaged Driver.</i>                                                                          | empty string                                  |
| Token_Auth                  | This attribute specifies the access token authentication type. Possible values are OCITOKEN, OAUTH, or DISABLED.<br>Only supported for managed ODP.NET and ODP.NET Core.                                             | DISABLED                                      |
| Token_Location              | This attribute is the file-based token location. The value can be a directory where a file named "token" is or it can be the file's full path specification.<br>Only supported for managed ODP.NET and ODP.NET Core. | Varies depending on token authentication type |
| User Id                     | Oracle user name.                                                                                                                                                                                                    | empty string                                  |
| Validate Connection         | Validation of connections coming from the pool.                                                                                                                                                                      | false                                         |
| Wallet_Location             | ODP.NET wallet directory or URL.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                | empty string                                  |
| Wallet_Password             | Stores PKCS #12 wallet password                                                                                                                                                                                      | empty string                                  |

The following example uses connection string attributes to connect to Oracle Database:

```
// C#

using System;
using Oracle.DataAccess.Client;

class ConnectionSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();
    }
}
```

```
//using connection string attributes to connect to Oracle Database
con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle";
con.Open();
Console.WriteLine("Connected to Oracle" + con.ServerVersion);

// Close and Dispose OracleConnection object
con.Close();
con.Dispose();
Console.WriteLine("Disconnected");
}
}
```

## Connection String Builder

The `OracleConnectionStringBuilder` class makes creating connection strings less error-prone and easier to manage.

Using this class, developers can employ a configuration file to provide the connection string and/or dynamically set the values through the key/value pairs. One example of a configuration file entry follows:

```
<configuration>
  <connectionStrings>
    <add name="Publications" providerName="Oracle.DataAccess.Client"
        connectionString="User Id=scott;Password=tiger;Data Source=inst1" />
  </connectionStrings>
</configuration>
```

Connection string information can be retrieved by specifying the connection string name, in this example, `Publications`. Then, based on the `providerName`, the appropriate factory for that provider can be obtained. This makes managing and modifying the connection string easier. In addition, this provides better security against string injection into a connection string.

## Specifying the Data Source Attribute

This section describes different ways of specifying the data source attribute.

The following example shows a connect descriptor mapped to a TNS alias called `sales` in the `tnsnames.ora` file:

```
sales=
(DESCRIPTION=
  (ADDRESS= (PROTOCOL=tcp)(HOST=sales-server)(PORT=1521))
  (CONNECT_DATA=
    (SERVICE_NAME=sales.us.acme.com)))
```

The connection pool will maintain the full descriptor of an alias so that subsequent connection requests with the same connection string will not need to resolve the alias again. This applies to `tnsnames.ora`, .NET config data sources, and LDAP aliases. To flush out the cached full descriptor maintained by the connection pool, invoke `OracleDataSourceEnumerator.GetDataSources()` followed by `OracleConnection.ClearPool()` or `OracleConnection.ClearAllPools()`.

If connection pooling is not used, the alias will need to be resolved to the full descriptor for each request. In the case of LDAP, the LDAP server is contacted for each connection request.

## Using the TNS Alias

To connect as `scott/tiger` using the TNS Alias, a valid connection appears as follows:

```
"user id=scott;password=tiger;data source=sales";
```

## Using the Connect Descriptor

ODP.NET also allows applications to connect without the use of the `tnsnames.ora` file. To do so, the entire connect descriptor can be used as the "data source".

The connection string appears as follows:

```
"user id=scott;password=tiger;data source=" +
  "(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)" +
  "(HOST=sales-server)(PORT=1521))(CONNECT_DATA="+
  "(SERVICE_NAME=sales.us.acme.com)))"
```

## Easy Connect and Easy Connect Plus Naming Methods

The Easy Connect and Easy Connect Plus naming methods enable clients to connect to a database without any configuration.

With this enabled, ODP.NET allows applications to specify the Data Source attribute in the form of:

```
//host:[port]/[service_name]
```

Using the same example, some valid connection strings follow:

```
"user id=scott;password=tiger;data source=//sales-server:1521/sales.us.acme.com"
"user id=scott;password=tiger;data source=//sales-server/sales.us.acme.com"
"user id=scott;password=tiger;data source=sales-server/sales.us.acme.com"
```

If the port number is not specified, 1521 is used by default.

Easy Connect has been enhanced in ODP.NET 19c to support a wider application breadth, including clustered or cloud databases, and for ease of use. These improvements are called Easy Connect Plus and its features include:

- TCP/IP with SSL/TLS
- Any SQL\*Net description level parameter can be used
- Multiple hosts and ports

- A straightforward name-value pair format

The syntax uses the question mark symbol ? to indicate the name-value pairs start and the ampersand symbol & to delimit each name-value pair. The entire connect string must be specified as a single string. Leading and trailing white spaces are ignored within parameter values. If whitespace is required as part of the value, it should be placed within double-quotes. In ODP.NET 23.5, Easy Connect Plus support for address lists was added.

Easy Connect Plus syntax:

```
[[protocol:][//]host1{,host2}[:port1]{,host3:port2}{;host4{,host5}[:port3]]
[/[service_name][:server][/instance_name]]{[?parameter_name=value{&parameter_name=value}]}
```

Easy Connect Plus samples:

- tcps://sales1.us.example.com:1522,sales2.us.example.com;sales3.us.example.com,sales4.us.example.com/MyServiceName?WALLET\_LOCATION=/wallets
- tcps://salesserver1:1521/sales.us.example.com
- salesserver1:1521,salesserver2,salesserver3:1522/sales.us.example.com
- tcps://salesserver1:1521/sales.us.example.com?wallet\_location=D:/oracle
- tcps://salesserver1:1521/sales.us.example.com?ssl\_server\_cert\_dn=cn=sales,cn=OracleContext,dc=us,dc=example,dc=com
- tcps://salesserver1:1521/sales.us.example.com?https\_proxy=www-proxy.mycompany.com&https\_proxy\_port=80
- salesserver1:1521/sales.us.example.com?connect\_timeout=60&transport\_connect\_timeout=30&retry\_count=3

## Using LDAP

ODP.NET can connect with connect identifiers mapped to connect descriptors in an LDAP-compliant directory server, such as Oracle Internet Directory and Microsoft Active Directory.

To enable ODP.NET LDAP connectivity, provide configuration information using an `ldap.ora` file.

To configure LDAP for ODP.NET, Unmanaged Driver, follow these Oracle documentation instructions in Configuring the Directory Naming Method in *Oracle AI Database Net Services Administrator's Guide*.

To configure LDAP for ODP.NET, Managed Driver, follow the instructions in "[settings section](#)" and "[LDAPsettings section](#)."

Beginning with Oracle Database release 18c, version 18.1, organizations can use centrally managed users (CMUs) with Active Directory. This feature is designed for organizations who prefer to use Active Directory as their centralized identity management solution. Organizations can use Kerberos, PKI, or password authentication with CMU and Active Directory.

LDAP channel binding and LDAP signing are ways to enhance the communication security between LDAP clients and Active Directory domain controllers. Beginning with version 19,

managed ODP.NET and ODP.NET Core LDAP Naming adapters fully comply with the Microsoft LDAP hardening guidance.

## LDAP URL Naming

LDAP URL Naming enable clients to resolve a TNS alias stored in a LDAP server without SQLNET.ORA and LDAP.ORA configuration files.

Supported Syntax:

```
ldap[s]://host[:port]/name[,context][?parameter=value{&parameter=value}]
```

host is host name or IP address.

port is port used. Default port number is 636 for LDAPS, 363 for LDAP.

name[,context] can be:

- alias, Default\_Admin\_Context
- alias, CN=OracleContext, Default\_Admin\_Context
- CN=alias, Default\_Admin\_Context
- CN=alias, CN=OracleContext, Default\_Admin\_Context

Default\_Admin\_Context is the value of the DEFAULT\_ADMIN\_CONTEXT parameter from LDAP.ORA.

parameters:

- DIRECTORY\_SERVER\_TYPE can be OID, OUD, AD, with OID as the default.
- AUTHENTICATE\_BIND can be true or false, with false as the default.
- AUTHENTICATE\_BIND\_METHOD can be LDAPS\_SIMPLE\_AUTH or NONE, to indicate to use user name/password from the wallet.
- WALLET\_LOCATION specifies the location of the wallet. If WALLET\_LOCATION is missing in the URL and required, it will be retrieved from the SQLNET.ORA.
- LDAP\_CONN\_TIMEOUT specifies the LDAP connection timeout in seconds.

When LDAP URL is used to resolve an alias, all LDAP related parameters in SQLNET.ORA and LDAP.ORA are ignored with the exception of WALLET\_LOCATION parameter in SQLNET.ORA.

## LDAPS Configuration without Wallets

Starting with versions 23.4, LDAP Naming adapter for ODP.NET managed and core drivers supports SSL without wallets. With one-way TLS, the LDAP client certificate is not required. A client wallet for the trusted Certificate Authority (CA) can be provided for ODP.NET LDAP Naming adapter authentication of the server. Without a wallet, the trusted CA will come from the local host's default trustpoints. LDAPS connection configuration is simpler without wallet files.

LDAPS Walletless One-way TLS can be used in one of two ways:

- If the LDAP server uses a certificate/wallet signed by a O/S-trusted certificate authority, as defined by the .NET root/localmachine store, then for LDAP client no changes are required besides un-setting the Oracle wallet location if it is already set.
- If the LDAP server uses a self-signed certificate/wallet, then the self-signed root certificate (public key) for the LDAP server certificate/wallet must be inserted into the root certificate store (root/localmachine) of the client machine.

ODP.NET LDAP Naming adapter will attempt to connect with one-way TLS when TCPS protocol is specified and either:

- no wallet location setting is present, or,
- wallet location is set to system.

## Data Source Enumerator

The data source enumerator enables the application to generically obtain a collection of the Oracle data sources that the application can connect to.

["OracleDataSourceEnumerator Class"](#)

## Using WebSocket

WebSocket is a protocol that offers full-duplex communication channels over a single TCP connection. WebSocket with SSL/TLS offers a secure WebSocket connection. WebSocket is an extension to HTTP and is able to work with HTTP proxies and intermediaries.

ODP.NET Core, managed, and unmanaged providers all support WebSocket and secure WebSocket protocols in Oracle Database 19c and higher.

### ODP.NET WebSocket Configuration

WebSocket and secure WebSocket can be set through the connect descriptor by setting PROTOCOL to WS for WebSocket or WSS for secure WebSocket in tnsnames.ora, .NET configuration file, or OracleDataSourceCollection Class.

The WebSocket uniform resource identifier (URI) can be set in tnsnames.ora, sqlnet.ora, .NET configuration file, and OracleConfiguration class.

ODP.NET Configuration File WebSocket URI Setting Sample:

```
<oracle.manageddataaccess.client>
  <version number="">
    <settings>
      <setting name="SQLNET.URI" value="<WebSocket URI>" />
    </settings>
  </version>
</oracle.manageddataaccess.client>
```

OracleConfiguration WebSocket URI Setting C# Sample:

```
OracleConfiguration.SqlNetURI = <WebSocket URI>;
```

When setting the URI in unmanaged ODP.NET, it cannot begin with a forward slash character. For managed ODP.NET, the forward slash at the beginning of the URI is optional.

## Using Transport Layer Security and Secure Sockets Layer

Transport Layer Security (TLS) and its predecessor, Secure Sockets Layer (SSL), are industry standard protocols for securing network connections.

ODP.NET core, managed, and unmanaged versions support one-way and two-way TLS/SSL with wallets for database and transport authentication. ODP.NET core, managed, and unmanaged also support one-way TLS without wallets. Not having to provide a wallet can simplify database connectivity, such as with Oracle Autonomous Database.

## Secure Sockets Layer and Transport Layer Security Differences

Although SSL was primarily developed by Netscape Communications Corporation, the Internet Engineering Task Force (IETF) took over development of it, and renamed it Transport Layer Security (TLS).

ODP.NET supports TLS 1.2 and 1.3.

The SSL/TLS client can ensure that the distinguished name (DN) is correct for the database server it is trying to connect to. Parameters for DN Matching are `SSL_SERVER_DN_MATCH` (`sqlnet.ora`) and `SSL_SERVER_CERT_DN` (`tnsnames.ora`), which can be defined in the `.NET` config file as well.

To turn DN Match on, set `SSL_SERVER_DN_MATCH` to True (or On or Yes). `SSL_SERVER_CERT_DN` is optional. It allows the administrator to specify exactly the DN they want to match. If the `SSL_SERVER_CERT_DN` is not set, then `HOSTNAME` based DN matching will be done.

`SSL_SERVER_DN_MATCH` can be set using:

- `sqlnet.ora`
- connect address: *Both* full description based and EZConnect
- `.NET` Configuration file, such as `web.config`
- `SSLServerDNMatch` in `OracleConfiguration` and `OracleConnection`
- `UseSSLServerDNMatch` in `OracleDataSourceBuilder`

`SSL_SERVER_CERT_DN` can be set using:

- connect address: *Both* full description based and EZConnect

### ① See Also

- The TLS Protocol Version 1.0 [RFC 2246] at the IETF Web site, which can be found at:  
<http://www.ietf.org>
- `SSL_VERSION` in the "[settings section](#)."

**Note**

To simplify the discussion, this section uses the term SSL where either SSL or TLS may be appropriate because SSL is the most widely recognized term. However, where distinctions occur between how you use or configure these protocols, this section specifies what is appropriate for either SSL or TLS.

## ODP.NET Secure Sockets Layer Configuration Using Wallets

When you configure Secure Sockets Layer on the client, you must confirm that the wallet is created and use TCP/IP with SSL on the client. Optionally, you can perform additional steps to enhance the configuration.

**Note**

ODP.NET supports auto login wallets, but not the local auto login wallet option.

**SSL Configuration Topics:**

- [Step 1: Confirm Client Wallet Creation](#)
- [Step 2: Use TCP/IP with SSL on the Client](#)
- [Step 3: Specify Required Client SSL Configuration \(Wallet Location\)](#)
- [Step 4: Set the SSL Version on the Client \(Optional\)](#)
- [Step 5: Set SSL as an Authentication Service on the Client \(Optional\)](#)

**Step 1: Confirm Client Wallet Creation**

Before proceeding to the next step, you must confirm that a wallet has been created on the client and that the client has a valid certificate.

ODP.NET, managed and core drivers support file and Microsoft Certificate Store (MCS) based wallets.

- For file-based wallets, use Oracle Wallet Manager to check that the wallet has been created. See Step 1A: Confirm Wallet Creation on the Server in *Oracle Database Security Guide* for information about checking a wallet.
- For MCS, ODP.NET will retrieve the credentials from the MY or Personal certificate store. Use Microsoft tools or the `orapki` utility to create certificates, then load the certificates into MCS for use.

**Step 2: Use TCP/IP with SSL on the Client**

The ODP.NET Data Source must be modified to use SSL. Specifically, the transport protocol must be changed to use TCP/IP with SSL or what Oracle calls "tcps". An example ODP.NET Data Source for use with SSL is:

```
finance = (DESCRIPTION=
  (ADDRESS = (PROTOCOL=tcps) (HOST=finance_server) (PORT=1575) )
  (CONNECT_DATA = (SERVICE_NAME=Finance.us.example.com) ) )
```

### Step 3: Specify Required Client SSL Configuration (Wallet Location)

Edit the `sqlnet.ora` or `.NET` application configuration to specify the wallet location.

- An example of setting the SSL wallet location for file based wallets, where `<wallet_location>` is the specified location where the client wallet is stored:

```
wallet_location = (SOURCE=(METHOD= File)
                  (METHOD_DATA=(DIRECTORY=<wallet_location>)))
```

- An example of setting the SSL wallet location for MCS based wallets is:

```
wallet_location = (SOURCE=(METHOD= MCS))
```

### Step 4: Set the SSL Version on the Client (Optional)

The `SSL_VERSION` parameter can be set through the `sqlnet.ora` or the `.NET` `application.config`, `web.config`, or `machine.config` file. Normally, it is not necessary to set this parameter. The default setting for this parameter is `any`, which allows the database server to apply any necessary restrictions to the SSL version accepted. An example setting in the `sqlnet.ora` is:

```
SSL_VERSION=1.2
```

### Step 5: Set SSL as an Authentication Service on the Client (Optional)

If TCPS is to be used as both a transport and as an external database authentication, set the `SQLNET.AUTHENTICATION_SERVICES` parameter in the `sqlnet.ora` or `application.config`, `web.config`, or `machine.config` file.

Note that SSL can be used as just a transport encryption vehicle. Hence, the "optional" designation for this setting.

If SSL/TLS is to be used as an external database authentication method, then an externally authenticated database user matching the client certificate must be created.

An example setting allowing SSL external authentication in the `sqlnet.ora` is:

```
SQLNET.AUTHENTICATION_SERVICES = (TCPS)
```

#### ① Note

Prior to ODAC 12c Release 4, ODP.NET, Managed Driver SSL connections would be redirected to dynamic (ephemeral) port on the database server machine. With ODAC 12c Release 4 and later, managed ODP.NET SSL connections will now continue to the original socket connection to the Oracle Listener. Hence, firewalls will now only need to allow access to the Oracle Listener's port (e.g., 1521).

- Creating a User Who Is Authenticated Externally in *Oracle Database Security Guide* for more information about creating externally identified database users.

## ODP.NET Secure Sockets Layer Configuration without Wallets

Starting with versions 19.13 and 21.4, ODP.NET managed and core drivers support SSL without wallets. Unmanaged ODP.NET introduced SSL support without wallets from versions 19.14 and 21.5. With one-way TLS, the client certificate is not required. A client wallet for the trusted Certificate Authority (CA) can be provided for ODP.NET authentication of the server. Without a wallet, the trusted CA will come from the local host's default trustpoints. Connection configuration is simpler without wallet files.

Walletless One-way TLS can be used in one of two ways:

- If the database server uses a certificate/wallet signed by a O/S-trusted certificate authority, as defined by the .NET root/localmachine store, then no client changes are required besides un-setting the Oracle wallet location if it is already set.
- If the database server uses a self-signed certificate/wallet, then the self-signed root certificate (public key) for the server certificate/wallet must be inserted into the root certificate store (root/localmachine) of the client machine.

ODP.NET will attempt to connect with one-way TLS when TCPS protocol is specified and either:

- no wallet location setting is present, or,
- wallet location is set to system.

ODP.NET essentially ignores existing static wallet configuration (file or `OracleConfiguration` based) when system is specified through the following dynamic configuration methods:

- TNS connect descriptor
  - `WALLET_LOCATION` or `MY_WALLET_DIRECTORY`
- Easy Connect Plus
  - `WALLET_LOCATION`
- ODP.NET connection string
  - `Wallet_Location`
- ODP.NET `OracleConnection` property
  - `WalletLocation`

These options allow administrators to specify at different granularities connections using a client certificate or SEPS and connections not using a wallet.

By default, Oracle Autonomous Database credentials use the `WALLET_LOCATION` in `sqlnet.ora`. To disable the wallet requirement, remove the `sqlnet.ora` `WALLET_LOCATION` setting completely or set one of the above dynamic wallet location settings to system.

## Inserting Public Keys into System Trusted Certificate Authority List

The Certificate Authority (CA) public key is stored in the CA certificate. This certificate is stored in the local trust store on the client system. Here are typical commands to install root certificate in different platform.

### Windows:

Base64/PEM format:

```
openssl pkcs12 -in ewallet.p12 -clcerts -nokeys -out rootca.pem  
certutil -addstore -enterprise -f -v root rootca.pem
```

**Linux (Oracle and Red Hat):**

Create PEM certificate from PKCS #12 file:

```
openssl pkcs12 -in ewallet.p12 -clcerts -nokeys -out rootca.pem -password pass:<password>  
sudo cp rootca.pem /etc/pki/ca-trust/source/anchors  
sudo update-ca-trust
```

On Linux, the administrator can manually edit the root PEM file by adding the PEM file contents resulting from the OPENSSL command shown above. The root PEM file on Linux is located in /etc/pki/tls/cert.pem, which is a link to /etc/pki/ca-trust/extracted/pem/tls-ca-bundle.pem.

**Linux (Ubuntu):**

Change the PEM (.pem) or CER (.cer) file extension to a CRT extension (.crt). Then, execute the following two commands:

```
sudo cp rootca.crt /usr/local/share/ca-certificates/rootca.crt  
sudo update-ca-certificates
```

**macOS:**

Base64/PEM format:

```
sudo security add-trusted-cert -d -r trustRoot -k "/Library/Keychains/System.keychain"  
"<directory>/rootca.pem"
```

## Troubleshooting TLS/SSL Setup

This section discusses commonly encountered issues and their typical resolution steps.

**Common TLS/SSL Wallet Errors**

Microsoft Windows now restricts wallets from using the MD5 algorithm. Oracle wallets may have been generated with this algorithm as that was the default option in Oracle Public Key Infrastructure (orapki) utility 12.1 and earlier.

orapki can be found in the ORACLE\_HOME\bin directory of the database server installation or Oracle client administrator install. It is not included with Oracle Instant Client. The utility is only needed to setup up the wallet; it is not necessary to deploy it with the wallet.

When you setup TLS/SSL and encounter an "ORA-0052: Failure during SSL handshake" error combined with a 0x80004005 error code and first inner exception "A SSPI-call failed" and second inner exception "A token sent to the function is invalid", then it is very likely that Microsoft Security Support Provider Interface (SSPI) rejected your Oracle Wallet, such as when MD5 is used. This is a failure on the handshake. You can resolve this error by using the SHA-2 algorithm instead.

If the second inner exception instead indicates "The credentials supplied to the package were not recognized", it is possible the user certificate was generated without a certificate authority (CA). You can resolve this error by using orapki to generate a CA/root certificate and then regenerating your user wallet/certificate to point to this new CA/root certificate.

The steps below will regenerate your Oracle Wallet using orapki and SHA-2. Any orapki version can be used to generate the wallet with these instructions.

1. Create root wallet, for example, a CA wallet.

```
orapki wallet create -wallet ./root -pwd <password>
```

2. Add a self-signed certificate (CA certificate) to the root wallet.

```
orapki wallet add -wallet ./root -dn 'CN=<my root>' -keysize 1024 -  
self_signed -validity 3650 -pwd <password> -sign_alg sha512
```

3. Export the self-signed certificate from the wallet.

```
orapki wallet export -wallet ./root -dn 'CN=<my root>' -cert ./root/  
b64certificate.txt -pwd <password>
```

4. Create a user wallet, for example, a customer wallet.

```
orapki wallet create -wallet ./user -pwd <password> -auto_login
```

5. Add a certificate request.

```
orapki wallet add -wallet ./user -dn 'CN=<client's hostname>' -keysize  
1024 -pwd <password> -sign_alg sha512
```

6. Export the certificate request.

```
orapki wallet export -wallet ./user -dn 'CN=<client's hostname>' -  
request ./user/creq.txt -pwd <password>
```

7. Create a certificate issued by a CA.

```
orapki cert create -wallet ./root -request ./user/creq.txt -cert ./user/  
cert.txt -validity 3650 -pwd <password> -sign_alg sha512
```

8. Add a trusted certificate (CA certificate) to the wallet. This example assumes the same CA for both the client and server wallets.

```
orapki wallet add -wallet ./user -trusted_cert -cert ./root/  
b64certificate.txt -pwd <password>
```

9. Add a user certificate.

```
orapki wallet add -wallet ./user -user_cert -cert ./user/cert.txt -pwd  
<password> -sign_alg sha512
```

10. Display contents of user wallet.

```
orapki wallet display -wallet ./user -pwd <password>
```

11. Create a server wallet.

```
orapki wallet create -wallet ./server -pwd <password> -auto_login
```

12. Add a server certificate request.

```
orapki wallet add -wallet ./server -dn 'CN=<server's hostname>' -keysize  
1024 -pwd <password> -sign_alg sha512
```

13. Export the certificate request.

```
orapki wallet export -wallet ./server -dn 'CN=<server's hostname>' -  
request ./server/creq.txt -pwd <password>
```

14. Create a server certificate issued by a CA.

```
orapki cert create -wallet ./root -request ./server/creq.txt -cert ./  
server/cert.txt -validity 3650 -pwd <password> -sign_alg sha512
```

15. Add a trusted certificate (CA certificate) to the server wallet. This example assumes the same CA for both the client and server wallets.

```
orapki wallet add -wallet ./server -trusted_cert -cert ./root/  
b64certificate.txt -pwd <password>
```

16. Add an user\_cert certificate for the server wallet.

```
orapki wallet add -wallet ./server -user_cert -cert ./server/cert.txt -pwd  
<password> -sign_alg sha512
```

17. Display contents of server wallet.

```
orapki wallet display -wallet ./server -pwd <password>
```

## Mutual TLS/SSL Certificate Selection

When ODP.NET connections use mutual TCPS (TLS/SSL), the user needs a signed certificate. This client certificate can be stored in an Oracle wallet, PEM file, or Microsoft Certificate Store (MCS).

PEM files are supported by ODP.NET Core only starting with version 23.9.

In MCS, if there is more than one certificate that can be used, then the user or application settings must specify the specific one to connect with. This choice can be made manually by the user through the graphical user interface (GUI) or automatically by the application using the thumbprint.

For the GUI, the end user selects the correct client certificate from the list available in a store, such as MCS. The key store can filter the visible certificates to simplify selecting the correct certificate. For example, the GUI should be able to filter certificates by private certificate and expiration state. By default, public key only trusted Certificate Authorities (CA) certificates should not be visible in the certificate store GUI as the selection process is for mutual TLS.

GUI certificate selection is disabled by default. To enable, set the `OracleConnection.AllowCertificateSelectionUI` property to true. When connecting from Windows, the end user gets a pop-up window to select a TLS/SSL certificate in MCS.

Alternatively to GUI selection, a thumbprint can uniquely identify the client certificate.

Developers can set the thumbprint in the `SSLCertificateThumbprint` property of `OracleConfiguration` or `OracleConnection`, TNS connect descriptor, Easy Connect Plus, or `sqlnet.ora` entries.

`orapki` (`orapki.exe`) can manage certificates and wallets for Oracle database. It can create, alter, view certificates in the Oracle wallet to include the SHA1 thumbprints. The thumbprint of a wallet can be displayed via the following `orapki` command:

```
orapki wallet display -wallet <wallet directory> -pwd <wallet password>
      -complete
```

Microsoft Windows automatically adds Personal Identity Verification (PIV) smart card certificates into the Windows MCS. When those smart card certificates are used, such as during a TLS/SSL connection, they require a successful PIN prompt entry. The initial PIN prompt success is cached at the process level for all subsequent same smart card certificate uses, except for "digital signature" PIV smart card certificate containers. For certificates in these containers, a PIN prompt is required for every certificate use.

#### ① See Also

[Registry keys for smart card PIN caching options are no longer available in Windows 10](#)

## Using Secure External Password Store

The Secure External Password Store (SEPS) is the use of a client-side wallet for securely storing the password credentials. All ODP.NET driver types can be configured to use the external password store.

An Oracle wallet is a container that securely stores authentication and signing credentials. Wallets can simplify large-scale deployments that rely on password credentials for database connections. Applications no longer need embedded user names and passwords, which reduces security risk.

Using SEPS with ODP.NET Core requires the NuGet package, `System.Security.Cryptography.Pkcs` version 4.7 or higher, as a dependency for your application project.

ODP.NET can use SEPS in conjunction with TCPS in two scenarios:

- SEPS wallet from `sqlnet.ora` `WALLET_LOCATION` and TCPS wallet from connect address `WALLET_LOCATION`
- Only SEPS wallet from `sqlnet.ora` `WALLET_LOCATION` is specified and `WALLET_LOCATION` is *not* specified in connect address

In the second scenario, if the wallet has a client certificate, mTLS is used. If there is no certificate, then walletless one-way TLS is used.

SEPS typically associates a TNS alias with a database username and password encrypted in the wallet file. When the TNS alias-based SEPS username and password are not found, a SEPS default username and password can be configured in the wallet as a backup option. ODP.NET would then use the default username and password instead to connect. ODP.NET support for default username and password requires version 23.8 or higher.

Also, starting in version 23.8, ODP.NET managed and core drivers support SEPS wallet location and password. These capabilities allow apps to separate the SEPS wallet

configuration from the database, LDAP, and WebSocket Secure wallet support. This decouples the SEPS configuration, allowing it to change independently from other wallet uses. SEPS wallet password is only required if you use a PKCS #12 wallet file, which typically has .p12 extension.

## Configuring Secure External Password Store (SEPS)

Steps for configuring SEPS:

- [Step 1. Create the wallet file](#)
- [Step 2. Point the configuration to the client wallet](#)
- [Step 3. Turn on SEPS](#)

### Step 1. Create the wallet file

Use the `mkstore` utility to create the wallet file and insert the credentials.

**Step 1a.** Create a wallet on the client by using the following syntax at the command line:

```
mkstore -wrl wallet_location -create
```

For example:

```
mkstore -wrl c:\oracle\product\12.1.0\db_1\wallets -create
Enter password: password
```

**Step 1b.** Create database connection credentials in the wallet by using the following syntax at the command line:

```
mkstore -wrl wallet_location -createCredential db_connect_string username
Enter password: password
```

For example:

```
mkstore -wrl c:\oracle\product\12.1.0\db_1\wallets -createCredential orcl system
Enter password: password
```

### Step 2. Point the configuration to the client wallet

In the client `sqlnet.ora` file, enter the `WALLET_LOCATION` parameter and set it to the directory location of the wallet you created in Step 1.

For example, if you created the wallet in `$ORACLE_HOME/network/admin` and your Oracle home is set to `C:\app\client\<user>\product\<version>\client_1\`, then you need to enter the following into your client `sqlnet.ora` file:

```
WALLET_LOCATION =
  (SOURCE =(METHOD = FILE)
    (METHOD_DATA =
      (DIRECTORY =
        C:\app\client\<user>\product\<version>\client_1\Network\Admin) ) )
```

### Step 3. Turn on SEPS

Enable SEPS in your application by setting the wallet override setting to `true` in the `OracleConfiguration.SqlNetWalletOverride` property or `SQLNET.WALLET_OVERRIDE` setting in `sqlnet.ora` or `.NET` configuration file.

```
SQLNET.WALLET_OVERRIDE = TRUE
```

This setting causes all `CONNECT /@db_connect_string` statements to use the information in the wallet at the specified location to authenticate to databases.

When external authentication is in use, an authenticated user with such a wallet can use the `CONNECT /@db_connect_string` syntax to access the previously specified databases without providing a user name and password. Note however, that the wallet file needs to be kept up to date with the database credentials. If the database credentials change, but the wallet file is not changed appropriately, then the connections will fail.

#### See Also

- [Oracle Data Provider for .NET, Managed Driver Configuration](#) for more details about the wallet settings.
- Managing the Secure External Password Store for Password Credentials in *Oracle Database Security Guide* for more information about secure external password store and configuration with Oracle database.

## Using Kerberos

Kerberos is a network authentication service for security in distributed environments. ODP.NET applications can use Kerberos for single sign-on and centralized user authentication.

All ODP.NET provider types support Kerberos for external authentication to the database server.

ODP.NET Core Kerberos requires the `Oracle.ManagedDataAccess.Kerberos` NuGet package, which uses `Kerberos.NET`. When using ODP.NET Core Kerberos, ensure that the local hostname is IP resolvable via DNS or a local hosts file.

Managed ODP.NET offers two Kerberos enablement options. Developers can use the `Oracle.ManagedDataAccess.Kerberos` NuGet package with `Kerberos.NET` just like they do for ODP.NET Core or they can use MIT Kerberos. Oracle recommends using the `Oracle.ManagedDataAccess.Kerberos` option.

#### Note

- Managed ODP.NET and ODP.NET Core do not support Kerberos constrained delegation.
- Managed ODP.NET and ODP.NET Core do not support Kerberos5Pre authentication adapter. Use Kerberos5 instead.

## File Based Credential Cache and MSLSA

ODP.NET supports both a file-based Kerberos client credential cache (CC) and the ability to use Windows logon credentials as Kerberos client credentials. The latter is called MSLSA-based Kerberos authentication.

In order to utilize a file based Kerberos client credential cache (CC), the following executables associated with the full Oracle Database Client install are needed:

- `okinit.exe`

- `oklist.exe`
- `okdstry.exe`

The executables are required in order to acquire the Kerberos5 credentials and store them in the file based credential cache (CC). However, after credential cache creation, as long as the credentials remain valid, the above executables are then unneeded by the ODP.NET application at run-time.

## Using ODP.NET, Managed Driver with Kerberos

Managed ODP.NET supports Kerberos authentication with either MIT Kerberos (default) or `Oracle.ManagedDataAccess.Kerberos` NuGet package. Managed ODP.NET 23.9 and higher support the `Oracle.ManagedDataAccess.Kerberos` option.

To use `Oracle.ManagedDataAccess.Kerberos`, set `OracleConfiguration.UseMITKerberos` to false and add the `Oracle.ManagedDataAccess.Kerberos` NuGet package into your project.

If set to true (default), then managed ODP.NET will use MIT Kerberos instead. You then install MIT Kerberos 4.0.1 onto the ODP.NET client machine. The software can be downloaded from the [MIT Website](#).

### ① See Also

Configuring Kerberos Authentication in *Oracle Database Security Guide* for more information about Kerberos and configuration with Oracle database.

## Configuring Kerberos Authentication with ODP.NET

Please reference the following "key" when viewing the below Kerberos configuration examples:

- `oracleclient` = Kerberos/Windows Domain user ID used by the Oracle database client program to represent the Oracle Client user on the domain
- `oracleserver` = Kerberos/Windows Domain user ID used by the Oracle database server
- `DOMAIN.COMPANY.COM` = Kerberos/Windows domain
- `dbhost.company.com` = Oracle database server machine hostname
- `kerberos_service_name` = Kerberos service name
- `dc.company.com` = hostname for Kerberos Key Distribution Center (KDC) and Windows Domain Controller

### Configuring Kerberos Authentication Topics:

- [Step 1. Update Windows services file to include a "kerberos5" entry](#)
- [Step 2. Create client and server Kerberos users \(Windows domain users for MSLSA\)](#)
- [Step 3. Associate the DB server's Kerberos principal name with the DB server's Kerberos Service \(SPN mapping\) and generate the server keytab file](#)
- [Step 4. Confirm the mapping of server user to service principal](#)
- [Step 5. Setup server `sqlnet.ora` to point to the keytab file generated in step 2](#)

- [Step 6. Create a kerberos configuration file that points to the Kerberos KDC \(Windows Domain Controller for MSLSA\)](#)
- [Step 7. Configure the Oracle database client and server sqlnet.ora or .NET config to point to the above Kerberos configuration file](#)
- [Step 8. Point the client sqlnet.ora or .NET config to a credential cache file or to MSLSA](#)
- [Step 9. Set the client and server authentication services in the sqlnet.ora or .NET config to Kerberos5](#)
- [Step 10. Setup an externally authenticated database user that matches the Kerberos client user setup in step 1 \(note the case\)](#)
- [Step 11. Login to the client machine via the Windows Domain client user \(for MSLSA\) or perform an okinit to authenticate the client Kerberos user \(for file based CC\):](#)
- [Step 12. Run the ODP.NET application](#)

### Step 1. Update Windows services file to include a "kerberos5" entry

Change the Kerberos entry in the Windows service file (C:\windows\system32\drivers\etc\services) from:

```
kerberos    88/tcp          krb5 kerberos-sec      #Kerberos
```

to:

```
kerberos    88/tcp kerberos5 krb5 kerberos-sec      #Kerberos
```

### Step 2. Create client and server Kerberos users (Windows domain users for MSLSA)

As noted in the above "key", we will use oracleclient and oracleserver as our client and server Kerberos user IDs, respectively.

ODP.NET supports MSLSA using Windows domain users which have the following attributes:

- "Kerberos DES" unchecked
- "Kerberos AES 128 bit" checked
- "Kerberos AES 256 bit" checked
- "Kerberos preauthentication not required" checked

### Step 3. Associate the DB server's Kerberos principal name with the DB server's Kerberos Service (SPN mapping) and generate the server keytab file

Run the following commands on the Kerberos KDC (Windows Domain Controller for MSLSA) as an administrator:

```
> ktpass -princ kerberos_service_name/dbhost.company.com@DOMAIN.COMPANY.COM /crypto all /mapuser oracleserver@DOMAIN.COMPANY.COM /pass <oracleserver password> /out v5srvtab
```

```
> setspn -A kerberos_service_name/dbhost.company.com@DOMAIN.COMPANY.COM oracleserver
```

### Step 4. Confirm the mapping of server user to service principal

Also on the Kerberos KDC, run the following command, noting the output:

```
> setspn -L oracleserver
```

```
Registered ServicePrincipalNames for
CN=oracleserver,CN=Users,DC=domain,DC=company,DC=com:
```

```
kerberos_service_name/dbhost.company.com  
kerberos_service_name/dbhost.company.com@DOMAIN.COMPANY.COM
```

### Step 5. Setup server sqlnet.ora to point to the keytab file generated in step 2

Add the following line to the server sqlnet.ora:

```
sqlnet.kerberos5_keytab = c:\krb\v5srvtab
```

### Step 6. Create a kerberos configuration file that points to the Kerberos KDC (Windows Domain Controller for MSLSA)

An example kerberos configuration file (krb.conf):

```
[libdefaults]  
default_realm = DOMAIN.COMPANY.COM  
  
[realms]  
DOMAIN.COMPANY.COM = {  
    kdc = dc.company.com  
}  
  
[domain_realm]  
.domain.company.com = DOMAIN.COMPANY.COM  
domain.company.com = DOMAIN.COMPANY.COM  
.DOMAIN.COMPANY.COM = DOMAIN.COMPANY.COM  
DOMAIN.COMPANY.COM = DOMAIN.COMPANY.COM
```

### Step 7. Configure the Oracle database client and server sqlnet.ora or .NET config to point to the above Kerberos configuration file

Edit the client or server sqlnet.ora to include:

```
sqlnet.kerberos5_conf = C:\krb\krb.conf
```

Or edit the client application config to include (in the [settings section](#)):

```
<setting name="sqlnet.kerberos5_conf" value="C:\krb\krb.conf" />
```

### Step 8. Point the client sqlnet.ora or .NET config to a credential cache file or to MSLSA

Example pointing to Credential Cache file:

```
sqlnet.kerberos5_cc_name = c:\krb\krb.cc
```

Example pointing to MSLSA:

```
sqlnet.kerberos5_cc_name = MSLSA:
```

### Step 9. Set the client and server authentication services in the sqlnet.ora or .NET config to Kerberos5

```
sqlnet.authentication_services=(Kerberos5)
```

### Step 10. Setup an externally authenticated database user that matches the Kerberos client user setup in step 1 (note the case)

```
create user "ORACLECLIENT@DOMAIN.COMPANY.COM" identified externally;  
grant connect, create session to "ORACLECLIENT@DOMAIN.COMPANY.COM";
```

**Step 11. Login to the client machine via the Windows Domain client user (for MSLSA) or perform an okinit to authenticate the client Kerberos user (for file based CC):**

```
okinit oracleclient
```

In the credential cache case, use `oklist` to verify there are valid credentials in the cache. If those credentials are expired, then use `okdstry` to clean the cache and then execute a new `okinit` command.

**Step 12. Run the ODP.NET application**

Set the ODP.NET connection string to User Id=/ and leave the Password blank.

**Note**

- After configuring the client and server, the last 2 steps are the only steps required on an ongoing basis to run the ODP.NET application.
- A Microsoft Visual C Run-Time Library (MSVCRT.DLL) bug can cause ODP.NET, Managed Driver's setting of the Kerberos5 configuration to be ignored by the Microsoft run-time. In such a case, you will encounter the error message:

```
OracleInternal.Network.NetworkException (0x80004005): NA Kerberos5:
Authentication handshake failure at stage: krb5_sname_to_principal: default
realm not found. Please set SQLNET.Kerberos5_conf.
```

To workaround this error, manually set `KRB5_CONFIG` in the ODP.NET application's run-time environment to point to the Kerberos5 configuration file pointed to by `SQLNET.Kerberos5_conf`. For example,

```
set KRB5_CONFIG=c:\oracle\network\admin\krb5.ini
```

**See Also**

Configuring Kerberos Authentication in *Oracle Database Security Guide* for more information about Kerberos and configuration with Oracle database.

## Using Windows Native Authentication (NTS)

With the Windows native authentication adapter, Oracle users can authenticate to the database using just their Windows user login credentials. It provides a way to enable single sign-on and to simplify user and role credential management. Windows native authentication is also known as Windows Native authentication (NTS).

**Note**

- ODP.NET Core supports Windows Native Authentication on Windows only
- Due to a limitation in the Microsoft .NET APIs, ODP.NET, Managed Driver only supports Windows Native authentication (NTS) via Microsoft NT LAN Manager (NTLM) instead of Kerberos-based credentials. Normally, this limitation would be invisible to the ODP.NET, Managed Driver application, since the Windows domain and the Oracle database server will transparently support both NTLM and Kerberos domain credentials by default.

## Configuring Windows Native Authentication (NTS) for the ODP.NET Client

Steps in configuring the NTS for the ODP.NET Client:

- [Step 1. Ensure OSAUTH\\_PREFIX\\_DOMAIN is set correctly](#)
- [Step 2. Setup the externally identified database user](#)
- [Step 3. Setup the client configuration to utilize NTS as the authentication methodology](#)

### Step 1. Ensure OSAUTH\_PREFIX\_DOMAIN is set correctly

Make sure OSAUTH\_PREFIX\_DOMAIN is set appropriately. If you desire the externally identified user ID to include the domain, set it to true, otherwise false. The parameter is a registry setting that can be found at HKLM/software/oracle/HOME<ORACLE\_SID>. For example, if your ORACLE\_SID is r1, it is located at HKLM/software/oracle/HOMEr1.

### Step 2. Setup the externally identified database user

If you set the parameter to true in Step 1, use the following commands to setup the externally identified database user associated with the desired Windows domain user:

```
create user "MYDOMAIN\MYUSER" identified externally;  
grant connect, create session to "MYDOMAIN\MYUSER";
```

### Step 3. Setup the client configuration to utilize NTS as the authentication methodology

Edit the client sqlnet.ora or app config to add NTS to the sqlnet.authentication\_services. For example.

```
sqlnet.authentication_services = (NTS)
```

**Note**

After configuring the client and server, the last 2 steps are the only steps required on an ongoing basis to run the ODP.NET application.

**See Also**

Authenticating Database Users with Windows in *Oracle Database Platform Guide for Microsoft Windows* for Windows for more information about Windows native authentication.

## Operating System Authentication Credentials

Oracle Database can use Windows user login credentials to authenticate database users. To open a connection using Windows user login credentials, the User Id connection string attribute must be set to a slash (/). If the Password attribute is provided, it is ignored.

### Note

ODP.NET Core supports operating system authentication for Windows only.

All ODP.NET, Unmanaged Driver connections, including those using operating system authentication, can be pooled. ODP.NET, Managed Driver supports operating system authentication, except when the Windows domain is constrained to only support Kerberos-based domain authentication. Connections are pooled by default, and no configuration is required, as long as pooling is enabled.

The following example shows the use of operating system authentication:

```
/* Create an OS-authenticated user in the database
   Assume init.ora has OS_AUTHENT_PREFIX set to "" and <OS_USER>
   is any valid OS or DOMAIN user.

       create user <OS_USER> identified externally;
       grant connect, resource to <OS_USER>;

   Login through OS Authentication and execute the sample. See Oracle
   documentation for details on how to configure an OS-Authenticated user
*/

// C#

using System;
using Oracle.DataAccess.Client;

class OSAuthenticationSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        //Establish connection using OS Authentication
        con.ConnectionString = "User Id=/;Data Source=oracle;";
        con.Open();
        Console.WriteLine("Connected to Oracle" + con.ServerVersion);

        // Close and Dispose OracleConnection object
        con.Close();
        con.Dispose();
        Console.WriteLine("Disconnected");
    }
}
```

## Network Data Encryption and Integrity

ODP.NET enables data encryption and integrity over a network for both intranet and cloud deployments. This ensures that data is disguised to all, except authorized users, and guarantees the original message contents are not altered. In earlier releases, these features were known as Oracle Advanced Security Option (ASO) encryption. Starting with Oracle Database 12c, Oracle ASO is not required to use network data encryption and data integrity.

The `SQLNET.ALLOW_WEAK_CRYPT0`, `OracleConfiguration.SqlNetAllowWeakCrypto`, or equivalent settings must be set to true (default) to use weaker encryption and checksum algorithms.

## Using Data Encryption

All ODP.NET provider types support the following encryption standards and algorithms.

- Advanced Encryption Standard (AES)
    - AES 128-bit
    - AES 192-bit
    - AES 256-bit
  - Triple-DES (3DES)
    - 112-bit\*
    - 168-bit\*
- \* = Encryption algorithms that are considered weak

ODP.NET, Managed Driver and ODP.NET Core use the following settings to configure network encryption:

- `SQLNET.ENCRYPTION_CLIENT`
- `SQLNET.ENCRYPTION_TYPES_CLIENT`

### ① See Also

[settings section](#) for definition and information on usage.

## Using Data Integrity

All ODP.NET provider types support the following data integrity algorithms:

- SHA-1
- SHA-2

- SHA-256
- SHA-384
- SHA-512

#### 📘 See Also

- For more information on network encryption and integrity or configuring them for ODP.NET, Unmanaged Driver, refer to the *Oracle Database Security Guide*.
- To configure network encryption or data integrity in ODP.NET, Managed Driver and ODP.NET Core, refer to the `SQLNET.CRYPTO_CHECKSUM_CLIENT` and `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT` settings in [Oracle Data Provider for .NET, Managed Driver Configuration](#) or `sqlnet.ora`. On the database server machine, you will likely have to configure the `SQLNET.CRYPTO_CHECKSUM_SERVER` and `SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER` parameters in the `sqlnet.ora` file.

## Schema Discovery

ADO.NET exposes five different types of metadata collections through the `OracleConnection.GetSchema` API. This permits application developers to customize metadata retrieval on an individual-application basis, for any Oracle data source. Thus, developers can build a generic set of code to manage metadata from multiple data sources.

The following types of metadata are exposed:

- `MetaDataCollections`  
A list of metadata collections that is available from the data source, such as tables, columns, and indexes.
- `Restrictions`  
The restrictions that apply to each metadata collection, restricting the scope of the requested schema information.
- `DataSourceInformation`  
Information about the instance of the database that is currently being used, such as product name and version.
- `DataTypes`  
A set of information about each data type that the database supports.
- `ReservedWords`  
Reserved words for the Oracle query language.

#### 📘 See Also

[Oracle Schema Collections](#)

## User Customization of Metadata

ODP.NET provides a comprehensive set of database schema information. Developers can extend or customize the metadata that is returned by the `GetSchema` method on an individual application basis.

To do this, developers must create a customized metadata file and provide the file name to the application as follows:

1. Create a customized metadata file and put it in the `CONFIG` subdirectory where the .NET framework is installed. This is the directory that contains `machine.config` and the security configuration settings.

This file must contain the entire set of schema configuration information, not just the changes. Developers provide changes that modify the behavior of the schema retrieval to user-specific requirements. For instance, a developer can filter out internal database tables and just retrieve user-specific tables

2. Add an entry in the `app.config` file of the application, similar to the following, to provide the name of the metadata file, in name-value pair format.

```
<oracle.dataaccess.client>
  <settings>
    <add name="MetaDataXml" value="CustomMetaData.xml" />
  </settings>
</oracle.dataaccess.client>
```

When the `GetSchema` method is called, ODP.NET checks the `app.config` file for the name of the customized metadata XML file. First, the `GetSchema` method searches for an entry in the file with a element named after the provider, in this example, `oracle.dataaccess.client`. In this XML element, the value that corresponds to the name `MetaDataXml` is the name of the customized XML file, in this example, `CustomMetaData.xml`.

If the metadata file is not in the correct directory, then the application loads the default metadata XML file, which is part of ODP.NET.

## Connection Pooling

ODP.NET connection pooling is enabled and disabled using the `Pooling` connection string attribute. By default, connection pooling is enabled. The following are `ConnectionString` attributes that control the behavior of the connection pooling service:

- `Connection Lifetime`
- `Connection Timeout`
- `Decr Pool Size`
- `HA Events`
- `Incr Pool Size`
- `Load Balancing`

- Max Pool Size
- Min Pool Size
- Pooling
- Validate Connection

### Connection Pooling Example

The following example opens a connection using `ConnectionString` attributes related to connection pooling.

```
// C#

using System;
using Oracle.DataAccess.Client;

class ConnectionPoolingSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        //Open a connection using ConnectionString attributes
        //related to connection pooling.
        con.ConnectionString =
            "User Id=scott;Password=tiger;Data Source=oracle;" +
            "Min Pool Size=10;Connection Lifetime=100000;Connection Timeout=60;" +
            "Incr Pool Size=5; Decr Pool Size=2";
        con.Open();
        Console.WriteLine("Connection pool successfully created");

        // Close and Dispose OracleConnection object
        con.Close();
        con.Dispose();
        Console.WriteLine("Connection is placed back into the pool.");
    }
}
```

## Using Connection Pooling

When connection pooling is enabled (the default), the `Open` and `Close` methods of the `OracleConnection` object implicitly use the connection pooling service, which is responsible for pooling and returning connections to the application.

The connection pooling service creates connection pools by using the `ConnectionString` property as a signature, to uniquely identify a pool.

In managed and Core versions of ODP.NET, connection strings themselves must be an exact match in their entirety. If keywords are supplied in a different order or a space is added to the connection string, a new pool is created. If a pool already exists with the requested signature, a connection is returned to the application from that pool.

In unmanaged ODP.NET, a new pool is created only when connection string attribute values change. Extra spaces or changing keyword order do not create a new pool.

When a connection pool is created, the connection pooling service initially creates the number of connections defined by the `Min Pool Size` attribute of the `ConnectionString` property. This number of connections is always maintained by the connection pooling service for the connection pool, except when Fast Connection Failover removes invalid connections is

exceeded. In this case, the connection number could drop below the Min Pool Size. ODP.NET would then attempt to restore the minimum pool size level upon the next connection request.

At any given time, these connections are in use by the application or are available in the pool.

The Incr Pool Size attribute of the `ConnectionString` property defines the number of new connections to be created by the connection pooling service when more connections are needed in the connection pool.

When the application closes a connection, the connection pooling service determines whether or not the connection lifetime has exceeded the value of the `Connection Lifetime` attribute. If so, the connection pooling service destroys the connection; otherwise, the connection goes back to the connection pool. The connection pooling service enforces the `Connection Lifetime` only when `Close()` or `Dispose()` is invoked.

The Max Pool Size attribute of the `ConnectionString` property sets the maximum number of connections for a connection pool. If a new connection is requested, but no connections are available and the limit for Max Pool Size has been reached, then the connection pooling service waits for the time defined by the `Connection Timeout` attribute. If the `Connection Timeout` time has been reached, and there are still no connections available in the pool, the connection pooling service raises an exception indicating that the connection pool request has timed-out. Upon a connection timeout, ODP.NET distinguishes whether the timeout occurred due to the database server failing to deliver a connection in the allotted time or no connection being available in the pool due to the maximum pool size having been reached. The exception text returned will either be "Connection request timed out" in the case of the former or "Pooled connection request timed out" in the case of the latter.

The `Validate Connection` attribute validates connections coming out of the pool. This attribute should be used only when absolutely necessary, because it causes a round-trip to the database to validate each connection immediately before it is provided to the application. If invalid connections are uncommon, developers can create their own exception/error handler to retrieve and validate a new connection, rather than using the `Validate Connection` attribute. This generally provides better performance.

The connection pooling service closes connections when they are not used; connections are closed every 3 minutes. The `Decr Pool Size` attribute of the `ConnectionString` property provides connection pooling service for the maximum number of connections that can be closed every 3 minutes.

Enabling connection pooling by setting "pooling=true" in the connection string (which is the case by default) will also pool operating system authenticated connections.

## Connection Pool Management

ODP.NET connection pool management provides explicit connection pool control to ODP.NET applications. Applications can explicitly clear connections in a connection pool.

Using connection pool management, applications can do the following:

### Note

- Clear connections from connection pools using the `ClearPool` method.
- Clear connections in all the connection pools in an application domain, using the `ClearAllPools` method.

### ① See Also

- ["ClearPool"](#)
- ["ClearAllPools"](#)

## Connection Performance Counters

Installing Oracle Data Provider for .NET creates a set of performance counters on the target system. All ODP.NET provider types (Core, managed, and unmanaged) publish these performance counters for each of their client applications. These performance counters can be viewed using Windows Performance Monitor (Perfmon) or the `PerformanceCounter` class in the `System.Diagnostics` namespace version 4.5.0 or higher.

### ① Note

ODP.NET performance counters are available on Windows platforms only.

As ODP.NET performance counters are not enabled nor registered after installation, administrators must register the counters, then enable the specific counters of interest before being able to monitor them.

## Registering Performance Counters

After installation, ODP.NET performance counters must be registered so that tools, such as Perfmon, can consume them. Registration requires running a PowerShell script for the respective provider.

ODP.NET installs six scripts for counters that must be run from PowerShell to take effect

- `register_odpc_perfmon_counters.ps1` – Registers ODP.NET Core counters
- `register_odpm_perfmon_counters.ps1` – Registers managed ODP.NET counters
- `register_odpu_perfmon_counters.ps1` – Registers unmanaged ODP.NET counters
- `unregister_odpc_perfmon_counters.ps1` – Unregisters ODP.NET Core counters
- `unregister_odpm_perfmon_counters.ps1` – Unregisters managed ODP.NET counters
- `unregister_odpu_perfmon_counters.ps1` – Unregisters unmanaged ODP.NET counters

These scripts are located in the `ORACLE_HOME\odp.net\PerfCounters` directory for Oracle Universal Installer and NuGet deployments, in the `<INSTALLATION_DIRECTORY>\odp.net\PerfCounters` directory for xcopy deployments, and `<VISUAL_STUDIO_SOLUTION_DIRECTORY>\packages\Oracle.ManagedDataAccess.<VERSION>\PerfCounters` directory for MSI deployments.

Windows Administrator privileges are required when running these PowerShell scripts.

To unregister, run the unregister PowerShell script that matches the ODP.NET provider type you wish to unregister.

Previously, the `OraProvCfg.exe` utility was included with ODP.NET for registering and unregistering counters. These PowerShell scripts replace the utility. If you registered ODP.NET counters with this utility, then unregister with the same `OraProvCfg.exe` version.

## Enabling Performance Counters

ODP.NET enables monitoring many different connection counters, including pooled and non-pooled connections. These counters can be monitored individually or together. Developers can set which counters to monitor prior to application startup using the `PerformanceCounters` setting in the `<settings>` section of the .NET config file, which is available in managed and unmanaged ODP.NET, or Windows Registry, which is available in unmanaged ODP.NET only. For ODP.NET Core, developers can set the `OracleConfiguration.PerformanceCounters` property.

[Table 3-7](#) lists the connection performance counters with their setting values.

**Table 3-7 Performance Counters for Connection Pooling**

| Performance Counter             | Valid Values | Description                                                                  |
|---------------------------------|--------------|------------------------------------------------------------------------------|
| None                            | 0            | Not enabled (Default)                                                        |
| HardConnectsPerSecond           | 1            | Number of sessions being established with the Oracle Database every second.  |
| HardDisconnectsPerSecond        | 2            | Number of sessions being severed from the Oracle Database every second.      |
| SoftConnectsPerSecond           | 4            | Number of active connections originating from connection pools every second. |
| SoftDisconnectsPerSecond        | 8            | Number of active connections going back to the connection pool every second. |
| NumberOfActiveConnectionPools   | 16           | Total number of active connection pools.                                     |
| NumberOfInactiveConnectionPools | 32           | Number of inactive connection pools.                                         |
| NumberOfActiveConnections       | 64           | Total number of connections in use.                                          |
| NumberOfFreeConnections         | 128          | Total number of connections available for use in all the connection pools.   |
| NumberOfPooledConnections       | 256          | Total number of pooled active and free connections.                          |
| NumberOfNonPooledConnections    | 512          | Number of non-pooled active connections.                                     |
| NumberOfReclaimedConnections    | 1024         | Number of connections which were garbage-collected implicitly.               |
| NumberOfStasisConnections       | 2048         | No operation. This counter is no longer supported.                           |

These settings are bitwise ORed in order to monitor more than one counter. For example, to collect counters for SoftConnectsPerSecond (4), Soft DisconnectsPerSecond (8), and NumberOfActiveConnectionPools (16), set PerformanceCounters to 28 (i.e. 4 + 8 + 12).

## Setting Performance Counters in .NET Configuration Files

Performance counters can be set using an .NET configuration file, such as web.config or app.config, in managed and unmanaged ODP.NET only. Since .NET configuration entries take precedence over Windows Registry settings, they can be used for a specific application.

As earlier described, populating the PerformanceCounters setting in the <settings> section enables individual performance counters to be monitored. Windows Perfmon uses very long and not easily human readable application instance names. To make identifying each application easier administrators can assign an identifier name in the <connectionPools> section of the .NET configuration file. This section supports the following settings:

- **connectionString:** This setting identifies the connections or pool to monitor using the connection string as the unique identifier. The connection string entered here must match the target connection string to be monitored, but without the password attribute.
- **poolName (optional):** Connection strings can be very long and hard to read with many that look similar. poolName allows using an arbitrary string to easily identify which pool is being monitored.

The following examples show how to use these settings.

### ODP.NET, Managed Driver

```
<oracle.manageddataaccess.client>
  <version number="*">
    <connectionPools>
      .
      .
      <connectionPool connectionString="[connection string without password]"
poolName="[Pool Name]"> </connectionPool>
      .
    </connectionPools>
  </version>
</oracle.manageddataaccess.client>
```

ODP.NET, Unmanaged Driver can use the same pool name setting and format as listed above by replacing the <oracle.manageddataaccess.client> tags with <oracle.unmanageddataaccess.client> tags. Alternatively, the legacy <oracle.dataaccess.client> format is available for unmanaged ODP.NET.

### ODP.NET, Unmanaged Driver

```
<configuration>
  <oracle.dataaccess.client>
    <settings>
      .
      .
      <add name="[connection string without password]" value="connectionPool name='[Pool
Name]'" />
      .
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

## Setting Performance Counters in Windows Registry

Publication of individual unmanaged ODP.NET performance counters is enabled or disabled using the Windows Registry value `PerformanceCounters` of type `REG_SZ`. This registry value is under:

`HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ODP.NET\Assembly_Version`

where *Assembly\_Version* is the full assembly version number of `Oracle.DataAccess.dll`.

Similarly to the .NET config file, multiple performance counters can be obtained by adding the valid values. For example, if `PerformanceCounters` is set to 3, then both `HardConnectsPerSecond` and `HardDisconnectsPerSecond` are enabled.

## Publishing Performance Counters

Commonly, ODP.NET performance counters are monitored using Perfmon. The counters are published under the following Category Names:

- ODP.NET, Core Driver
- ODP.NET, Managed Driver
- ODP.NET, Unmanaged Driver

Administrators can choose the individual ODP.NET counters to monitor after selecting one or more of these categories. PerfMon shows all ODP.NET counters, but only the explicitly enabled counters generate statistics.

After choosing the counters to monitor, administrators then select the running instance(s) to monitor. ODP.NET instances must be actively running for them to appear in PerfMon. Otherwise, no instances will appear available to monitor. After instance selection occurs, they are added to PerfMon as counters to monitor.

Performance counters can monitor at the application domain, pool, or database instance level. Database instance level monitoring only applies if load balancing or Fast Connection Failover features are enabled.

The instance name format is as follows:

`<Application Domain Name> [<Process Id>, <Application Domain Id>][<Connection String/Pool Name>][<Instance Name>]`. The entry is limited to 127 characters. There is a restriction length on every field in the instance name. The following table shows the maximum number of characters allocated for each field:

**Table 3-8 Field Names of Performance Counters and Maximum Number of Characters**

| Field Name                  | Maximum Number of Characters |
|-----------------------------|------------------------------|
| Application Domain          | 40                           |
| Pool Name/Connection String | 70                           |
| Database Instance Name      | 16                           |

When the length of a field value exceeds the length limit, the string is truncated and appended with ". . ." to fit within the length limit and indicate the continuation. For example, for a given application called `Program.exe` with a connection string user `id=hr;Password=<password>;data source=inst1;max pool size=125;min pool size=50,`

one may see the following similar to the following for a process that has two application domains:

- Program.exe [123, 1]
- Program.exe [123, 1][ user id=hr;data source=inst1;max pool siz...]
- Program.exe [123, 1][ user id=hr;data source=inst1;max pool siz...] [instA]
- Domain 2[123, 2]
- Domain 2[123, 2][ user id=hr;data source=inst1;max pool siz...]
- Domain 2[123, 2][ user id=hr;data source=inst1;max pool siz...] [instB]
- Domain 2[123, 2][ user id=hr;data source=inst1;max pool siz...] [instC]

Since connection pool attributes can be similar in their first 70 characters, applications can set a Pool Name to uniquely identify each one in the monitoring tool. For example, when using Pool Name, the process will show up as follows:

Domain 2[123, 2][Pool Name][instC]

## Database Resident Connection Pooling and Connection Manager in Traffic Director Mode

Client side connection pooling can be very efficient for middle tier machines. However, it can consume a great deal of database server resources if there are numerous middle tier servers with idle connections. While the intent is to keep the number of idle connections to a minimum, it becomes difficult as the number of middle tier servers increase, each possibly having idle connections that cannot be shared across applications.

Database Resident Connection Pooling (DRCP) is intended to optimize resource usage by pooling connections at the database server level, which can then be shared across many applications. The benefit is better scalability and lower resource usage at the database server level.

Oracle's database proxy solution, Connection Manager in Traffic Director Mode (CMAN-TDM) has its own pooling feature, Proxy Resident Connection Pooling (PRCP). PRCP works similarly to DRCP. If an application works well with DRCP, it will work just as well with PRCP. The only change necessary on the application side is the TNS alias or Easy Connect string should point to the PRCP server instead of the database/DRCP server.

ODP.NET supports DRCP and PRCP, which allows dispensing and releasing these connections to better utilize database server resources.

### About DRCP

DRCP pools server processes, each of which is the equivalent to a dedicated server process and database session combined. These are called pooled servers. Pooled servers can be shared by multiple applications running on the same or multiple hosts.

When DRCP is configured for Oracle Database Real Application Clusters (Oracle RAC), the pool configuration is applied to each database instance. Starting or stopping the pool on one instance starts or stops the pool on all instances.

### DRCP and ODP.NET

DRCP is a server side pool that complements ODP.NET client side pooling. These two pools can be used together.

In a typical dedicated server mode, client side connection pooling saves both on server round trips and socket/session creation. In a connection open/close sequence, a server round trip is involved only upon the first `Open()`. For subsequent open/close sequences on the same connection, no client to server interaction is required because the connection is pooled locally in the client address space.

With DRCP enabled, when the client creates a connection, the connection is assigned a pooled server when needed. When the connection is closed, the database server releases the DRCP server session back to the server side pool, effectively making the DRCP server session available for reuse. This server session can be reused by the same pool or a different pool on the same or different middle tier hosts.

### Configuring DRCP and ODP.NET

The following section describe how DRCP can be configured on the client side and the server side.

- Configuring DRCP on the Client Side

ODP.NET developers can enable DRCP on the client side by using `(SERVER=POOLED)` in the connect descriptor.

Sample Descriptor:

```
(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=myhost)(PORT=1521))
(CONNECT_DATA=(SERVICE_NAME=sales.example.com)(SERVER=POOLED)))
```

- Configuring DRCP on the Server Side

Oracle database includes a default connection pool called `SYS_DEFAULT_CONNECTION_POOL`. By default, this pool is created, but not started. To enable database resident connection pooling, you must explicitly start the connection pool.

You must be a database administrator (DBA) and must log on as SYSDBA to start and end a pool.

```
SQL> EXECUTE DBMS_CONNECTION_POOL.START_POOL();
```

For DRCP connections to be shared across multiple client-side ODP.NET connection pools, then set the `OracleConnection.DRCPConnectionClass` property to a string value before opening the ODP.NET connection. ODP.NET will first try to obtain an idle connection with the same DRCP connection class property value. If it does not find one, then it will create a new connection instead.

### Example 3-1 Using Database Resident Connection Pooling: Sample Code

```
// This application uses the following connect descriptor:
// oracle = (DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=<hostname>)(PORT=1521))
// (CONNECT_DATA=(SERVICE_NAME=<service name>)(SERVER=POOLED)))
```

```
using System;
using Oracle.ManagedDataAccess.Client;
```

```
class DRCP
{
    static void Main()
    {
        string constr = "user id=hr;password=hr;data source=oracle";
```

```
        OracleConnection con = new OracleConnection(constr);  
        con.DRCPConnectionClass = "GroupA";  
        con.Open();  
  
        con.Dispose();  
    }  
}
```

#### ① Note

To use DRCP with ODP.NET, Unmanaged Driver,:

- the .NET configuration setting, CPVersion, must be set to 2.0, or,
- have CPVersion not set at all, but have (SERVER=POOLED) in the TNS full descriptor that is used by the application.

Refer to [settings section](#) for more information.

#### ① See Also

*Oracle Database Administrator's Guide* for more information on configuring the default connection pool or end pool.

### DRCP for Oracle Multitenant

In Oracle Database 21c and higher, each PDB can have its own separate DRCP.

In Oracle Database 19c and earlier, a DRCP can only be created on the CDB level and then be shared among all its PDBs. Thus, ODP.NET would have one DRCP for the entire CDB that would be configured and managed (start, stop, or reconfigure) only by connecting to the root container.

To configure, set a session to point to the CDB and start the DRCP pool. For example:

```
alter session set container = cdb$root;  
execute dbms_connection_pool.configure_pool('SYS_DEFAULT_CONNECTION_POOL');  
execute dbms_connection_pool.start_pool();
```

### DRCP for Oracle Real Application Clusters (RAC)

In an Oracle Real Application Clusters (RAC) environment, when a user creates a DRCP on an instance, that DRCP is replicated on all the instances of an Oracle RAC database and you can use any instance to manage the connection pool. Any changes you make to the pool configuration are applicable on all Oracle RAC instances.

### DRCP Restrictions for ODP.NET

ODP.NET does not support the following features with DRCP:

- Open the proxy connection with end user authentication
- Open the sysoper connection

- Open using `OpenWithNewPassword`
- Set the `SQLNET.AUTHENTICATION_SERVICES` parameter value to `nts`, which enables Microsoft Windows native operating system authentication
- .NET Framework versions earlier than .NET Framework 4

## Oracle Multitenant and Pluggable Databases

Oracle Database 12c introduced Oracle Multitenant, which enables an Oracle database to contain a portable collection of schemas, schema objects, and nonschema objects that appears to ODP.NET as a separate database. This self-contained collection is called a pluggable database (PDB).

Oracle Multitenant is a database architecture that enables customers to easily consolidate multiple pluggable databases without changing their application. This architecture delivers all the benefits of managing many databases as one, yet retains the isolation and resource prioritization of separate databases. In addition, Oracle Multitenant enables rapid provisioning and upgrades, and fully complements other Oracle database options.

Managed and unmanaged ODP.NET fully support Oracle Multitenant. In addition to being able to connect to individual pluggable databases, ODP.NET has been enhanced so that applications can request and obtain connections to specific PDBs from the same connection pool. The application can connect to any of the PDBs that are part of the same container database (CDB) and they must have the same common user. Moreover, if connections span multiple instances, such as with Oracle Real Application Clusters, then every instance must uniformly have the same exact PDBs and services for the common user to connect to. If these conditions are met, then ODP.NET will be able to connect to or implicitly switch connections from one PDB to another within the same pool in a highly performant manner.

To obtain a connection to a specific PDB (as a common user) set the `OracleConnections` properties, `PDBName` and `ServiceName`, and then call `OracleConnection.Open()` to obtain the a connection to the specified PDB and Service name. `PDBName` and `ServiceName` identify the PDB and service that the connection needs to be established to or switched to if using an existing idle connection from the connection pool. They are the pluggable database name and database service name, respectively. If only the `PDBName` property is set and the service name is not set by the user, then the provider will return a connection that uses the default (administrative) service.

### Note

For ODP.NET, Unmanaged Driver to be able to switch PDB connections within the same pool:

- the .NET configuration setting, `CPVersion`, must be set to 2.0, or,
- have `CPVersion` not set at all, but set `PDBName` and/or `ServiceName` to a non-null/non-empty value for the first connection request for a given connection string.

Refer to [settings section](#) for more information.

### Example 3-2 Using Pluggable Database: Sample Code

```
// C#
using System;
using Oracle.ManagedDataAccess.Client;
```

```
class PDB
{
    static void Main()
    {
        string constr = "user id=hr;password=hr;data source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.PDBName = "pdb1";
        con.ServiceName = "db1.company.com";
        con.Open();
        con.Close();
    }
}
```

ODP.NET keeps track of the PDBName and ServiceName to which the pooled connections are established to. Upon the application requesting for a connection with a specified PDBName and ServiceName, ODP.NET will return a connections that matches that request. However, if a matching connection is not found, ODP.NET will create a new connection and/or alter the session to switch to the requested PDBName and ServiceName. If the PDBName and/or ServiceName has been altered, then the SwitchedConnection property will return true if called with the Open() method invocation.

ODP.NET does not support usage of the ALTER SESSION statement to modify the container database during the lifetime of a process. If using PDBs with Oracle Continuous Query Notification, you must connect to Oracle Database 12c Release 2 or higher. Hosting connections to multiple PDBs from the same pool requires ODP.NET for .NET Framework 4 or higher.

#### ① Note

When the connection is implicitly being switched from one PDB/Service to another, Service Relocation Connection Timeout(SRCT) will not take effect.

#### ① See Also

Managing Pluggable Databases in *Oracle Database Administrator's Guide*

## Edition-Based Redefinition

Edition-based redefinition enables you to upgrade the database component of an application even while the application is being used. This minimizes or eliminates downtime for the application.

ODP.NET does not support usage of the ALTER SESSION statement to modify the Edition during the lifetime of a process.

Managed and unmanaged ODP.NET can connect to a database edition, and also have the ability to host connections to multiple Editions from within the same pool. An ODP.NET application can obtain a connection that is associated with a specified database edition by setting the OracleConnection.DatabaseEditionName property to the name of the database edition that the connection should be associated with. To use a single pool, the same user must be able to connect to both Editions. Applications will perform better and more efficiently

when using Editions because ODP.NET can use the same connection pool and even share the same `OracleConnection` object by only changing Edition-specific properties.

### Example 3-3 Using Edition-Based Redefinition: Sample Code

```
using System;
using Oracle.ManagedDataAccess.Client;

class Editions
{
    static void Main()
    {
        // Create a connection
        string constr = "user id=hr;password=hr;data source=oracle";
        OracleConnection con = new OracleConnection(constr);

        // Obtain a connection associated with EditionX
        con.DatabaseEditionName = "EditionX";
        con.Open();

        // Obtain a connection associated with EditionY
        con.Close();
        con.DatabaseEditionName = "EditionY";
        con.Open();
        con.Dispose();
    }
}
```

Changing the edition name through `DatabaseEditionName` while the connection is open is not allowed. It must be changed while the connection is in a closed state.

ODP.NET supports Editions when connecting to Oracle Database 11g Release 2 or later. Hosting multiple Editions in the same pool is available only in ODP.NET for .NET Framework 4 and above.

#### Note

To use this Edition-Based Redefinition feature with unmanaged ODP.NET connection pools:

- the .NET configuration setting, `CPVersion`, must be set to 2.0, or,
- have `CPVersion` not set at all, but set the `DatabaseEditionName` property to a non-null/non-empty value for the first connection request for a given connection string.

Refer to [settings section](#) for more information.

Applications can specify an Edition at deployment time using the registry or configuration file. An application can create the following registry entry of type `REG_SZ`:

`HKLM\Software\Oracle\ODP.NET\version\Edition`

Here *version* is the version of ODP.NET, and *Edition* is a valid Edition string value.

An application can alternatively use the `web.config` or `application.config` configuration file to specify the Edition at deployment time. The `machine.config` configuration file can be used to specify the Edition for all applications that use a particular version of the .NET framework.

The following example sets the Edition to E1 in a .NET configuration file for ODP.NET, Unmanaged Driver:

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="Edition" value="E1"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

To summarize, the Edition name can be set by the `DatabaseEditionName` property, in the .NET configuration file, or in the Windows Registry. If `DatabaseEditionName` is set, then it takes precedence over the other two settings. If the .NET configuration file has an Edition set, then it takes precedence over the registry.

For more information on Editions refer to the *Oracle AI Database Administrator's Guide* and *Oracle AI Database Development Guide*

## Privileged Connections

Oracle allows database administrators to connect to Oracle Database with various privileges, such as SYSDBA, SYSASM, and SYSOPER. This is done through the DBA Privilege attribute of the `ConnectionString` property.

The following example connects `scott/tiger` as SYSDBA:

```
// C#

using System;
using Oracle.DataAccess.Client;

class PrivilegedConnectionSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        //Connect scott/tiger as SYSDBA
        con.ConnectionString = "User Id=scott;Password=tiger;" +
            "DBA Privilege=SYSDBA;Data Source=oracle;";
        con.Open();
        Console.WriteLine("Connected to Oracle" + con.ServerVersion);

        // Close and Dispose OracleConnection object
        con.Close();
        con.Dispose();
        Console.WriteLine("Disconnected");
    }
}
```

**① See Also**

DBA Privilege "[Table 6-51](#)" for further information on privileged connections in the database

## Connection Pooling with OracleCredential

To better secure passwords, all ODP.NET applications can use `OracleCredential` to store user names and passwords outside of the connection string. `OracleCredential` mitigates the possibility of exposing user credentials in a page file swap or in a crash dump.

`OracleCredential` can be used with or without connection pooling.

When using the `OracleCredential` object, one should be aware of the connection pool algorithm that has been modified to take this new feature into consideration, when opening connection to the Oracle database. With earlier implementations of ODP.NET connection pool algorithm, the uniqueness of connection string attribute values were used to decide if a new connection pool needs to be created or an existing connection pool can be used to dispense connections. But with the introduction of `OracleCredential`, the reference of this object is also used to decide which connection pool that `OracleConnection` object is associated with.

The decision to create a new connection pool now depends on two factors, first is the uniqueness of connection string (as in earlier releases) and the second is the reference comparison of the `OracleCredential` provided to the `OracleConnection` object while opening a new connection. If either of these is different, a separate pool is used. In order to keep re-using the same connection pool and not create additional connection pools while using the `OracleCredential` object, simply create one `OracleCredential` object per database user and re-use the same object when opening connections.

Here is an example to clarify the new algorithm:

```
using System;
using System.Security;
using Oracle.ManagedDataAccess.Client;
//using Oracle.DataAccess.Client;

class Test
{
    static void Main()
    {
        string connStr1 = "user id=hr; password=hr; data source=oracle";
        string connStr2 = "data source=oracle";

        SecureString secPwd = new SecureString();
        secPwd.AppendChar('h');
        secPwd.AppendChar('r');
        secPwd.MakeReadOnly();

        OracleCredential oc1 = new OracleCredential("hr", secPwd);
        OracleCredential oc2 = new OracleCredential("hr", secPwd);
        OracleCredential oc3 = new OracleCredential("hr", secPwd);

        // con1 and con2 are associated with the same connection pool since both are using
        the same
        // connection string and OracleCredential remains null in both cases.
        OracleConnection con1 = new OracleConnection(connStr1);
```

```
OracleConnection con2 = new OracleConnection(connStr1, null);

// con3 and con4 use the same connection string but different OracleCredential
objects
// (although same contents) so they are associated with different connection pools.
OracleConnection con3 = new OracleConnection(connStr2, oc1);
OracleConnection con4 = new OracleConnection(connStr2, oc2);

// con5 and con6 use the same connection string and same OracleCredential object
// so they are associated with the same connection pool.
OracleConnection con5 = new OracleConnection(connStr2, oc3);
OracleConnection con6 = new OracleConnection(connStr2, oc3);

// Open the connections
con1.Open();
con2.Open();
con3.Open();
con4.Open();
con5.Open();
con6.Open();

// Please note that con1 and con2 use the same connection pool.
// In addition, con3 and con4 use different connection pools
// And lastly con5 and con6 use the same connection pool.
// Thus, in the end, there will be 4 different connection pools created in total.
}
}
```

**Note**

OracleCredential does not support double quotes around a SecureString password. Double quotes can be used within a password, however.

[OracleCredential Class](#)

## Securing Passwords with OracleOpaqueString

Passwords can be stored as a .NET SecureString. However, the data type has weaknesses in keeping the text confidential. OracleOpaqueString better obfuscates string data without SecureString's limitations.

Oracle recommends using OracleOpaqueString for more robust security instead of SecureString.

Existing ODP.NET APIs that contain a SecureString parameter have a matching overloaded API that uses OracleOpaqueString as well. ODP.NET developers have the flexibility to use either SecureString or the more secure OracleOpaqueString.

Apps populate an empty OracleOpaqueString instance one character at a time. To use the data type, apps then make it read-only and immutable. This immutable state is permanent. Once the OracleOpaqueString is read-only, it can be used by ODP.NET to create a connection. This behavior matches that of SecureString.

One programmatic difference between `SecureString` and `OracleOpaqueString` is usage with the `OracleCredential` class. In order to set the Password or Proxy Password using an `OracleOpaqueString`, use one of the existing constructors with passwords set as null. Then, set the passwords using `SetPassword()` and `SetProxyPassword()` methods.

If an app wants to set or update a proxy user and password in an `OracleCredential`, it can only be done using `OracleOpaqueString` and the `SetPassword()` and `SetProxyPassword()` methods.

A benefit of the `SetPassword` and `SetProxyPassword` methods are that they can update an existing `OracleCredential` instance's passwords anytime the credentials change. This is only possible when using `OracleOpaqueString` and `OracleCredential`.

The following code sample shows how to use an `OracleOpaqueString` password with ODP.NET user credentials:

```
//Create OracleOpaqueString and populate it with the password
OracleOpaqueString opaquePassword = new OracleOpaqueString();
foreach (char c in "<PASSWORD>")
    opaquePassword.AppendChar(c);
opaquePassword.MakeReadOnly();

//Create OracleCredential and set the instance's values
OracleCredential cred = new OracleCredential("HR, null, OracleDBAPrivilege.NONE);
cred.SetPassword(opaquePassword);

//Create the connection, populate the connection string with the OracleCredential
values, and open
OracleConnection conn = new OracleConnection("data source=<DATA SOURCE>");
conn.Credential = cred;
conn.Open();
```

## Password Expiration

Oracle allows users passwords to expire. ODP.NET lets applications handle the password expiration by providing a new method, `OpenWithNewPassword`, that opens the connection with a new password.

The following example uses the `OracleConnection` `OpenWithNewPassword` method to connect with a new password of panther:

```
/* Database Setup
connect / as sysdba;
drop user testexpire cascade;
-- create user "testexpire" with password "testexpire"
grant connect , resource to testexpire identified by testexpire;
alter user testexpire password expire;
*/
```

```
// C#

using System;
using Oracle.DataAccess.Client;

class PasswordExpirationSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        try
        {
            con.ConnectionString =
                "User Id=testexpire;Password=testexpire;Data Source=oracle";
            con.Open();
            Console.WriteLine("Connected to Oracle" + con.ServerVersion);
        }
        catch (OracleException ex)
        {
            Console.WriteLine(ex.Message);

            //check the error number
            //ORA-28001 : the password has expired
            if (ex.Number == 28001)
            {
                Console.WriteLine("\nChanging password to panther");
                con.OpenWithNewPassword("panther");
                Console.WriteLine("Connected with new password.");
            }
        }
        finally
        {
            // Close and Dispose OracleConnection object
            con.Close();
            con.Dispose();
            Console.WriteLine("Disconnected");
        }
    }
}
```

#### Note

- The `OpenWithNewPassword` method should be used only when the user password has expired, not for changing the password.
- If connection pooling is enabled, then invoking the `OpenWithNewPassword` method also clears the connection pool. This closes all idle connections created with the old password.

#### See Also

["OpenWithNewPassword\(String\)"](#)

## Proxy Authentication

With proper setup in the database, proxy authentication enables middle-tier applications to control the security by preserving database user identities and privileges, and auditing actions taken on behalf of these users. This is accomplished by creating and using a proxy database user that connects and authenticates against the database on behalf of a database user (that is, the *real* user) or database users.

Proxy authentication can then be used to provide better scalability with connection pooling. When connection pooling is used in conjunction with proxy authentication, the proxy authenticated connections can be shared among different real users. This is because only the connection and session established for the proxy is cached. An additional session is created for the real user when a proxy authenticated connection is requested, but it will be destroyed appropriately when the proxy authenticated connection is placed back into the pool. This design enables the application to scale well without sacrificing security.

ODP.NET applications can use proxy authentication by setting the "Proxy User Id" and "Proxy Password" attributes in the connection string. The real user is specified by the "User Id" attribute. Optionally, to enforce greater security, the real user's password can be provided through the "Password" connection string attribute. When using distributed transactions in conjunction with proxy authentication, the real user's password is no longer optional, and it must be supplied.

The following example illustrates the use of ODP.NET proxy authentication:

```
/* Log on as DBA (SYS or SYSTEM) that has CREATE USER privilege.
   Create a proxy user and modified scott to allow proxy connection.

   create user appserver identified by eagle;
   grant connect, resource to appserver;
   alter user scott grant connect through appserver;
*/

// C#

using System;
using Oracle.DataAccess.Client;

class ProxyAuthenticationSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        // Connecting using proxy authentication
        con.ConnectionString = "User Id=scott;Password=tiger;" +
            "Data Source=oracle;Proxy User Id=appserver;Proxy Password=eagle; ";
        con.Open();
        Console.WriteLine("Connected to Oracle" + con.ServerVersion);

        // Close and Dispose OracleConnection object
        con.Close();
        con.Dispose();
        Console.WriteLine("Disconnected");
    }
}
```

ODP.NET proxy authentication can also use the connection string syntax: User Id=<PROXY USER ID>[<REAL USER ID>];Password=<PROXY PASSWORD> in managed ODP.NET and

ODP.NET Core. For example, if we use the same credentials as the above proxy user code sample, `User Id=appserver[scott];Password=eagle`. This format applies to single session proxy connections. This format does not support two session proxy connections. ODP.NET supports this format when stored in SEPS wallets as well.

## Dynamic Distributed Transaction Enlistment

For those applications that dynamically enlist in distributed transactions through the `EnlistDistributedTransaction` of the `OracleConnection` object, the "Enlist" connection string attribute must be set to a value of "true". If "Enlist=true", the connection enlists in a transaction when the `Open` method is called on the `OracleConnection` object, if it is within the context of a COM+ transaction or a `System.Transactions`. If not, the `OracleConnection` object does not enlist in a distributed transaction, but it can later enlist explicitly using the `EnlistDistributedTransaction` or the `EnlistTransaction` method. If "Enlist" is equal to "false" or "dynamic", the connection cannot enlist in the transaction. ODP.NET, Unmanaged Driver in ODAC 12c Release 3 first introduced this new behavior for "Enlist=dynamic".

#### 📘 See Also

- ["Connection String Attributes and URLs"](#)
- ["EnlistDistributedTransaction"](#)

## Client Identifier and End-to-End Tracing

The client identifier is a predefined attribute from the Oracle application context namespace `USERENV`. It is similar to proxy authentication because it can enable tracking of user identities. However, client identifier does not require the creation of two sessions (one for the proxy user and another for the end user) as proxy authentication does. In addition, the client identifier does not have to be a database user. It can be set to any string. But most importantly, by using client identifier, ODP.NET developers can use application context and Oracle Label Security, and configure Oracle Virtual Private Database (VPD) more easily. To set the client identifier, ODP.NET applications can set the `ClientId` property on the `OracleConnection` object after opening a connection. If connection pooling is enabled in unmanaged ODP.NET, then the `ClientId` is reset to null whenever a connection is placed back into the pool. In managed ODP.NET, the `ClientId` is reset to null (assuming no new value is provided) upon the first database round trip after a connection is placed back into the pool.

The client identifier can also be used for end-to-end application tracing. End-to-end tracing simplifies the process of diagnosing performance problems in multitier environments. In multitier environments, a request from an end client is routed to different database sessions by the middle tier making it difficult to track a client across different database sessions. End-to-

end tracing uses the client identifier to uniquely trace a specific end-client through all tiers to the database server.

ODP.NET exposes the `ActionName`, `ClientId`, `ClientInfo`, and `ModuleName` write-only properties on the `OracleConnection` object. These properties correspond to the following end-to-end tracing attributes:

- `ActionName` - Specifies an action, such as an INSERT or UPDATE operation, in a module
- `ClientId` - Specifies an end user based on the logon ID, such as HR.HR
- `ClientInfo` - Specifies user session information
- `ModuleName` - Specifies a functional block, such as Accounts Receivable or General Ledger, of an application

## Automatic Connection Recovery

ODP.NET can detect invalid connections that occur through planned or unplanned outages, such as database failovers and network failures, at the start of a request boundary. When an invalid session is detected, ODP.NET fails over by creating a new session to any remaining database instance. The end user experiences no error since the invalid connection is not dispensed.

Automatic Connection Recovery (ACR) is enabled automatically starting in ODP.NET 23.8. It is available in all ODP.NET provider types (core, managed, and unmanaged) and requires no code nor configuration changes on the client nor database server side to use.

ACR is a different high availability feature than Application Continuity (AC), Fast Connection Failover (FCF), and Transparent Application Failover (TAF). ACR's primary goal is ensuring new requests receive valid connections. It does not recover a connection's session and transaction state and return it to the same end user after a failover as AC and TAF do.

ACR has the most functional similarity to FCF among the three. But unlike FCF, ACR checks the connection's session state, one by one, as each is dispensed. FCF sends connection and database status messages in real-time and removes invalid connections altogether once the failure message is received. FCF is a more responsive and faster approach.

ACR has the benefit that it requires no setup to use and is always on.

## Reset Session State to Limit Application State Leaks

The `RESET_STATE` database service attribute partially clears ODP.NET session state when set to the value `LEVEL1`. It executes at the end of a request before processing the next request to limit session state leaks from one session to the next. The `RESET_STATE` service attribute is

recommended for all stateless applications to prevent the leakage of a session state to later reuses.

No ODP.NET code changes are required to use this feature. All ODP.NET provider types support this feature.

RESET\_STATE does not reset all session state attributes.

**Note**

About Application Continuity to learn more about RESET\_STATE and the session state attributes it resets.

## Real Application Clusters and Global Data Services

This section discusses optimizations for the following products:

- Oracle Real Application Clusters (Oracle RAC) is a cluster database with a shared cache architecture that overcomes the limitations of traditional shared-nothing and shared-disk approaches to provide highly scalable and available database solutions for business applications.
- Oracle Data Guard provides one or more standby databases to protect Oracle data from failures, disasters, human error, and data corruptions for high availability in mission critical applications.
- Oracle GoldenGate replicates data among heterogeneous data environments. It enables high availability solutions, real-time data integration, transactional change data capture, data replication, transformations, and verification between operational and analytical enterprise systems.
- Global Data Services (GDS), new in Oracle Database 12c, provides database workload management features across replicated databases, such as Data Guard and GoldenGate.

ODP.NET supports Oracle Real Application Clusters (Oracle RAC), Data Guard, and GoldenGate transparently, meaning you do not need to change ODP.NET code to use these Oracle components. To further take advantage of these technologies, ODP.NET offers connection pooling optimization features for achieving better application high availability and performance. You can do this through configuring ODP.NET to receive, respond, and send database status messages to .NET applications.

These optimization configurations include the use of features such as Fast Application Notification (FAN), Runtime Connection Load Balancing, and Fast Connection Failover (FCF).

These connection pooling optimizations can improve high availability and performance for Oracle Real Application Clusters and Global Data Services products:

- [Fast Application Notification](#)
- [In-Band Fast Application Notification](#)
- [Runtime Connection Load Balancing](#)
- [Fast Connection Failover \(FCF\)](#)

**① See Also**

- *Oracle Real Application Clusters Administration and Deployment Guide.*
- *Oracle Data Guard Concepts and Administration.*

## Fast Application Notification

Fast Application Notification (FAN) is a high availability and load balancing notification mechanism that Oracle RAC, Data Guard, and GoldenGate use to notify ODP.NET applications about cluster configuration and service-level information, including status changes such as UP or DOWN events and server load. FAN UP and DOWN events can apply to instances, services, and nodes. Based on information received, ODP.NET can adjust its connection pool accordingly to improve application availability and performance.

With out-of-band FAN, Oracle RAC, Data Guard, and GoldenGate, use Oracle Notification Service (ONS) as its messaging infrastructure to send notifications to ODP.NET applications.

[Table 3-9](#) describes when each messaging system is used and the ODP.NET-related client configuration.

**Table 3-9 Configurations for ODP.NET Driver Types**

| ODP.NET Driver Type | FAN Infrastructure | Configuration       | Manual ONS Configuration Locations                                                                                                    |
|---------------------|--------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Core and managed    | ONS                | Automatic or Manual | Either of these two files: <ul style="list-style-type: none"><li>• .NET configuration file</li><li>• ONS configuration file</li></ul> |
| unmanaged           | ONS                | Automatic or Manual | oraaccess.xml file                                                                                                                    |

For automatic ONS configuration, developers can add more nodes and ports for ODP.NET to listen to, in addition to the nodes and ports that ODP.NET obtains from the database automatically.

In earlier Oracle database versions, Oracle Database Advanced Queueing (AQ) provided the messaging infrastructure prior to ONS. ODP.NET applications do not require code changes to migrate from the AQ to ONS FAN infrastructure. However, some ODP.NET client configuration changes may be necessary when migrating to ONS, a newer database server version, or from ODP.NET, Unmanaged Driver to the managed driver, as documented above.

On the database server side, FAN must be set up and configured for out-of-band messages.

Using out-of-band FAN from the database, ODP.NET can do the following:

- With Runtime Connection Load Balancing, ODP.NET load balances connections among Oracle RAC nodes, services, and service members and GDS resources. This feature improves ODP.NET response time and ensures better resource allocation of server resources.
- With the Fast Connection Failover (FCF) feature, Oracle RAC, Data Guard, and GoldenGate can inform the ODP.NET connection pool if database nodes, services, service members, or the databases have gone down. These DOWN messages indicate which connections in the pool are invalid and must be removed.

## In-Band Fast Application Notification

Oracle recommends using out of band notifications when possible as they support more high availability event types than in band and can be more reliable. In some scenarios, such as cloud deployments and when firewalls block notification messages between the database and client, out of band messages and using ONS may not be possible. ODP.NET can use in-band FAN notifications instead in these scenarios. In-band FAN notifications support the following usage scenarios:

- Pluggable database relocation
- Database service relocation
- Database rolling upgrade
- Connection Manager planned maintenance

In-band notifications rely on existing ODP.NET connections to communicate messages and for connection pooling to be enabled. ODP.NET will check for notifications every time a connection makes a database round trip, is checked in, or checked out. When a DOWN notification is received, ODP.NET will scan the pool for affected connections and close them. Applications should not see any errors as long as connections are returned to the pool prior to the drain timeout.

To use in-band notifications, no database server nor ODP.NET configuration changes are required. They are enabled automatically in ODP.NET Core and managed 19.9 and unmanaged ODP.NET 19.10 or higher versions. On the server side, in-band notifications are automatically enabled in Oracle Database 18c or higher versions.

As an HA best practice, out of band notifications should be enabled along with the default in-band notifications when possible.

## Runtime Connection Load Balancing

With Runtime Connection Load Balancing, Oracle Data Provider for .NET balances work requests across Oracle RAC instances based on the load balancing advisory and service goal. Because workloads can constantly change, load balancing occurs when the application requests a new connection. Thus, ODP.NET optimizes service levels by connecting users to the least loaded nodes in real-time.

In Oracle Database 12c, Runtime Connection Load Balancing has been extended to Oracle Data Guard and Oracle GoldenGate so that ODP.NET 12c connections can be load balanced with these two database services as part of Global Data Services. No ODP.NET applications require code changes to use Global Data Services if they are already using Runtime Connection Load Balancing.

When Runtime Connection Load Balancing is enabled:

- The ODP.NET connection pool dispenses connections based on the load balancing advisory and service goal.
- The ODP.NET connection pool also balances the number of connections to each service member providing the service, based on the load balancing advisory and service goal.

By default, ODP.NET is enabled to receive Runtime Connection Load Balancing FAN messages from the server. The feature has been enabled via the "Load\_Balancing=true" and "pooling=true" settings in the connection string, which are the default values. This feature can only be used if "pooling=true". In order to use Runtime Connection Load Balancing, specific Oracle server configurations must be set.

The following connection string example enables Runtime Connection Load Balancing:

```
"user_id=scott;password=tiger;data_source=erp;load_balancing=true;"
```

## Fast Connection Failover (FCF)

When an Oracle RAC service, service member, node, or a Data Guard database fails, the severed ODP.NET connection objects may continue to exist in the application. If users attempt to use these invalid connections, they will encounter errors. FCF enables ODP.NET to free these severed connections proactively and quickly. Users then will be able to use the application after a server side failure without manual intervention from an administrator.

In Oracle Database 12c, FCF has been extended to Oracle Data Guard and Oracle GoldenGate for ODP.NET 12c connections through Global Data Services. No ODP.NET applications require code changes to use Global Data Services if they already use FCF.

ODP.NET applications can enable FCF through the High Availability Events, "HA Events", connection string attribute. When HA Events are enabled:

- ODP.NET connection pool proactively removes connections from the pool when a Global Data Service or Oracle RAC service, service member, node, or database goes down.

- ODP.NET proactively forces threads waiting for responses from the downed database to exit out from the existing call to avoid any hangs. When such a connection is then returned to the pool, any resource associated with that connection is freed.
- ODP.NET establishes connections to existing Oracle instances if the removal of severed connections brings the total number of connections below the "min pool size", upon the next connection request.

By default, ODP.NET is enabled to receive FCF FAN messages from the server. This feature have been enabled via the HA Events=true and pooling=true settings in the connection string, which are the default values.

The following connection string example enables HA Events:

```
"user id=scott;password=tiger;data source=erp;HA events=true;"
```

## Using FCF Planned Outage to Minimize Service Disruption

FCF not only provides high availability services for unplanned outages, such as node failures, but also for planned outages, such as server repairs, upgrades, and changes, to minimize service disruption to ODP.NET application users.

When a database service is set to be stopped or relocated, a FAN message is published with a planned reason code. A FCF-aware ODP.NET connection pool (HA Events=true) receives the notification and commences to close idle connections, no longer allowing new connections to that specific database service. Active connections to that specific database service remain until users complete their tasks and the connection is returned to the pool. Thus, no users must stop work mid-stream due to a planned outage.

Eventually, all users complete their tasks and no connections remain to that database service. The database administrator can then stop the service for the planned outage task. This feature allows the database service to be stopped as quickly as possible without end user disruption.

Oracle planned outage support works with Oracle Real Application Clusters (Oracle RAC), Oracle Data Guard, and some single instance scenarios.

### Oracle RAC Planned Outage

A typical planned outage scenario for Oracle RAC follows below. Note that the database server commands apply to Oracle RAC 12c Release 2 or higher. Commands for earlier releases may be different.

1. There is a need to upgrade, patch, or repair a software or hardware issue on a database server. Stop the instance gracefully such that existing users experience no to few errors. You can wait until all users complete their work before doing so. Business requirements will dictate whether you wait for all users to log out or begin the planned outage after a set time. An administrator could issue the following command line operation using Oracle Server Control Utility (srvctl):

```
srvctl relocate service -database <unique database name> -service <service name> -
drain_timeout 120 -stopoption IMMEDIATE -oldinst <existing instance>
```

This command relocates the database service from the existing instance to any instance it is configured to run on. Oracle Cluster Ready Services (CRS) will choose this instance, as the command line specifies no target. CRS will wait 120 seconds (-drain\_timeout 120) for any active sessions to drain, after which any sessions remaining on the existing instance will be forcibly disconnected (-stopoption IMMEDIATE). If Application Continuity is used in conjunction with planned outage, an attempt is made to recover these killed sessions, masking the outage from end users.

The relocate operation starts the service in the new location prior to stopping the service in its existing location. Immediate relocation allows draining with no brownout. If the service cannot be started, it is not stopped at the original location to maintain availability.

2. Meanwhile in the connection pool, the FAN planned DOWN event clears idle sessions for the instance being shutdown from the ODP.NET connection pool immediately and marks that instance's active sessions to be released at the next check-in. These FAN actions drain the sessions from this instance without disrupting the users.  
  
Existing connections on other instances remain usable, and new connections can be opened to these other instances.
3. Not all sessions will check their connections into the pool immediately. The timeout period specified by -drain\_timeout after which the instance is forcibly shut down, evicting any remaining client connections. Administrators can check whether any active sessions to the instance remain by querying the v\$session table.
4. Once the upgrade, patch, or repair is complete, restart the instance and the service on the original node. The FAN UP event will inform the ODP.NET pool that it can now use the original machine again.

### Oracle Data Guard Planned Outage

Oracle Data Guard performs switchovers from primary databases to standby databases in planned failover scenarios. During the switchover, administrators will want to limit end user disruptions. In Oracle Database 12c Release 2 and higher, these administrators can use the Data Guard command-line interface (DGMGRL) command to switch roles between primary and standby databases:

```
SWITCHOVER TO <database name> [WAIT <timeout in seconds> ];
```

The WAIT option specifies to wait for sessions to drain before proceeding with the switchover.

Similar to the Oracle RAC scenario, FAN informs the ODP.NET to remove idle connections from the pool. Connections subsequently checked in are destroyed until no active connections remain to that primary database, which will allow the switchover to begin.

When switchover to the standby completes, a FAN UP event informs ODP.NET that it can start creating connections to the standby instance.

During the Data Guard service relocation process, new incoming connection requests will not be accepted until the service has fully relocated. Incoming connection requests arriving during

the interim, such as in the middle of an Oracle Data Guard switchover, will receive connectivity errors.

To prevent these errors, ODP.NET can pause connection attempts until the new database service is available. ODP.NET blocks any connection attempts until the service is up or until the configured time limit expires from the time when the service DOWN event was received. This feature is useful for planned outages and service relocations. It works with Oracle RAC and Oracle Data Guard.

This time limit is the `ServiceRelocationConnectionTimeout` setting, which can be set in the `.NET` configuration file.

[ServiceRelocationConnectionTimeout](#)

## Pool Behavior in an Oracle RAC Database

When connection pools are created for a single-instance database, pool size attributes are applied to the single service. Similarly, when connection pools are created for an Oracle RAC database, the pool size attributes are applied to a service and not to service members. For example, if "Min Pool Size" is set to  $N$ , then ODP.NET does not create  $N$  connections for each service member. Instead, it creates, at minimum,  $N$  connections for the entire service, where  $N$  connections are distributed among the service members.

The following pool size connection string attributes are applied to a service.

- Min Pool Size
- Max Pool Size
- Incr Pool Size
- Decr Pool Size

ODP.NET connects to the same Oracle RAC node when required by a distributed transaction that has already begun on a particular node, by an Oracle runtime connection load balancing advisory, or by Oracle RAC load balancing gravitation in which connections will gravitate to an under utilized node. If the connection pool has no idle connections to this particular node, then ODP.NET will create a new connection to this node. Node affinity is honored even when the connection pool runs out of idle connections to dispense.

In the case of ODP.NET Core experiencing an unplanned database outage failing over to another database instance, connections may experience `System.PlatformNotSupportedException` errors upon an `Open()` method invocation on the `OracleConnection` object. This exception is a result of attempting to promote a local transaction to a distributed transaction due to multiple database instances having to be involved in the transaction due to the unplanned outage. The `PlatformNotSupportedException` occurs because `.NET (Core)` has limited support for distributed transactions. This behavior does not occur with managed ODP.NET nor unmanaged ODP.NET as `.NET Framework` supports distributed transactions.

## Using Transaction Guard to Prevent Logical Corruption

Transaction Guard allows managed and unmanaged ODP.NET applications to use at-most-once execution in case of planned and unplanned outages and repeated submissions. Without

Transaction Guard, applications that attempt to retry operations following outages can cause logical corruption by committing duplicate transactions.

After an outage, one of the traditional problems for recovering applications had been the non-durable commit message sent back to the client. If there is a break between the client and the server, the client sees an error message indicating that the communication failed, also known as a recoverable error. This error does not inform the application if the submission executed any commit operations, or if a procedural call ran to completion while executing all expected commits. The error also does not indicate session state changes or intermittent failures. The client is left wondering if the transaction committed and if it fully completed.

These recoverable errors may require end users or applications to attempt replay by issuing duplicate transaction submissions or other forms of logical corruption. The transaction cannot be validly resubmitted if the non-transactional state is incorrect or if it is committed. Continuing to process a committed but not completed call can result in the application using a database session that is in the wrong state.

## ODP.NET and Transaction Guard

Transaction Guard allows ODP.NET, Managed Driver and ODP.NET, Unmanaged Driver to eliminate duplicate transactions automatically and transparently, and in a manner that scales.

When a failure occurs, such as a node, network, or database failure, ODP.NET applications can deterministically conclude whether the transaction committed by querying its status, if the database service is up. Oracle retains the transaction status automatically, even after one of these failures.

In ODAC 12c Release 4, using Transaction Guard application development has been streamlined, reducing the application logic needed to determine the transaction outcome. Moreover, these benefits are available to both managed and unmanaged ODP.NET.

When a recoverable error is raised by a Transaction Guard enabled database service upon a database commit or upon a SQL or PL/SQL execution, which could have called a commit, then an ODP.NET `OracleException` is created with an `OracleLogicalTransaction` instance. `OracleLogicalTransaction` is always non-null. The database maintains the outcome of the logical transaction for the retention period specified by the administrator. ODP.NET automatically queries the database on behalf of the application when a recoverable error occurs so that the `OracleLogicalTransaction` object instance on the `OracleException` object can indicate whether the transaction has committed or not and whether the user call has completed or not.

If the status is committed, then the transaction has completed successfully. No other action is likely needed by the administrator.

If not committed, then ODP.NET applications can learn the current transaction state, whether it is recoverable, and whether it can be retried using `OracleLogicalTransaction`. If the error is recoverable, then the transaction is safe to re-submit. If the error is not recoverable, the application will need to determine the transaction outcome using an alternative mechanism.

### Note

Transaction Guard supports only local transactions. It does not support distributed transactions.

The Transaction Guard feature is enabled or disabled through the Oracle service-level configuration through the `COMMIT_OUTCOME` setting. By default, it is not enabled. This setting can be changed without bringing down the database. Only new connections created against the service will use the new setting.

Here's an example of setting the `COMMIT_OUTCOME` using `SRVCTL`:

```
srvctl modify service -d orcl -s GOLD -commit_outcome TRUE
```

**Note**

Grant the `EXECUTE` privilege on the `DBMS_APP_CONT` package to the database users that retrieve the transaction status:

```
GRANT EXECUTE ON DBMS_APP_CONT TO <user name> ;
```

The following is an example ODP.NET Transaction Guard application scenario:

An ODP.NET application receives a Fast Application Notification (FAN) down event or error. FAN automatically aborts the dead session and the application receives an `OracleException`. A Transaction Guard application built to handle errors transparently would do the following:

1. `OracleException.OracleLogicalTransaction.LogicalTransactionId` property

The value returned by this property will be non-null if

- Transaction Guard is enabled,
- Transparent Application Failover (TAF) is not enabled on the connection, and
- ODP.NET was not able to determine the outcome of the transaction.

For a given `OracleException` object, if `OracleLogicalTransaction.Committed` and `OracleLogicalTransaction.UserCallCompleted` return all nulls, then the error is either a non-recoverable error, Transaction Guard is not enabled, or TAF is enabled on the connection. In any of these cases, the application should rollback then re-submit the transaction.

The `LogicalTransactionId` property will return null even if Transaction Guard is enabled and a recoverable error happens, if `OracleLogicalTransaction.Committed` is true or false.

2. `OracleException.OracleLogicalTransaction.Committed` property

This property returns true or false, depending on whether the transaction has been committed or not. If it returns null, then

- ODP.NET could not determine the outcome of the transaction,
- Error is not recoverable,
- Transaction Guard was not enabled, or
- TAF is enabled on the connection.

3. `OracleException.OracleLogicalTransaction.UserCallCompleted` property

This property returns true if the user call has completed, else it returns false. This property returns null if

- Transaction Guard was not enabled,
- Error is not recoverable,
- TAF is enabled on the connection, or

- ODP.NET is not able to determine if the user call has completed or not.

See the following table for the implications of what Committed and UserCallCompleted values mean.

**Table 3-10 Implication of Committed and UserCallCompleted Values**

| Committed Value | UserCallCompleted Value | Outcome                                                                                                                                                             |
|-----------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| True            | True                    | The transaction was successful. The result can be returned to the application.                                                                                      |
| False           | False                   | The transaction was not successful. The application can resubmit the transaction again.                                                                             |
| True            | False                   | The transaction committed, but there may be additional state, such as row counts or nested PL/SQL logic, that prevents the application from continuing as expected. |

**Example 3-4 Using Transaction Guard: Sample Code**

```
using System;
using Oracle.DataAccess.Client;
//alternatively can use using Oracle.ManagedDataAccess.Client;

class TransactionGuardSample
{
    static void Main()
    {
        bool bReadyToCommit = false;

        string constr = "user id=hr;password=hr;data source=oracle";
        OracleConnection con = new OracleConnection(constr);
        OracleTransaction txn = null;
        OracleCommand cmd = null;

        try
        {
            string sql = " update employees set salary=10000 where
employee_id=103";
            con.Open();
            txn = con.BeginTransaction();
            cmd = new OracleCommand(con, sql);
            cmd.ExecuteNonQuery();
            bReadyToCommit = true;
        }
        catch (Exception ex)
        {
            // rollback here as the SQL execution is unsuccessful
            txn.Rollback();
            Console.WriteLine(ex.ToString());
        }
    }
}
```

```
try
{
    if (bReadyToCommit)
        txn.Commit();
}
catch (Exception ex)
{
    if (ex is OracleException)
    {
        // It's safe to re-submit the work if the error is
recoverable and the transaction has not been committed
        if (ex.IsRecoverable && ex.OracleLogicalTransaction.Committed
== false)
        {
            // safe to re-submit work
        }
        else
        {
            // do not re-submit work
        }
    }
}
finally
{
    // dispose all objects
    txn.Dispose();
    cmd.Dispose();
    con.Dispose(); // place the connection back to the connection pool
}
}
```

Transaction Guard is not supported when Transparent Application Failover (TAF) is enabled for the service. As such, when TAF is enabled, the `LogicalTransactionId` will always be null and the transaction outcome will not be determined.

#### ① See Also

- ["OracleLogicalTransaction Class"](#)
- *Oracle Database Development Guide* for more information on Transaction Guard

## Application Continuity

Oracle Application Continuity enables database requests to automatically replay transactional or non-transactional operations in a non-disruptive and rapid manner in the event of a severed database session, which results in a recoverable error. Application Continuity improves end-user experience by masking planned and unplanned related errors. Applications can be developed without complex logic to handle exceptions, while automatically replaying database operations upon a recoverable error.

Without Application Continuity, it is almost impossible to mask outages in a safe and reliable manner. Common issues encountered include:

- The client state remains at present time, with entered data, returned data, and variables cached, while the database state changes are lost.
- If a transaction commit has occurred, the commit message is not durable. Moreover, checking a lost request does not guarantee that it will not commit after being checked.
- Non-transactional database session state is lost.
- If the request can continue, the database and the client session must be synchronized.

Application Continuity is a feature available with the Oracle Real Application Clusters (RAC), Oracle RAC One Node, Oracle Active Data Guard, and Oracle Autonomous Database in both Shared and Dedicated Infrastructure.

In Oracle Database 18c, Application Continuity improves transparent session and transactional state tracking and recording of the database session to enable recovery following recoverable outages. This enhancement is called Transparent Application Continuity (TAC). TAC has no reliance on application knowledge or application code changes, allowing it to be enabled for your applications. ODP.NET application transparency and failover are achieved by consuming the state-tracking information that captures and categorizes the session state usage as the application issues user calls.

## ODP.NET and Application Continuity

All ODP.NET provider types, core, managed, and unmanaged, support Application Continuity and Transparent Application Continuity.

### Note

Asynchronous ODP.NET does not support Application Continuity and Transparent Application Continuity.

With Application Continuity or TAC enabled, ODP.NET ensures all the application's executed statements are logged appropriately so that they can be replayed upon a recoverable error. This applies for all application SQL and PL/SQL, as well as any internal ODP.NET operations.

On the client side, Application Continuity or TAC is enabled by setting the ODP.NET connection string attribute, `Application Continuity=true`. The attribute is set to true by default.

If Application Continuity is set to true, but the database server does not enable Application Continuity or TAC, then ODP.NET will still create new connections. However, these connections will not be Application Continuity enabled.

Both Application Continuity and TAC can be used with ODP.NET connection pool by implicitly `BeginRequest/EndRequest` calls, as well as without ODP.NET connection pool, by explicitly calling `BeginRequest/EndRequest` calls.

- *Oracle Database High Availability Overview and Best Practices* for more information about High Availability Overview and Best Practices - Configuring Level 3: Mask Unplanned and Planned Failovers from Applications.

## Application Continuity Work Requests

AC and TAC operate on request boundaries. A request is an application unit of work. Typically, it exists between when an application borrows and returns a database connection from the connection pool. All ODP.NET providers use this model by default to demarcate work request boundaries.

ODP.NET Core and managed ODP.NET include an additional capability for developers to explicitly identify request boundaries themselves using the `OracleConnection.BeginRequest` and `EndRequest` methods. Preferably, applications will not need to use these methods and just rely on the default behavior. When a connection is checked out, ODP.NET implicitly calls `BeginRequest`. And when the connection is checked in, ODP.NET implicitly calls `EndRequest`. This model scales well and makes AC and TAC easier for developer use.

Applications that do not use ODP.NET connection pools should explicitly mark request boundaries, such as the case with custom connection pools. The `BeginRequest` method should be called upon connection check out and the `EndRequest` method should be called upon connection check in.

With an understanding of the request demarcation points, ODP.NET knows when it is safe to release the database call history. Proper request boundary identification conserves memory consumption for long living connections, such as when they exist in a custom pool.

These methods have no application impact other than improving resource consumption, recovery, and load balancing performance. They do not alter connection state by calling any method, SQL, nor PL/SQL.

If a begin or end request is made while a local transaction is open, ODP.NET returns an error.

# Transparent Application Failover

Oracle Transparent Application Failover (TAF) is a client-side high availability feature. It enables a client to automatically reconnect to a secondary database instance if the connected primary instance fails or shuts down.

No new failover code is required to use TAF. As the name implies, the feature is transparent, meaning ODP.NET and Oracle database will manage the instance failure detection and connection re-establishment process if TAF is enabled and configured.

ODP.NET Core, managed, and unmanaged provider types all support TAF. ODP.NET Core and managed started support with ODP.NET 23.3.3. There are differences in the TAF features each provider type supports.

TAF can be configured in the database or client side. On the client side, TAF settings can be made in the Oracle connect descriptor or through ODP.NET APIs.

TAF automatically restores some or all the elements associated with active database connections. If other elements require recovery, they should be added in the application code, such as within an ODP.NET TAF callback. Here are more details about ODP.NET TAF recovery features:

- Database connections

TAF automatically reestablishes the ODP.NET connection using the same connection string or an alternate connection string specified for failover.

- User database sessions

TAF automatically logs a user in with the same login credentials as originally used. If multiple users use the same connection, then TAF automatically logs them in as they attempt to process database commands. Unfortunately, TAF cannot automatically restore other session properties, but those properties can be restored by invoking a callback function.

- Completed commands

If a command completed at the time of connection failure and changed the database state, then TAF does not resend the command upon reconnection. If TAF reconnects and another command may have changed the database, then TAF issues an error message to the application. This TAF feature is available from unmanaged ODP.NET, but not managed nor core drivers.

- Open cursors for results fetching

TAF allows applications that began fetching rows from a cursor before failover to continue fetching rows after recovery. This is called select failover. It re-runs a SELECT statement using the same snapshot, discarding those rows already fetched and retrieving those rows that were not fetched initially. TAF verifies that the discarded rows are those that were returned initially, or it returns an error message. This TAF feature is available from unmanaged ODP.NET, but not managed nor core drivers.

- Active transactions

Any active transactions are rolled back at the time of failure. TAF cannot preserve active transactions after failover. The application instead receives an error message until a ROLLBACK command is submitted.

- Server-side program variables

Server-side program variables, such as PL/SQL package states, are lost during failures. TAF cannot recover them. They can be re-initialized by making a call from the failover callback.

TAF can be configured on the client side through the `FAILOVER_MODE` attribute in the TNS connect descriptor.

**Table 3-11 ODP.NET TAF Failover Mode Support**

| TAF Failover Mode | ODP.NET Core Support | Managed ODP.NET Support | Unmanaged ODP.NET Support | Description                             |
|-------------------|----------------------|-------------------------|---------------------------|-----------------------------------------|
| Session Failover  | Y                    | Y                       | Y                         | Recreates lost connections and sessions |
| Select Failover   | N                    | N                       | Y                         | Replays in-progress queries             |

**Table 3-12 ODP.NET TAF Failover Method Support**

| TAF Failover Method | ODP.NET Core Support | Managed ODP.NET Support | Unmanaged ODP.NET Support | Description                                                                                                                                                          |
|---------------------|----------------------|-------------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Basic               | Y                    | Y                       | Y                         | Establishes connections at failover time. This option requires almost no work on the backup database server until failover.                                          |
| Preconnect          | N                    | N                       | Y                         | Pre-establishes connections on backup instance. This provides faster failover but requires the backup instance to support all connections from the primary instance. |

**Note**

Managed ODP.NET and ODP.NET Core do not support BACKUP and TRANSACTION TAF parameters. BACKUP specifies the failover node. TRANSACTION allows the database to complete the current transaction following a recoverable error.

## TAF Notification

Given the delays that failovers can cause, applications may wish to be notified by a TAF callback. ODP.NET supports the TAF callback function through the Failover event of the OracleConnection object, which allows applications to be notified whenever a failover occurs. To receive TAF callbacks, an event handler function must be registered with the Failover event.

## When Failover Occurs

When a failover occurs, the Failover event is raised and the registered event handler is invoked several times during the course of reestablishing the connection to another Oracle instance.

The first call to the event handler occurs when Oracle Database first detects an instance connection loss. This allows the application to act accordingly for the upcoming delay for the failover.

If the failover is successful, the Failover event is raised again when the connection is reestablished and usable. At this time, the application can resynchronize the OracleGlobalization session setting and inform the application user that a failover has occurred. No significant database operation should occur immediately after a FailoverEvent.Begin event. SQL and major database operations should wait until the

`FailoverEvent.End` event. `FailoverEvent.Begin` is primarily used to reject failover or to trace it. `FailoverEvent.Begin` can also be used for non-database application operations, such as informing the end user a failover is in progress and to wait until it completes before proceeding. Transactions can be used in the `FailoverEvent.End` callback phase, such as to file fault tickets or audit. These transactions must be committed before the callback completes.

If failover is unsuccessful, the Failover event is raised to inform the application that a failover did not take place.

The application can determine whether or not the failover is successful by checking the `OracleFailoverEventArgs` object that is passed to the event handler.

## Registering an Event Handler for Failover

The following example registers an event handler method called `OnFailover`:

```
// C#

using System;
using Oracle.DataAccess.Client;

class TAFCallbackSample
{
    public static FailoverReturnCode OnFailover(object sender,
                                                OracleFailoverEventArgs eventArgs)
    {
        switch (eventArgs.FailoverEvent)
        {
            case FailoverEvent.Begin :
                Console.WriteLine(
                    " \nFailover Begin - Failing Over ... Please standby \n");
                Console.WriteLine(
                    " Failover type was found to be " + eventArgs.FailoverType);
                break;

            case FailoverEvent.Abort :
                Console.WriteLine(" Failover aborted. Failover will not take place.\n");
                break;

            case FailoverEvent.End :
                Console.WriteLine(" Failover ended ...resuming services\n");
                break;

            case FailoverEvent.Reauth :
                Console.WriteLine(" Failed over user. Resuming services\n");
                break;

            case FailoverEvent.Error :
                Console.WriteLine(" Failover error gotten. Sleeping...\n");
                return FailoverReturnCode.Retry;

            default :
                Console.WriteLine("Bad Failover Event: %d.\n", eventArgs.FailoverEvent);
                break;
        }
        return FailoverReturnCode.Success;
    } /* OnFailover */

    static void Main()
    {
        OracleConnection con = new OracleConnection();
```

```
con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle;";
con.Open();
con.Failover += new OracleFailoverEventHandler(OnFailover);
Console.WriteLine("Event Handler is successfully registered");

// Close and Dispose OracleConnection object
con.Close();
con.Dispose();
}
}
```

The Failover event invokes only one event handler. If multiple Failover event handlers are registered with the Failover event, only the event handler registered last is invoked.

#### ① Note

Distributed transactions are not supported in an environment where failover is enabled.

## Oracle Globally Distributed Database

Oracle Globally Distributed Database is a data tier architecture, where data is horizontally partitioned across independent databases. Each database in such a configuration is called a shard. All shards together make up a single logical database, which is referred to as a sharded database. Oracle Globally Distributed Database is a shared-nothing database architecture. The independent physical databases do not share CPU, memory, or storage devices. However, from the perspective of an application, the collection of physical databases looks like a single logical database.

Oracle Globally Distributed Database uses Global Data Services (GDS), where GDS routes a client request to an appropriate database based on parameters such as availability, load, network latency, and replication lag. A GDS pool is a set of replicated databases that offers the same global service. The databases in a GDS pool can be located in multiple data centers across different regions. A sharded GDS pool contains all shards of a sharded database and their replicas, and appears as a single sharded database to database clients.

Applications can connect to multiple databases (shards) where data is partitioned based on one or more sharding strategies. The strategy can be hash based, range based, or list based. Each time a database operation is required, the application needs to determine which shard it must connect to.

A sharding key provides the partitioning key that determines in which shard a row of data is stored. A table can be partitioned using a sharding key.

A super sharding key is a collection of shard chunks, where only those chunks, which have a specific value of the super shard key identifier, are stored. A super sharding key is used for distributing data across database groups. Specifying super sharding keys are a way through which user-controlled data partitioning is possible.

## ODP.NET Sharding

Starting from version 12.2, unmanaged ODP.NET and Oracle Database both support sharding. Managed ODP.NET and ODP.NET Core started supporting sharding with version 21. All three providers support the same sharding features with the exception that unmanaged ODP.NET does not support the chunk migration connection timeout property.

Starting with ODP.NET 26ai, Raft replication and Oracle Data Guard are supported to improve failover reliability and performance. Existing apps can use both these features without any ODP.NET code changes necessary.

ODP.NET applications must provide the sharding key and super sharding key information before opening the database connection for single shard queries. These sharding values cannot be set or changed after opening the connection. If any of the shard key values need to be modified, a new connection must be created with the new values and then opened.

If shard keys are set after the connection has been opened, the ODP.NET connection will not use these new shard key values until after the next `OracleConnection.Open()` call.

The `OracleShardingKey` object stores one or more key values. Multiple keys can be set to create a composite key. ODP.NET recognizes the sharding key(s) specified and connects to the correct shard and chunk.

Sharding is supported with or without connection pooling. The ODP.NET connection pool maintains connections to different shards and chunks of the sharded GDS database within the same shared pool.

The shard key (`SHARD_KEY`) and super sharding key (`GROUP_KEY`) can be specified in the TNS connect descriptor, rather than in the application code. The .NET developer then chooses the connect descriptor applicable to the shard that the application will use.

The data distribution across the shards and chunks in the database is transparent to the end user. ODP.NET minimizes the end user impact of chunk resharding within GDS.

To perform cross-shard queries, no ODP.NET shard APIs are used. Instead, applications connect to the GDS catalog service, allowing access to all the sharded databases. The SQL query is specifically constructed to iterate over all the necessary shards. For example, the non-shard database query `select count(*) from employees` is equivalent to the cross-shard query `select sum(c) from (Iterator(select count(*) c from employees(i)))`.

### ODP.NET Single Shard Query Example

```
using System;
using Oracle.DataAccess.Client;

class Sharding
{
    static void Main()
    {
        OracleConnection con = new OracleConnection("user id=hr;password=hr;Data
Source=orcl;");
        //Setting a shard key
        OracleShardingKey shardingKey = new OracleShardingKey(OracleDbType.Int32, 123);
        //Setting a second shard key value for a composite key
        shardingKey.SetShardingKey(OracleDbType.Varchar2, "gold");
    }
}
```

```

//Creating and setting the super shard key
OracleShardingKey superShardingKey = new OracleShardingKey();
superShardingKey.SetShardingKey(OracleDbType.Int32, 1000);

//Setting super sharding key and sharding key on the connection
con.SetShardingKey(shardingKey, superShardingKey);
con.Open();

//perform SQL query
}
}

```

By default, ODP.NET only dispenses connections to shards with chunks with read and write privileges available. If some chunks in a shard are read-only, ODP.NET will not dispense a connection to that shard unless `READONLY_CHUNK_OK` is set to `TRUE` in the `CONNECT_DATA` section of the connect descriptor. Connect descriptors are generally stored in `tnsnames.ora` files. Enabling `READONLY_CHUNK_OK` just means that both read/write and read-only connections can be dispensed. It does not specify only read-only connections are dispensed.

Shards are made read-only when chunks are migrating from one shard to another, usually to re-balance data or workload across shards.

Here's an example using `READONLY_CHUNK_OK` in a connect descriptor:

```

SHARDDDB =
(DESCRIPTION =
  (ADDRESS = (PROTOCOL = tcp)(HOST = myhost)(PORT = 1521))
  (CONNECT_DATA =
    (SERVICE_NAME = myservicename)
    (READONLY_CHUNK_OK=true)
  )
)

```

In ODP.NET, super shard keys can use range sharding or list sharding. With composite sharding, the shard keys must use hash sharding. The table below describes operations supported for different shard key types, not super shard keys.

**Table 3-13 Supported Operations for Shard Key Types**

| Chunk Event Type                                             | Hash | Range | List |
|--------------------------------------------------------------|------|-------|------|
| Chunk Read Only<br><i>Not supported in unmanaged ODP.NET</i> | Yes  | Yes   | Yes  |
| Chunk Up                                                     | Yes  | Yes   | Yes  |
| Chunk Down                                                   | Yes  | Yes   | Yes  |
| Chunk Split                                                  | Yes  | Yes   | Yes  |
| Add Chunk                                                    | No   | Yes   | Yes  |
| Add Chunk Values                                             | No   | No    | Yes  |
| Drop Chunk                                                   | No   | Yes   | Yes  |
| Drop Chunk Values                                            | No   | No    | Yes  |
| Merge Chunk                                                  | No   | Yes   | Yes  |
| Invalidate Chunk                                             | No   | Yes   | Yes  |

**Table 3-13 (Cont.) Supported Operations for Shard Key Types**

| Chunk Event Type                                                | Hash | Range | List |
|-----------------------------------------------------------------|------|-------|------|
| Partitionset Split<br><i>Not supported in unmanaged ODP.NET</i> | Yes  | No    | No   |
| New Partitionset<br><i>Not supported in unmanaged ODP.NET</i>   | Yes  | No    | No   |

**Sharding Split Partitionset**

Over time, changing business needs require modifying data organization to optimize resource usage. Multiple super sharding keys grouped in the same shardspace may have been optimal under past conditions. If it becomes necessary to move one or more of the super sharding keys into their own shardspace, such as on a faster machine, then split partitionset operations can facilitate efficient data movement with little down time.

Because each chunk contains data for multiple super sharding keys, a split operation occurs first. Then, the data is moved. The operation is performed one chunk at a time. When the chunk needs to be split, its data will be read-only for a short time. The chunk's sharding key range does not change.

To limit connectivity errors while the chunk is unavailable during a chunk migration or split partitionset, developers can set the `ChunkMigrationConnectionTimeout` property to wait for the set time or whenever the operation completes, whichever comes first. Users then do not receive connection timeout errors while the migration or split occurs if the operation completes in the expected time frame.

A key benefit for developers is they do not have to maintain and track split partitionset activity in their applications. ODP.NET performs this activity for them automatically and routes connections appropriately. It has a shard routing cache to manage the sharding topology and record changes. The ODP.NET connection pool will dispense the appropriate connection for a given sharding key and super sharding key, including after a split partitionset.

ODP.NET split partitionset is supported for hash sharding only with either list or range super shard keys. Oracle Database 23.8 and higher supports sharding split partitionset.

## OracleCommand Object

The `OracleCommand` object represents SQL statements executed on Oracle Database.

**Note**

Optimizer hint syntax in the form `--+ ...` is not supported. ODP.NET supports this syntax: `/*+ ... */`.

This section includes the following topics:

- [Command Auto-Commit](#)
- [Transactions](#)
- [System.Transactions and Promotable Transactions](#)
- [Distributed Transactions](#)
- [Sessionless Transactions](#)
- [Parameter Binding](#)
- [Batch Processing](#)
- [Statement Caching](#)
- [Self-Tuning](#)
- [Data Transmission Performance](#)
- [Securing Identifiers and Literals from SQL Injection Attacks](#)

## Command Auto-Commit

By default, ODP.NET commits each SQL operation immediately upon execution outside of a transaction. Starting with 26ai, managed ODP.NET and ODP.NET Core can disable auto-commit so that SQL statements are executed only after an explicit commit statement.

Unmanaged ODP.NET cannot disable auto-commit without a transaction.

Developers disable auto-commit by setting the `OracleConnection AutoCommit` property to false. ODP.NET can then start transactions implicitly. After the `AutoCommit` property is set, that setting is honored for all subsequent `Open()` calls on that specific `OracleConnection` object until the `AutoCommit` value is modified.

`OracleConnection` includes APIs to manage local transactions, such as the ability to commit, rollback, and create savepoints. It can check if the application is currently within a transaction. It can set the transaction isolation level.

When `AutoCommit` is set while enlisted in an explicit (that is, `BeginTransaction`), local, or distributed (that is, `System.Transactions`) transaction, an error will occur. Calling any `OracleConnection` transaction management API while enlisted in `System.Transactions` will also result in an error.

## Transactions

Oracle Database starts a transaction only in the context of a connection. Once a transaction starts, all the successive command execution on that connection run in the context of that transaction. Transactions can be started only on an `OracleConnection` object, and the read-only `Transaction` property on the `OracleCommand` object is implicitly set by the `OracleConnection` object. Therefore, the application cannot set the `Transaction` property, nor does it need to.

Explicit transactions are required with SQL statements containing "FOR UPDATE" and "RETURNING" clauses. This is not necessary if global transactions are used.

## System.Transactions and Promotable Transactions

ODP.NET supports System.Transactions. A local transaction is created for the first connection opened in the System.Transactions scope to Oracle Database. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. This functionality provides enhanced performance and scalability.

Connections created within a transaction context, such as TransactionScope or ServicedComponent, can be established to different versions of Oracle Database. However, in order to enable the local transaction to be promotable, the following must be true:

- The first connection in the transaction context must be established to an Oracle Database.
- Promoting local transactions requires Oracle Services for Microsoft Transaction Server. If this requirement is not met, then a second connection request in the same transaction context throws an exception.

Transaction promotion will throw an ORA-24797 error when the database transaction is already distributed due to the use of database links.

If applications use System.Transactions, it is required that the enlist connection string attribute is set to either true (default) or dynamic. However, enlist=dynamic cannot be used with TransactionScope because auto-enlistment requires enlist=true.

ODP.NET supports the following System.Transactions programming models for applications using distributed transactions.

- [Implicit Transaction Enlistment Using TransactionScope](#)
- [Explicit Transaction Enlistment Using CommittableTransaction](#).

## Implicit Transaction Enlistment Using TransactionScope

The TransactionScope class provides a mechanism to write transactional applications where the applications do not need to explicitly enlist in transactions. To accomplish this, the application uses the TransactionScope object to define the transactional code. Connections created within this transactional scope will enlist in a local transaction that can be promoted to a distributed transaction.

Note that the application must call the Complete method on the TransactionScope object to commit the changes. Otherwise, the transaction is aborted by default.

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using System.Data;  
using System.Data.Common;  
using System.Transactions;  
  
class psfTxnScope  
{  
    static void Main()  
    {  
        int retVal = 0;  
        string providerName = "Oracle.DataAccess.Client";  
        string constr =
```

```

        @"User Id=scott;Password=tiger;Data Source=oracle;enlist=true";

// Get the provider factory.
DbProviderFactory factory = DbProviderFactories.GetFactory(providerName);

try
{
    // Create a TransactionScope object, (It will start an ambient
    // transaction automatically).
    using (TransactionScope scope = new TransactionScope())
    {
        // Create first connection object.
        using (DbConnection conn1 = factory.CreateConnection())
        {
            // Set connection string and open the connection. this connection
            // will be automatically enlisted in a promotable local transaction.
            conn1.ConnectionString = constr;
            conn1.Open();

            // Create a command to execute the sql statement.
            DbCommand cmd1 = factory.CreateCommand();
            cmd1.Connection = conn1;
            cmd1.CommandText = @"insert into emp (empno, ename, job) values
                                (1234, 'emp1', 'dev1')";

            // Execute the SQL statement to insert one row in DB.
            retVal = cmd1.ExecuteNonQuery();
            Console.WriteLine("Rows to be affected by cmd1: {0}", retVal);

            // Close the connection and dispose the command object.
            conn1.Close();
            conn1.Dispose();
            cmd1.Dispose();
        }

        // The Complete method commits the transaction. If an exception has
        // been thrown or Complete is not called then the transaction is
        // rolled back.
        scope.Complete();
    }
}
catch (Exception ex)
{
    Console.WriteLine(ex.Message);
    Console.WriteLine(ex.StackTrace);
}
}
}

```

## Explicit Transaction Enlistment Using CommittableTransaction

The instantiation of the `CommittableTransaction` object and the `EnlistTransaction` method provides an explicit way to create and enlist in a transaction. Note that the application must call `Commit` or `Rollback` on the `CommittableTransaction` object.

```

// C#

using System;
using Oracle.DataAccess.Client;
using System.Data;
using System.Data.Common;
using System.Transactions;

```

```

class psfEnlistTransaction
{
    static void Main()
    {
        int retVal = 0;
        string providerName = "Oracle.DataAccess.Client";
        string constr =
            @"User Id=scott;Password=tiger;Data Source=oracle;enlist=dynamic";

        // Get the provider factory.
        DbProviderFactory factory = DbProviderFactories.GetFactory(providerName);

        try
        {
            // Create a committable transaction object.
            CommittableTransaction cmtTx = new CommittableTransaction();

            // Open a connection to the DB.
            DbConnection conn1 = factory.CreateConnection();
            conn1.ConnectionString = constr;
            conn1.Open();

            // enlist the connection with the committable transaction.
            conn1.EnlistTransaction(cmtTx);

            // Create a command to execute the sql statement.
            DbCommand cmd1 = factory.CreateCommand();
            cmd1.Connection = conn1;
            cmd1.CommandText = @"insert into emp (empno, ename, job) values
                                (1234, 'emp1', 'dev1')";

            // Execute the SQL statement to insert one row in DB.
            retVal = cmd1.ExecuteNonQuery();
            Console.WriteLine("Rows to be affected by cmd1: {0}", retVal);

            // commit/rollback the transaction.
            cmtTx.Commit(); // commits the txn.
            //cmtTx.Rollback(); // rolls back the txn.

            // close and dispose the connection
            conn1.Close();
            conn1.Dispose();
            cmd1.Dispose();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.Message);
            Console.WriteLine(ex.StackTrace);
        }
    }
}

```

## Distributed Transactions

A distributed transaction includes one or more statements that, individually or as a group, update data on two or more distinct nodes of a distributed database.

ODP.NET Core, Managed, and Unmanaged Drivers integrate with Microsoft Distributed Transaction Coordinator (MSDTC) and Oracle databases. MSDTC coordinates with all the resource managers that are enlisted to the same System.Transactions object, to perform a 2-phase commit or rollback atomically. With that, Oracle distributed transactions can then be committed or rolled back across networks properly.

ODP.NET only supports the read committed isolation level for distributed transactions.

ODP.NET Core 23.9 and higher supports distributed transactions on Windows operating systems only. .NET Core applications require [TransactionManager.ImplicitDistributedTransactions](#) to be set to true to use distributed transactions. Failure to do so will result in an ORA-50130.

## Microsoft Distributed Transaction Coordinator Integration

Managed ODP.NET and ODP.NET Core include a native fully managed implementation that supports integration with MSDTC for distributed transactions enlistments, commits, and rollbacks.

For unmanaged ODP.NET, Oracle Services for Microsoft Transaction (OraMTS) provides MSDTC integration that allows client components to participate in Oracle database distributed transactions. OraMTS act as a proxy for the Oracle database to MSDTC to ensure that Oracle distributed database transactions commit or rollback together with the rest of the distributed transaction.

Unmanaged ODP.NET can use either a managed or unmanaged OraMTS implementation. Oracle recommends using the managed OraMTS for applications requiring high availability from Oracle RAC or Data Guard.

If a failure occurs in a distributed transaction, such as a network failure or server hardware failure, then it can leave an in-process transaction in-doubt. All ODP.NET provider types use the OraMTS recovery service to resolve these in-doubt transactions. This recovery service runs as a Windows service. Administrators must install and configure the OraMTS Windows recovery service to manage recovery scenarios whether they use managed or unmanaged ODP.NET. Only one recovery service is needed per machine.

It is required to install the OraMTS Recovery Service on all the client machines where ODP.NET is running and participating in MSDTC. As a machine may have multiple IP addresses, administrators for managed ODP.NET applications can specify the host machine name or IP address that has the running recovery service in the application's .NET configuration file. ODP.NET, Unmanaged Driver resolves the IP/machine name for the recovery service automatically.

**Table 3-14 ODP.NET Distributed Transaction Support Matrix**

| ODP.NET Type | Minimum Version    | Distributed Transaction Support                                              |
|--------------|--------------------|------------------------------------------------------------------------------|
| Core         | .NET 8             | NET's distributed transaction implementation                                 |
| Managed      | .NET Framework 4.8 | .NET Framework's native managed implementation for distributed transactions. |

**Table 3-14 (Cont.) ODP.NET Distributed Transaction Support Matrix**

| ODP.NET Type | Minimum Version    | Distributed Transaction Support                                                                                                                                                         |
|--------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unmanaged    | .NET Framework 4.8 | OraMTS (default) or managed OraMTS implementation. Oracle recommends using managed OraMTS for unmanaged ODP.NET applications requiring high availability from Oracle RAC or Data Guard. |

## ODP.NET Core and Managed Driver Setup

This section explains the setup and configuration steps required for using distributed transactions with ODP.NET Core and Managed Driver. Follow these steps to configure distributed transactions:

1. Create and setup the OraMTS recovery service or make sure an existing recovery service is running.
2. Set the port number the OraMTS recovery service listens on to resolve in-doubt transactions. The property can be set on `OracleConfiguration`, `OracleDataSourceBuilder`, or .NET configuration file.

## ODP.NET, Unmanaged Driver Setup

**① Note**

ODP.NET, Unmanaged Driver is deprecated in 26ai. See Oracle Database Upgrade Guide for more information.

This section explains the setup and configuration steps required for using distributed transactions with ODP.NET, Unmanaged Driver.

ODP.NET, Unmanaged Driver includes managed OraMTS in its assembly. OraMTS is the default option for ODP.NET, Unmanaged Driver, to ensure implementation continuity during upgrades. However, Oracle recommends the managed OraMTS option when using any high availability FAN operations (HA Events = true) with Oracle Real Application Clusters or Oracle Data Guard. The managed OraMTS option support high availability functionality, while the traditional OraMTS does not.

Applications can set OraMTS (default) or managed OraMTS usage through the `UseOraMTSManaged` parameter in the .NET configuration file.

Install and configure OraMTS, including its recovery service to use traditional OraMTS implementation for ODP.NET, Unmanaged Driver.

To set managed OraMTS up, perform the following steps:

1. Set UseOraMTSManaged to true in the .NET configuration file.
2. Create and setup the OraMTS recovery service or make sure an existing recovery service is running.

## Sessionless Transactions

A transaction that can perform work and span across multiple database sessions is called a sessionless transaction.

Oracle database sessionless transactions enable apps to start a transaction, submit a unit of work, and suspend the transaction in one session. The transaction can then be resumed in a different database session, any session, and continue to perform work before committing or rolling back.

A local transaction must operate within the same session, which is a limitation sessionless transactions do not have. No transaction manager, such as distributed transaction coordinator (DTC), is required for sessionless transactions that span across database sessions. Transaction manager involvement generally requires higher overhead and slows performance to perform two-phase commit and might result in in-doubt transaction when network failure occurs.

With sessionless transactions, a transaction manager, like DTC, is not needed. The database internally coordinates the two-phase commit (2PC) protocol without the need for any application-side logic. Therefore, there is no risk of in-doubt transactions and no need for any recovery mechanism.

With sessionless transactions, neither keeping a connection open for long periods of time to support a long running transaction nor a transaction manager is necessary. This flexibility gives transactional apps more possibilities to make design choices that are efficient, easier to manage, and better performing.

Oracle Database release 23.6 introduced support for sessionless transactions on the server side. Managed ODP.NET and ODP.NET Core 23.7 established client side sessionless transaction support.

ODP.NET sessionless transactions do not support promotable nor distributed transactions. They do not support transaction savepoints nor Transparent Application Failover. They also do not support temporary tables as temporary table data is not allowed to span sessions.

Sessionless transaction support with Application Continuity and Transparent Application Continuity will be enabled in a future ODP.NET release.

### Sessionless Transaction Operations

An ODP.NET sessionless transaction can have the following operations:

- **Begin** – Start a sessionless transaction in an ODP.NET session using `OracleConnection.BeginSessionlessTransaction()`.
- **Suspend** – Suspend a sessionless transaction to allow it to be resumed later in a different session.

- Resume – Resume the transaction in a different or the same session. Further DML can occur until the transaction finally commits or aborts.
- Commit – Commit the sessionless transaction and permanently save changes.
- Abort – Roll back the sessionless transaction without saving the transaction changes.

### Sessionless Transaction ODP.NET Code Sample

```
OracleConnection conn1 = new OracleConnection(ConnStr1);
conn1.Open();

//Specify sessionless transaction options.
//Parameter 1 (timeout): Specify transaction timeout, such as 100 seconds
//Parameter 2 (start behavior): Specify the transaction start behavior, such as start
before the command execution
//Parameter 3 (resume behavior): Specify the resume transaction behavior, such as resume
before the command execution
//Parameter 4 (suspend sessionless transaction after execution): Specify whether to
suspend the transaction after command execution, such as true to suspend
conn1.SessionlessTransactionOptions = new OracleSessionlessTransactionOptions(100,
OracleSessionlessTransactionStartBehavior.StartBeforeExecution,
OracleSessionlessTransactionStartBehavior.StartBeforeExecution, true);

//Begin sessionless transaction. The transaction ID can be used to resume in separate
session when the transaction is suspended.
byte[] txnId = conn1.BeginSessionlessTransaction();

//Execute data update in first connection.
//The sessionless transaction is started, the insert is executed under the transaction
context and the sessionless transaction is suspended after the execution.
OracleCommand cmd = new OracleCommand("insert into emp values (23, 'abc')", conn1);
cmd.ExecuteNonQuery();

//Open new connection to same database
OracleConnection conn2 = new OracleConnection(connStr);
conn2.Open();

//Resume the sessionless transaction using the transaction ID
conn2.ResumeSessionlessTransaction(txnId);

//Execute a data update with the new connection in the existing sessionless transaction
OracleCommand cmd2 = new OracleCommand("insert into dept values (2, 'dept1')", conn2);

//The sessionless transaction resumes and the second DML is executed under the same
sessionless transaction context.
cmd2.ExecuteNonQuery();

//Execute another command, the third DML is executed under the same sessionless
transaction context
cmd2.CommandText = "insert into emp values (25, 'def')";
cmd2.ExecuteNonQuery();

//Commit the sessionless transaction. All three DMLs commit.
conn2.Commit();
```

## Parameter Binding

When the `DbType` property of an `OracleParameter` object is set, the `OracleDbType` property of the `OracleParameter` object changes accordingly, or vice versa. The parameter set last prevails. An application can bind the data and have ODP.NET infer both the `DbType` and `OracleDbType` properties from the .NET type of the parameter value. ODP.NET allows applications to obtain an output parameter as either a .NET Framework type or an ODP.NET type. The application can specify which type to return for an output parameter by setting the `DbType` property of the output parameter (.NET type) or the `OracleDbType` property (ODP.NET type) of the `OracleParameter` object. For example, if the output parameter is set as a `DbType.String` type by setting the `DbType` property, the output data is returned as a .NET `String` type. On the other hand, if the parameter is set as an `OracleDbType.Char` type by setting the `OracleDbType` property, the output data is returned as an `OracleString` type. If both `DbType` and `OracleDbType` properties are set before the command execution, the last setting takes affect.

ODP.NET populates `InputOutput`, `Output`, and `ReturnValue` parameters with the Oracle data, through the execution of the following `OracleCommand` methods:

- `ExecuteReader`
- `ExecuteNonQuery`
- `ExecuteScalar`

An application should not bind a value for output parameters; it is the responsibility of ODP.NET to create the value object and populate the `OracleParameter.Value` property with the object.

When binding by position (default) to a function, ODP.NET expects the return value to be bound first, before any other parameters.

This section describes the following:

## Command Timeouts

The `OracleCommand.CommandTimeout` property limits how long a command is allowed to execute before terminating with an exception. This setting prevents long running commands from consuming excessive resources or from blocking other necessary operations from occurring.

The database server can be interrupted via either TCP/IP urgent data or normal TCP/IP data, called out of band (OOB) or in band data, respectively. Windows-based database servers only support in band breaks, whereas all other (predominantly UNIX-based) database servers can support OOB or in band breaks.

ODP.NET, Managed Driver uses OOB breaks by default with database servers that support it. For certain network topologies, the routers or firewalls involved in the route to the database may have been configured to drop urgent data or in band the data. If the routers or firewalls can not be changed to handle urgent data appropriately, then the ODP.NET, Managed Driver can be configured to utilize in band breaks by setting the .NET configuration parameter `Disable_Oob` to on.

## OracleDbType Enumeration Type

`OracleDbType` enumerated values are used to explicitly specify the `OracleDbType` value of an `OracleParameter` object.

[Table 3-15](#) lists all the `OracleDbType` enumeration values with a description of each enumerated value.

**Table 3-15 OracleDbType Enumeration Values**

| Member Name  | Description                                |
|--------------|--------------------------------------------|
| Array        | Oracle Collection (VArray or Nested Table) |
| BFile        | Oracle BFILE type                          |
| BinaryFloat  | Oracle BINARY_FLOAT type                   |
| BinaryDouble | Oracle BINARY_DOUBLE type                  |
| Blob         | Oracle BLOB type                           |
| Boolean      | Oracle BOOLEAN type                        |
| Byte         | byte type                                  |
| Char         | Oracle CHAR type                           |
| Clob         | Oracle CLOB type                           |
| Date         | Oracle DATE type                           |
| Decimal      | Oracle NUMBER type                         |
| Double       | 8-byte FLOAT type                          |
| Int16        | 2-byte INTEGER type                        |
| Int32        | 4-byte INTEGER type                        |
| Int64        | 8-byte INTEGER type                        |
| IntervalDS   | Oracle INTERVAL DAY TO SECOND type         |
| IntervalYM   | Oracle INTERVAL YEAR TO MONTH type         |
| Json         | Oracle JSON type                           |
| Long         | Oracle LONG type                           |
| LongRaw      | Oracle LONG RAW type                       |
| NChar        | Oracle NCHAR type                          |
| Object       | Oracle Object type                         |

**Table 3-15 (Cont.) OracleDbType Enumeration Values**

| Member Name  | Description                                |
|--------------|--------------------------------------------|
| NCLob        | Oracle NCLOB type                          |
| NVarchar2    | Oracle NVARCHAR2 type                      |
| Raw          | Oracle RAW type                            |
| Ref          | Oracle REF type                            |
| RefCursor    | Oracle REF CURSOR type                     |
| Single       | 4-byte FLOAT type                          |
| TimeStamp    | Oracle TIMESTAMP type                      |
| TimeStampLTZ | Oracle TIMESTAMP WITH LOCAL TIME ZONE type |
| TimeStampTZ  | Oracle TIMESTAMP WITH TIME ZONE type       |
| Varchar2     | Oracle VARCHAR2 type                       |
| XmlType      | Oracle XMLType type                        |

**Note**

PL/SQL LONG, LONG RAW, RAW, and VARCHAR data types can be bound with a size up to 32512 bytes.

## Inference of DbType, OracleDbType, and .NET Types

This section explains the inference from the `System.Data.DbType`, `OracleDbType`, and `Value` properties in the `OracleParameter` class.

In the `OracleParameter` class, `DbType`, `OracleDbType`, and `Value` properties are linked. Specifying the value of any of these properties infers the value of one or more of the other properties.

### Inference of DbType from OracleDbType

In the `OracleParameter` class, specifying the value of `OracleDbType` infers the value of `DbType` as shown in [Table 3-16](#).

**Table 3-16 Inference of System.Data.DbType from OracleDbType**

| OracleDbType | System.Data.DbType |
|--------------|--------------------|
| Array        | Object             |
| BFile        | Object             |
| Blob         | Object             |
| BinaryFloat  | Single             |
| BinaryDouble | Double             |
| Boolean      | Boolean            |
| Byte         | Byte               |

**Table 3-16 (Cont.) Inference of System.Data.DbType from OracleDbType**

| OracleDbType | System.Data.DbType |
|--------------|--------------------|
| Char         | StringFixedLength  |
| Clob         | Object             |
| Date         | Date               |
| Decimal      | Decimal            |
| Double       | Double             |
| Int16        | Int16              |
| Int32        | Int32              |
| Int64        | Int64              |
| IntervalDS   | Object             |
| IntervalYM   | Int64              |
| Json         | String             |
| Long         | String             |
| LongRaw      | Binary             |
| NChar        | StringFixedLength  |
| NClob        | Object             |
| NVarchar2    | String             |
| Object       | Object             |
| Raw          | Binary             |
| Ref          | Object             |
| RefCursor    | Object             |
| Single       | Single             |
| TimeStamp    | DateTime           |
| TimeStampLTZ | DateTime           |
| TimeStampTZ  | DateTimeOffset     |
| Varchar2     | String             |
| XmlType      | String             |

## Inference of OracleDbType from DbType

In the `OracleParameter` class, specifying the value of `DbType` infers the value of `OracleDbType` as shown in [Table 3-17](#).

**Table 3-17 Inference of OracleDbType from DbType**

| System.Data.DbType | OracleDbType         |
|--------------------|----------------------|
| Binary             | Raw                  |
| Boolean            | Boolean              |
| Byte               | Byte                 |
| Currency           | <i>Not Supported</i> |

**Table 3-17 (Cont.) Inference of OracleDbType from DbType**

| System.Data.DbType | OracleDbType         |
|--------------------|----------------------|
| Date               | Date                 |
| DateTime           | TimeStamp            |
| DateTimeOffset     | TimeStampTZ          |
| Decimal            | Decimal              |
| Double             | Double               |
| Guid               | Blob                 |
| Int16              | Int16                |
| Int32              | Int32                |
| Int64              | Int64                |
| Object             | Object               |
| Sbyte              | <i>Not Supported</i> |
| Single             | Single               |
| String             | Varchar2             |
| StringFixedLength  | Char                 |
| Time               | TimeStamp            |
| UInt16             | <i>Not Supported</i> |
| UInt32             | <i>Not Supported</i> |
| UInt64             | <i>Not Supported</i> |
| VarNumeric         | <i>Not Supported</i> |

## Inference of DbType and OracleDbType from Value

In the `OracleParameter` class, `Value` is an object type that can be of any .NET Framework data type or ODP.NET type. If the `OracleDbType` and `DbType` properties of the `OracleParameter` class are not specified, the `OracleDbType` property is inferred from the type of the `Value` property.

[Table 3-18](#) shows the inference of `DbType` and `OracleDbType` properties from the `Value` property when the type of `Value` is one of the .NET Framework data types.

**Table 3-18 Inference of DbType and OracleDbType from Value (.NET Datatypes)**

| Value (.NET Datatypes) | System.Data.DbType | OracleDbType |
|------------------------|--------------------|--------------|
| Boolean                | Boolean            | Boolean      |
| Byte                   | Byte               | Byte         |
| Byte[]                 | Binary             | Raw          |
| Char / Char []         | String             | Varchar2     |
| DateTime               | DateTime           | TimeStamp    |
| DateTimeOffset         | DateTimeOffset     | TimeStampTZ  |
| Decimal                | Decimal            | Decimal      |

**Table 3-18 (Cont.) Inference of DbType and OracleDbType from Value (.NET Datatypes)**

| Value (.NET Datatypes) | System.Data.DbType | OracleDbType |
|------------------------|--------------------|--------------|
| Double                 | Double             | Double       |
| Float                  | Single             | Single       |
| Guid                   | Guid               | Blob         |
| Int16                  | Int16              | Int16        |
| Int32                  | Int32              | Int32        |
| Int64                  | Int64              | Int64        |
| IOracleCustomType      | Object             | Object       |
| Single                 | Single             | Single       |
| String                 | String             | Varchar2     |
| TimeSpan               | Object             | IntervalDS   |

**Note**

Using other .NET Framework data types as values for the `OracleParameter` class without specifying either the `DbType` or the `OracleDbType` properties raises an exception because inferring `DbType` and `OracleDbType` properties from other .NET Framework data types is not supported.

[Table 3-19](#) shows the inference of `DbType` and `OracleDbType` properties from the `Value` property when type of `Value` is one of `Oracle.DataAccess.Types`.

**Table 3-19 Inference of DbType and OracleDbType from Value (ODP.NET Types)**

| Value (Oracle.DataAccess.Types) | System.Data.DbType | OracleDbType |
|---------------------------------|--------------------|--------------|
| OracleBFile                     | Object             | BFile        |
| OracleBinary                    | Binary             | Raw          |
| OracleBlob                      | Object             | Blob         |
| OracleBoolean                   | Boolean            | Boolean      |
| OracleClob                      | Object             | Clob         |
| OracleDate                      | Date               | Date         |
| OracleDecimal                   | Decimal            | Decimal      |
| OracleIntervalDS                | Object             | IntervalDS   |
| OracleIntervalYM                | Int64              | IntervalYM   |
| OracleRef                       | Object             | Ref          |
| OracleRefCursor                 | Object             | RefCursor    |
| OracleString                    | String             | Varchar2     |
| OracleTimeStamp                 | DateTime           | TimeStamp    |

| Value (Oracle.DataAccess.Types) | System.Data.DbType | OracleDbType |
|---------------------------------|--------------------|--------------|
| OracleXmlType                   | String             | XmlType      |

## PL/SQL Associative Array Binding

ODP.NET supports PL/SQL Associative Arrays (formerly known as PL/SQL Index-By Tables) binding.

An application can bind an `OracleParameter` object, as a PL/SQL Associative Array, to a PL/SQL stored procedure. The following `OracleParameter` properties are used for this feature:

- **CollectionType**  
This property must be set to `OracleCollectionType.PLSQLAssociativeArray` to bind a PL/SQL Associative Array.
- **ArrayBindSize**  
This property is ignored for the fixed-length element types (such as `Int32`).  
For variable-length element types (such as `Varchar2`), each element in the `ArrayBindSize` property specifies the size of the corresponding element in the `Value` property.  
For Output parameters, InputOutput parameters, and return values, this property must be set for variable-length variables.  
If the database server supports up to 32 KB `VARCHAR2`, then each ODP.NET array element can store up to 32 KB characters or binary data. If the database server supports up to 4 KB `VARCHAR2`, then each ODP.NET array element can store up to 4 KB characters or 2 KB binary data.
- **ArrayBindStatus**  
This property specifies the execution status of each element in the `OracleParameter.Value` property.
- **Size**  
This property specifies the maximum number of elements to be bound in the PL/SQL Associative Array.
- **Value**  
This property must be set to an array of values, null, or the `DBNull.Value` property.

ODP.NET supports binding parameters of PL/SQL Associative Arrays which contain the following data types.

- `BINARY_FLOAT`
- `CHAR`
- `DATE`
- `NCHAR`
- `NUMBER`
- `NVARCHAR2`
- `RAW`

- ROWID
- UROWID
- VARCHAR2

Using unsupported data types with associative arrays can cause an ORA-600 error.

### Example of PL/SQL Associative Arrays

This example binds three OracleParameter objects as PL/SQL Associative Arrays: Param1 as an In parameter, Param2 as an InputOutput parameter, and Param3 as an Output parameter.

PL/SQL Package: MYPACK

```

/* Setup the tables and required PL/SQL:

connect scott/tiger@oracle
CREATE TABLE T1(COL1 number, COL2 varchar2(20));

CREATE or replace PACKAGE MYPACK AS
  TYPE AssocArrayVarchar2_t is table of VARCHAR(20) index by BINARY_INTEGER;
  PROCEDURE TestVarchar2(
    Param1 IN      AssocArrayVarchar2_t,
    Param2 IN OUT AssocArrayVarchar2_t,
    Param3      OUT AssocArrayVarchar2_t);
END MYPACK;
/

CREATE or REPLACE package body MYPACK as
  PROCEDURE TestVarchar2(
    Param1 IN      AssocArrayVarchar2_t,
    Param2 IN OUT AssocArrayVarchar2_t,
    Param3      OUT AssocArrayVarchar2_t)
  IS
    i integer;
  BEGIN
    -- copy a few elements from Param2 to Param1\n
    Param3(1) := Param2(1);
    Param3(2) := NULL;
    Param3(3) := Param2(3);
    -- copy all elements from Param1 to Param2\n
    Param2(1) := Param1(1);
    Param2(2) := Param1(2);
    Param2(3) := Param1(3);
    -- insert some values to db\n
    FOR i IN 1..3 LOOP
      insert into T1 values(i,Param2(i));
    END LOOP;
  END TestVarchar2;
END MYPACK;
/
*/

// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class AssociativeArraySample
{
  static void Main()

```

```
{
    OracleConnection con = new OracleConnection();

    con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle";
    con.Open();
    Console.WriteLine("Connected to Oracle" + con.ServerVersion);

    OracleCommand cmd = new OracleCommand(
        "begin MyPack.TestVarchar2(:1, :2, :3); end;", con);

    OracleParameter Param1 = cmd.Parameters.Add("1", OracleDbType.Varchar2);
    OracleParameter Param2 = cmd.Parameters.Add("2", OracleDbType.Varchar2);
    OracleParameter Param3 = cmd.Parameters.Add("3", OracleDbType.Varchar2);

    Param1.Direction = ParameterDirection.Input;
    Param2.Direction = ParameterDirection.InputOutput;
    Param3.Direction = ParameterDirection.Output;

    // Specify that we are binding PL/SQL Associative Array
    Param1.CollectionType = OracleCollectionType.PLSQLAssociativeArray;
    Param2.CollectionType = OracleCollectionType.PLSQLAssociativeArray;
    Param3.CollectionType = OracleCollectionType.PLSQLAssociativeArray;

    // Setup the values for PL/SQL Associative Array
    Param1.Value = new string[3] {
        "First Element", "Second Element ", "Third Element "
    };
    Param2.Value = new string[3] {
        "First Element", "Second Element ", "Third Element "
    };
    Param3.Value = null;

    // Specify the maximum number of elements in the PL/SQL Associative Array
    Param1.Size = 3;
    Param2.Size = 3;
    Param3.Size = 3;

    // Setup the ArrayBindSize for Param1
    Param1.ArrayBindSize = new int[3] { 13, 14, 13 };

    // Setup the ArrayBindStatus for Param1
    Param1.ArrayBindStatus = new OracleParameterStatus[3] {
        OracleParameterStatus.Success, OracleParameterStatus.Success,
        OracleParameterStatus.Success};

    // Setup the ArrayBindSize for Param2
    Param2.ArrayBindSize = new int[3] { 20, 20, 20 };

    // Setup the ArrayBindSize for Param3
    Param3.ArrayBindSize = new int[3] { 20, 20, 20 };

    // execute the cmd
    cmd.ExecuteNonQuery();

    //print out the parameter's values
    Console.WriteLine("parameter values after executing the PL/SQL block");
    for (int i = 0; i < 3; i++)
        Console.WriteLine("Param2[{0}] = {1} ", i,
            (cmd.Parameters[1].Value as Array).GetValue(i));

    for (int i = 0; i < 3; i++)
        Console.WriteLine("Param3[{0}] = {1} ", i,
```

```

        (cmd.Parameters[2].Value as Array).GetValue(i));

    // Close and Dispose OracleConnection object
    con.Close();
    con.Dispose();
    Console.WriteLine("Disconnected");
}
}

```

## Array Binding

The array bind feature enables applications to bind arrays of a type using the `OracleParameter` class. Using the array bind feature, an application can insert multiple rows into a table in a single database round-trip.

The following example inserts three rows into the `Dept` table with a single database round-trip. The `OracleCommand` `ArrayBindCount` property defines the number of elements of the array to use when executing the statement.

```

// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class ArrayBindSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();
        con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle;";
        con.Open();
        Console.WriteLine("Connected successfully");

        int[] myArrayDeptNo = new int[3] { 10, 20, 30 };
        OracleCommand cmd = new OracleCommand();

        // Set the command text on an OracleCommand object
        cmd.CommandText = "insert into dept(deptno) values (:deptno)";
        cmd.Connection = con;

        // Set the ArrayBindCount to indicate the number of values
        cmd.ArrayBindCount = 3;

        // Create a parameter for the array operations
        OracleParameter prm = new OracleParameter("deptno", OracleDbType.Int32);

        prm.Direction = ParameterDirection.Input;
        prm.Value = myArrayDeptNo;

        // Add the parameter to the parameter collection
        cmd.Parameters.Add(prm);

        // Execute the command
        cmd.ExecuteNonQuery();
        Console.WriteLine("Insert Completed Successfully");

        // Close and Dispose OracleConnection object
        con.Close();
        con.Dispose();
    }
}

```

```
}  
}
```

## OracleParameter Array Bind Properties

The `OracleParameter` class provides two properties for granular control when using the array bind feature:

- `ArrayBindSize`

The `ArrayBindSize` property is an array of integers specifying the maximum size for each corresponding value in an array. The `ArrayBindSize` property is similar to the `Size` property of an `OracleParameter` object, except the `ArrayBindSize` property specifies the size for each value in an array.

Before the execution, the application must populate the `ArrayBindSize` property; after the execution, ODP.NET populates it.

The `ArrayBindSize` property is used only for parameter types that have variable length such as `Clob`, `Blob`, and `Varchar2`. The size is represented in bytes for binary data types, and characters for the Unicode string types. The count for string types does not include the terminating character. The size is inferred from the actual size of the value, if it is not explicitly set. For an output parameter, the size of each value is set by ODP.NET. The `ArrayBindSize` property is ignored for fixed-length data types.

The maximum `ArrayBindSize` size is 2 GB for both character and binary data.

- `ArrayBindStatus`

The `ArrayBindStatus` property is an array of `OracleParameterStatus` values that specify the status of each corresponding value in an array for a parameter. This property is similar to the `Status` property of the `OracleParameter` object, except that the `ArrayBindStatus` property specifies the status for each array value.

Before the execution, the application must populate the `ArrayBindStatus` property. After the execution, ODP.NET populates the property. Before the execution, an application using the `ArrayBindStatus` property can specify a `NULL` value for the corresponding element in the array for a parameter. After the execution, ODP.NET populates the `ArrayBindStatus` property, indicating whether the corresponding element in the array has a `null` value, or if data truncation occurred when the value was fetched.

## Error Handling for Array Binding

If an error occurs during an array bind execution, it can be difficult to determine which element in the `Value` property caused the error. ODP.NET provides a way to determine the row where the error occurred, making it easier to find the element in the row that caused the error.

When an `OracleException` object is thrown during an array bind execution, the `OracleErrorCollection` object contains one or more `OracleError` objects. Each of these `OracleError` objects represents an individual error that occurred during the execution, and contains a provider-specific property, `ArrayBindIndex`, which indicates the row number at which the error occurred.

The following example demonstrates error handling for array binding:

```
/* Database Setup
connect scott/tiger@oracle
drop table depttest;
create table depttest(deptno number(2));
*/

// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class ArrayBindExceptionSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();
        con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle;";
        con.Open();

        OracleCommand cmd = new OracleCommand();

        // Start a transaction
        OracleTransaction txn = con.BeginTransaction(IsolationLevel.ReadCommitted);

        try
        {
            int[] myArrayDeptNo = new int[3] { 10, 200000, 30 };
            // int[] myArrayDeptNo = new int[3]{ 10,20,30};

            // Set the command text on an OracleCommand object
            cmd.CommandText = "insert into depttest(deptno) values (:deptno)";
            cmd.Connection = con;

            // Set the ArrayBindCount to indicate the number of values
            cmd.ArrayBindCount = 3;

            // Create a parameter for the array operations
            OracleParameter prm = new OracleParameter("deptno", OracleDbType.Int32);

            prm.Direction = ParameterDirection.Input;
            prm.Value = myArrayDeptNo;

            // Add the parameter to the parameter collection
            cmd.Parameters.Add(prm);

            // Execute the command
            cmd.ExecuteNonQuery();
        }
        catch (OracleException e)
        {
            Console.WriteLine("OracleException {0} occurred", e.Message);
            if (e.Number == 24381)
            {
                for (int i = 0; i < e.Errors.Count; i++)
                {
                    Console.WriteLine("Array Bind Error {0} occurred at Row Number {1}",
                        e.Errors[i].Message, e.Errors[i].ArrayBindIndex);
                }
            }

            txn.Commit();
        }
        cmd.Parameters.Clear();
        cmd.CommandText = "select count(*) from depttest";
    }
}
```

```
decimal rows = (decimal)cmd.ExecuteScalar();

Console.WriteLine("{0} row have been inserted", rows);
con.Close();
con.Dispose();
}
}
```

## OracleParameterStatus Enumeration Types

[Table 3-20](#) lists OracleParameterStatus enumeration values.

**Table 3-20 OracleParameterStatus Members**

| Member Names | Description                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Success      | For input parameters, indicates that the input value has been assigned to the column.<br>For output parameters, indicates that the provider assigned an intact value to the parameter. |
| NullFetched  | Indicates that a NULL value has been fetched from a column or an OUT parameter.                                                                                                        |
| NullInsert   | Indicates that a NULL value is to be inserted into a column.                                                                                                                           |
| Truncation   | Indicates that truncation has occurred when fetching the data from the column.                                                                                                         |

## Batch Processing

The `OracleDataAdapter.UpdateBatchSize` property enables batch processing when the `OracleDataAdapter.Update` method is called. `UpdateBatchSize` is a numeric property that indicates how many `DataSet` rows to update the Oracle database for each round-trip.

This enables the developer to reduce the number of round-trips to the database.

["UpdateBatchSize"](#)

## Statement Caching

Statement caching eliminates the need to parse each SQL or PL/SQL statement before execution by caching server cursors created during the initial statement execution. Subsequent executions of the same statement can reuse the parsed information from the cursor, and then execute the statement without reparsing, for better performance.

In order to see performance gains from statement caching, Oracle recommends caching only those statements that will be repeatedly executed. Furthermore, SQL or PL/SQL statements

should use parameters rather than literal values. Doing so takes full advantage of statement caching, because parsed information from parameterized statements can be reused even if the parameter values change in subsequent executions. However, if the literal values in the statements are different, the parsed information cannot be reused unless the subsequent statements also have the same literal values.

## Statement Caching Connection String Attributes

The following connection string attributes control the behavior of the ODP.NET statement caching feature:

- **Statement Cache Size**

This attribute enables or disables ODP.NET statement caching. By default, this attribute is set to 0 (disabled). If it is set to a value greater than 0, ODP.NET statement caching is enabled and the value specifies the maximum number of statements that can be cached for a connection. Once a connection has cached up to the specified maximum cache size, the least recently used cursor is freed to make room to cache the newly created cursor.

If self tuning is enabled, then statement caching is enabled as well. The Statement Cache Size is configured automatically in such cases.

- **Statement Cache Purge**

This attribute provides a way for connections to purge all statements that are cached when a connection is closed or placed back into the connection pool. By default, this attribute is set to false, which means that cursors are not freed when connections are placed back into the pool.

## Enabling Statement Caching through the Registry

To enable statement caching by default for all ODP.NET applications running in a system, without changing the application, set the registry key of `HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ODP.NET\Assembly_Version\StatementCacheSize` to a value greater than 0. This value specifies the number of cursors that are to be cached on the server.

The default value for the system can be overridden at the connection pool level. The Statement Cache Size attribute can be set to a different size than the registry value or it can be turned off. The Statement Cache Size can also be configured through an XML configuration file.

### See Also

[Configuring Oracle Data Provider for .NET](#) for more details.

## Statement Caching Methods and Properties

The following property and method are relevant only when statement caching is enabled:

- `OracleCommand.AddToStatementCache` property

If statement caching is enabled, having this property set to true (default) adds statements to the cache when they are executed. If statement caching is disabled or if this property is set to false, the executed statement is not cached.

- `OracleConnection.PurgeStatementCache` method

This method purges all the cached statements by closing all open cursors on the database that are associated with the particular connection. Note that statement caching remains enabled after this call.

## Connections and Statement Caching

Statement caching is managed separately for each connection. Therefore, executing the same statement on different connections requires parsing once for each connection and caching a separate cursor for each connection.

## Pooling and Statement Caching

Pooling and statement caching can be used in conjunction. If connection pooling is enabled and the Statement Cache Purge attribute is set to false, statements executed on each separate connection are cached throughout the lifetime of the pooled connection.

If the Statement Cache Purge attribute is set to true, all the cached cursors are freed when the connection is placed back into the pool. When connection pooling is disabled, cursors are cached during the lifetime of the connection, but the cursors are closed when the `OracleConnection` object is closed or disposed of.

If schema object metadata is changed, such as dropping a table column, while the .NET app is running, ODP.NET should not use the cached schema information. The cache is now out of date and returns an "ORA-01007 variable not in select list" or similar error. If your app changes schema objects during the .NET app's running lifetime, then disable both statement caching and metadata pooling for ODP.NET commands that use those schema objects to avoid the error.

## Self-Tuning

ODP.NET applications can be self-tuned for performance optimization. ODP.NET dynamically monitors application queries during runtime.

### Note

Self-tuning for applications does not take place if the `Pooling` connection string attribute is set to false.

The statement cache size ([StatementCacheSize](#)) is tuned automatically by monitoring the statements that are executed by the application. The following sections discuss self-tuning in applications:

- [Self-Tuning Statement Caching](#)
- [Enabling or Disabling Self-Tuning for Applications](#)
- [Tracing Optimization Changes](#)

## Self-Tuning Statement Caching

Statement caching helps improve performance by eliminating the need to re-parse each SQL or PL/SQL statement before execution.

If self-tuning is enabled for an application, then ODP.NET continuously monitors application behavior in order to determine the optimum value for the statement cache size. Any statement cache size value specified in the connection string, configuration file, or registry is ignored.

When the application first initializes, it uses the default value of statement cache size. As the application executes statements, ODP.NET collects statistics that are used to self-tune the value of statement cache size. Self-tuning of statement cache size results in increased performance.

**Note**

To take full advantage of statement caching, you should not dynamically generate statements, with different inline values, for every statement execution. Instead, use parameterized commands to minimize the number of unique statements that need to be executed and cached. This is because only one statement needs to be cached for every unique command text, regardless of the parameter values and the number of times that the statement is executed.

The maximum number of statements that can be cached per connection is determined by the `MaxStatementCacheSize` configuration attribute. The `MaxStatementCacheSize` value can be specified in the Windows registry or XML configuration file.

The `MaxStatementCacheSize` setting is useful in limiting the number of cached statements, as well as the number of open cursors. This is because a cached statement equates to a cursor being opened on the server. For this reason, you should not set `MaxStatementCacheSize` to a value that is greater than the database `OPEN_CURSORS` setting.

The following Windows registry key is used to configure the `MaxStatementCacheSize` configuration attribute:

```
HKLM\Software\Oracle\ODP.NET\version\MaxStatementCacheSize
```

The `MaxStatementCacheSize` key is of type `REG_SZ`. It can be set to an integer value between 0 and `System.Int32.MaxValue`.

The following example sets the `MaxStatementCacheSize` property in an ADO.NET 2.0, or above, configuration file:

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="MaxStatementCacheSize" value="300"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

If self-tuning is disabled for an application, then the value of statement cache size is determined by the settings in the connection string, configuration file, or the registry. If statement cache size is not specified in any of these sources, then the default value of statement cache size is set to 0. To have ODP.NET configured with the same default settings as previous releases of ODP.NET, disable self-tuning and set the `StatementCacheSize` value to 10.

**① See Also**

["Statement Caching"](#)

## Enabling or Disabling Self-Tuning for Applications

Self-tuning for ODP.NET applications is enabled by default. An application can enable or disable self-tuning using one of the following methods:

- Self-Tuning Connection String Attribute

An application can modify the Self Tuning connection string attribute to enable or disable self-tuning for a particular connection pool. The default value for Self Tuning is true.

- Windows Registry

An application can enable or disable self-tuning for a particular version of ODP.NET by modifying the following registry entry:

HKLM\Software\Oracle\ODP.NET\version\SelfTuning

The SelfTuning key is of type REG\_SZ. It can be set to either 1 (enabled) or 0 (disabled).

- Configuration File

An ODP.NET application can modify the application configuration file (app.config) or Web configuration file (web.config) to enable or disable self-tuning.

The following example shows how to enable self-tuning in an ADO.NET 2.0 application configuration file:

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="SelfTuning" value="1"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

**① Note**

If the optimal statement cache size is known for an application, then you can disable self-tuning and set StatementCacheSize to its optimum value in the registry, configuration file, or the application. If self-tuning is disabled and StatementCacheSize is not set at all, then the default value of 0 is used for StatementCacheSize.

## Tracing Optimization Changes

Applications can trace optimization changes made by self-tuning. All changes to StatementCacheSize are traced. Errors, if any, are also traced.

The TraceLevel used for tracing self-tuning is 64 for unmanaged ODP.NET. Managed ODP.NET and ODP.NET Core uses TraceLevel to 7.

**① See Also**

[Table 2-3](#) for details on `TraceLevel` values

## Data Transmission Performance

ODP.NET data transmission performance can be optimized via the Session Data Unit (SDU) size setting. The SDU is a buffer that Oracle uses to place data before transmitting it across the network. Oracle sends the data in the buffer either when requested or when it is full.

Adjusting the size of the SDU buffers relative to the amount of data to send at any one time can improve performance, network utilization, and memory consumption. When large amounts of data are being transmitted, increasing the SDU size can improve performance and network throughput. SDU size can be adjusted lower or higher to achieve higher throughput for a specific deployment. A larger SDU size allows more data to be sent per buffer, reducing number of database round trips for large amounts of data. To accommodate the larger buffer, more memory consumption occurs.

This buffer size can be set on either the ODP.NET client side or database server side. ODP.NET supports SDU sizes between 256 and 2,097,152 bytes. In ODP.NET, this can be set in the .NET configuration file (.NET Framework), `tnsnames.ora`, or `sqlnet.ora`.

For managed ODP.NET and ODP.NET Core, if the application does not provide a client side SDU value, then connections will use the database server's SDU size. If the client side SDU size is set, then connections will compare it against the DB server's SDU size, and then choose the lower of the two values for the SDU size to use.

Unmanaged ODP.NET SDU setting behavior is the same as the Oracle database client's.

**① See Also**

Optimizing Performance in *Oracle AI Database Net Services Administrator's Guide* for more SDU details.

## Securing Identifiers and Literals from SQL Injection Attacks

ODP.NET command parameter binding is recommended to protect against many SQL injection attack types. In cases in which literal or database identifier values cannot be bound as parameters, developers historically had to then validate those input values programmatically. In essence, their code took on the onus of SQL injection protection.

Managed ODP.NET and ODP.NET Core 23.8 introduce methods to make securing ODP.NET app code easier when using these literal and identifier values. These methods sanitize the input values to prevent their usage as SQL injection vectors.

The new methods validate literals and database identifiers, and then add quotes around them if they are missing.

Database identifiers include Oracle SQL reserved words.

**Note**

- [OracleDBMSAssert Class](#)
- Oracle SQL Reserved Words

## ODP.NET Types Overview

ODP.NET types represent Oracle native data types and PL/SQL data types as a structure or as a class. ODP.NET type structures follow [value semantics](#), while ODP.NET type classes follow [reference semantics](#). ODP.NET types provide safer and more efficient ways of obtaining Oracle native data and PL/SQL data types in a .NET application than .NET types. For example, an `OracleDecimal` structure holds up to 38 digits of precision, while a .NET `Decimal` only holds up to 28.

[Table 3-21](#) lists data types supported by ODP.NET and their corresponding ODP.NET types: data types in the first column refer to both Oracle native data types and PL/SQL data types of that name. Those data types that exist only in PL/SQL are indicated by (PL/SQL only) after the data type name. The entries for the PL/SQL data types also represent the subtypes of the data types, if any. The third column lists the .NET Framework data type that corresponds to the `Value` property of each ODP.NET type.

**Table 3-21 Value Property Type of ODP.NET Type**

| Oracle Native Data Type or PL/SQL Data Type | ODP.NET Type                            | .NET Framework Data Types    |
|---------------------------------------------|-----------------------------------------|------------------------------|
| BFILE                                       | <code>OracleBFile</code> class          | <code>System.Byte[]</code>   |

**Deserializing ODP.NET Types into DataSet and DataTable**

Due to a change in all .NET versions to enhance application security, the allowed DataSet and DataTable data types that can be deserialized are now restricted. This change applies to .NET 5, plus .NET Core and .NET Framework updates. If your DataSets and DataTables use Oracle data types with one of these new .NET versions, then you will have to add ODP.NET-specific data types to the “allow” list so that they can be deserialized into DataSet or DataTable. If an attempt is made to deserialize ODP.NET-specific types without adding them to the allow list, an ODP.NET type initializer exception will be encountered.

The most straightforward way to add all ODP.NET data types to the allow list to call the OracleConfiguration AddOracleTypesDeserialization method in your application.

Alternatively, in .NET Framework 4, the specific ODP.NET data types can be added individually to the application .NET configuration file. Here's a sample configuration file for adding all managed ODP.NET 21c data types to the allow list.

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <configSections>
    <sectionGroup name="system.data.dataset.serialization"
type="System.Data.SerializationSettingsSectionGroup, System.Data, Version=4.0.0.0,
Culture=neutral, PublicKeyToken=b77a5c561934e089">
      <section name="allowedTypes" type="System.Data.AllowedTypesSectionHandler,
System.Data, Version=4.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089"/>
    </sectionGroup>
  </configSections>
  <system.data.dataset.serialization>
    <allowedTypes>
      <!-- <add type="assembly qualified type name" /> -->
      <add type="Oracle.ManagedDataAccess.Types.OracleBinary,
Oracle.ManagedDataAccess, Version=4.122.21.1, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
    </allowedTypes>
  </system.data.dataset.serialization>
</configuration>
```

```

    <add type="Oracle.ManagedDataAccess.Types.OracleBlob, Oracle.ManagedDataAccess,
Version=4.122.21.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleClob, Oracle.ManagedDataAccess,
Version=4.122.21.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleDate, Oracle.ManagedDataAccess,
Version=4.122.21.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleDecimal, Oracle.ManagedDataAccess,
Version=4.122.21.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleIntervalDS,
Oracle.ManagedDataAccess, Version=4.122.21.1, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleIntervalYM,
Oracle.ManagedDataAccess, Version=4.122.21.1, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleRef, Oracle.ManagedDataAccess,
Version=4.122.21.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleString, Oracle.ManagedDataAccess,
Version=4.122.21.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleTimeStamp,
Oracle.ManagedDataAccess, Version=4.122.21.1, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleTimeStampLTZ,
Oracle.ManagedDataAccess, Version=4.122.21.1, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleTimeStampTZ,
Oracle.ManagedDataAccess, Version=4.122.21.1, Culture=neutral,
PublicKeyToken=89b483f429c47342" />
    <add type="Oracle.ManagedDataAccess.Types.OracleXmlType, Oracle.ManagedDataAccess,
Version=4.122.21.1, Culture=neutral, PublicKeyToken=89b483f429c47342" />
    <!-- additional <add /> elements as needed -->
  </allowedTypes>
</system.data.dataset.serialization>
</configuration>

```

With the .NET configuration file, developers can enable specific ODP.NET data types to allow, rather than enable all of them with `AddOracleTypesDeserialization` method.

## GUIDs

ODP.NET does support GUIDs. GUIDs can be inserted into a RAW(16) column which is big enough to hold any GUID value. But caution needs to be taken in order to handle GUIDs appropriately. This is due to the fact that as the .NET Guid structure flips the byte values in reverse order for the integer-based parts of the GUID values when `Guid(byte[])` constructor is used and when the `ToByteArray()` method on the Guid struct is invoked.

When the Guid is provided to ODP.NET as an input parameter, for example, ODP.NET invokes the `ToByteArray()` method before passing the values to the Oracle Database as raw bytes. This means that if the Guid originally has a sequence of bytes of

```
9D4E51F764A940E4854D667F0DD61093
```

then the `byte[ ]` representation of the GUID would be changed to

```
F7514E9DA964E440854D667F0DD61093
```

after the `ToByteArray()` method invocation that is invoked by ODP.NET internally before it's inserted into the `RAW(16)` column.

And when the same column value is then retrieved from the Oracle database, the value that is obtained is

```
F7514E9DA964E440854D667F0DD61093
```

which is how it was stored in the database. When the `GetGuid()` method is invoked on the `OracleDataReader` object, ODP.NET constructs the `Guid` structure using the `Guid(byte[ ])` constructor, which flips it back to the original sequence of bytes:

```
9D4E51F764A940E4854D667F0DD61093
```

This means that the sequence of bytes of the GUID in the application is not in the exact same order as how it is stored in the database. In other words, if the application executes a SQL using literal byte values, such as

```
select * from ... where <raw/guid_column> = '9D4E51F764A940E4854D667F0DD61093';
```

there will be no rows returned. The same GUID was inserted into the table as:

```
F7514E9DA964E440854D667F0DD61093
```

The application will be able to query for the row with the matching GUID if the application

- binds the guid value using `Guid` structure as an input parameter
- constructs the byte literal value that is to be used in the SQL from the `byte[ ]` returned from the `ToByteArray()` method invocation on the `Guid` structure.

The application developer should be cautious and mindful as to when the `Guid(byte[ ])` constructor and the `ToByteArray()` method of the `Guid` structure is called, which can alter the sequence of the bytes. A simple program below demonstrates how the integer-based parts of the GUID values are flipped when `Guid(byte[ ])` constructor and when the `ToByteArray()` method are invoked.

```
using System;
using System.Text;
using System.Data;
using Oracle.ManagedDataAccess.Client;

class T
{
    static string ByteToString(byte[] data)
    {
        StringBuilder sb = new StringBuilder(16);
        foreach (var b in data)
            sb.Append($"{b:X2}");
        return sb.ToString();
    }

    static void Main()
    {
        try
        {
            OracleConnection con = new OracleConnection("user id=<user
id>;password=<password>;data source=<data source>");
```

```

con.Open();

//
// Generate a new GUID
//
Guid guid = Guid.NewGuid();
string original = guid.ToString().ToUpper().Replace("-", "");
Console.WriteLine("Original Guid           : " + original);

//
// Drop the table
//
OracleCommand cmd = new OracleCommand("drop table test_guid_table", con);
try { cmd.ExecuteNonQuery(); } catch {}

//
// Create the table
//
cmd.CommandText = "create table test_guid_table (col1 RAW(16), col2 VARCHAR2(64))";
cmd.ExecuteNonQuery();

//
// Insert the newly generated GUID to the DB
//
cmd.CommandText = "insert into test_guid_table values (:1, 'new guid')";
cmd.Parameters.Add(string.Empty, OracleDbType.Raw);
cmd.Parameters[0].Value = guid;
cmd.ExecuteNonQuery();

//
// Query from the test table
//
cmd.CommandText = "select * from test_guid_table";
OracleDataReader reader = cmd.ExecuteReader();

while (reader.Read())
{
    //
    // Get the RAW data as byte[]
    //
    byte[] guid_byte_array = (byte[])reader.GetValue(0);
    Console.WriteLine("GetValue() as byte[] / as-is in DB: " +
ByteToString(guid_byte_array));
    Console.WriteLine();

    //
    // Get the RAW data as Guid then convert to byte[]
    //
    Guid retrieved_guid = (Guid)reader.GetGuid(0);
    byte[] retrieved_guid_byte_array = retrieved_guid.ToByteArray();
    Console.WriteLine("GetGuid() then Guid.ToString()      : " +
retrieved_guid_byte_array.ToString());
    Console.WriteLine("GetGuid() then Guid.ToByteArray() : " +
ByteToString(retrieved_guid.ToByteArray()));
}

//
// Find a matching row by binding the original GUID as-is
//
cmd.Parameters.Clear();
Console.WriteLine("\nGuid Input Parameter           : " +
ByteToString(guid.ToByteArray()));

```

```

cmd.CommandText = "select count(*) from test_guid_table where col1 = :1";
cmd.Parameters.Add(string.Empty, OracleDbType.Raw);
cmd.Parameters[0].Value = guid;
reader = cmd.ExecuteReader();
while (reader.Read())
{
    Console.WriteLine("Rows found by binding GUID          : " +
(decimal)reader.GetValue(0));
}

//
// Find a matching row by binding a byte[] from the original GUID
//
byte[] byte_array_param = guid.ToByteArray();
Console.WriteLine("\nbyte[] Input Parameter          : " +
ByteToString(byte_array_param));
cmd.CommandText = "select count(*) from test_guid_table where col1 = :1";
cmd.Parameters.Clear();
cmd.Parameters.Add(string.Empty, OracleDbType.Raw);
cmd.Parameters[0].Value = byte_array_param;
reader = cmd.ExecuteReader();
while (reader.Read())
{
    Console.WriteLine("Rows found by binding byte[]      : " +
(decimal)reader.GetValue(0));
}

//
// Find a matching row by matching the binary/raw data (inline) using
Guid.ToByteArray()
//
cmd.CommandText = "select count(*) from test_guid_table where col1 = '" +
ByteToString(guid.ToByteArray()) + "'";
Console.WriteLine("\nLiteral RAW (from byte array)      : " +
ByteToString(guid.ToByteArray()));
cmd.Parameters.Clear();
reader = cmd.ExecuteReader();
while (reader.Read())
{
    Console.WriteLine("Rows found by inlined data        : " +
(decimal)reader.GetValue(0));
}

//
// Find a matching row by matching the binary/raw data (inline) using
Guid.ToString()
//
cmd.CommandText = "select count(*) from test_guid_table where col1 = '" + original
+ "'";
Console.WriteLine("\nLiteral RAW (from string)          : " + original);
cmd.Parameters.Clear();
reader = cmd.ExecuteReader();
while (reader.Read())
{
    Console.WriteLine("Rows found by inlined data        : " +
(decimal)reader.GetValue(0));
}
} catch (Exception ex) { Console.WriteLine(ex); }
}
}

```

A sample output from the sample code could be:

```

Original Guid                : D54909F4169541CFA919F6752414909F
GetValue() as byte[] / as-is in DB: F40949D59516CF41A919F6752414909F

GetGuid() then Guid.ToString() : System.Byte[]
GetGuid() then Guid.ToByteArray() : F40949D59516CF41A919F6752414909F

Guid Input Parameter         : F40949D59516CF41A919F6752414909F
Rows found by binding GUID   : 1

byte[] Input Parameter       : F40949D59516CF41A919F6752414909F
Rows found by binding byte[] : 1

Literal RAW (from byte array) : F40949D59516CF41A919F6752414909F
Rows found by inlined data    : 1

Literal RAW (from string)     : D54909F4169541CFA919F6752414909F
Rows found by inlined data    : 0

```

**Note**

Every execution of the test generates a new or different GUID.

## Obtaining Data from an OracleDataReader Object

The `ExecuteReader` method of the `OracleCommand` object returns an `OracleDataReader` object, which is a read-only, forward-only result set.

This section provides the following information about the `OracleDataReader` object:

- [Typed OracleDataReader Accessors](#)
- [Obtaining LONG and LONG RAW Data](#)
- [Obtaining LOB Data](#)
- [Controlling the Number of Rows Fetched in One Database Round-Trip](#)

### Typed OracleDataReader Accessors

The `OracleDataReader` class provides two types of typed accessors:

- [.NET Type Accessors](#)
- [ODP.NET Type Accessors](#)

### .NET Type Accessors

[Table 3-22](#) lists all the Oracle native database types that ODP.NET supports, and the corresponding .NET types that can represent the Oracle native type. If more than one .NET type can be used to represent an Oracle native type, the first entry is the .NET type that best represents the Oracle native type. The third column indicates the valid typed accessor that can be invoked for an Oracle native type to be obtained as a .NET type. If an invalid typed accessor is used for a column, an `InvalidCastException` is thrown. Oracle native data types depend on the version of the database; therefore, some data types are not available in earlier versions of Oracle Database.

**Table 3-22 (Cont.) .NET Type Accessors**

| Oracle Native Data Type | .NET Type            | Typed Accessor |
|-------------------------|----------------------|----------------|
| VECTOR                  | System.Byte[]        | GetByteArray   |
|                         | System.Double[]      | GetDoubleArray |
|                         | System.Single[]      | GetFloatArray  |
|                         | System.Int16[]       | GetInt16Array  |
|                         | System.String        | GetString      |
| XMLType                 | System.String        | GetString      |
|                         | System.Xml.XmlReader | GetXmlReader   |

- Superscript <sup>1</sup>: The typed accessor is available in managed ODP.NET and ODP.NET Core only. The GetString accessors were added starting in ODP.NET 19.10.
- Superscript <sup>2</sup>: The typed accessor is available in unmanaged ODP.NET only.

Certain methods and properties of the `OracleDataReader` object require ODP.NET to map a `NUMBER` column to a .NET type based on the precision and scale of the column. These members are:

- `Item` property
- `GetFieldType` method
- `GetValue` method
- `GetValues` method

ODP.NET determines the appropriate .NET type by considering the following .NET types in order, and selecting the first .NET type from the list that can represent the entire range of values of the column:

- `System.Byte`
- `System.Int16`
- `System.Int32`
- `System.Int64`
- `System.Single`
- `System.Double`
- `System.Decimal`

If no .NET type exists that can represent the entire range of values of the column, then an attempt is made to represent the column values as a `System.Decimal` type. If the value in the column cannot be represented as `System.Decimal`, then an exception is raised.

For example, consider two columns defined as `NUMBER(4,0)` and `NUMBER(10,2)`. The first .NET types from the previous list that can represent the entire range of values of the columns are `System.Int16` and `System.Double`, respectively. However, consider a column defined as `NUMBER(20,10)`. In this case, there is no .NET type that can represent the entire range of values on the column, so an attempt is made to return values in the column as a `System.Decimal` type. If a value in the column cannot be represented as a `System.Decimal` type, then an exception is raised.

The `Fill` method of the `OracleDataAdapter` class uses the `OracleDataReader` object to populate or refresh a `DataTable` or `DataSet` with .NET types. As a result, the .NET type used to

represent a NUMBER column in the DataTable or DataSet also depends on the precision and scale of the column.

## ODP.NET Type Accessors

ODP.NET exposes provider-specific types that natively represent the data types in the database. In some cases, these ODP.NET types provide better performance and functioning than the corresponding .NET types. The ODP.NET types can be obtained from the OracleDataReader object by calling their respective typed accessor.

[Table 3-23](#) lists the valid type accessors that ODP.NET uses to obtain ODP.NET types for an Oracle native type.

**Table 3-23 ODP.NET Type Accessors**

| Oracle Native Data Type | ODP.NET Type     | Typed Accessor         |
|-------------------------|------------------|------------------------|
| BFILE                   | OracleBFile      | GetOracleBFile         |
| BINARY_DOUBLE           | OracleDecimal    | GetOracleDecimal       |
| BINARY_FLOAT            | OracleDecimal    | GetOracleDecimal       |
| BLOB                    | OracleBlob       | GetOracleBlob          |
|                         | OracleBlob       | GetOracleBlobForUpdate |
|                         | OracleBinary     | GetOracleBinary        |
| BOOLEAN                 | OracleBoolean    | GetOracleBoolean       |
| CHAR                    | OracleString     | GetOracleString        |
| CLOB                    | OracleClob       | GetOracleClob          |
|                         | OracleClob       | GetOracleClobForUpdate |
|                         | OracleString     | GetOracleString        |
| DATE                    | OracleDate       | GetOracleDate          |
| FLOAT                   | OracleBoolean    | GetOracleBoolean       |
|                         | OracleDecimal    | GetOracleDecimal       |
|                         | OracleString     | GetOracleString        |
| INTERVAL DAY TO SECOND  | OracleIntervalDS | GetOracleIntervalDS    |
| INTERVAL YEAR TO MONTH  | OracleIntervalYM | GetOracleIntervalYM    |

"[ODP.NET Types Overview](#)" for a list of all ODP.NET types

## Obtaining LONG and LONG RAW Data

ODP.NET fetches and caches rows from the database during the Read method invocations on the OracleDataReader object. The amount of LONG and LONG RAW column data that is retrieved from this operation is determined by InitialLONGFetchSize. The different behaviors observed when InitialLONGFetchSize is set to 0, greater than 0, and -1 are explained in the following sections.

**① Note**

ODP.NET does not support the CommandBehavior.SequentialAccess enumeration value. Therefore, LONG and LONG RAW data can be fetched randomly.

## Setting InitialLONGFetchSize to Zero or a Value Greater than Zero

The specified amount of `InitialLONGFetchSize` characters or bytes for LONG or LONG RAW column data is retrieved into the cache during the Read method invocations on the `OracleDataReader` object.

By default, `InitialLONGFetchSize` is set to 0. In this case, ODP.NET does not fetch any LONG or LONG RAW column data during the Read method invocations on the `OracleDataReader` object. The LONG or LONG RAW data is fetched when the typed accessor method is explicitly invoked for the LONG or LONG RAW column, which incurs a database round-trip because no data is cached.

If `InitialLONGFetchSize` is set to a value greater than 0, that amount of specified data is cached by ODP.NET during the Read method invocations on the `OracleDataReader` object. If the application requests an amount of data less than or equal to the `InitialLONGFetchSize` through the typed accessor methods, no database round-trip is incurred. However, an additional database round-trip is required to fetch data beyond `InitialLONGFetchSize`.

To obtain data beyond the `InitialLONGFetchSize` characters or bytes, one of the following must be in the select list:

- Primary key
- ROWID
- Unique columns - (defined as a set of columns on which a unique constraint has been defined or a unique index has been created, where at least one of the columns in the set has a NOT NULL constraint defined on it)

To be able to fetch the entire LONG or LONG RAW data without having a primary key column, a ROWID, or unique columns in the select list, set the size of the `InitialLONGFetchSize` property on the `OracleCommand` object to equal or greater than the number of characters or bytes needed to be retrieved.

The LONG or LONG RAW data is returned when the appropriate typed accessor method (`GetChars`, `GetOracleString`, or `GetString` for LONG or `GetOracleBinary` or `GetBytes` for LONG RAW) is called on the `OracleDataReader` object.

## Setting InitialLONGFetchSize to -1

By setting `InitialLONGFetchSize` to -1, it is possible to fetch the entire LONG or LONG RAW data from the database for a select query, without requiring a primary key, ROWID, or unique column in the select list.

When `InitialLONGFetchSize` is set to -1, the entire LONG or LONG RAW data is retrieved and cached during Read method invocations on the `OracleDataReader` object. Calls to `GetString`, `GetOracleString`, `GetChars`, `GetBytes`, or `GetOracleBinary` in the `OracleDataReader` return the entire column data.

## Obtaining LOB Data

ODP.NET fetches and caches rows from the database during the Read method invocations on the `OracleDataReader` object. The amount of LOB column data that is retrieved from this operation is determined by `InitialLOBFetchSize`.

The following is a complete list of typed accessor methods that an application can call for the CLOB and BLOB columns, if `InitialLOBFetchSize` is set to 0, greater than 0, or -1:

- Methods callable for BLOB column
  - GetBytes
  - GetValue
  - GetValues
  - GetOracleBinary
  - GetOracleBlob
  - GetOracleBlobForUpdate
  - GetOracleValue
  - GetOracleValues
- Methods callable for CLOB column
  - GetChars
  - GetString
  - GetValue
  - GetValues
  - GetOracleString
  - GetOracleClob
  - GetOracleClobForUpdate
  - GetOracleValue
  - GetOracleValues

The following sections explain the different behaviors observed when `InitialLOBFetchSize` is set to 0, greater than 0, and -1.

## Setting InitialLOBFetchSize to Zero

By default, the `InitialLOBFetchSize` property is 0. This value dictates to ODP.NET that any LOBs selected will have their client LOB data fetches deferred until after the `OracleDataReader.Read`, such as when using the an accessor. Each LOB value is retrieved only at the point it is individually accessed.

The advantage of using this retrieval strategy is that it conserves client memory and bandwidth. If the LOBs selected are either very large or not necessary to be immediately consumed by the end user, or both, then the application can perform better if LOBs are retrieved as needed, rather than all at once.

## Setting InitialLOBFetchSize to a Value Greater than Zero

If `InitialLOBFetchSize` is set to a value greater than 0, ODP.NET caches LOB data up to `InitialLOBFetchSize` characters or bytes for each LOB selected during the `Read` method invocations on the `OracleDataReader` object. The maximum value is 2,147,483,647 (2GB). If the total size of a selected LOB is less than this number, the entire LOB data will be read.

By pre-fetching all LOB entries in one or more database round trips, applications can perform faster by reducing round trips. This approach is most advantageous when most LOBs are either small in size, or consumed by the end user almost immediately, or both. The down side of a large fetch size is higher memory consumption.

This section discusses the ways to fetch beyond the `InitialLOBFetchSize` characters or bytes that are cached.

The remaining LOB data is returned when a typed accessor is invoked, regardless of the value set to the `InitialLOBFetchSize` property. Primary key, ROWID, or unique columns are not required to be in the query select list to obtain data beyond the specified `InitialLOBFetchSize`.

The `GetOracleBlob`, `GetOracleClob`, `GetOracleBlobForUpdate`, and `GetOracleClobForUpdate` methods can now be invoked even if `InitialLOBFetchSize` is greater than 0.

## Setting InitialLOBFetchSize to -1

To fetch all LOB data selected during the read operation and not be bound by a set limit per LOB, set `InitialLOBFetchSize` to -1. A new default behavior has been introduced for ODP.NET Release 12.1.0.2 and higher when `InitialLobFetchSize` is set to -1.

When `LegacyEntireLOBFetch = 0`, which is the default value, the following operations are invoked for a LOB column:

- `OracleDataReader.GetOracleClob()`: returns `OracleClob` object
- `OracleDataReader.GetOracleBlob()` : returns `OracleBlob` object
- `OracleDataReader.GetOracleClobForUpdate()`: returns `OracleClob` object
- `OracleDataReader.GetOracleBlobForUpdate()`: returns `OracleBlob` object
- `OracleDataReader.GetOracleValue()`: returns `OracleClob` object for a CLOB column
- `OracleDataReader.GetOracleValue()`: returns `OracleBlob` object for a BLOB column
- `OracleDataAdapter.Fill()` with `ProviderSpecificTypes=true`: populates `DataTable` with `OracleClob` for a CLOB column
- `OracleDataAdapter.Fill()` with `ProviderSpecificTypes=true`: populates `DataTable` with `OracleBlob` for a BLOB column

To use the old behavior, set `LegacyEntireLobFetch = 1` in the ODP.NET configuration.

When `LegacyEntireLobFetch = 1` and `InitialLOBFetchSize = -1`, `GetOracleClob`, `GetOracleClobForUpdate`, `GetOracleBlob`, and `GetOracleBlobForUpdate` methods are not supported. The following operations are invoked for a LOB column in this scenario:

- `OracleDataReader.GetOracleClob()`: throws `InvalidCastException()`
- `OracleDataReader.GetOracleBlob()`: throws `InvalidCastException()`
- `OracleDataReader.GetOracleClobForUpdate()`: throws `InvalidCastException()`
- `OracleDataReader.GetOracleBlobForUpdate()`: throws `InvalidCastException()`
- `OracleDataReader.GetOracleValue()`: returns `OracleString` object for a CLOB column
- `OracleDataReader.GetOracleValue()`: returns `OracleBinary` object for a BLOB column
- `OracleDataAdapter.Fill()` with `ProviderSpecificTypes=true`: populates `DataTable` with `OracleString` for a CLOB column
- `OracleDataAdapter.Fill()` with `ProviderSpecificTypes=true`: populates `DataTable` with `OracleBinary` for a BLOB column

For releases prior to ODP.NET 12.1.0.2, by setting `InitialLOBFetchSize` to -1, it is possible to fetch the entire LOB data from the database for a select query, without requiring a primary key, ROWID, or unique column in the select list. When `InitialLOBFetchSize` is set to -1, the entire

LOB column data is fetched and cached during the Read method invocations on the OracleDataReader object. Calls to GetString, GetOracleString, GetChars, GetBytes, or GetOracleBinary in the OracleDataReader allow retrieving all data.

## Methods Supported for InitialLOBFetchSize of -1 and LegacyEntireLobFetch of 1

This section lists supported and not supported methods for the CLOB and BLOB data types when the InitialLOBFetchSize property is set to -1 and LegacyEntireLobFetch property is set to 1.

[Table 3-24](#) lists supported and not supported methods for the CLOB data types.

**Table 3-24 Supported OracleDataReader CLOB Methods for InitialLOBFetchSize of -1 and LegacyEntireLobFetch of 1**

| OracleDataReader CLOB Methods | Supported |
|-------------------------------|-----------|
| GetChars                      | Yes       |
| GetString                     | Yes       |
| GetValue                      | Yes       |
| GetValues                     | Yes       |
| GetOracleString               | Yes       |
| GetOracleValue                | Yes       |
| GetOracleValues               | Yes       |
| GetOracleClob                 | No        |
| GetOracleClobForUpdate        | No        |

[Table 3-25](#) lists supported and not supported methods for the BLOB data types.

**Table 3-25 Supported OracleDataReader BLOB Methods for InitialLOBFetchSize of -1 and LegacyEntireLobFetch of 1**

| OracleDataReader BLOB Methods | Supported |
|-------------------------------|-----------|
| GetBytes                      | Yes       |
| GetValue                      | Yes       |
| GetValues                     | Yes       |
| GetOracleBinary               | Yes       |
| GetOracleValue                | Yes       |
| GetOracleValues               | Yes       |
| GetOracleBlob                 | No        |
| GetOracleBlobForUpdate        | No        |

## Performance Considerations Related to the InitialLOBFetchSize Property

This section discusses the advantages and disadvantages of the various InitialLOBFetchSize property settings in different situations.

An application does not have to choose between performance and OracleBlob and OracleClob functionality. Setting the InitialLOBFetchSize property results in a performance boost and still gives the flexibility to use the OracleBlob and OracleClob objects.

If the size of the LOB data is unknown or if the LOB data size varies irregularly, then it is better to leave the `InitialLOBFetchSize` property to its default value of 0. This still gives better performance in most cases.

Setting the `InitialLOBFetchSize` property to a size equal to or greater than the LOB data size for most rows improves performance. It is generally recommended that the `InitialLOBFetchSize` property be set to a value larger than the size of the LOB data for more than 80% of the rows returned by the query. For example, if the size of the LOB data is less than 1 KB in 80% of the rows, and more than 1 MB for 20% of the rows, set the `InitialLOBFetchSize` property to 1 KB.

## Controlling the Number of Rows Fetched in One Database Round-Trip

Application performance depends on the number of rows the application needs to fetch, and the number of database round-trips that are needed to retrieve them. There are two main ways for developers to control the number of rows to fetch per round trip: the `RowsToFetchPerRoundTrip` property or `FetchSize` property.

The easier method is to use `RowsToFetchPerRoundTrip`. On the other hand, `FetchSize` provides more flexibility and granular control if that is needed. In most cases, developers will use `RowsToFetchPerRoundTrip`.

### Use of RowsToFetchPerRoundTrip

This `RowsToFetchPerRoundTrip` property represents the total number of rows ODP.NET retrieves from the database per round trip.

If you set the property value to 25, then ODP.NET will retrieve 25 rows in the first data retrieval round trip and another 25 rows in each subsequent data retrieval round trip. If there are fewer rows than 25 that remain, it will retrieve whatever number of rows are left in the result set.

The more rows that are retrieved per round trip, the faster the performance, especially for the result sets that have many, many rows. The downside is that more memory is required to store the data within the larger number of rows.

This property is available in managed ODP.NET and ODP.NET Core only. It can be set on the .NET configuration file, `OracleConfiguration`, `OracleConnection`, `OracleCommand`, `OracleDataReader`, or `OracleRefCursor` objects.

### Use of FetchSize

The `FetchSize` property represents the total memory size in bytes that ODP.NET allocates to cache the data fetched from a database round-trip.

The `FetchSize` property can be set on the `OracleCommand`, `OracleDataReader`, or `OracleRefCursor` object, depending on the situation. It controls the fetch size for filling a `DataSet` or `DataTable` using an `OracleDataAdapter`.

If the `FetchSize` property is set on the `OracleCommand` object, then the newly created `OracleDataReader` object inherits the `FetchSize` property of the `OracleCommand` object. This inherited `FetchSize` value can be left as is, or modified to override the inherited value. The `FetchSize` property of the `OracleDataReader` object can be changed before the first `Read` method invocation, which allocates memory specified by the `FetchSize` property. All subsequent fetches from the database use the same cache allocated for that `OracleDataReader` object. Therefore, changing the `FetchSize` value after the first `Read` method invocation has no effect.

## Fine-Tuning FetchSize

By fine-tuning the `FetchSize` property, applications can control memory usage and the number of rows fetched in one database round-trip for better performance.

For example, if a query returns 100 rows and each row takes 1024 bytes, then setting the `FetchSize` property to 102400 takes just one database round-trip to fetch 100 rows. For the same query, if the `FetchSize` property is set to 10240, it takes 10 database round-trips to retrieve 100 rows. If the application requires all the rows to be fetched from the result set, the first scenario is faster than the second. However, if the application requires just the first 10 rows from the result set, the second scenario can perform better because it fetches only 10 rows, not 100 rows. When the next 10 rows are fetched, then the memory allocated for rows 1-10 is reused for rows 11-20.

The larger the `FetchSize`, the more system memory is used. Developers should not set large fetch sizes if their client systems have limited memory resources.

## Using the RowSize Property

The `RowSize` property of the `OracleCommand` or `OracleRefCursor` object is populated with the row size (in bytes) after an execution of a `SELECT` statement. The `FetchSize` property can then be set to a value relative to the `RowSize` property by setting it to the result of multiplying the `RowSize` value times the number of rows to fetch for each database round-trip.

For example, setting the `FetchSize` to `RowSize * 10` forces the `OracleDataReader` object to fetch exactly 10 rows for each database round-trip. Note that the `RowSize` value does not change due to the data length in each individual column. Instead, the `RowSize` value is determined strictly from the metadata information of the database table(s) that the `SELECT` statement is executed against.

The `RowSize` property can be used to set the `FetchSize` property at design time or at run time, as described in the following sections.

## Setting FetchSize Value in the Registry

The `HKLM\Software\Oracle\ODP.NET\ version\FetchSize` registry entry can be set to specify the default result set fetch size (in bytes) for all applications that use that particular version of ODP.NET or the `FetchSize` attribute in the application configuration or `web.config` file can specify the default value for a given application. By default, the fetch size is 131072 bytes. This value can be overridden programmatically by having the applications set the `FetchSize` property on either the `OracleCommand` or the `OracleDataReader` at run time.

## Setting FetchSize Value at Design Time

If the row size for a particular `SELECT` statement is already known from a previous execution, the `FetchSize` value of the `OracleCommand` object can be set at design time to the result of multiplying that row size times the number of rows the application wishes to fetch for each

database round-trip. The `FetchSize` value set on the `OracleCommand` object is inherited by the `OracleDataReader` object that is created by the `ExecuteReader` method invocation on the `OracleCommand` object. Rather than setting the `FetchSize` value on the `OracleCommand` object, the `FetchSize` value can also be set on the `OracleDataReader` object directly. In either case, the `FetchSize` value is set at design time, without accessing the `RowSize` property value at run time.

## Setting FetchSize Value at Run Time

Applications that do not know the row size at design time can use the `RowSize` property of the `OracleCommand` object to set the `FetchSize` property of the `OracleDataReader` object. The `RowSize` property provides a dynamic way of setting the `FetchSize` property based on the size of a row.

After an `OracleDataReader` object is obtained by invoking the `ExecuteReader` method on the `OracleCommand` object, the `RowSize` property is populated with the size of the row (in bytes). By using the `RowSize` property, the application can dynamically set the `FetchSize` property of the `OracleDataReader` object to the product of the `RowSize` property value multiplied by the number of rows the application wishes to fetch for each database round-trip. In this scenario, the `FetchSize` property is set by accessing the `RowSize` property at run time.

## PL/SQL REF CURSOR and OracleRefCursor

The `REF CURSOR` is a data type in the Oracle PL/SQL language. It represents a cursor or a result set in Oracle Database. The `OracleRefCursor` object is a corresponding ODP.NET type for the `REF CURSOR` type.

This section discusses the following aspects of using the `REF CURSOR` data type and `OracleRefCursor` objects:

- [Obtaining an OracleRefCursor Object](#)
- [Obtaining a REF CURSOR Data Type](#)
- [Populating an OracleDataReader from a REF CURSOR](#)
- [Populating the DataSet from a REF CURSOR](#)
- [Populating an OracleRefCursor from a REF CURSOR](#)
- [Updating a DataSet Obtained from a REF CURSOR](#)
- [Behavior of ExecuteScalar Method for REF CURSOR](#)
- [Passing a REF CURSOR to a Stored Procedure](#)

## Obtaining an OracleRefCursor Object

There are no constructors for `OracleRefCursor` objects. They can be acquired only as parameter values from PL/SQL stored procedures, stored functions, or anonymous blocks.

Starting with managed ODP.NET and ODP.NET Core 23.5, they can also be acquired by `OracleDataReader.GetOracleRefCursor()` from a `REF CURSOR` type column without any parameters.

An `OracleRefCursor` object is a connected object. The connection used to execute the command returning an `OracleRefCursor` object is required for its lifetime. Once the connection associated with an `OracleRefCursor` object is closed, the `OracleRefCursor` object cannot be used.

## Obtaining a REF CURSOR Data Type

A REF CURSOR data type can be obtained as an `OracleDataReader`, `DataSet`, or `OracleRefCursor` object. If the REF CURSOR data type is obtained as an `OracleRefCursor` object, it can be used to create an `OracleDataReader` object or populate a `DataSet` from it. When accessing a REF CURSOR data type, always bind it as an `OracleDbType.RefCursor` parameter.

Starting with managed ODP.NET and ODP.NET Core 23.5, a REF CURSOR type column value can be obtained as an `OracleDataReader`, or `OracleRefCursor` object from `OracleDataReader`; its result set can be a JSON formatted string or `OracleString` from `OracleDataReader`.

## Populating an OracleDataReader from a REF CURSOR

A REF CURSOR data type can be obtained as an `OracleDataReader` object by calling the `ExecuteReader` method of the `OracleCommand` object. The output parameter with the `OracleDbType` property set is bound to `OracleDbType.RefCursor`. None of the output parameters of type `OracleDbType.RefCursor` is populated after the `ExecuteReader` method is invoked.

If there are multiple output REF CURSOR parameters, use the `NextResult` method of the `OracleDataReader` object to access the next REF CURSOR data type. The `OracleDataReader.NextResult` method provides sequential access to the REF CURSOR data types; only one REF CURSOR data type can be accessed at a given time.

The order in which `OracleDataReader` objects are created for the corresponding REF CURSOR data types depends on the order in which the parameters are bound. If a PL/SQL stored function returns a REF CURSOR data type, then it becomes the first `OracleDataReader` object and all the output REF CURSOR data types follow the order in which the parameters are bound.

Starting with managed ODP.NET and ODP.NET Core 23.5, a REF CURSOR type column value can be obtained as an `OracleDataReader` object by calling `Read()` and `GetOracleDataReader(int i)` methods of the `OracleDataReader` object using the index of the REF CURSOR type column.

## Populating the DataSet from a REF CURSOR

For the `Fill` method to populate the `DataSet` properly, the `SelectCommand` property of the `OracleDataAdapter` class must be bound with an output parameter of type `OracleDbType.RefCursor`. If the `Fill` method is successful, the `DataSet` is populated with a `DataTable` that represents a REF CURSOR data type.

If the command execution returns multiple REF CURSOR data types, the `DataSet` is populated with multiple `DataTable` objects.

With Oracle Data Provider for .NET release 11.1.0.6.20, the extended property, `RefCursorName`, has been introduced on the `DataTable`, to identify the REF CURSOR that populates the `DataTable`.

This property is particularly useful when a `DataSet` is being populated with more than one REF CURSOR, one or more of which is NULL. For example, if a `DataSet` is populated by executing a stored procedure that returns three REF CURSORS and the second REF CURSOR is NULL, the `RefCursorName` property value for the first `DataTable` is `RefCursor` and for the second `DataTable`, `RefCursor2`. No `DataTable` is populated for the NULL REF CURSOR.

## Populating an OracleRefCursor from a REF CURSOR

When the `ExecuteNonQuery` method is invoked on a command that returns one or more REF CURSOR data types, each of the `OracleCommand` parameters that are bound as an `OracleDbType.RefCursor` gets a reference to an `OracleRefCursor` object.

To create an `OracleDataReader` object from an `OracleRefCursor` object, invoke the `GetDataReader` method from the `OracleRefCursor` object. Subsequent calls to the `GetDataReader` method return a reference to the same `OracleDataReader` object.

To populate a `DataSet` with an `OracleRefCursor` object, the application can invoke a `Fill` method of the `OracleDataAdapter` class that takes an `OracleRefCursor` object. Similar to the `OracleDataReader` object, an `OracleRefCursor` object is forward-only. Therefore, once a row is read from an `OracleRefCursor` object, that same row cannot be obtained again from it unless it is populated again from a query.

When multiple REF CURSOR data types are returned from a command execution as `OracleRefCursor` objects, the application can choose to create an `OracleDataReader` object or populate a `DataSet` with a particular `OracleRefCursor` object. All the `OracleDataReader` objects or `DataSet` objects created from the `OracleRefCursor` objects are active at the same time, and can be accessed in any order.

Starting with managed ODP.NET and ODP.NET Core 23.5, a REF CURSOR type column value can be obtained as an `OracleRefCursor` object by calling `Read()` and `GetOracleOracleRefCursor(int i)` methods of the `OracleDataReader` object using the index of the REF CURSOR type column.

## Updating a DataSet Obtained from a REF CURSOR

REF CURSOR types cannot be updated. However, data that is retrieved into a `DataSet` can be updated. Therefore, the `OracleDataAdapter` class requires a custom SQL statement to flush any REF CURSOR data updates to the database.

The `OracleCommandBuilder` object cannot be used to generate SQL statements for REF CURSOR updates.

## Behavior of ExecuteScalar Method for REF CURSOR

The `ExecuteScalar` method returns the value of the first column of the first row of the REF CURSOR if it is one of the following:

- A return value of a stored function execution
- The first bind parameter of a stored procedure execution

## Passing a REF CURSOR to a Stored Procedure

An application can retrieve a REF CURSOR type from a PL/SQL stored procedure or function and pass it to another stored procedure or function. This feature is useful in scenarios where a stored procedure or a function returns a REF CURSOR type to the .NET application, and based on the application logic, the application passes this REF CURSOR to another stored procedure for processing. Note that if you retrieve the data from a REF CURSOR type in the .NET application, you cannot pass it back to another stored procedure.

The following example demonstrate passing a REF CURSOR:

```
/*
connect scott/tiger@oracle
create table test (col1 number);
insert into test(col1) values (1);
commit;

create or replace package testPkg as type empCur is REF Cursor;
end testPkg;
/

create or replace procedure testSP(param1 IN testPkg.empCur, param2 OUT NUMBER)
as
begin
FETCH param1 into param2;
end;
/
*/

// C#

using System;
using Oracle.DataAccess.Client;
using System.Data;

class InRefCursorParameterSample
{
    static void Main()
    {
        OracleConnection conn = new OracleConnection
            ("User Id=scott; Password=tiger; Data Source=oracle");

        conn.Open(); // Open the connection to the database

        // Command text for getting the REF Cursor as OUT parameter
        String cmdTxt1 = "begin open :1 for select col1 from test; end;";

        // Command text to pass the REF Cursor as IN parameter
        String cmdTxt2 = "begin testSP (:1, :2); end;";

        // Create the command object for executing cmdTxt1 and cmdTxt2
        OracleCommand cmd = new OracleCommand(cmdTxt1, conn);

        // Bind the Ref cursor to the PL/SQL stored procedure
        OracleParameter outRefPrm = cmd.Parameters.Add("outRefPrm",
            OracleDbType.RefCursor, DBNull.Value, ParameterDirection.Output);

        cmd.ExecuteNonQuery(); // Execute the anonymous PL/SQL block
```

```
// Reset the command object to execute another anonymous PL/SQL block
cmd.Parameters.Clear();
cmd.CommandText = cmdTxt2;

// REF Cursor obtained from previous execution is passed to this
// procedure as IN parameter
OracleParameter inRefPrm = cmd.Parameters.Add("inRefPrm",
    OracleDbType.RefCursor, outRefPrm.Value, ParameterDirection.Input);

// Bind another Number parameter to get the REF Cursor column value
OracleParameter outNumPrm = cmd.Parameters.Add("outNumPrm",
    OracleDbType.Int32, DBNull.Value, ParameterDirection.Output);

cmd.ExecuteNonQuery(); //Execute the stored procedure

// Display the out parameter value
Console.WriteLine("out parameter is: " + outNumPrm.Value.ToString());
}
}
```

## Implicit REF CURSOR Binding

ODP.NET enables applications to run stored procedures with REF CURSOR parameters without using explicit binding for these parameters in the .NET code. ODP.NET unmanaged and managed drivers support REF CURSOR implicit binding through configuration done in .NET configuration files.

For a read-only result set, such as a REF CURSOR using `OracleDataReader`, REF CURSOR schema information is retrieved automatically.

For some scenarios, such as when updateable REF CURSORS or Entity Framework is used, developers need to define the REF CURSOR schema information so that the application can bind the implicit REF CURSOR. Entity Framework applications use implicit REF CURSOR binding to instantiate complex types from REF CURSOR data. Applications must specify REF CURSOR bind and metadata information in the `app.config`, `web.config`, or `machine.config` .NET configuration file.

The attributes supplied in the .NET configuration file are also used when the application requests for schema information from the `OracleDataReader` object that represents a REF CURSOR. This means that for REF CURSORS that are created using a SELECT from a single table, the application can update that table through the use of `OracleDataAdapter` and `OracleCommandBuilder`.

When using the Entity Framework, function imports can return an implicitly-bound REF CURSOR. The REF CURSOR can be returned as a collection of complex types or entity types. To return a complex type collection, the .NET configuration file needs to define the REF CURSOR bind and metadata information. To return an entity type collection, only the bind information needs to be defined in the .NET configuration file.

This section contains the following topics:

- [Specifying REF CURSOR Bind and Metadata Information in the .NET Configuration File](#)
- [Sample Configuration File and Application](#)
- [Usage Considerations](#)

## Specifying REF CURSOR Bind and Metadata Information in the .NET Configuration File

Specify the REF CURSOR information in the `oracle.dataaccess.client` or in the `oracle.manageddataaccess.client` configuration section of the .NET configuration file. Use an `<add>` element for each piece of information. The `add` element uses name-value attributes to specify REF CURSOR information. Use the following format to specify bind information:

```
<add
name="SchemaName.PackageName.StoredProcedureName.RefCursor.RefCursorParameterPositionOrName"
value="implicitRefCursor bindinfo='mode=InputOutput|Output|ReturnValue'" />
```

Use the following format to specify metadata information:

```
<add
name="SchemaName.PackageName.StoredProcedureName.RefCursorMetaData.RefCursorParameterPositionOrName.Column.ColumnOrdinal"
value="implicitRefCursor metadata=AttributesList" />
```

Each REF CURSOR column needs to have an `add` element defined for it. For example, if you have a REF CURSOR returning five columns, then you need to define five `add` elements in the config file.

Each `add` element contains the name and value attributes. The value attribute must begin with the word `implicitRefCursor` followed by the `bindinfo` or `metadata` attribute for specifying bind or metadata information.

The `bindinfo` information is used by ODP.NET for binding REF CURSOR parameters. The `metadata` information is used by ODP.NET to associate the schema information with the appropriate REF CURSOR. The `metadata` comprises of an attributes list that includes parameters together with their values.

The `SchemaName`, `PackageName`, and `StoredProcedureName` are case-sensitive. In order to run a stored procedure with implicit REF CURSOR binding, the `SchemaName.PackageName.StoredProcedureName` portion of the name attribute must exactly match the name specified in the data dictionary for that stored procedure.

### Note

If the application uses implicit REF CURSOR binding feature outside of Entity Framework, then the .NET configuration file and `OracleCommand.CommandText` do not require the schema name concatenated before the stored procedure name.

If any schema, package, or stored procedure name in the database contains lowercase characters, then it must be enclosed within double quotation marks (") in the config file to preserve the case. Double quotation marks are used within the name attribute by using `&quot;`; when needed. For example, if the schema name is `HrSchema`, the package name is `HrPackage`, and the stored procedure name is `HrStoredProcedure` in the database, the config file should use the following:

```
<add
name="&quot;HrSchema&quot;;&quot;HrPackage&quot;;&quot;HrStoredProcedure&quot;;.RefCursorMetadata" />
```

By default, Oracle Database stores these names as uppercase characters. ODP.NET assumes default behavior, and converts all names to uppercase characters unless you explicitly preserve the case by using double quotation marks.

**Note**

The *SchemaName*, *PackageName*, *StoredProcedureName*, or *ParameterName* cannot contain a period (".") in the name. For example, P.0 is an unacceptable parameter name.

Depending on whether the application uses bind-by-name or bind-by-position, the *RefCursorParameterPositionOrName* portion of the name attribute must be set with the correct parameter position (for bind by position) or parameter name (for bind by name). For functions, the position is 0-based, where the position 0 represents the return value. For procedures, the position is 1-based, as there are no return values for procedures. For example, if a stored procedure accepts five parameters, returning only two REF CURSORS in the third and fifth parameter positions, then the .NET config REF CURSOR bind information should contain one entry for position 3 and one entry for position 5.

If bind-by-name is used, the attribute name is used to identify the REF CURSOR parameter. The name should use the same name and case as the one specified in the data dictionary for that stored procedure.

For *bindinfo*, the mode specifies the parameter direction of the parameter. The mode must be either *InputOutput*, *Output*, or *ReturnValue*.

**Note**

Implicit REF CURSOR binding for an input REF CURSOR parameter is not supported.

An exception is thrown at runtime if the .NET configuration file contains an entry for a REF CURSOR whose mode is set to *Input*.

For metadata, The *AttributesList* contains the list of parameters. [Table 3-26](#) describes the parameters that can be included in the *AttributesList*.

[Example 3-5](#) shows a sample add element that uses *bindinfo*. Here, the schema name is SCOTT and the stored procedure name is TESTPROC. The parameter name is parameter1. The mode is output.

[Example 3-6](#) shows a sample add element that uses metadata.

**Table 3-26 Allowed Parameters in Attributes List**

| Name       | Type          | Required/Optional<br>for Entity<br>Framework | Description             |
|------------|---------------|----------------------------------------------|-------------------------|
| ColumnName | System.String | Required                                     | The name of the column. |

**Table 3-26 (Cont.) Allowed Parameters in Attributes List**

| Name             | Type                                                                                  | Required/Optional for Entity Framework | Description                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ProviderType     | Oracle.DataAccess.Client.OracleDbType or Oracle.ManagedDataAccess.Client.OracleDbType | Required                               | The database column type (OracleDbType) of the column                                                                                                                                                     |
| NativeDataType   | System.String                                                                         | Required                               | The Oracle type. For example, NCL0B.                                                                                                                                                                      |
| BaseColumnName   | System.String                                                                         | Optional                               | The name of the column in the database if an alias is used for the column.                                                                                                                                |
| BaseSchemaName   | System.String                                                                         | Optional                               | The name of the schema in the database that contains the column.                                                                                                                                          |
| BaseTableName    | System.String                                                                         | Optional                               | The name of the table or view in the database that contains the column.                                                                                                                                   |
| ColumnSize       | System.Int64                                                                          | Optional                               | The maximum possible length of a value in the column                                                                                                                                                      |
| NumericPrecision | System.Int16                                                                          | Optional                               | The maximum precision of the column, if the column is a numeric data type.                                                                                                                                |
| NumericScale     | System.Int16                                                                          | Optional                               | The maximum scale of the column, if the column is a numeric data type.                                                                                                                                    |
| IsUnique         | System.Boolean                                                                        | Optional                               | Indicates whether or not the column is unique.                                                                                                                                                            |
| IsKey            | System.Boolean                                                                        | Optional                               | Indicates whether or not the column is a key column. For a table to be updated with the REF CURSOR information, at least one of the columns in the REF CURSOR metadata should have this value set to true |
| IsRowID          | System.Boolean                                                                        | Optional                               | true if the column is a ROWID, otherwise false.                                                                                                                                                           |
| DataType         | System.RuntimeType                                                                    | Optional                               | Maps to the common language runtime type.                                                                                                                                                                 |
| AllowDBNull      | System.Boolean                                                                        | Optional                               | true if null values are allowed, otherwise false                                                                                                                                                          |
| IsAliased        | System.Boolean                                                                        | Optional                               | true if the column is an alias; otherwise false.                                                                                                                                                          |
| IsByteSemantic   | System.Boolean                                                                        | Optional                               | IsByteSemantic is: <ul style="list-style-type: none"> <li>true if the ColumnSize value uses bytes semantics</li> <li>false if ColumnSize uses character semantics</li> </ul>                              |

**Table 3-26 (Cont.) Allowed Parameters in Attributes List**

| Name           | Type               | Required/Optional for Entity Framework | Description                                                                     |
|----------------|--------------------|----------------------------------------|---------------------------------------------------------------------------------|
| IsExpression   | System.Boolean     | Optional                               | true if the column is an expression, else false.                                |
| IsHidden       | System.Boolean     | Optional                               | true if the column is hidden, else false.                                       |
| IsReadOnly     | System.Boolean     | Optional                               | true if the column is read-only, else false                                     |
| IsLong         | System.Boolean     | Optional                               | true if the column is of LONG, LONG RAW, BLOB, CLOB, or BFILE type, else false. |
| UdtTypeName    | System.String      | Optional                               | The type name of the UDT.                                                       |
| ProviderDbType | System.Data.DbType | Optional                               | System.Data.DbType                                                              |
| ObjectName     | System.String      | Optional                               | Represents the name of the object.                                              |

Some of the attributes, listed in [Table 3-26](#), automatically have their values set using the result set's metadata. Developers can override these default values by setting a value explicitly.

You may have to explicitly define some attributes listed as optional for certain operations. For example, updateable REF CURSOR requires the developer to define key information.

#### Example 3-5 Using the add Element with bindinfo

```
<add name="SCOTT.TESTPROC.RefCursor.parameter1" value="implicitRefCursor"
  bindinfo='mode=Output' />
```

#### Example 3-6 Using the add Element with metadata

```
<add name="scott.TestProc.RefCursorMetaData.parameter1.Column.0"
  value="implicitRefCursor metadata='ColumnName=EMPNO;BaseColumnName=EMPNO;
  BaseSchemaName=SCOTT;BaseTableName=EMP;NativeDataType=number;
  ProviderType=Int32;DataType=System.Int32;ColumnSize=4;AllowDBNull=false;
  IsKey=true' />
```

## Sample Configuration File and Application

This section builds a sample application to illustrate implicit REF CURSOR binding. It contains the following topics:

- [Sample Stored Procedure and Function](#)
- [Sample Application Configuration File](#)
- [Sample Application That Uses the Configuration File](#)

#### Sample Stored Procedure and Function

```
CREATE OR REPLACE FUNCTION GETEMP (
  EMPID IN NUMBER) return sys_refcursor is
  emp sys_refcursor;
BEGIN
  OPEN emp FOR SELECT empno, ename FROM emp where empno = EMPID;
```

```

        return emp;
    END;
/

CREATE OR REPLACE PROCEDURE "GetEmpAndDept" (
    EMPS OUT sys_refcursor,
    DEPTS OUT sys_refcursor) AS
BEGIN
    OPEN EMPS for SELECT empno, ename from emp;
    OPEN DEPTS for SELECT deptno, dname from dept;
END;
/

```

### Sample Application Configuration File

```

<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <oracle.dataaccess.client>
    <settings>

      <!-- The following is for SCOTT.GETEMP -->
      <add name="SCOTT.GETEMP.RefCursor.0"
        value="implicitRefCursor bindinfo='mode=ReturnValue'" />

      <!-- The following is for SCOTT.GETEMP's REF CURSOR metadata -->
      <add name="SCOTT.GETEMP.RefCursorMetaData.0.Column.0"
        value="implicitRefCursor metadata='ColumnName=EMPNO;
        BaseColumnName=EMPNO;BaseSchemaName=SCOTT;BaseTableName=EMP;
        NativeDataType=number;ProviderType=Int32;ProviderDBType=Int32;
        DataType=System.Int32;ColumnSize=4;NumericPrecision=10;
        NumericScale=3;AllowDBNull=false;IsKey=true'" />

      <add name="SCOTT.GETEMP.RefCursorMetaData.0.Column.1"
        value="implicitRefCursor metadata='ColumnName=ENAME;
        BaseColumnName=ENAME;BaseSchemaName=SCOTT;BaseTableName=EMP;
        NativeDataType=varchar2;ProviderType=Varchar2;
        ProviderDBType=String;DataType=System.String;
        ColumnSize=10;AllowDBNull=true'" />

      <!-- The following is for "SCOTT"."GetEmpAndDept" -->
      <add name="SCOTT."GetEmpAndDept".RefCursor.EMPS"
        value="implicitRefCursor bindinfo='mode=Output'" />

      <!-- The following is for SCOTT.GETEMP's EMPS REF CURSOR metadata -->
      <add name="SCOTT."GetEmpAndDept".RefCursorMetaData.EMPS.Column.0"
        value="implicitRefCursor metadata='ColumnName=EMPNO;
        BaseColumnName=EMPNO;BaseSchemaName=SCOTT;BaseTableName=EMP;
        NativeDataType=number;ProviderType=Int32;ProviderDBType=Int32;
        DataType=System.Int32;ColumnSize=4;NumericPrecision=10;
        NumericScale=3;AllowDBNull=false;IsKey=true'" />

      <add name="SCOTT."GetEmpAndDept".RefCursorMetaData.EMPS.Column.1"
        value="implicitRefCursor metadata='ColumnName=ENAME;
        BaseColumnName=ENAME;BaseSchemaName=SCOTT;BaseTableName=EMP;
        NativeDataType=varchar2;ProviderType=Varchar2;
        ProviderDBType=String;DataType=System.String;
        ColumnSize=10;AllowDBNull=true'" />

      <!-- The following is for SCOTT.GETEMP's DEPTS REF CURSOR metadata -->
      <add name="SCOTT."GetEmpAndDept".RefCursor.DEPTS"

```

```

        value="implicitRefCursor bindinfo='mode=Output'" />

<add name="SCOTT."GetEmpAndDept"
      .RefCursorMetaData.DEPTS.Column.0"
      value="implicitRefCursor metadata='ColumnName=DEPTNO;
      BaseColumnName=DEPTNO;BaseSchemaName=SCOTT;BaseTableName=DEPT;
      NativeDataType=number;ProviderType=Int32;ProviderDbType=Int32;
      DataType=System.Int32;ColumnSize=4;NumericPrecision=10;
      NumericScale=3;AllowDBNull=false;IsKey=true'" />

<add name="SCOTT."GetEmpAndDept"
      .RefCursorMetaData.DEPTS.Column.1"
      value="implicitRefCursor metadata='ColumnName=DNAME;
      BaseColumnName=DNAME;BaseSchemaName=SCOTT;BaseTableName=DEPT;
      NativeDataType=varchar2;ProviderType=Varchar2;
      ProviderDbType=String;DataType=System.String;
      ColumnSize=10;AllowDBNull=true'" />
</settings>
</oracle.dataaccess.client>
</configuration>

```

### Sample Application That Uses the Configuration File

```

using System;
using System.Data;
using Oracle.DataAccess.Client;

class Program
{
    static void Main(string[] args)
    {
        try
        {
            // Open a connection
            string constr =
                "User Id=scott;Password=tiger;Data Source=inst1";
            OracleConnection con = new OracleConnection(constr);
            con.Open();

            // Use implicit REF CURSOR binding
            // to execute SCOTT.GETEMP function
            // Use bind by position as configured
            // in app.config for SCOTT.GETEMP
            OracleCommand cmd = con.CreateCommand();
            cmd.CommandText = "SCOTT.GETEMP";
            cmd.CommandType = CommandType.StoredProcedure;
            cmd.BindByName = false;
            OracleParameter empid = cmd.Parameters.Add("empid",
                OracleDbType.Int32, ParameterDirection.Input);
            empid.Value = 7654;

            // Populate the DataSet
            OracleDataAdapter adapter = new OracleDataAdapter(cmd);
            DataSet ds = new DataSet();
            adapter.Fill(ds);
            Console.WriteLine("Retrieved {0} row from EMP",
                ds.Tables[0].Rows.Count);

            // Use implicit REF CURSOR binding
            // to execute "SCOTT"."GetEmpAndDept" procedure
            // Use bind by name as configured
            // in app.config for "SCOTT"."GetEmpAndDept"

```

```

        cmd = con.CreateCommand();
        cmd.CommandText = @"\SCOTT\." + GetEmpAndDept + "";
        cmd.CommandType = CommandType.StoredProcedure;
        cmd.BindByName = true;
        adapter = new OracleDataAdapter(cmd);
        adapter.Fill(ds);
        Console.WriteLine("Retrieved {0} rows from DEPT",
            ds.Tables[1].Rows.Count);
    }
    catch (Exception ex)
    {
        // Output the message
        Console.WriteLine(ex.Message);
        if (ex.InnerException != null)
        {
            // If any details are available regarding
            // errors in the app.config, print them out
            Console.WriteLine(ex.InnerException.Message);
            if (ex.InnerException.InnerException != null)
            {
                Console.WriteLine(
                    ex.InnerException.InnerException.Message);
            }
        }
    }
}
}
}

```

## Usage Considerations

This section discusses the following usage considerations when using implicit REF CURSOR:

- [CommandText Property Considerations](#)
- [Bind Considerations](#)
- [Overloaded Stored Procedures](#)
- [Type Initialization Exceptions](#)
- [Using Stored Functions with Function Import](#)

## CommandText Property Considerations

ODP.NET applications should ensure that the stored procedure name and the `OracleCommand.CommandText` match exactly. Let's take a scenario where the stored procedure name in the database is `SCOTT.TESTPROC`. Now, if the `CommandText` uses `TESTPROC`, ODP.NET will look for entries matching `TESTPROC` only. The current schema name will not be automatically appended to `TESTPROC`. So, the correct `CommandText` to use in this scenario would be `SCOTT.TESTPROC`.

Also, the `CommandText` is case-sensitive and must use the same case as the stored procedure name in the database. So if the stored procedure name in the database is `SCOTT.Testproc`, then the `CommandText` must use `SCOTT.Testproc`.

## Bind Considerations

If information about a REF CURSOR parameter has been added to the configuration file, then applications should not try to explicitly bind the REF CURSOR parameter to `OracleCommand`. ODP.NET automatically binds the REF CURSOR parameter at the appropriate locations based on the information provided in the configuration file. If the application stored procedure also has

non-REF CURSOR parameters, then these parameters must still be explicitly bound to `OracleCommand`.

If the information specified in the configuration file for a stored procedure identifies the REF CURSOR parameter by name, then all the other non-REF CURSOR parameters should also be bound by name. Also the `BindByName` property for the `OracleCommand` object should be set to `true` in this case. Entity Framework always uses `BindByName` to run stored procedures. Your .NET configuration file parameter names must use the same case that was used when creating the stored procedure in the database.

If the `OracleCommand.BindByName` property is set to `false` (default), then ODP.NET assumes that the parameters have been bound based on their position, and all parameters have been specified in the correct order. For such cases, the parameters specified in the configuration file are bound in the same order in which they appear in the configuration file.

## Overloaded Stored Procedures

ODP.NET does not support multiple stored procedures with the same name inside the configuration file. If an ODP.NET application uses an overloaded stored procedure, the application can store only one overloaded stored procedure information in the configuration file.

## Type Initialization Exceptions

Type initialization exceptions can be caused by invalid .NET configuration file entries. Evaluate the exception that is caught as well as its inner exceptions to determine the .NET configuration file entry or the attribute setting that is causing the exception.

ODP.NET tracing logs the valid and invalid .NET configuration file entries that ODP.NET has parsed. To look for .NET configuration file related entries, set the `TraceLevel` to the *Entry, exit, and SQL statement information* level setting. Trace entries related to implicit REF CURSOR binding have a (REFCURSOR) entry along with (ERROR), if any errors are encountered.

## Using Stored Functions with Function Import

Function Import only supports stored procedures, and does not support functions. When using the **Add Function Import** dialog for the Entity Data Model that you have created, the **Get Column Information** button does not return the metadata information for the REF CURSOR that is being returned by a stored function, even if it is configured properly in the .NET configuration file.

# LOB Support

ODP.NET provides an easy and optimal way to access and manipulate large object (LOB) data types.

### Note

SecureFiles can be used with existing ODP.NET LOB classes.

This section includes the following topics:

- [Large Character and Large Binary Data Types](#)

- [Oracle Data Provider for .NET LOB Objects](#)
- [Updating LOBs Using a DataSet](#)
- [Updating LOBs Using OracleCommand and OracleParameter](#)
- [Updating LOBs Using ODP.NET LOB Objects](#)
- [Temporary LOBs](#)

## Large Character and Large Binary Data Types

Oracle Database supports large character and large binary data types.

### Large Character Data Types

- CLOB - Character data can store up to 4 gigabytes.
- NCLOB - Unicode National character set data can store up to 4 gigabytes.

### Large Binary Data Types

- BLOB - Unstructured binary data can store up to 4 gigabytes.
- BFILE - Binary data stored in external file can store up to 4 gigabytes.

#### Note

LONG and LONG RAW data types are made available for backward compatibility in Oracle9i, but should not be used in new applications.

## Oracle Data Provider for .NET LOB Objects

ODP.NET provides three objects for manipulating LOB data: `OracleBFile`, `OracleBlob`, and `OracleClob`.

[Table 3-27](#) shows the proper ODP.NET object to use for a particular Oracle LOB type.

**Table 3-27 ODP.NET LOB Objects**

| Oracle LOB Type | ODP.NET LOB Object       |
|-----------------|--------------------------|
| BFILE           | <code>OracleBFile</code> |
| BLOB            | <code>OracleBlob</code>  |
| CLOB            | <code>OracleClob</code>  |
| NCLOB           | <code>OracleClob</code>  |

The ODP.NET LOB objects can be obtained by calling the proper typed accessor on the `OracleDataReader` object, or by calling the proper typed accessor as an output parameter on a command execution with the proper bind type.

All ODP.NET LOB objects inherit from the .NET `Stream` class to provide generic `Stream` operations. The LOB data (except for BFILE types) can be updated using the ODP.NET LOB objects by using methods such as `Write`. Data is not cached in the LOB objects when read and write operations are carried out. Therefore, each read or write request incurs a database round-trip. The `OracleClob` object overloads the `Read` method, providing two ways to read data

from a CLOB. The Read method that takes a byte[] as the buffer populates it with CLOB data as Unicode byte array. The Read method that takes a char[] as the buffer populates it with Unicode characters.

Additional methods can also be found on the OracleBFile object. An OracleBFile object must be explicitly opened using the OpenFile method before any data can be read from it. To close a previously opened BFILE, use the CloseFile method.

Every ODP.NET LOB object is a connected object and requires a connection during its lifetime. If the connection associated with a LOB object is closed, then the LOB object is not usable and should be disposed of.

If an ODP.NET LOB object is obtained from an OracleDataReader object through a typed accessor, then its Connection property is set with a reference to the same OracleConnection object used by the OracleDataReader object. If a LOB object is obtained as an output parameter, then its Connection property is set with a reference to the same OracleConnection property used by the OracleCommand object. If a LOB object is obtained by invoking an ODP.NET LOB object constructor to create a temporary LOB, the Connection property is set with a reference to the OracleConnection object provided in the constructor.

The ODP.NET LOB object Connection property is read-only and cannot be changed during its lifetime. In addition, the ODP.NET LOB types object can be used only within the context of the same OracleConnection referenced by the ODP.NET LOB object. For example, the ODP.NET LOB Connection property must reference the same connection as the OracleCommand object if the ODP.NET LOB object is a parameter of the OracleCommand. If that is not the case, ODP.NET raises an exception when the command is executed.

## Updating LOBs Using a DataSet

BFILE and BLOB data are stored in the DataSet as byte arrays while CLOB and NCLOB data are stored as strings. In a similar manner to other types, an OracleDataAdapter object can be used to fill and update LOB data changes along with the use of the OracleCommandBuilder object for automatically generating SQL.

Note that an Oracle LOB column can store up to 4 GB of data. When the LOB data is fetched into the DataSet, the actual amount of LOB data the DataSet can hold for a LOB column is limited to the maximum size of a .NET string type, which is 2 GB. Therefore, when fetching LOB data that is greater than 2 GB, ODP.NET LOB objects must be used to avoid any data loss.

## Updating LOBs Using OracleCommand and OracleParameter

To update LOB columns, LOB data can be bound as a parameter for SQL statements, anonymous PL/SQL blocks, or stored procedures. The parameter value can be set as a .NET Framework type, ODP.NET type, or as an ODP.NET LOB object type. For example, when inserting .NET string data into a LOB column in an Oracle9i database or later, that parameter can be bound as OracleDbType.VarChar2. For a parameter whose value is set to an OracleClob object, the parameter should be bound as OracleDbType.Clob.

## Updating LOBs Using ODP.NET LOB Objects

Oracle BFILEs cannot be updated; therefore, `OracleBFile` objects do not allow updates to BFILE columns.

Two requirements must be met to update LOB data using ODP.NET LOB objects:

1. A transaction must be started before a LOB column is selected.

The transaction must be started using the `BeginTransaction` method on the `OracleConnection` object before the command execution, so that the lock can be released when the `OracleTransaction Commit` or `Rollback` method is invoked.

2. The row in which the LOB column resides must be locked; as part of an entire result set, or on a row-by-row basis.

- a. Locking the entire result set

Add the `FOR UPDATE` clause to the end of the `SELECT` statement. After execution of the command, the entire result set is locked.

- b. Locking the row - there are two options:

- Invoke one of the `OracleDataReader` typed accessors (`GetOracleClobForUpdate` or `GetOracleBlobForUpdate`) on the `OracleDataReader` object to obtain an ODP.NET LOB object, while also locking the current row.

This approach requires a primary key, unique column(s), or a `ROWID` in the result set because the `OracleDataReader` object must uniquely identify the row to re-select it for locking.

- Execute an `INSERT` or an `UPDATE` statement that returns a LOB in the `RETURNING` clause.

## Temporary LOBs

Temporary LOBs can be instantiated for `BLOB`, `CLOB`, and `NCLOB` objects. To instantiate an ODP.NET LOB object that represents a temporary LOB, the `OracleClob` or the `OracleBlob` constructor can be used.

Temporary ODP.NET LOB objects can be used for the following purposes:

- To initialize and populate a LOB column with empty or non-empty LOB data.
- To pass a LOB type as an input parameter to a SQL statement, an anonymous PL/SQL block, or a stored procedure.
- To act as the source or the destination of data transfer between two LOB objects as in the `CopyTo` operation.

### Note

Temporary LOBs are not transaction aware. Commit and rollback operations do not affect the data referenced by a temporary LOB.

## Native JSON Support

Oracle Database 21c adds a native JavaScript Object Notation (JSON) data type. ODP.NET Core, managed, and unmanaged drivers support this native JSON data type starting with version 21.

In ODP.NET, the database JSON data type can be retrieved or passed to the database. When using a .NET string or `OracleString`, it can be bound as a parameter using the `OracleDbType.Json` enumeration value. This enumeration value directs ODP.NET to perform decoding from and encoding to the native Oracle Database JSON binary format, OSON, on the client side, offloading the task from the server side.

Alternatively, JSON data can be bound as parameters to other ODP.NET and .NET data types or not use the `OracleDbType.Json` enumeration value. Oracle Database will then implicitly encode to and decode from OSON to the desired data type format instead of the client in these cases. In `DataSet`, the Oracle JSON type is converted to and stored as either a .NET string or `OracleString`.

Managed ODP.NET and ODP.NET Core JSON features require the `System.Text.Json` assembly be included as a project dependency. ODP.NET does not add the `System.Text.Json` package as a dependency itself. In many cases, .NET Core 3.1 and higher does automatically include this assembly with the .NET runtime, while .NET Framework 4.8 does not.

Unmanaged ODP.NET does not have a requirement for `System.Text.Json`.

### JSON Numeric Values

For managed ODP.NET and ODP.NET Core, JSON documents bound as `OracleDbType.Json` input parameters have a 28 precision upper limit for numeric values. In all other cases, up to 38 precision will be retained for JSON numeric values when sent to or retrieved from the database.

Unmanaged ODP.NET supports JSON numeric values with a maximum precision of 38, as does the database.

If a JSON document bound as `OracleDbType.Json` contains numeric values with higher precision than can be retained, then ODP.NET will round the value to the maximum supported precision. If more precision must be retained than the maximum, then store the numeric value as a string by placing double quotes around the JSON value before binding the JSON document as an input parameter.

### JSON Relational Duality

JSON Relational Duality is a landmark capability introduced in Oracle Database that provides game-changing flexibility and simplicity for Oracle Database developers. This breakthrough innovation overcomes the historical challenges that developers faced when building applications, either when using the relational model or when using the document model.

JSON Relational Duality delivers a solution with the benefits of both relational tables and JSON documents, without the tradeoffs of either model.

In the database, JSON Relational Duality manifests as fully updatable JSON views over relational data. These views are called JSON Relational Duality Views.

**① See Also**

To learn more about the feature, refer to the Oracle Database JSON-Relational Duality Developer's Guide

**ODP.NET and JSON Relational Duality Views**

All ODP.NET provider types (core, managed, and unmanaged) support using JSON Relational Duality Views. ODP.NET supports the feature starting with release 19c.

With 21c and higher, ODP.NET can retrieve this JSON data as a .NET string or `OracleString` data type when parameters are bound with the `OracleDbType.Json` enumeration value.

ODP.NET 19c uses an earlier implementation that does not include this enumeration value. It fetches JSON data as a `BLOB` data type, then converts it to a string in .NET. With JSON Relational Duality, ODP.NET retrieves the data with `OracleDataReader.GetValue(s)` or `GetOracleValue(s)` methods, but not `GetString` nor `GetOracleString`.

For the ODP.NET developer, the data type conversion and changes are transparent. No .NET data management needs to occur beyond treating the data as a string consisting of JSON in .NET.

Oracle JSON data can also be consumed and operated in .NET `DataSet`. When saving changes back to the Oracle Database from `DataSet`, the default generated `OracleCommandBuilder` insert operations will successfully complete. However, the default updates and deletes require some custom SQL with parameter binds to make these JSON data changes. Here's a code snippet of how to perform these JSON updates and deletes.

```
// "JRDVIEW" is the JSON Relational Duality View being updated in the example below
// Custom UPDATE SQL
string customUpdateSQL = @"UPDATE JRDVIEW SET data = :updatedJSON where json_value(data,
'$.ID.number()') = json_value(:DBData, '$.ID.number()')";
adapter.UpdateCommand = new OracleCommand(customUpdateSQL, conn);
// Parameter bound to the updated data
adapter.UpdateCommand.Parameters.Add("updatedJSON", OracleDbType.Json, 100, "data");
// Parameter bound to row on DB
adapter.UpdateCommand.Parameters.Add("DBData", OracleDbType.Varchar2, 100,
"data").SourceVersion = DataRowVersion.Original;

// Custom DELETE SQL
string customDeleteSQL = @"DELETE FROM JRDVIEW WHERE json_value(data, '$.ID.number()') =
json_value(:DBData, '$.ID.number()')";
adapter.DeleteCommand = new OracleCommand(customDeleteSQL, conn);
// Parameter bound to row on DB
adapter.DeleteCommand.Parameters.Add("DBData", OracleDbType.Varchar2, 100,
"data").SourceVersion = DataRowVersion.Original;

adapter.Update(ds);
```

In the sample code above, the ID field is a numeric type. We can specify it is a number by appending `.number()` to it in the SQL. Doing so is optional. However, the main benefit it provides is it allows the query to leverage indexes on the base tables, thereby improving execution performance. Other data types can be specified:

- `.string()` for string data types
- `.date()` for date data type

- `.timestamp()` for timestamp data type

#### Note

When modifying the `DataSet`, do not change the `_metadata` member nor any of its constituent parts. That metadata is used to protect against dirty writes back to the database.

## Artificial Intelligence Vectors and Semantic Search

Oracle AI Database 26ai introduces semantic search capabilities using Artificial Intelligence (AI) vector search. These capabilities include a new vector data type, vector indexes, and vector search SQL operators that allow the database to store semantic document content, images, and other unstructured data as vectors and then run fast performing similarity queries. The key innovation is that the database better understands user intent and the search context to find similar matches, rather than only find exact matches.

Building upon this capability, the Oracle database can use Generative AI constructs, such as Retrieval Augmented Generation (RAG) to combine large language models (LLMs) and private business data to respond to natural language questions. RAG provides higher accuracy and avoids exposing any of the private data to the LLM training data.

### Oracle Database Vector Data Types

There are two Oracle database vector types: dense and sparse. Dense vectors were the first AI vector type Oracle introduced in Oracle AI Database 26ai. They are ideal for data sets in which nearly every dimension stores a non-zero value, meaning they hold much rich and complex information, patterns, and relationships. A great use case for dense vectors is semantic search when word meaning nuances better identify matches.

On the other hand, sparse vectors typically have a large number of dimensions and few non-zero dimension values. To improve efficiency, they only store non-zero values. That makes sparse vectors more storage and memory efficient. Moreover, ODP.NET can process them faster than dense vectors assuming the data profile has few non-zero dimension values. They are suited for other AI application types, such as text retrieval systems in which a search phrase identifies relevant matching documents.

### ODP.NET Vectors

Starting with version 23.3.2, managed ODP.NET and ODP.NET Core support Oracle database vector data access as existing .NET or ODP.NET data types: arrays, strings, CLOBs, and VARCHAR2s. In managed ODP.NET and ODP.NET Core 23.8, new ODP.NET vector-specific types for dense vectors (`OracleVector`) and sparse vectors (`OracleSparseVector`) are introduced for richer user interfaces that more naturally and easily operate on vectors.

ODP.NET vector data types are flexible to use. They have one or more dimensions, up to 65,536 (64K) dimensions. Developers can define vectors with a fixed or variable number of dimensions. The numeric format of each dimension in a vector can be of the same numeric format or a different numeric format for each dimension:

**Table 3-28 Dense Vector Numeric Formats**

| Vector Numeric Format | Description                                             | Mapped .NET Type | Mapped ODP.NET Type | Size    | Examples                                                 |
|-----------------------|---------------------------------------------------------|------------------|---------------------|---------|----------------------------------------------------------|
| BINARY                | packed UINT8 bytes where each dimension is a single bit | Byte             | OracleVector        | 1 byte  | Vector(1024, BINARY),<br>Vector(1024, BINARY, DENSE)     |
| INT8                  | 8-bit integers                                          | Int16            | OracleVector        | 2 bytes | Vector(4, INT8),<br>Vector(4, INT8, DENSE)               |
| FLOAT32               | 32-bit floating point                                   | Float            | OracleVector        | 4 bytes | Vector(768, FLOAT32),<br>Vector(768, FLOAT32, DENSE)     |
| FLOAT64               | 64-bit floating point                                   | Double           | OracleVector        | 8 bytes | Vector(10000, FLOAT64),<br>Vector(10000, FLOAT64, DENSE) |

For example, a one dimension INT8 vector would be Vector(1, INT8). A four dimension FLOAT32 vector would be Vector(4, FLOAT32). A variable dimension FLOAT64 vector would be Vector(\*, FLOAT64).

To specify that each vector dimension can be either an INT8, FLOAT32, or FLOAT64 data type, use the \* notation, such as Vector(4, \*) to represent a four dimensional vector. You may specify a vector as Vector(\*, \*) to have a variable number of dimensions and variable data type vector.

**Table 3-29 Sparse Vector Numeric Formats**

| Vector Numeric Format | Description                                             | Mapped .NET Type | Mapped ODP.NET Type | Size    | Example                        |
|-----------------------|---------------------------------------------------------|------------------|---------------------|---------|--------------------------------|
| BINARY                | packed UINT8 bytes where each dimension is a single bit | Byte             | OracleSparse Vector | 1 byte  | Vector(16, BINARY, SPARSE)     |
| INT8                  | 8-bit integers                                          | Int16            | OracleSparse Vector | 2 bytes | Vector(4, INT8, SPARSE)        |
| FLOAT32               | 32-bit integers                                         | Float            | OracleSparse Vector | 4 bytes | Vector(768, FLOAT32, SPARSE)   |
| FLOAT64               | 64-bit integers                                         | Double           | OracleSparse Vector | 8 bytes | Vector(10000, FLOAT64, SPARSE) |

ODP.NET `OracleVector` (dense) and `OracleSparseVector` (sparse) both can use all four numeric formats.

ODP.NET can retrieve the database vector data type in .NET as any of the following:

| Data Type          | ODP.NET or .NET Data Type | Description                                                                                                                             |
|--------------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| .NET numeric array | .NET                      | This array type can be <code>Int16[]</code> , <code>float[]</code> , or <code>double[]</code> depending on the vector's numeric format. |
| .NET byte array    | .NET                      | Oracle <code>BINARY</code> numeric format must be retrieved as a .NET byte array.                                                       |

**Note**

InvalidCastException is thrown for any `Get*Array()` methods, except `GetByteArray()` method, for `BINARY` format.

|                           |         |                                                                                                        |
|---------------------------|---------|--------------------------------------------------------------------------------------------------------|
| .NET string               | .NET    | This contains the vector representation in JSON format.                                                |
| <code>OracleString</code> | ODP.NET | This contains the vector representation in JSON format.                                                |
| <code>OracleClob</code>   | ODP.NET | This contains the vector representation in JSON format.                                                |
| <code>OracleVector</code> | ODP.NET | ODP.NET native dense vector data type. This is the base type for all ODP.NET native vector data types. |

| Data Type          | ODP.NET or .NET Data Type | Description                             |
|--------------------|---------------------------|-----------------------------------------|
| OracleSparseVector | ODP.NET                   | ODP.NET native sparse vector data type. |

ODP.NET can bind vector data as the following .NET types for SQL or stored procedure execution:

| Data Type                           | .NET or ODP.NET Data Type | Bind Type                                                                                                                                                           | Description                                                                                                                                                                                                                     |
|-------------------------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OracleVector,<br>OracleSparseVector | ODP.NET                   | OracleDbType.Vector                                                                                                                                                 | ODP.NET native vector data types. ODP.NET will bind the Vector data type as the OracleVector's ProviderType.                                                                                                                    |
| OracleVector,<br>OracleSparseVector | ODP.NET                   | OracleDbType.Vector<br>_Binary,<br>OracleDbType.Vector<br>_Int8,<br>OracleDbType.Vector<br>_Float32,<br>OracleDbType.Vector<br>_Float64                             | ODP.NET native vector data types. ODP.NET will bind the Vector data type based on the binding type accordingly.                                                                                                                 |
| Any numeric array                   | .NET                      | OracleDbType.Vector                                                                                                                                                 | This array type can be any numeric array type. ODP.NET will infer the numeric array type and bind the Vector data type as OracleDbType.Vector _Int8, OracleDbType.Vector _Float32, or OracleDbType.Vector _Float64 accordingly. |
| Any numeric array                   | .NET                      | OracleDbType.Vector<br>_Int8,<br>OracleDbType.Vector<br>_Float32,<br>OracleDbType.Vector<br>_Float64                                                                | This array type can be any numeric array type. ODP.NET will bind the Vector data type based on the binding type accordingly.                                                                                                    |
| .NET byte array                     | .NET                      | OracleDbType.Vector<br>,<br>OracleDbType.Vector<br>_Binary,<br>OracleDbType.Vector<br>_Int8,<br>OracleDbType.Vector<br>_Float32,<br>OracleDbType.Vector<br>_Float64 | All vector numeric formats can be bound as .NET byte arrays. BINARY vectors can only be bound as .NET byte arrays.                                                                                                              |

| Data Type                 | .NET or ODP.NET Data Type | Bind Type                                                                                                              | Description                                                                                                                                                                                                                                                             |
|---------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .NET string, OracleString | .NET or ODP.NET           | OracleDbType.Vector                                                                                                    | This contains the vector representation in JSON format. If the vector string is in BINARY sparse vector format, ODP.NET will bind the vector data type as OracleDbType.Vector_Binary; otherwise, ODP.NET will bind the vector data type as OracleDbType.Vector_Float32. |
| .NET string, OracleString | .NET or ODP.NET           | OracleDbType.Vector_Binary<br>OracleDbType.Vector_Int8,<br>OracleDbType.Vector_Float32,<br>OracleDbType.Vector_Float64 | This contains the vector representation in JSON format. ODP.NET will bind the Vector data type based on the binding type accordingly.                                                                                                                                   |
| OracleClob                | ODP.NET                   | OracleDbType.Clob<br>OracleDbType.VarChar2                                                                             | This contains the vector representation in JSON format.                                                                                                                                                                                                                 |

When using vectors with `OracleDataAdapter.ReturnProviderSpecificTypes` set to `false`, for dense VECTORS, a .NET numeric array will populate the `DataTable` or `DataSet` after the `Fill` method is called; and for sparse VECTORS, a .NET string representing the sparse vector will be used. When `true`, `OracleVector` or `OracleSparseVector` will be used.

For dense VECTOR columns of '\*' numeric format and `ReturnProviderSpecificTypes` set to `false`, a mix of `short[]`, `float[]`, `double[]`, and/or `byte[]` will be populated based on the VECTOR's numeric format upon an `OracleDataAdapter.Fill()`. For dense VECTOR columns of all other formats, `short[]`, `float[]`, `double[]`, or `byte[]` will be populated based on the VECTOR column's numeric format.

Since vectors cannot be compared directly with each other, they cannot be used as JOIN keys, ORDER BY keys, GROUP BY keys, or other related scenarios. Thus, for `OracleCommandBuilder`, vector comparison is not included in the SQL WHERE clause of the generated commands.

### Vectors as CLOB or VARCHAR2 Data Type

Unmanaged ODP.NET, as well as managed ODP.NET and ODP.NET Core prior to version 23.3.2, support vectors using existing CLOB or VARCHAR2 data types. In these cases, vectors are stored with a JSON format. Data retrieval and manipulation use existing CLOB or VARCHAR2 or .NET APIs.

In later managed ODP.NET and ODP.NET Core versions, vectors can remain stored as CLOBs or VARCHAR2s for backwards compatibility purposes by setting the `OracleConfiguration.MapVectorColumnAsClob` property to `true`.

When sparse vectors are sent to ODP.NET versions that do not support sparse vectors natively, the vector data becomes CLOB data in JSON dense vector format.

### ODP.NET Vector Sample Code

//This ODP.NET artificial intelligence (AI) vector sample demonstrates how to insert, retrieve, update, and delete multi-dimensional FLOAT64, FLOAT32, and INT8 vector data types using the Oracle database.

//Requires ODP.NET 23ai (23.3.2) or higher and Oracle AI Database 26ai (23.4) or higher.

//Add User Id, Password, and Data Source, such as Easy Connect Plus or TNS, to the connection string to connect to the DB.

```
using Oracle.ManagedDataAccess.Client;
```

```
namespace VectorDemo
```

```
{
```

```
    public class VectorDemo
```

```
    {
```

```
        //Provide User Id, Password, and Data Source values for your database.
```

```
        public const string conStr = "User Id=<USER>;Password=<PASSWORD>;Data Source=<DATA SOURCE>;";
```

```
        public const int id = 1;
```

```
        public static void Main(string[] args)
```

```
        {
```

```
            using (OracleConnection con = new OracleConnection(conStr))
```

```
            {
```

```
                using (OracleCommand cmd = con.CreateCommand())
```

```
                {
```

```
                    try
```

```
                    {
```

```
                        con.Open();
```

```
                        cmd.CommandText = "begin " +
```

```
                            "execute immediate 'drop table VectorTable';" +
```

```
                            "exception when others then if sqlcode <> -942
```

```
then raise;" +
```

```
                            "end if;" +
```

```
                            "end;";
```

```
                        cmd.ExecuteNonQuery();
```

```
                            //Create table with 2 dimensional FLOAT64, 3
```

```
dimensional FLOAT32, and 4 dimensional INT8 vector columns
```

```
                            cmd.CommandText = "create table VectorTable (id
```

```
number, float64s vector(2, float64),
```

```
float32s vector(3, float32), int8s vector(4, INT8), constraint pk primary key
```

```
(id));"
```

```
                            cmd.ExecuteNonQuery();
```

```
                            //Insert vector row into DB
```

```
                            InsertVectors();
```

```

        //Update vector values in DB
        UpdateVectors();

        //Delete vector values in DB
        DeleteVectors();
    }
    catch (Exception ex)
    {

### .NET Vectors and Semantic Kernel

ODP.NET Core and managed ODP.NET support .NET vectors and Microsoft Semantic Kernel to build AI and vector-powered Oracle Database applications. Oracle.VectorData NuGet package provides these capabilities.

Refer to the following documentation resources describing the features and APIs:

- [Using the Oracle Database Vector Store connector \(Preview\)](#)
- [Oracle Database Vector Store Connector for Semantic Kernel Classes](#)

## ODP.NET XML Support

ODP.NET allows the extraction of data from relational and object-relational tables and views as XML documents. The use of XML documents for insert, update, and delete operations to the database is also allowed. Oracle Database supports XML natively in the database, through Oracle XML DB, a distinct group of technologies related to high-performance XML storage and retrieval. Oracle XML DB is an evolution of the database that encompasses both SQL and XML data models in a highly interoperable manner, providing native XML support.

ODP.NET, Managed Driver follows XPath 1.0 specification and hence it does not support default XML namespaces. XML namespaces must be explicitly added to search or update nodes. This behavior differs from ODP.NET, Unmanaged Driver.

For samples related to ODP.NET XML support in ODAC installations done using Oracle Universal Installer, see the following directory:

`ORACLE_BASE\ORACLE_HOME\ODACsamples`

This section includes these topics:

- [Supported XML Features](#)
- [OracleXmlType and Connection Dependency](#)
- [Updating XMLType Data in the Database](#)
- [Updating XML Data in OracleXmlType](#)
- [Characters with Special Meaning in XML](#)
- [Retrieving Query Result Set as XML](#)
- [Data Manipulation Using XML](#)

## Supported XML Features

XML support in ODP.NET provides the ability to do the following:

- Store XML data natively in the database as the Oracle database native type, `XMLType`.
- Access relational and object-relational data as XML data from an Oracle Database instance into the Microsoft .NET environment, and process the XML using the Microsoft .NET Framework.
- Save changes to the database using XML data.
- Execute XQuery statements.

For the .NET application developer, these features include the following:

- Enhancements to the `OracleCommand`, `OracleConnection`, and `OracleDataReader` classes.
- The following XML-specific classes:
  - `OracleXmlType`  
`OracleXmlType` objects are used to retrieve Oracle native `XMLType` data.
  - `OracleXmlStream`  
`OracleXmlStream` objects are used to retrieve XML data from `OracleXmlType` objects as a read-only .NET Stream object.
  - `OracleXmlQueryProperties`  
`OracleXmlQueryProperties` objects represent the XML properties used by the `OracleCommand` class when the `XmlCommandType` property is `Query`.
  - `OracleXmlSaveProperties`  
`OracleXmlSaveProperties` objects represent the XML properties used by the `OracleCommand` class when the `XmlCommandType` property is `Insert`, `Update`, or `Delete`.

## XQuery Support

ODP.NET supports the XQuery language through a native implementation of SQL/XML functions, `XMLQuery` and `XMLTable`. When executing XQuery statements, Oracle XML DB generally evaluates XQuery expressions by compiling them into the same underlying structures as relational queries. Queries are optimized, leveraging both relational-database

and XQuery-specific optimization technologies, so that Oracle XML DB serves as a native XQuery engine. The treatment of all XQuery expressions, whether natively compiled or evaluated functionally, is transparent: programmers do not need to change their code to take advantage of XQuery optimizations.

## OracleXmlType and Connection Dependency

The read-only `Connection` property of the `OracleXmlType` class holds a reference to the `OracleConnection` object used to instantiate the `OracleXmlType` class.

How the `OracleXmlType` object obtains a reference to an `OracleConnection` object depends on how the `OracleXmlType` class is instantiated:

- Instantiated from an `OracleDataReader` class using the `GetOracleXmlType`, `GetOracleValue`, or `GetOracleValues` method:  
The `Connection` property is set with a reference to the same `OracleConnection` object used by the `OracleDataReader` object.
- Instantiated by invoking an `OracleXmlType` constructor with one of the parameters of type `OracleConnection`:  
The `Connection` property is set with a reference to the same `OracleConnection` object provided in the constructor.
- Instantiated by invoking an `OracleXmlType(OracleClob)` constructor:  
The `Connection` property is set with a reference to the `OracleConnection` object used by the `OracleClob` object.

An `OracleXmlType` object that is associated with one connection cannot be used with a different connection. For example, if an `OracleXmlType` object is obtained using `OracleConnection A`, that `OracleXmlType` object cannot be used as an input parameter of a command that uses `OracleConnection B`. By checking the `Connection` property of the `OracleXmlType` objects, the application can ensure that `OracleXmlType` objects are used only within the context of the `OracleConnection` referenced by its connection property. Otherwise, ODP.NET raises an exception.

## Updating XMLType Data in the Database

Updating XMLType columns does not require a transaction. However, encapsulating the entire database update process within a transaction is highly recommended. This allows the updates to be rolled back if there are any errors.

XMLType columns in the database can be updated using Oracle Data Provider for .NET in a few ways:

- [Updating with DataSet, OracleDataAdapter, and OracleCommandBuilder](#)
- [Updating with OracleCommand and OracleParameter](#)

## Updating with DataSet, OracleDataAdapter, and OracleCommandBuilder

If the XMLType column is fetched into the DataSet, the XMLType data is represented as a .NET String.

Modifying XMLType data in the DataSet does not require special treatment. XMLType data can be modified in the same way as any data that is stored in the DataSet. When a change is made and the OracleDataAdapter.Update method is invoked, the OracleDataAdapter object ensures that the XMLType data is handled properly. The OracleDataAdapter object uses any custom SQL INSERT, UPDATE, or DELETE statements that are provided. Otherwise, valid SQL statements are generated by the OracleCommandBuilder object as needed to [flush](#) the changes to the database.

## Updating with OracleCommand and OracleParameter

The OracleCommand class provides a powerful way of updating XMLType data, especially with the use of an OracleParameter object. To update columns in a database table, the new value for the column can be passed as an input parameter of a command.

### Input Binding

To update an XMLType column in the database, a SQL statement can be executed using static values. In addition, input parameters can be bound to SQL statements, anonymous PL/SQL blocks, or stored procedures to update XMLType columns. The parameter value can be set as .NET Framework Types, ODP.NET Types, or OracleXmlType objects.

While XMLType columns can be updated using an OracleXmlType object, having an instance of an OracleXmlType class does not guarantee that the XMLType column in the database can be updated.

## Setting XMLType Column to NULL Value

Applications can set an XMLType column in the database to a NULL value, with or without input binding, as follows:

- Setting NULL values in an XMLType column with input binding

To set the XMLType column to NULL, the application can bind an input parameter whose value is DBNull.Value. This indicates to the OracleCommand object that a NULL value is to be inserted.

Passing in a null OracleXmlType object as an input parameter does not insert a NULL value into the XMLType column. In this case, the OracleCommand object raises an exception.

- Setting NULL Values in an XMLType Column without input binding

The following example demonstrates setting NULL values in an XMLType column without input binding:

```
// Create a table with an XMLType column in the database
CREATE TABLE XML_TABLE(NUM_COL number, XMLTYPE_COL xmltype);
```

An application can set a NULL value in the XMLType column by explicitly inserting a NULL value or by not inserting anything into that column as in the following examples:

```
insert into xml_table(xmltype_col) values(NULL);
```

```
update xml_table t set t.xmltype_col=NULL;
```

## Setting XMLType Column to Empty XML Data

The XMLType column can be initialized with empty XML data, using a SQL statement:

```
// Create a table with an XMLType column in the database
CREATE TABLE XML_TABLE(NUM_COL number, XMLTYPE_COL xmltype);

INSERT INTO XML_TABLE (NUM_COL, XMLTYPE_COL) VALUES (4,
XMLType.createxml('<DOC/>'));
```

## Updating XML Data in OracleXmlType

The following are ways that XML data can be updated in an OracleXmlType object.

- The XML data can be updated by passing an XPATH expression and the new value to the Update method on the OracleXmlType object.
- The XML data can be retrieved on the client side as the .NET Framework XmlDocument object using the GetXmlDocument method on the OracleXmlType object. This XML data can then be manipulated using suitable .NET Framework classes. A new OracleXmlType can be created with the updated XML data from the .NET Framework classes. This new OracleXmlType is bound as an input parameter to an update or insert statement.

## Characters with Special Meaning in XML

The following characters in [Table 3-30](#) have special meaning in XML. For more information, refer to the XML 1.0 specifications

**Table 3-30 Characters with Special Meaning in XML**

| Character | Meaning in XML                      | Entity Encoding |
|-----------|-------------------------------------|-----------------|
| <         | Begins an XML tag                   | &lt;            |
| >         | Ends an XML tag                     | &gt;            |
| "         | Quotation mark                      | &quot;          |
| '         | Apostrophe or single quotation mark | &apos;          |
| &         | Ampersand                           | &amp;           |

When these characters appear as data in an XML element, they are replaced with their equivalent entity encoding.

Also certain characters are not valid in XML element names. When SQL identifiers (such as column names) are mapped to XML element names, these characters are converted to a sequence of hexadecimal digits, derived from the Unicode encoding of the character, bracketed by an introductory underscore, a lowercase x and a trailing underscore. A blank space is not a valid character in an XML element name. If a SQL identifier contains a space character, then in the corresponding XML element name, the space character is replaced by `_x0020_`, which is based on Unicode encoding of the space character.

## Retrieving Query Result Set as XML

This section discusses retrieving the result set from a SQL query as XML data.

## Handling Date and Time Format

The generated XML DATE and TIMESTAMP formats are based on the standard XML Schema formats.

### See Also

<http://www.w3.org/TR/2004/REC-xmlschema-2-20041028/datatypes.html#isoformats> for more information on the XML Schema specification.

## Characters with Special Meaning in Column Data

If the data in any of the select list columns in the query contains any characters with special meaning in XML (see [Table 3-30](#)), these characters are replaced with their corresponding entity encoding in the result XML document.

The following examples demonstrate how ODP.NET handles the angle bracket characters in the column data:

```
/* Database Setup
connect scott/tiger@oracle
drop table specialchars;
create table specialchars ("id" number, name varchar2(255));
insert into specialchars values (1, '<Jones>');
commit;
*/

// C#

using System;
using System.Data;
using System.Xml;
using Oracle.DataAccess.Client;

class QueryResultAsXMLSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle;";
        con.Open();

        // Create the command
        OracleCommand cmd = new OracleCommand("", con);

        // Set the XML command type to query.
        cmd.XmlCommandType = OracleXmlCommandType.Query;

        // Set the SQL query
        cmd.CommandText = "select * from specialchars";

        // Set command properties that affect XML query behavior.
        cmd.BindByName = true;

        // Set the XML query properties
        cmd.XmlQueryProperties.MaxRows = -1;
```

```

// Get the XML document as an XmlReader.
XmlReader xmlReader = cmd.ExecuteXmlReader();
XmlDocument xmlDocument = new XmlDocument();

xmlDocument.PreserveWhitespace = true;
xmlDocument.Load(xmlReader);
Console.WriteLine(xmlDocument.OuterXml);

// Close and Dispose OracleConnection object
con.Close();
con.Dispose();
}
}

```

The following XML document is generated for that table: The XML entity encoding that represents the angle brackets appears in bold.

```

<?xml version = '1.0'?>
<ROWSET>
  <ROW>
    <id>1</id>
    <NAME>&lt;Jones&gt;</NAME>
  </ROW>
</ROWSET>

```

## Characters in Table or View Name

If a table or view name has any non-alphanumeric characters other than an underscore (\_), the table or view name must be enclosed in quotation marks.

For example, to select all entries from a table with the name test'ing, the CommandText property of the OracleCommand object must be set to the following string:

```
"select * from \"test'ing\"";
```

## Case-Sensitivity in Column Name to XML Element Name Mapping

The mapping of SQL identifiers (column names) to XML element names is case-sensitive, and the element names are in exactly the same case as the column names of the table or view.

However, the root tag and row tag names are case-insensitive. The following example demonstrates case-sensitivity in this situation:

```

//Create the following table
create table casesensitive_table ("Id" number, NAME varchar2(255));

//insert name and id
insert into casesensitive_table values(1, 'Smith');

```

The following XML document is generated:

```

<?xml version = '1.0'?>
<ROWSET>
  <ROW>
    <Id>1</Id>
    <NAME>Smith</NAME>
  </ROW>
</ROWSET>

```

Note that the element name for the Id column matches the case of the column name.

## Column Name to XML Element Name Mapping

For each row generated by the SQL query, the SQL identifier (column name) maps to an XML element in the generated XML document, as shown in the following example:

```
// Create the following table
create table emp_table (EMPLOYEE_ID NUMBER(4), LAST_NAME varchar2(25));
// Insert some data
insert into emp_table values(205, 'Higgins');
```

The SQL query, `SELECT * FROM EMP_TABLE`, generates the following XML document:

```
<?XML version="1.0"?>
<ROWSET>
  <ROW>
    <EMPLOYEE_ID>205</EMPLOYEE_ID>
    <LAST_NAME>Higgins</LAST_NAME>
  </ROW>
</ROWSET>
```

The `EMPLOYEE_ID` and `LAST_NAME` database columns of the `employees` table map to the `EMPLOYEE_ID` and `LAST_NAME` elements of the generated XML document.

This section demonstrates how Oracle database handles the mapping of SQL identifiers to XML element names, when retrieving query results as XML from the database. The demonstration uses the `specialchars` table involving the `some id` column.

```
// Create the specialchars table
create table specialchars ("some id" number, name varchar2(255));
```

Note that the `specialchars` table has a column named `some id` that contains a blank space character. The space character is not allowed in an XML element name.

When retrieving the query results as XML, the SQL identifiers in the query select list can contain characters that are not valid in XML element names. When these SQL identifiers (such as column names) are mapped to XML element names, each of these characters is converted to a sequence of hexadecimal digits, derived from the Unicode encoding of the characters, bracketed by an introductory underscore, a lowercase x, and a trailing underscore.

Thus, the SQL query in the following example can be used to get a result as an XML document from the `specialchars` table:

```
select "some id", name from specialchars;
```

### ① See Also

["Characters with Special Meaning in XML"](#)

## Improving Default Mapping

You can improve the default mapping of SQL identifiers to XML element names by using the following techniques:

- Modify the source. Create an object-relational view over the source schema, and make that view the new source.

- Use cursor subqueries and cast-multiset constructs in the SQL query.
- Create an alias for the column or attribute names in the SQL query. Prefix the aliases with an at sign (@) to map them to XML attributes instead of XML elements.
- Modify the XML document. Use [Extensible Stylesheet Language Transformation \(XSLT\)](#) to transform the XML document. Specify the XSL document and parameters. The transformation is done automatically after the XML document is generated from the relational data. Note that this may have an impact on performance.
- Specify the name of the root tag and row tag used in the XML document.

## Object-Relational Data

ODP.NET can generate an XML document for data stored in object-relational columns, tables, and views, as shown in the following example:

```
// Create the following tables and types
CREATE TYPE "EmployeeType" AS OBJECT (EMPNO NUMBER, ENAME VARCHAR2(20));
/
CREATE TYPE EmployeeListType AS TABLE OF "EmployeeType";
/
CREATE TABLE mydept (DEPTNO NUMBER, DEPTNAME VARCHAR2(20),
                     EMPLIST EmployeeListType)
                     NESTED TABLE EMPLIST STORE AS EMPLIST_TABLE;
INSERT INTO mydept VALUES (1, 'depta',
                          EmployeeListType("EmployeeType"(1, 'empa')));
```

The following XML document is generated for the table:

```
<?xml version = "1.0"?>
<ROWSET>
  <ROW>
    <DEPTNO>1</DEPTNO>
    <DEPTNAME>depta</DEPTNAME>
    <EMPLIST>
      <EmployeeType>
        <EMPNO>1</EMPNO>
        <ENAME>empa</ENAME>
      </EmployeeType>
    </EMPLIST>
  </ROW>
</ROWSET>
```

ODP.NET encloses each item in a collection element, with the database type name of the element in the collection. The mydept table has a collection in the EMPLIST database column and each item in the collection is of type EmployeeType. Therefore, in the XML document, each item in the collection is enclosed in the type name EmployeeType, which appears in bold in the example.

## NULL Values

If any database row has a column with a NULL value, then that column does not appear for that row in the generated XML document.

## Data Manipulation Using XML

This section discusses making changes to the database data using XML.

## Handling Date and Time Format

The generated XML DATE and TIMESTAMP formats are based on the standard XML Schema formats.

### See Also

<http://www.w3.org/TR/2004/REC-xmlschema-2-20041028/datatypes.html#isoformats> for more information on the XML Schema specification.

## Saving Changes Using XML

Changes can be saved to database tables and views using XML data. However, insert, update, and delete operations cannot be combined in a single XML document. ODP.NET cannot accept a single XML document and determine which are insert, update, or delete changes.

The insert change must be in an XML document containing only rows to be inserted, the update changes only with rows to be updated, and the delete changes only with rows to be deleted.

For example, using the employees table that comes with the HR sample schema, you can specify the following query:

```
select employee_id, last_name from employees where employee_id = 205;
```

The following XML document is generated:

```
<?xml version = '1.0'?>
<ROWSET>
  <ROW>
    <EMPLOYEE_ID>205</EMPLOYEE_ID>
    <LAST_NAME>Higgins</LAST_NAME>
  </ROW>
</ROWSET>
```

To change the name of employee 205 from **Higgins** to **Smith**, specify the employees table and the XML data containing the changes as follows:

```
<?xml version = '1.0'?>
<ROWSET>
  <ROW>
    <EMPLOYEE_ID>205</EMPLOYEE_ID>
    <LAST_NAME>Smith</LAST_NAME>
  </ROW>
</ROWSET>
```

## Characters with Special Meaning in Column Data

If the data in any of the elements in the XML document contains characters that have a special meaning in XML (see [Table 3-30](#)), these characters must be replaced with appropriate entity encoding, or be preceded by an escape character in the XML document, so that the data is stored correctly in the database table column. Otherwise, ODP.NET throws an exception.

The following example demonstrates how ODP.NET handles the angle bracket special characters in the column data, using entity encoding:

```
// Create the following table
create table specialchars ("id" number, name varchar2(255));
```

The following XML document can be used to insert values (1, '<Jones>') into the specialchars table. The XML entity encoding that represents the angle brackets appears in bold.

```
<?xml version = '1.0'?>
<ROWSET>
  <ROW>
    <id>1</id >
    <NAME>&lt;Jones&gt;</NAME>
  </ROW>
</ROWSET>
```

## Characters with Special Meaning in Table or View Name

If a table or view name has any non-alphanumeric characters other than an underscore (\_), the table or view name must be enclosed in quotation marks.

For example, to save changes to a table with the name test 'ing, the OracleCommand.XmlSaveProperties.TableName property must be set to "\"test 'ing\"".

## Case-Sensitivity in XML Element Name to Column Name Mapping

For each XML element that represents a row of data in the XML document, the child XML elements map to database column names. The mapping of the child element name to the column name is always case-sensitive, but the root tag and row tag names are case-insensitive. The following example demonstrates this case-sensitivity:

```
//Create the following table
create table casesensitive_table ("Id" number, NAME varchar2(255));
```

The following XML document can be used to insert values (1, Smith) into the casesensitive\_table:

```
<?xml version = '1.0'?>
<ROWSET>
  <ROW>
    <Id>1</Id>
    <NAME>Smith</NAME>
  </ROW>
</ROWSET>
```

Note that the element name for the Id column matches the case of the column name.

## XML Element Name to Column Name Mapping

This section describes how Oracle database handles the mapping of XML element names to column names when using XML for data manipulation in the database. The following specialchars table involving the some id column demonstrates this handling.

```
// Create the specialchars table
create table specialchars ("some id" number, name varchar2(255));
```

Note that the specialchars table has a column named some id that contains a blank space character. The space character is not allowed in an XML element name.

## Saving Changes to a Table Using an XML Document

When an XML document is used to save changes to a table or view, the `OracleCommand.XmlSaveProperties.UpdateColumnsList` property is used to specify the list of columns to update or insert.

When an XML document is used to save changes to a column in a table or view, and the corresponding column name contains any of the characters that are not valid in an XML element name, the escaped column name must be specified in the `UpdateColumnsList` property as in the following example.

The following XML document can be used to insert values (2, <Jones>) into the `specialchars` table:

```
<?xml version = '1.0'?>
<ROWSET>
  <ROW>
    <some_x0020_id>2</some_x0020_id>
    <NAME>&lt;Jones&gt;</NAME>
  </ROW>
</ROWSET>
```

The following example specifies the list of columns to update or insert:

```
/* Database Setup
connect scott/tiger@oracle
drop table specialchars;
create table specialchars ("some id" number, name varchar2(255));
insert into specialchars values (1, '<Jones>');
commit;
*/

// C#

using System;
using System.Data;
using System.Xml;
using Oracle.DataAccess.Client;

class InsertUsingXmlDocSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle;";
        con.Open();
        Console.WriteLine("Connected Successfully");

        // Create the command
        OracleCommand cmd = new OracleCommand("", con);

        // Set the XML command type to query.
        cmd.XmlCommandType = OracleXmlCommandType.Insert;

        // Set the XML document
        cmd.CommandText = "<?xml version = '1.0'?>\n" + "<ROWSET>\n" + "<ROW>\n" +
            "<some_x0020_id>2</some_x0020_id>\n" + "<NAME>&lt;Jones&gt;</NAME>\n" +
            "</ROW>\n" + "</ROWSET>\n";
        cmd.XmlSaveProperties.Table = "specialchars";
```

```
string[] ucols = new string[2];

ucols[0] = "some_x0020_id";
ucols[1] = "NAME";
cmd.XmlSaveProperties.UpdateColumnsList = ucols;

// Insert rows
int rows = cmd.ExecuteNonQuery();

Console.WriteLine("Number of rows inserted successfully : {0} ", rows);

// Close and Dispose OracleConnection object
con.Close();
con.Dispose();
}
}
```

## Improving Default Mapping

You can improve the default mapping by using the following techniques:

- Modify the target. Create an object-relational view over the target schema, and make the view the new target.
- Modify the XML document. Use XSLT to transform the XML document. Specify the XSL document and parameters. The transformation is done before the changes are saved. Note that this may have an impact on performance.
- Specify the name of the row tag used in the XML document.

## Object-Relational Data

Changes in an XML document can also be saved to object-relational data. Each item in a collection can be specified in one of the following ways in the XML document:

- By enclosing the database type name of the item as the XML element name.
- By enclosing the name of the database column holding the collection with `_ITEM` appended as the XML element name.

## Multiple Tables

Oracle Database does not save changes to multiple relational tables that have been joined together. Oracle recommends that you create a view on those relational tables, and then update that view. If the view cannot be updated, triggers can be used instead.

### See Also

*Oracle Database SQL Language Reference* for the description and syntax of the `CREATE VIEW` statement

## Commit Transactions

When the changes in an XML document are made, either all the changes are committed, or if an error occurs, all changes are rolled back.

# Oracle User-Defined Types (UDTs) and .NET Custom Types

ODP.NET has the ability to represent Oracle UDTs found in the database as custom types in .NET applications. UDTs are useful in representing complex entities as a single object that can be shared among applications. Oracle products, such as Oracle Spatial and Oracle XML DB, use their own complex types frequently.

To represent Oracle UDTs as .NET custom types, applications must apply .NET attributes to custom classes and structs, and to their public fields and properties.

To convert between UDTs and custom types, ODP.NET uses custom interfaces.

Starting with version 21.2, managed ODP.NET and ODP.NET Core support Oracle UDTs and .NET custom types. These providers are near-parity with unmanaged ODP.NET UDT APIs and features, which makes migrating to managed or core more straightforward for developers. Only a few code changes may be needed.

This section discusses the ODP.NET UDT topics below. All the topics, except [Using UDTs with Managed ODP.NET and ODP.NET Core](#) and [Migrating from Unmanaged ODP.NET to Managed or Core](#), discuss unmanaged ODP.NET UDT features and Oracle UDTs generally. These two topics contrast unmanaged ODP.NET UDTs with managed ODP.NET and ODP.NET Core UDTs.

## Oracle User-Defined Types (UDTs)

Oracle Data Provider for .NET supports Oracle object types or user-defined types (UDTs), which are defined in the Oracle database.

There are two kinds of UDTs:

- Object types (Oracle Object)
- Collection types (which can be VARRAY types or nested table types)

Additionally, ODP.NET supports references (REF) to object types.

The term UDT is used interchangeably with Oracle object types and abstract data types (ADTs).

The name of the Oracle UDT is case-sensitive and must be in the form *schema\_name.type\_name*.

#### See Also

- UDT samples are available online on GitHub in the UDT directory:  
<https://github.com/oracle/dotnet-db-samples/tree/master/samples>

## Custom Types

Oracle Data Provider for .NET supports UDTs by representing Oracle UDTs defined in the database as .NET types, that is, custom types. For every Oracle UDT that the application wishes to fetch and manipulate, one custom type factory and one custom type are needed. The custom factory class is solely responsible for instantiating the custom type. ODP.NET uses the interfaces implemented on the custom factory classes to instantiate custom types at run time. Custom types define the mapping between the Oracle UDT attributes or elements to the .NET members. ODP.NET uses the interfaces implemented on the custom type instances to transfer values between the Oracle UDT and the custom type at run time.

Custom types can be .NET classes or structures. They can represent either Oracle Objects or Oracle Collections. Custom types can be implemented manually by the application developer or generated through an ODP.NET code generation tool.

Once the factory class and the custom type are defined and meet the implementation requirements, the application may set ODP.NET to automatically discover the mapping between the Oracle UDT and the custom type. This discovery process is based on the attribute that is applied on the custom factory class. Alternatively, the application can provide an explicit mapping through a configuration file.

Oracle Collections can be represented as an array of .NET Types. For example, an Oracle Collection type of NUMBER can be mapped to an `int[]`. Moreover, an Oracle Collection type of an Oracle UDT can be mapped to an array of the custom type.

Custom types must adhere to certain requirements in order for ODP.NET to represent Oracle UDTs as custom types. These requirements are as follows:

## Required Custom Type Implementations

This section lists the required implementations for a custom .NET class or structure.

- `Oracle.DataAccess.Types.IOracleCustomType` interface implementation  
This interface is used for conversions between custom types and Oracle UDTs.  
The interface methods are implemented using the static methods of the `OracleUdt` class.
- Custom Type Factories

A custom type factory is used to create an instance of a custom type. A custom type factory is an implementation of either the `IOracleCustomTypeFactory` interface, the `IOracleArrayTypeFactory` interface, or both interfaces, as follows:

- To create a custom type that represents an Oracle Object, the custom type or a separate custom type factory class must implement the `Oracle.DataAccess.Types.IOracleCustomTypeFactory` interface.
  - To create a custom type that represents an Oracle Collection, the custom type or a separate custom type factory class must implement the `Oracle.DataAccess.Types.IOracleCustomTypeFactory` interface and the `Oracle.DataAccess.Types.IOracleArrayTypeFactory` interface.
  - To create an array type that represents an Oracle Collection, a custom type factory class must implement the `Oracle.DataAccess.Types.IOracleArrayTypeFactory` interface.
- Custom Type Member Mapping Attributes

The custom type member mapping attributes specify the mapping between custom type members and either Oracle object attributes or Oracle collection elements.

There are two types of custom type member mapping attributes:

- `OracleObjectMappingAttribute`

This attribute specifies the mapping between custom type members and Oracle object attributes for custom types that represent Oracle objects. This attribute must be applied to each custom type member (either field or property) that represents an Oracle Object attribute.

**Note**

Not all Oracle object attributes need to be mapped to custom type members. If there is no `OracleObjectMappingAttribute` for a particular object attribute, ODP.NET ignores that object attribute when converting between Oracle objects and custom types.

- `OracleArrayMappingAttribute`

This attribute specifies the custom type member that stores the elements of an Oracle collection for custom types representing Oracle collections. The attribute must be specified on only one of the custom type members.

- `Oracle.DataAccess.Types.INullable` interface implementation

This interface is used to determine if an instance of a custom type represents a null UDT. The `IsNull` property of the interface enables applications and ODP.NET to determine whether or not the UDT is null.

- Static Null field

The public static `Null` property is used to return a null UDT. This property returns a custom type with an `IsNull` property that returns true.

## Optional Custom Type Implementations

The following are optional:

- `IXMLSerializable`

The `IXMLSerializable` interface is used in the .NET 2.0 framework to enable conversion between the custom type and its XML representation. This interface is only used if the serialization and deserialization of a custom type is needed in the `DataSet`.

- `Static Parse` and `Public ToString` methods

These methods enable conversion between the custom type and its string representation.

These methods are invoked when a `DataGrid` control is used to accept changes and display instance values.

- `Type Inheritance`

Type Inheritance refers to the process of deriving an Oracle UDT in the database from a super type.

If the custom type represents an Oracle UDT that is derived from a super type, the custom class should follow the same type hierarchy, that is, the custom class should be derived from another custom class that represents the super type defined in the database.

- `OracleCustomTypeMappingAttribute`

The `OracleCustomTypeMappingAttribute` object specifies the mapping between a custom type (or an array type) and an Oracle UDT.

There must be a unique custom type factory for each Oracle UDT used by the application as follows:

- `Oracle Object Types`:

The custom type factory must return a custom type that only represents the specified Oracle Object Type.

- `Oracle Collection Types`:

The custom type factory may return a custom type that can be used by other Oracle Collection Types. This is common when an array type is used to represent an Oracle Collection, for example, when an `int[]` is used to represent a collection of `NUMBERS`.

If the `OracleCustomTypeMappingAttribute` is not specified, then custom type mappings must be specified through XML configuration files, that is, `machine.config`, and either `app.config` for Windows applications or `web.config` for web applications.

#### See Also

- ["IOracleCustomType Interface"](#)
- ["OracleRef Class"](#)
- ["IOracleCustomTypeFactory Interface"](#)

## Specifying Custom Type Mappings

After creating a custom type, the application must specify a custom type mapping that maps the custom type to an Oracle UDT in the database. This can be done using a custom type factory or XML in configuration files.

Using XML to specify custom type mappings has priority, if both techniques have been implemented. At run time, if ODP.NET finds custom type mappings specified in configuration files, it ignores any custom type mappings specified through the `OracleCustomTypeMappingAttribute` object. If a .NET application dynamically loads .NET

assemblies, which contain .NET classes that Oracle UDTs are mapped to, then the mapping between .NET classes and Oracle UDTs must be configured using a .NET config file.

Custom type mappings cannot be specified using synonyms, regardless of whether or not the mapping is provided through the `OracleCustomTypeMappingAttribute` object or the XML configuration file.

#### 📘 See Also

*Oracle Developer Tools for Visual Studio help* sections on User-Defined Types Node under Server Explorer in Visual Studio for further information on UDT mapping.

This section contains these topics:

- ["Using a Custom Type Factory to Specify Custom Type Mappings"](#)
- ["Using XML in Configuration Files to Specify Custom Type Mappings"](#)

## Using a Custom Type Factory to Specify Custom Type Mappings

The application can specify a custom type mapping using a custom type factory. The application supplies the name of the Oracle UDT, in the format `schema_name.type_name`, to an `OracleCustomTypeMappingAttribute` object and applies the name to the corresponding custom type factory. A custom type factory is a class or struct that implements either or both the `IOracleCustomTypeFactory` and `IOracleArrayTypeFactory` interfaces.

Note that for each Oracle UDT used by the application, there must be a unique custom type factory. Additionally, for Oracle Object Types, the custom type factory must return a custom type that uniquely represents the specified Oracle Object Type. For Oracle Collection Types, the custom type factory returns a custom type that can be used by other Oracle Collection Types. This is common when an custom type that is an array type represents an Oracle Collection, that is, when an `int[]` is used to represent a collection of NUMBERS.

At run time, using reflection programming, ODP.NET discovers all the custom type mappings specified by the application through the `OracleCustomTypeMappingAttribute` object.

#### 📘 Note

The UDT name that is specified in the `OracleCustomTypeMappingAttribute` may not contain a period.

## Using XML in Configuration Files to Specify Custom Type Mappings

The application can specify a custom type mapping with XML in configuration files, for example: using `machine.config`, and either `app.config` for Windows applications or `web.config` for web applications.

The custom type mappings must be specified in the `oracle.dataaccess.client` configuration section group. Each custom type mapping must be added to the collection of custom type mappings using the XML element `<add>`.

Each custom type mapping is consists of a name attribute and a value attribute. The name attribute may be any user-specified name that represents the custom type mapping. The value

attribute must begin with `udtMapping` and be followed by the required and optional attributes listed below.

## Required Attributes

- `factoryName`

The case-sensitive assembly qualified name of the custom type factory class or struct.

If the assembly that defines the custom type factory does not have a strong name, then a partial assembly name consisting of just the assembly name is sufficient. In the case of strongly named assemblies, a complete assembly name is required. It must include the assembly name, the Version, Culture, PublicKeyToken.

- `typeName`

The case-sensitive name of the UDT defined in the database. By default all UDTs are created in the database with upper case names

- `schemaName`

The case-sensitive schema in which the UDT is defined in the database. By default all schemas are created in the database with upper case names

## Optional Attributes

- `dataSource`

If specified, indicates that the custom type mapping applies only to Oracle UDTs defined in the database that the application connects to, as specified by the TNS name alias.

The Data Source is case-insensitive.

The following is an example of the format of the XML that can be specified in the configuration file for .NET 2.0:

```
<oracle.dataaccess.client>
  <settings>
    <add name="Person" value="udtMapping factoryName='Sample.PersonFactory,
      Sample, Version=1.0.0.0, Culture=neutral, PublicKeyToken=null'
      typeName='PERSON' schemaName='SCOTT' dataSource='oracle'"/>
    <add name="Student" value="udtMapping factoryName='Sample.StudentFactory,
      Sample, Version=1.0.0.0, Culture=neutral, PublicKeyToken=null'
      typeName='STUDENT' schemaName='SCOTT'"/>
  </settings>
</oracle.dataaccess.client>
```

## Using Custom Type Mappings

During data retrieval, the application uses the custom type mappings to convert an Oracle UDT to a custom type. When data is provided back to the database through an input or input/output parameter, or by an update through an Oracle REF, the application uses the mappings to convert the custom type to an Oracle UDT.

In the case of input and input/output parameters, the application must also set the `OracleParameter.UdtTypeName` property to the user-defined type name of the parameter.

In certain cases, where Oracle UDTs are part of a type hierarchy, the custom type must be instantiated as a specific type in the type hierarchy. The Oracle UDT provided by the custom type mapping must be a subtype of the Oracle UDT specified by the `OracleParameter.UdtTypeName` property.

For example, the parameter for a stored procedure is of type, `SCOTT.PERSON` and has a subtype, `SCOTT.STUDENT`. The application has a custom class instance that represents `SCOTT.STUDENT`. The `UdtTypeName` is set to `SCOTT.PERSON`, but the custom type mapping indicates that the custom class is mapped to `SCOTT.STUDENT` and overrides the `UdtTypeName` when it instantiates the Oracle UDT. Thus, ODP.NET instantiates and binds Oracle UDTs appropriately when the custom object represents an Oracle UDT that is a subtype of the parameter type.

## Converting Between Custom Types and Oracle UDTs

ODP.NET can convert between Oracle UDTs and custom types, if the proper attribute mappings are specified and the custom types are defined properly.

ODP.NET performs a conversion whenever an Oracle UDT is fetched as:

- In, out, in/out parameters bound for SQL or PL/SQL execution

The `DbType` property of `OracleParameter` must be set to `DbType.Object` or the `OracleDbType` property must be set to `OracleDbType.Object` or `OracleDbType.Array`.

For parameters that are user-defined types, the `UdtTypeName` property of the `OracleParameter` object must be always set to the parameter type.

Note: The `UdtTypeName` may differ from the Oracle UDT specified in the custom type mapping. This is the case when the parameter type is a super type of the Oracle UDT that the custom type represents.

- Column value retrieved from an `OracleDataReader` object

If the application requests for the value either through the `GetValue`, `GetValues`, `GetOracleValue`, `GetOracleValues`, `GetProviderSpecificValue`, or `GetProviderSpecificValues` methods or the `Item[]` property for a UDT column, ODP.NET finds the corresponding custom type that represents the Oracle UDT and carries out the proper conversion.

- Part of a `ResultSet` that populates the `DataSet`

If the application populates the `DataSet` with a result that contains UDTs using the `Fill` method on the `OracleDataAdapter`, the `DataSet` is populated with custom types that represent Oracle UDTs. With ADO.NET 2.0, the `DataSet` is populated with custom types for UDT columns regardless of whether the `ReturnProviderSpecificTypes` on the `OracleDataAdapter` is set to `true` or `false`.

- A `Object` referenced through a `REF`

When an `Object` referenced by a `REF` is retrieved, the custom type that represents the Oracle UDT is returned.

The application can use the `OracleUdtFetchOption` method to control the copy of the `Object` that is returned as follows:

- If the `OracleUdtFetchOption.Cache` option is specified and a cached copy of the object exists, the cached copy is immediately returned. If no cached copy exists, the latest object copy from the database is cached and returned.
- If the `OracleUdtFetchOption.Server` option is specified, the latest object copy from the database is cached and returned. If the object is already cached, the latest object copy overwrites the existing one.
- If the `OracleUdtFetchOption.TransactionCache` option is specified, there are two possibilities within the same transaction:

- \* If the object copy was previously retrieved using the Server or TransactionCache option, the TransactionCache option behavior becomes equivalent to the Cache option behavior.
- \* If the object copy was not previously retrieved using the Server or TransactionCache option, the TransactionCache option behavior becomes equivalent to the Server option behavior.

## Oracle UDT Attribute Mappings

[Table 3-31](#) lists valid mappings of attributes (for objects) and elements (for collections), between Oracle UDT types and custom object types which can be either .NET types or Oracle provider-specific types (ODP.NET types).

Oracle collections do not have to map to a custom class. They can map to arrays of a specific type. [Table 3-31](#) indicates those collections with elements of a specified Oracle type that can map to arrays of a .NET Type or a provider-specific type. For example, if an Oracle Collection is a VARRAY of NUMBER(8), it can map to a `typeof(int[])`. This eliminates the need to construct a class that only holds an `int[]`.

For .NET 2.0, Oracle Collections can be mapped to Nullable types. This allows .NET 2.0 applications to obtain a nullable `int[]` which can hold null values in the `int[]`.

Note that Oracle UDT attributes and elements cannot be mapped to `object` or `object[]`.

**Table 3-31 Attribute Mappings Between UDTs and Custom Object Types**

| Type of UDT Attribute or Element | .NET Type                                                                                                             | ODP.NET Type     |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------|------------------|
| BFILE                            | System.Byte[]                                                                                                         | OracleBFile      |
| BINARY FLOAT                     | System.Byte,<br>System.Int16,<br>System.Int32,<br>System.Int64,<br>System.Single,<br>System.Double,<br>System.Decimal | OracleDecimal    |
| BINARY DOUBLE                    | System.Byte,<br>System.Int16,<br>System.Int32,<br>System.Int64,<br>System.Single,<br>System.Double,<br>System.Decimal | OracleDecimal    |
| BLOB                             | System.Byte[]                                                                                                         | OracleBlob       |
| CHAR                             | System.Char[],<br>System.String                                                                                       | OracleString     |
| CLOB                             | System.Char[],<br>System.String                                                                                       | OracleClob       |
| DATE                             | System.DateTime                                                                                                       | OracleDate       |
| INTERVAL DAY TO SECOND           | System.TimeSpan,                                                                                                      | OracleIntervalDS |
| INTERVAL YEAR TO MONTH           | System.Int64                                                                                                          | OracleIntervalYM |
| LONG RAW                         | System.Byte[]                                                                                                         | OracleBinary     |

**Table 3-31 (Cont.) Attribute Mappings Between UDTs and Custom Object Types**

| Type of UDT Attribute or Element | .NET Type                                                                                                             | ODP.NET Type       |

| VARRAY                           | <i>custom type, .NET<br/>type[], or custom<br/>type[]</i>                                                             | <i>ODP Type[]</i>  |
| XMLTYPE                          | System.Char[],<br>System.String                                                                                       | OracleXmlType      |

**Notes:**

1. Conversion from a System.Byte[] to a BFILE is not supported, and therefore, System.Byte[] only represents a BFILE in read-only scenarios.

## Oracle UDT Retrieval from OracleDataReader

In order to retrieve Oracle UDTs from the `OracleDataReader`, an application must specify a custom type mapping that determines the type that will represent the Oracle UDT. Once a custom type mapping has been specified and any necessary custom types have been created, the application can retrieve Oracle UDTs.

[Table 3-32](#) shows the type and value returned from an `OracleDataReader` object based on the method invoked, the column type, and whether or not there is a valid Custom type mapping.

**Note**

*PS Object* refers to a provider-specific object.

**Table 3-32 Type and Value Returned from OracleDataReader Object**

| OracleDataReader method/<br>property invocation                                                                          | Column Data<br>Type   | Custom Type<br>Mapping    | Value Returned for<br>Oracle UDT                                                                        | NULL Value<br>Returned for<br>Oracle UDT |

## Oracle UDT Metadata Retrieval from OracleDataReader

An `OracleDataReader` object can return metadata used to determine the custom type that represents an Oracle UDT when a .NET Type or Provider-Specific Type accessor is invoked.

The same custom type is used when populating the DataSet using the `OracleDataAdapter.Fill` method.

[Table 3-33](#) shows the values returned from the `OracleDataReader.GetFieldType` and `GetProviderSpecificFieldType` methods that specify the .NET type of the column.

**Table 3-33 Values Returned from OracleDataReader Methods**

| OracleDataReader Method/<br>Property invocation       | Column Data<br>Type   | Custom Type<br>Mapping       | Return Value                                                                                                   |

## Oracle UDT Parameter Binding with OracleParameter

This section discusses using UDT output and input parameter bindings with an `OracleParameter` object.

### ① See Also

["Parameter Binding"](#)

This section contains these topics:

- [Guidelines for Binding UDT Input and Output Parameters](#)
- [UDT Input Parameter Binding with OracleParameters](#)
- [UDT Output Parameter Binding with OracleParameters](#)

## Guidelines for Binding UDT Input and Output Parameters

Developers must consider the following when using UDT parameter bindings with an `OracleParameter` object.

- The `UdtTypeName` property must be set. Binding is based on the `UdtTypeName` property regardless of the parameter direction.

#### Note

The `UdtTypeName` may differ from the Oracle UDT specified in the custom type mapping. This occurs when the parameter type is a super type of the Oracle UDT that the custom type represents.

- In case of Input/Output binding, the behavior is the same as Input and Output parameters.
- For Input parameter values, the bind value is converted to the UDT specified by the custom type mapping.
- For Output parameters:
  - If the value being returned is an Oracle Object or Collection, it is converted to a custom type or array type as specified by the custom type mapping. The value returned is always a custom type or an array type, regardless of whether the property most recently set was `DbType` or `OracleDbType`.
  - If the value being returned is a REF, then no custom type mapping is required.

## UDT Input Parameter Binding with OracleParameters

Only certain combinations of these `OracleParameter` property values, `DbType`, `OracleDbType`, and `UdtTypeName`, can exist on the `OracleParameter` object. `OracleParameter` objects cannot be set to combinations that are not listed.

[Table 3-34](#) describes the valid ways of binding input parameters for Oracle UDTs.

The last column indicates the Oracle type that ODP.NET converts the `OracleParameter` value to before binding.

**Table 3-34 Valid Ways to Bind Input Parameters for Oracle UDTs**

| OracleParameter.<br>Value                                                                                                                                   | OracleParameter. ## UDT Output Parameter Binding with OracleParameters

Only certain combinations of these OracleParameter property values, DbType, OracleDbType, and UdtTypeName, can exist on the OracleParameter object. OracleParameter objects cannot be set to combinations that are not listed.

[Table 3-35](#) shows the supported ODP.NET output parameter bindings of Oracle database objects.

The last column indicates the type that ODP.NET converts the OracleParameter value to before binding.

**Table 3-35 Valid Ways to Bind Output Parameters for Oracle UDTs**

| Type returned<br>from Oracle | OracleParameter. DbType                                                              | OracleParameter.<br>UdtTypeName | Custom Type<br>Mappings   | Type converted to |

## Populating the DataSet with Oracle UDTs

The DataSet is a disconnected result set. With ADO.NET 2.0, both .NET types and provider-specific types can be used to populate the DataSet. This section describes the types used to populate the DataSet when the column is an Oracle UDT.

[Table 3-36](#) lists the types that populate the DataSet column, based on the Oracle column type, the ReturnProviderSpecificTypes property of the DataAdapter, the existence of a custom type mapping, the DataSet column type, the DataSet column value, and the DataSet column null value.

**Table 3-36 Types that Populate the DataSet with ADO.NET 2.0**

| Oracle Column Type  | ReturnProviderSpecificTypes Property | Custom Type Mappings | DataSet Column Type        | DataSet Column Value | DataSet Column Null Value |
|---------------------|--------------------------------------|----------------------|----------------------------|----------------------|---------------------------|
| Object / Collection | False/True                           | none                 | Exception thrown           | Exception thrown     | Exception thrown          |
| Object / Collection | False                                | <i>schema.type</i>   | <i>typeof(custom type)</i> | <i>custom object</i> | DBNull.Value              |

Table 3-36 (Cont.) Types that Populate the DataSet with ADO.NET 2.0

| Oracle Column Type  | ReturnProvider-SpecificTypes Property | Custom Type Mappings | DataSet Column Type                                             | DataSet Column Value                        | DataSet Column Null Value |
|---------------------|---------------------------------------|----------------------|-----------------------------------------------------------------|---------------------------------------------|---------------------------|
| Object / Collection | True                                  | schema.type          | typeof(custom type)                                             | custom object                               | custom object.Null        |
| Collection          | False                                 | schema.type          | typeof(custom type[])   typeof(.NET type[])   typeof(PS type[]) | .NET type[]   PS object[]   custom object[] | DBNull.Value              |
| Collection          | True                                  | schema.type          | typeof(custom type[])   typeof(.NET type[])   typeof(PS type[]) | .NET type[]   PS object[]   custom object[] | null                      |
| REF                 | False                                 | none   schema.type   | typeof(string)                                                  | string/HEX                                  | DBNull.Value              |
| REF                 | True                                  | none   schema.type   | typeof(OracleRef)                                               | OracleRef                                   | OracleRef.Null            |

## UDT Method Invocation

ODP.NET supports invocation of methods defined for a UDT on the database. This can be accomplished by doing the following:

1. Set the CommandType as CommandType.StoredProcedure.
2. Set the CommandText as "type\_name.procedure\_name"
3. Execute the command using any of the Execute methods on the OracleCommand object.

For instance functions, the parameters are as follows:

- The first parameter must be the return value.
- The second parameter must be the UDT instance on which the instance method is invoked, which is the instance of the .NET custom object.
- Subsequent parameters are for the function.

For instance procedures, the first parameter must be the UDT instance.

For static methods, the UDT instance is not needed.

## Configuration Settings for Oracle UDTs

ODP.NET exposes two configuration settings to determine how ODP.NET handles Oracle UDTs.

- [StatementCacheWithUdts](#)
- [UdtCacheSize](#)

These configuration settings can be specified as machine-wide settings for a particular version of ODP.NET, using the registry key with the name that exists under HKEY\_LOCAL\_MACHINE\SOFTWARE\ORACLE\ODP.NET\Assembly\_Version. The configuration settings specified in the registry can be overridden if an entry is created in the machine.config

for .NET framework-wide settings, or in the `app.config` or `web.config` for application-specific settings.

**See Also**

[Configuring Oracle Data Provider for .NET](#) for details on configuring ODP.NET.

## StatementCacheWithUdts

`StatementCacheWithUdts` specifies whether or not ODP.NET caches Oracle UDTs retrieved by a `SELECT` statement along with the statement when it is returned to the statement cache. Possible values are 1 - Yes (the default) or 0 - No.

For the value of 1, the Oracle UDTs are cached along with the statements. Therefore, the memory that contained the UDTs can be re-used; subsequent executions of the same statement do not require additional memory. This may result in an overall higher performance.

For the value of 0, ODP.NET frees the memory for the retrieved Oracle UDTs before the statement is returned to the statement cache. This may result in poorer performance because subsequent executions will require new memory allocations.

## UdtCacheSize

`UdtCacheSize` specifies the size of the object cache for each connection that ODP.NET uses when retrieving and manipulating Oracle UDTs. The value for this setting must be specified in kilobytes (KB) with the default 4096KB, equivalent to 4 MB.

This configuration setting is used to determine how frequently the objects in the object cache will be purged (using an LRU approach) as the limit of the object cache size approaches.

## Using UDTs with Managed ODP.NET and ODP.NET Core

Managed ODP.NET and ODP.NET Core support the same or similar UDT APIs and features as unmanaged ODP.NET. The differences are listed in this documentation section.

Managed ODP.NET and ODP.NET Core UDT features require connecting to Oracle Database 12.1 or higher versions.

### XML Configuration Files Not Supported

Managed ODP.NET and ODP.NET Core do not support Oracle custom type mapping via XML configuration files, such as in `app.config` or `web.config`. For these providers, custom type mapping occurs through using the `OracleCustomTypeMapping` attribute.

### OracleUdt FromCustomObject and ToCustomObject Method Changes

The unmanaged ODP.NET `OracleUdt FromCustomObject` and `ToCustomObject` method declarations are as follows:

- `FromCustomObject(OracleConnection con, IntPtr pObject)`
- `ToCustomObject(OracleConnection con, IntPtr pObject)`

For managed ODP.NET and ODP.NET Core, the declarations are, respectively:

- `FromCustomObject(OracleConnection con, object pObject)`

- `ToCustomObject(OracleConnection con, object pObject)`

The second parameter is an object instead of a pointer.

### OracleUdt Static Methods

`OracleUdt` static methods, `GetValue`, `IsDBNull`, and `SetValue`, and their overloads all have one `InPtr` parameter. For managed ODP.NET and ODP.NET Core, the `InPtr` is replaced with an object that represents the UDT. In unmanaged ODP.NET, the static methods are as follows:

- `GetValue`
  - `GetValue(OracleConnection con, IntPtr pUdt, string attrName)`
  - `GetValue(OracleConnection con, IntPtr pUdt, int attrIndex)`
  - `GetValue(OracleConnection con, IntPtr pUdt, string attrName, out object statusArray)`
  - `GetValue(OracleConnection con, IntPtr pUdt, int attrIndex, out object statusArray)`
- `IsDBNull`
  - `IsDBNull(OracleConnection con, IntPtr pUdt, string attrName)`
  - `IsDBNull(OracleConnection con, IntPtr pUdt, int attrIndex)`
- `SetValue`
  - `SetValue(OracleConnection con, IntPtr pUdt, string attrName, object value)`
  - `SetValue(OracleConnection con, IntPtr pUdt, int attrIndex, object value)`
  - `SetValue(OracleConnection con, IntPtr pUdt, string attrName, object value, object statusArray)`
  - `SetValue(OracleConnection con, IntPtr pUdt, int attrIndex, object value, object statusArray)`

The managed ODP.NET and ODP.NET Core static methods are, respectively:

- `GetValue`
  - `GetValue(OracleConnection con, object udt, string attrName)`
  - `GetValue(OracleConnection con, object udt, int attrIndex)`
  - `GetValue(OracleConnection con, object udt, string attrName, out object statusArray)`
  - `GetValue(OracleConnection con, object udt, int attrIndex, out object statusArray)`
- `IsDBNull`
  - `IsDBNull(OracleConnection con, object udt, string attrName)`
  - `IsDBNull(OracleConnection con, object udt, int attrIndex)`
- `SetValue`
  - `SetValue(OracleConnection con, object udt, string attrName, object value)`
  - `SetValue(OracleConnection con, object udt, int attrIndex, object value)`
  - `SetValue(OracleConnection con, object udt, string attrName, object value, object statusArray)`

- SetValue(OracleConnection con, object udt, int attrIndex, object value, object statusArray)

### OracleConnection Class Changes

Managed ODP.NET and ODP.NET Core do not support the following OracleConnection method:

- FlushCache()

### OracleRef Class Changes

Managed ODP.NET and ODP.NET Core do not support object caches and other functionality without a managed code implementation. Thus, the following unmanaged ODP.NET class members are *not* supported in managed and core:

- Constructors
  - OracleRef(OracleConnection conn, string udtTypeName, string objTableName)
  - OracleRef(OracleConnection conn, string hexStr)
- Methods
  - Flush()
  - GetCustomObject(OracleUdtFetchOption fetchOption, int depthLevel)
  - GetCustomObjectForUpdate(bool bWait)
  - GetCustomObjectForUpdate(bool bWait, int depthLevel)
  - Lock(bool bWait)
- Properties
  - HasChanges {get}
  - ObjectTableName {get}

The following OracleRef class members are supported in a modified manner:

**Table 3-37 OracleRef class members**

| Method in Unmanaged                               | Equivalent Core/Managed Method | Core/Managed Behavior                                          |
|---------------------------------------------------|--------------------------------|----------------------------------------------------------------|
| Delete(bool bFlush)                               | Delete()                       | Equivalent to Delete(true) in unmanaged ODP.NET.               |
| GetCustomObject(OracleUdtFetchOption fetchOption) | GetCustomObject()              | Always retrieves object from database. No object cache.        |
| Update(object customObject, bool bFlush)          | Update(object customObject)    | Equivalent to Update(customObject, true) in unmanaged ODP.NET. |

## Migrating from Unmanaged ODP.NET to Managed or Core

The following changes are required to migrate UDT applications from unmanaged ODP.NET to either managed ODP.NET or ODP.NET Core:

- Assembly: Reference managed ODP.NET or ODP.NET Core assembly (i.e. `Oracle.ManagedDataAccess.dll`) in your .NET project.
- Namespace: Use the `Oracle.ManagedDataAccess.*` namespace in your source files.
- Configuration: Use `OracleCustomTypeMapping` attribute to define the custom type mapping.
- API: Use the managed/core `OracleUdt FromCustomObject` and `ToCustomObject` methods in the custom class.
- API: Use the managed/core `OracleUdt` static methods.
- API: Change `OracleRef` class invocation, including constructors, properties, and methods, to the members managed/core `OracleRef` class use.

## Handling NULL Attribute Values in UDTs

A UDT attribute can be mapped to either a .NET type or to a provider-specific type.

To be able to properly represent NULL UDT attribute values as .NET types within the .NET custom classes, they can be defined as nullable .NET types. For example, if the UDT has a DATE attribute that can be NULL, then it can be mapped to a `DateTime? nullable` type rather than `DateTime`. This is due to fact that `DateTime` cannot be used to represent NULL values.

But when it comes to mapping UDT attributes as provider-specific types, then the .NET custom classes should simply have the non-nullable provider-specific type, for example, `OracleDate`. Each provider type can represent a NULL value through the provider-specific type's `Null` static field, for example, `OracleDate.Null`.

## Bulk Copy

ODP.NET provides a Bulk Copy feature which enables applications to efficiently load large amounts of data from a table in one database to another table in the same or a different database.

The ODP.NET Bulk Copy feature uses a direct path load approach, which is similar to, but not the same as Oracle SQL\*Loader. Using direct path load is faster than conventional loading (using conventional SQL INSERT statements). Direct path loading formats Oracle data blocks and writes the data blocks directly to the data files. Bulk Copy eliminates considerable processing overhead.

The ODP.NET Bulk Copy feature can load data into older Oracle databases.

The ODP.NET Bulk Copy feature is subject to the same basic restrictions and integrity constraints for direct path loads, as discussed in the next few sections.

ODP.NET Bulk Copy supports local transactions.

When using DRCP implicit connection pooling with a transaction boundary (`POOL_BOUNDARY=TRANSACTION`), explicitly start a local transaction before invoking `OracleBulkCopy.WriteToServer()`. ODP.NET's default behavior is auto-commit. Internal bulk copy SQL execution will auto-commit without a transaction and then return its session to the pool, which can cause errors for LOBs and cursors that depend on the session context.

## Data Types Supported by Bulk Copy

Bulk Copy supports the following Oracle database data types:

- NUMBER
- BINARY\_DOUBLE
- BINARY\_FLOAT
- CHAR
- JSON
- NCHAR
- VARCHAR2
- NVARCHAR2
- LONG
- CLOB
- BLOB
- DATE
- TIMESTAMP
- TIMESTAMP WITH TIME ZONE
- TIMESTAMP WITH LOCAL TIME ZONE
- INTERVAL YEAR TO MONTH
- INTERVAL DAY TO SECOND
- BOOLEAN
- VECTOR

**① Note**

BOOLEAN and VECTOR are supported for managed ODP.NET and ODP.NET Core only

Bulk copy does not support overwrites.

ODP.NET converts the .NET source data into an Oracle format based on the destination table column definitions. If the source data is too large to be stored in the destination column, then the data may be truncated or converted to allow it to be stored in the database. For example, if the .NET string source is "abc" and the destination column is VARCHAR2(2), the data is truncated to "ab" when saved to the column.

## Restrictions on Oracle Bulk Copy of a Single Partition

- The table that contains the partition cannot have any global indexes defined on it.
- The tables that the partition is a member of cannot have referential and check constraints enabled.
- Enabled triggers are not allowed.

## Integrity Constraints Affecting Oracle Bulk Copy

During a Oracle bulk copy, some integrity constraints are automatically enabled or disabled, as follows:

### Enabled Constraints

During an Oracle bulk copy, the following constraints are automatically enabled by default:

- NOT NULL
- UNIQUE
- PRIMARY KEY (unique-constraints on not-null columns)
- CHECK constraints

NOT NULL constraints are checked at column array build time. Any row that violates the NOT NULL constraint is rejected.

UNIQUE constraints are verified when indexes are rebuilt at the end of the load. The index is left in an Index Unusable state if it violates a UNIQUE constraint.

To enforce primary key and unique constraints, use the `EnforceIndexChecks` member in `OracleBulkCopyOptions`. Bulk copy will not load any rows and leave indexes unchanged when it detects an index-related error.

### Disabled Constraints

During an Oracle bulk copy, the following constraints are automatically disabled by default:

- Referential constraints (FOREIGN KEY)

## Database Insert Triggers

Table insert triggers are disabled when a direct path load begins. After the rows are loaded and indexes rebuilt, any triggers that were disabled are automatically reenabled. The log file lists all triggers that were disabled for the load. There should be no errors reenabling triggers.

Unlike integrity constraints, insert triggers are not reapplied to the whole table when they are enabled. As a result, insert triggers do not fire for any rows loaded on the direct path. When using the direct path, the application must ensure that any behavior associated with insert triggers is carried out for the new rows.

## Field Defaults

Default column specifications defined in the database are not available with direct path loading. Fields for which default values are desired must be specified with the `DEFAULTIF` clause. If a

DEFAULTIF clause is not specified and the field is NULL, then a null value is inserted into the database.

## Asynchronous Programming and Pipelining

Asynchronous programming and Oracle Database pipelining remove performance bottlenecks and enhance overall responsiveness that can limit synchronous apps.

Starting with Release 26ai, managed ODP.NET and ODP.NET Core, support both asynchronous programming and database pipelining. Both these technologies are simple for developers to learn and incorporate into their existing or new ODP.NET apps.

### Asynchronous Programming

Synchronous provider database operations, such as opening a connection, executing a query, or reading data, may take significant time to complete. Single-threaded applications block other operations to wait for the original operation to finish. In contrast, assigning the long-running operation to a background thread allows the foreground thread to remain active throughout. The long-running operation no longer blocks other app operations thereby realizing overall improved performance from using asynchronous behavior.

Asynchronous operations are ideal for long running operations whose results or completion are not needed immediately. Use it when user interfaces must remain as responsive as possible or when other operations can execute simultaneously without relying on the asynchronous operation completing.

.NET has a language-level asynchronous programming model. It allows writing asynchronous code without juggling callbacks nor conforming to an asynchronous library, which have historically complicated asynchronous .NET code. This model is called Task-based Asynchronous Pattern (TAP) and developers have found it easiest to develop with compared to earlier asynchronous patterns.

TAP uses the `async` modifier to specify an asynchronous method. When calling an `async` method, a task is returned. When the `await` operator is applied to the task, the current method exits immediately. When the task finishes, execution resumes in the same method. Most importantly, calling an `async` method does not allocate additional threads. Asynchronous functionality can be selectively added to existing ODP.NET apps to iteratively provide better runtime user experience.

Managed ODP.NET and ODP.NET Core support TAP starting with version 23. The feature is backwards compatible with Oracle Database 19c and higher. ODP.NET `async` APIs are identical to standard ADO.NET `async` APIs. Only `OracleBulkCopy.WriteToServerAsync` method is not currently supported. This makes developing ODP.NET `async` apps easy for experienced ADO.NET developers.

Oracle extends `async` capabilities to ODP.NET-specific classes as well, including `OracleBlob`, `OracleClob`, `OracleBFile`, and `OracleXmlStream`. They have `async` methods for reading, copying, and writing data as these data types can have very large sizes with their operations I/O bound.

Asynchronous ODP.NET sample code:

```

static async void Main(){
    OracleConnection oc = new OracleConnection(connectionString);

    // Establish a connection, asynchronously
    Task task = oc.OpenAsync(CancellationToken.None);

    // Execute operation(s) that do not require the connection
    Console.WriteLine("Hello World");
    OracleCommand cmd = oc.CreateCommand();
    cmd.CommandText = " select * from employees";

    // "await" OpenAsync completion before executing operations needing connection
    await task;

    // Execute the command
    OracleDataReader = await cmd.ExecuteReaderAsync();
}

```

### ODP.NET Async Methods

#### OracleConnection:

```

public Task OpenAsync()

public override Task OpenAsync(CancellationToken cancellationToken)

public Task OpenWithNewPasswordAsync(string newPassword)

public Task OpenWithNewPasswordAsync(string newPassword, CancellationToken
cancellationToken)

public Task OpenWithNewPasswordAsync(SecureString secureNewPassword)

public Task OpenWithNewPasswordAsync(SecureString secureNewPassword,
CancellationToken cancellationToken)

```

#### OracleCommand:

```

public Task<int> ExecuteNonQueryAsync()

public override Task<int> ExecuteNonQueryAsync(CancellationToken
cancellationToken)

public Task<OracleDataReader> ExecuteReaderAsync()

public Task<OracleDataReader> ExecuteReaderAsync(CancellationToken
cancellationToken);

public Task<OracleDataReader> ExecuteReaderAsync(CommandBehavior behavior)

public Task<OracleDataReader> ExecuteReaderAsync(CommandBehavior behavior,
CancellationToken cancellationToken)

public Task<object> ExecuteScalarAsync()

public override Task<object> ExecuteScalarAsync(CancellationToken
cancellationToken)

public Task<XmlReader> ExecuteXmlReaderAsync()

public Task<XmlReader> ExecuteXmlReaderAsync(CancellationToken cancellationToken)

```

#### OracleDataReader:

```

public Task<bool> IsDBNullAsync(int i)

public override Task<bool> IsDBNullAsync(int i, CancellationToken
cancellationToken)

public Task<T> GetFieldValueAsync<T>(int i)

public override Task<T> GetFieldValueAsync<T>(int i, CancellationToken
cancellationToken)

public Task<bool> NextResultAsync()

public override Task<bool> NextResultAsync(CancellationToken cancellationToken)

public Task<bool> ReadAsync()

public override Task<bool> ReadAsync(CancellationToken cancellationToken)

```

**OracleDataSource:**

```

public ValueTask<DbConnection> OpenConnectionAsync(CancellationToken
cancellationToken)

public void DisposeAsync()

```

**OracleBlob:**

```

public Task<Int64> CopyToAsync(OracleBlob obj)

public Task<Int64> CopyToAsync(OracleBlob obj, CancellationToken
cancellationToken)

public Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset)

public Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset,
CancellationToken cancellationToken)

public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64
dst_offset, Int64 amount)

public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64
dst_offset, Int64 amount, CancellationToken cancellationToken)

public Task<int> ReadAsync(byte[] buffer, int offset, int count)

public override Task<int> ReadAsync(byte[] buffer, int offset, int count,
CancellationToken cancellationToken)

public Task<int> WriteAsync(byte[] buffer, int offset, int count)

public override Task<int> WriteAsync(byte[] buffer, int offset, int count,
CancellationToken cancellationToken)

```

**OracleClob:**

```

public Task<Int64> CopyToAsync(OracleClob obj)

public Task<Int64> CopyToAsync(OracleClob obj, CancellationToken
cancellationToken)

public Task<Int64> CopyToAsync(OracleClob obj, Int64 dst_offset)

public Task<Int64> CopyToAsync(OracleClob obj, Int64 dst_offset,
CancellationToken cancellationToken)

```

```
public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64
dst_offset, Int64 amount)

public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64
dst_offset, Int64 amount, CancellationTokens cancellationToken)

public Task<int> ReadAsync(byte[] buffer, int offset, int count)

public override Task<int> ReadAsync(byte[] buffer, int offset, int count,
CancellationTokens cancellationToken)

public Task<int> ReadAsync(char[] buffer, int offset, int count)

public Task<int> ReadAsync(char[] buffer, int offset, int count,
CancellationTokens cancellationToken)

public Task<int> WriteAsync(byte[] buffer, int offset, int count)

public override Task<int> WriteAsync(byte[] buffer, int offset, int count,
CancellationTokens cancellationToken)

public Task<int> WriteAsync(char[] buffer, int offset, int count)

public Task<int> WriteAsync(char[] buffer, int offset, int count,
CancellationTokens cancellationToken)
```

**OracleBFile:**

```
public Task<Int64> CopyToAsync(OracleBlob obj)

public Task<Int64> CopyToAsync(OracleBlob obj, CancellationTokens
cancellationToken)

public Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset)

public Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset,
CancellationTokens cancellationToken)

public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64
dst_offset, Int64 amount)

public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64
dst_offset, Int64 amount, CancellationTokens cancellationToken)

public Task<Int64> CopyToAsync(OracleClob obj)

public Task<Int64> CopyToAsync(OracleClob obj, CancellationTokens
cancellationToken)

public Task<Int64> CopyToAsync(OracleClob obj, Int64 dst_offset)

public Task<Int64> CopyToAsync(OracleClob obj, Int64 dst_offset,
CancellationTokens cancellationToken)

public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64
dst_offset, Int64 amount)

public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64
dst_offset, Int64 amount, CancellationTokens cancellationToken)

public Task<int> ReadAsync(byte[] buffer, int offset, int count)
```

```
public override Task<int> ReadAsync(byte[] buffer, int offset, int count,
CancellationTokentoken cancellationToken)
```

#### OracleXmlStream:

```
public Task<int> ReadAsync(byte[] buffer, int offset, int count)

public override Task<int> ReadAsync(byte[] buffer, int offset, int count,
CancellationTokentoken cancellationToken)

public Task<int> ReadAsync(char[] buffer, int offset, int count)

public Task<int> ReadAsync(char[] buffer, int offset, int count,
CancellationTokentoken cancellationToken)
```

### Database Pipelining

Asynchronous ODP.NET calls send requests to the database and read the responses on the client side asynchronously. On the database server, operations are independent of the client and are synchronous by default.

Database pipelining, a new Oracle AI Database 26ai feature, provides asynchronous execution capability on the database server side. Subsequent operations can send requests even before previous operations responses are received. ODP.NET will still receive results in the same order as their respective commands were submitted to the database.

The key runtime benefit is higher throughput and performance. The database is ready to receive new ODP.NET commands as they arrive instead of blocking until after the previous command completes.

Pipelining requires using ODP.NET asynchronous APIs. Apps can add pipelining to async ODP.NET apps with virtually no code changes. Functionally, there is no difference for the client application when pipelining is enabled or disabled since it is a database server capability.

Managed ODP.NET and ODP.NET Core support database pipelining. By default, the feature is disabled. To enable it, set the OracleConfiguration Pipelining property to true. Alternatively for managed ODP.NET, change the .NET configuration file Pipelining setting to true. No database setup is required other than using Oracle AI Database 26ai or higher.

ODP.NET Pipelining sample code:

```
static async void Main(){

    //Enable Pipelining
    OracleConfiguration.Pipelining = true;

    OracleConnection oc = new OracleConnection(connectionString);
    await oc.OpenAsync(CancellationTokentoken.None);

    OracleCommand cmd = oc.CreateCommand();
    OracleCommand cmd2 = oc.CreateCommand();

    cmd.CommandText = "update table1 set col1 = 1 where col2 = 2";
    cmd2.CommandText = "update table2 set col3 = 3 where col4 = 4";

    //Execute commands asynchronously with pipelining
    Task<int> task = cmd.ExecuteNonQueryAsync(CancellationTokentoken.None);
    Task<int> task2 = cmd2.ExecuteNonQueryAsync(CancellationTokentoken.None);

    //Execute other operations that do not require query results
    Console.WriteLine("Hello World");
}
```

```
//Await the asynchronous tasks to complete
int updatedRows = await task;
int updatedRows2 = await task2;

Console.WriteLine("Number updated rows are " + updatedRows + " and " + updatedRows2);
}
```

Async ODP.NET command cancellation by the `OracleCommand.Cancel` method call, command timeout and `CancellationToken` is not supported when pipelining is enabled. When pipelining is disabled, async ODP.NET command cancellation and timeout are supported and has the same behavior as synchronous ODP.NET command cancellation and timeout.

## Advanced Queuing and Transactional Event Queues

Oracle Database Advanced Queuing (AQ) and Oracle Transactional Event Queues (TxEventQ) provide database-integrated message queuing functionality. AQ leverages the functions of Oracle Database so that messages can be stored persistently, propagated between queues on different computers and databases, and transmitted using Oracle Net Services and HTTP(S). TxEventQ provides robust real-time messaging, streaming events, and publish/subscribe messaging with multiple publishers and multiple consumers. It is a high performance partitioned implementation with multiple event streams per queue, while AQ is a disk-based implementation for simpler workflow use cases.

ODP.NET uses the same APIs when executing operations against either AQ or TxEventQ. From a .NET application level, both queue types have the same functionality. Thus, ODP.NET developers can use the same code for working with either AQ or TxEventQ. Where the two queue types differ is in their implementations and administration.

Due to the commonality at the .NET app level, this book will use the term "AQ" to refer synonymously to both AQ and TxEventQ. When differences exist, the book will refer to each queue type separately.

ODP.NET queuing APIs execute operational functions, such as enqueueing and dequeuing messages. Administrative functions, such as creating and managing queues, are not available in ODP.NET. Use Oracle Developer Tools for Visual Studio or DBMS\_AQADM PL/SQL package to perform these administrative functions.

As Oracle Database AQ is implemented in database tables, all operational benefits of high availability, scalability, and reliability are also applicable to queue data. Oracle Database AQ supports standard database features such as recovery, restart, and security.

The following items discuss Oracle Database AQ concepts:

- Queues and Queue Tables

Messages enqueued in a queue are stored in a queue table. A queue table must be created before creating a queue based on it. Use the DBMS\_AQADM PL/SQL package or Oracle Developer Tools for Visual Studio to create and administer queue tables and queues.

Queues are represented by `OracleAQQueue` objects.

- Single-Consumer and Multiple-Consumer Queues

A single-consumer queue is created based on a single consumer queue table. Messages enqueued in a single-consumer queue can be dequeued by only a single consumer.

A multiple-consumer queue is based on a multiple-consumer queue table. This queue supports queue subscribers and message recipients.

- Message Recipients

A message producer can submit a list of recipients when enqueueing a message. This allows for a unique set of recipients for each message in the queue. The recipient list associated with the message overrides the subscriber list, if any, associated with the queue. The recipients need not be in the subscriber list. However, recipients can be selected from among the subscribers. The `Recipients` property of an `OracleAQMessage` can be used to specify the recipients to a specific message in terms of `OracleAQAgent` objects.

- Enqueue

Messages are enqueued when producer applications push the messages into a queue. This is accomplished by calling the `Enqueue` method on an `OracleAQQueue` object. Multiple messages can be enqueued using the `EnqueueArray` method.

- Dequeue

Messages are dequeued when consumer applications pull the messages from a queue. This is accomplished by calling the `Dequeue` method on an `OracleAQQueue` object. Multiple messages can be dequeued using the `DequeueArray` method.

- Listen

Subscriber applications can use a `Listen` call to monitor multiple queues for subscriptions on different queues. This is a more scalable solution for cases where a subscriber application has subscribed to many queues and wishes to receive messages that arrive in any of the queues. This is accomplished by calling the `Listen` method of the `OracleAQQueue` class, passing the list of subscriptions in form of an array.

- Notification

Subscriber applications can utilize the notification mechanism to get notifications about message availability in a queue. The applications can decide to skip or dequeue the message from the queue based on the information received.

A subscriber application must register for event notification on the queues from which it wants to receive notifications. This is represented by the `MessageAvailable` event on `OracleAQQueue`. The event is triggered when messages matching the subscriptions arrive.

Notifications can be registered as regular or grouping notifications. A time out value for these notifications can also be specified. Various notification options can be set using the `OracleAQQueue.Notification` property. Notifications set on an `OracleAQQueue` object gets cancelled automatically when the object gets disposed.

- Buffered Messaging

In buffered messaging, messages reside in a shared memory area. This makes it faster than persistent messaging. The messages are written to disk only when the total memory consumption of buffered messages approaches the available shared memory limit. Buffered messaging is ideal for applications that do not require the reliability and transaction support of Oracle Database AQ persistent messaging.

Buffered and persistent messages use the same single-consumer or multi-consumer queues, and the same administrative and operational interfaces. They are distinguished from each other by a delivery mode parameter. When an application enqueues a message to an Oracle Database AQ queue, it sets the delivery mode parameter as well.

- Messages

Messages consist of control information (metadata) and a payload (data). The control information represents message properties AQ uses to manage messages. The payload data is the information stored in the queue and is transparent to Oracle AQ. A message can reside in only one queue. A message is created by the `enqueue` call and consumed by the `dequeue` call.

The possible message payload data types are:

- JSON
- RAW
- User-Defined Type
- XML

Unmanaged ODP.NET does not support JSON payloads.

|-----------------------|------------------------------------------------------------------------------------------------------------------|
| Message Notifications | Use <code>OracleAQQueue.MessageAvailable Event</code> along with the <code>NotificationConsumers</code> property |

## Enqueuing and Dequeuing Example

The following example demonstrates enqueueing and dequeuing messages using a single consumer queue. The first part of the example performs the requisite database setup for the database user, SCOTT. The second part of the example demonstrates enqueueing and dequeuing messages.

-- Part I: Database setup required for this demo

```

-----
-- SQL to grant appropriate privilege to database user, SCOTT
-----
SQL> ALTER USER SCOTT ACCOUNT UNLOCK IDENTIFIED BY Pwd4Sct;
User altered.
SQL> GRANT ALL ON DBMS_AQADM TO scott;

-----
-- PL/SQL to create queue-table and queue and start queue for SCOTT
-----
BEGIN
  DBMS_AQADM.CREATE_QUEUE_TABLE(
    queue_table=>'scott.test_q_tab',
    queue_payload_type=>'RAW',
    multiple_consumers=>FALSE);

  DBMS_AQADM.CREATE_QUEUE(
    queue_name=>'scott.test_q',
    queue_table=>'scott.test_q_tab');

  DBMS_AQADM.START_QUEUE(queue_name=>'scott.test_q');
END;
/

-----
-- PL/SQL to stop queue and drop queue & queue-table from SCOTT
-----
BEGIN
  DBMS_AQADM.STOP_QUEUE('scott.test_q');

  DBMS_AQADM.DROP_QUEUE(
    queue_name => 'scott.test_q',
    auto_commit => TRUE);

  DBMS_AQADM.DROP_QUEUE_TABLE(
    queue_table => 'scott.test_q_tab',
    force => FALSE,
    auto_commit => TRUE);
END;
/
-- End of Part I, database setup.

//Part II: Enqueueing and dequeuing messages

```

```
//C#
using System;
using System.Text;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

namespace ODPSample
{
    /// <summary>
    /// Demonstrates Enqueuing and Dequeuing raw message
    /// using a single consumer queue
    /// </summary>
    class EnqueueDequeue
    {
        static void Main(string[] args)
        {
            // Create connection
            string constr = "user id=scott;password=Pwd4Sct;data source=oracle";
            OracleConnection con = new OracleConnection(constr);

            // Create queue
            OracleAQQueue queue = new OracleAQQueue("scott.test_q", con);

            try
            {
                // Open connection
                con.Open();

                // Begin txn for enqueue
                OracleTransaction txn = con.BeginTransaction();

                // Set message type for the queue
                queue.MessageType = OracleAQMessageType.Raw;

                // Prepare message and RAW payload
                OracleAQMessage enqMsg = new OracleAQMessage();
                byte[] bytePayload = { 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 };
                enqMsg.Payload = bytePayload;

                // Prepare to Enqueue
                queue.EnqueueOptions.Visibility = OracleAQVisibilityMode.OnCommit;

                // Enqueue message
                queue.Enqueue(enqMsg);

                Console.WriteLine("Enqueued Message Payload      : "
                    + ByteArrayToString(enqMsg.Payload as byte[]));
                Console.WriteLine("MessageId of Enqueued Message : "
                    + ByteArrayToString(enqMsg.MessageId));

                // Enqueue txn commit
                txn.Commit();

                // Begin txn for Dequeue
                txn = con.BeginTransaction();

                // Prepare to Dequeue
                queue.DequeueOptions.Visibility = OracleAQVisibilityMode.OnCommit;
                queue.DequeueOptions.Wait = 10;

                // Dequeue message
                OracleAQMessage deqMsg = queue.Dequeue();
```

```

        Console.WriteLine("Dequeued Message Payload      : "
            + ByteArrayToString(deqMsg.Payload as byte[]));
        Console.WriteLine("MessageId of Dequeued Message : "
            + ByteArrayToString(deqMsg.MessageId));

        // Dequeue txn commit
        txn.Commit();
    }
    catch (Exception e)
    {
        Console.WriteLine("Error: {0}", e.Message);
    }
    finally
    {
        // Close/Dispose objects
        queue.Dispose();
        con.Close();
        con.Dispose();
    }
}

// Function to convert byte[] to string
static private string ByteArrayToString(byte[] byteArray)
{
    StringBuilder sb = new StringBuilder();
    for (int n = 0; n < byteArray.Length; n++)
    {
        sb.Append((int.Parse(byteArray[n].ToString())).ToString("X"));
    }
    return sb.ToString();
}
}
}

```

## Continuous Query Notification Support

Oracle Data Provider for .NET provides a notification framework that supports Continuous Query Notification, enabling applications to receive client-side notifications when there is a change in a query result set, schema objects, or the state of the database, even if no Oracle Data Provider for .NET database connection exists. Using Continuous Query Notification, an application can maintain the validity of the client-side cache (for example, the ADO.NET DataSet) easily. Continuous Query Notification was previously known as Database Change Notification.

Using the notification framework, applications can specify a query result set as a registered query for notification request on the database, and create this notification registration to maintain the validity of the query result set. When there is a change on the database that could affect the client-side cache's query results, the notification framework notifies the application.

### Note

The content of a change notification is referred to as an *invalidation message*. It indicates that the query result set is now invalid and provides information about the changes.

Based on the information provided by the invalidation message, the application can then act accordingly. For example, the application might need to refresh its own copy of the data for the registered query that is stored locally in the application.

**Note**

If a registered object is dropped from the database and a new one is created with the same name in the same schema, re-registration is required to receive notifications for the newly created object.

Firewalls, such as Windows Firewall, may be set up to block TCP network ports, which blocks incoming database notifications. Ensure the firewall is configured so that database applications can use the designated port for Continuous Query Notification. If the firewall configuration cannot be changed to allow notifications be sent to the client, consider enabling Client Initiated Continuous Query Notifications.

Continuous Query Notification queries can be query-based (default) or object-based. The query-based registrations allow ODP.NET to notify applications when the selected rows have changed in the database. The object-based registrations allow ODP.NET to notify applications for any changes that occur in the table(s) containing the selected rows.

Query-based registrations have two modes: guaranteed mode and best-effort mode. In guaranteed mode, any continuous query notification ensures that a change occurred to something contained in the queried result set. However, if a query is complex, then it cannot be registered in guaranteed mode. Best-effort mode is used in such cases.

Best-effort mode simplifies the query for query-based registration. No notifications are lost from the simplification. However, the simplification may cause false positives, as the simpler version's query result could change when the original query result would not. There still remain some restrictions on which queries can have best-effort mode query-based registrations. In such cases, developers can use object-based registrations, which can register most query types. Object-based registrations generate notifications when the query object changes, even if the actual query result does not. This also means that object-based registrations are more prone to false positives than query-based registrations. Developers should be aware of the relative strengths and weaknesses of each continuous query notification option and choose the one that best suits their requirements.

If a large number of rows are modified at once, consuming significant shared pool resources, the application will not receive any change notifications with specific row information that had undergone changes. Rather, it will receive a notification with `OracleNotificationEventArgs.Info` property set to `OracleNotificationInfo.Error`.

## Client Initiated Continuous Query Notifications

ODP.NET 21c introduces support for Client Initiated Continuous Query Notifications (CICQN). Traditional Continuous Query Notification (CQN) communicates database change notifications back to clients using a listening end point, a client's IP/hostname and a port. In cloud deployments or when firewalls between the database server and client cannot be configured to permit messages to the listening end point, these notifications will be blocked.

CICQN uses a dedicated connection instead of the listening end point. This connection aggregates all the database change notifications for the pool's users. ODP.NET attempts to always keep this connection open. It does not count toward Min Pool Size and Max Pool Size limits.

ODP.NET 23ai supports CICQN with Oracle Database 19c and higher. ODP.NET 21c CICQN requires Oracle Database 21c or higher. It can be enabled by setting the `OracleConfiguration.UseClientInitiatedCQN` static Boolean property or .NET Framework configuration file `UseClientInitiatedCQN` setting to true. By default, it is false.

For most on-premises deployments, traditional CQN is recommended.

## Continuous Query Notification Classes

The following classes are associated with Continuous Query Notification Support:

- `OracleDependency`

Represents a dependency between an application and an Oracle database based on the database events which the application is interested in. It contains information about the dependency and provides the mechanism to notify the application when specified database events occurs. The `OracleDependency` class is also responsible for creating the notification listener to listen for database notifications. There is only one database notification listener for each application domain. This notification listener terminates when the application process terminates.

The dependency between the application and the database is not established when the `OracleDependency` object is created. The dependency is established when the command that is associated with this `OracleDependency` object is executed. That command execution creates a continuous query notification registration in the database.

When a change has occurred in the database, the `HasChanges` property of the `OracleDependency` object is set to true. Furthermore, if an event handler was registered with the `OnChange` event of the `OracleDependency` object, the registered event handler function will be invoked.

- `OracleNotificationRequest`

Represents a notification request to be registered in the database. It contains information about the request and the properties of the notification.

- `OracleNotificationEventArgs`

Represents the [invalidation message](#) generated for a notification when a specified database event occurs and contains details about that database event.

## Supported Operations

The ODP.NET notification framework in conjunction with Continuous Query Notification supports the following activities:

- Creating a notification registration by:
  - Creating an `OracleDependency` instance and binding it to an `OracleCommand` instance.
- Grouping multiple notification requests into one registration by:
  - Using the `OracleDependency.AddCommandDependency` method.
  - Setting the `OracleCommand.Notification` request using the same `OracleNotificationRequest` instance.
- Registering for Continuous Query Notification by:
  - Executing the `OracleCommand`. If either the notification property is null or `NotificationAutoEnlist` is false, the notification will not be made.
- Removing notification registration by:
  - Using the `OracleDependency.RemoveRegistration` method.
  - Setting the `Timeout` property in the `OracleNotificationRequest` instance before the registration is created.
  - Setting the `IsNotifiedOnce` property to true in the `OracleNotificationRequest` instance before the registration is created. The registration is removed once a database notification is sent.
- Ensuring Change Notification Persistence by:
  - Specifying whether or not the invalidation message is queued persistently in the database before delivery. If an invalidation message is to be stored persistently in the database, then the change notification is guaranteed to be sent. If an invalidation message is stored in an in-memory queue, the change notification can be received faster, however, it could be lost upon database shutdown or crashes.
- Retrieving notification information including:
  - The changed object name.
  - The schema name of the changed object.
  - Database events that cause the notification, such as insert, delete, and so on.

- The RowID of the modified object row.

In Oracle SQL, the `ROWIDTOCHAR(ROWID)` and `ROWIDTONCHAR(ROWID)` functions convert a ROWID value to VARCHAR2 and NVARCHAR data types, respectively. If these functions are used within a SQL statement, ROWIDs are not returned in the `OracleNotificationEventArgs` object that is passed to the continuous query notification callback.

- Defining the listener port number.

By default, the static `OracleDependency.Port` property is set to -1. This indicates that the ODP.NET listens on a port that is randomly picked when ODP.NET registers a continuous query notification request for the first time during the execution of an application.

ODP.NET creates only one listener that listens on one port within an application domain. Once ODP.NET starts the listener, the port number cannot be changed; Changes to the static `OracleDependency.Port` property will generate an error if a listener has already been created.

## Requirements of Notification Registration

The connected user must have the `CHANGE NOTIFICATION` privilege to create a notification registration.

This SQL statement grants the `CHANGE NOTIFICATION` privilege:

```
grant change notification to user name
```

This SQL statement revokes the `CHANGE NOTIFICATION` privilege:

```
revoke change notification from user name
```

## Using Continuous Query Notification

This section describes what the application should do, and the flow of the process, when an application uses Continuous Query Notification to receive notifications for any changes in the registered query result set.

## Application Steps

The application should do the following:

1. Create an `OracleDependency` instance.
2. Assign an event handler to the `OracleDependency.OnChange` event property if the application wishes to have an event handler invoked when database changes are

detected. Otherwise, the application can choose to poll on the HasChanges property of the OracleDependency object. This event handler is invoked when the change notification is received.

3. Set the port number for the listener to listen on. The application can specify the port number for one notification listener to listen on. If the application does not specify a port number, a random one is used by the listener.
4. Bind the OracleDependency instance to an OracleCommand instance that contains the actual query to be executed. Internally, the Continuous Query Notification request (an OracleNotificationRequest instance) is created and assigned to the OracleCommand.Notification property.

## Flow of Notification Process

1. When the command associated with the notification request is executed, the notification registration is created in the database. The command execution must return a result set, or contain one or more REF cursors for a PL/SQL stored procedure.
2. ODP.NET starts the application listener on the first successful notification registration.
3. When a change related to the registration occurs in the database, the application is notified through the event delegate assigned to the OracleDependency.OnChange event property, or the application can poll the OracleDependency.HasChanges property.

The following example demonstrates the continuous query notification feature.

```
// Database Setup
// NOTE: unless the following SQL command is executed,
// ORA-29972 will be obtained from running this sample
/*
grant change notification to scott;
*/
using System;
using System.Threading;
using System.Data;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

//This sample shows the continuous query notification feature in ODP.NET.
//Application specifies to get a notification when emp table is updated.
//When emp table is updated, the application will get a notification
//through an event handler.
namespace NotificationSample
{
    public class MyNotificationSample
    {
        public static bool IsNotified = false;

        public static void Main(string[] args)
        {
            //To Run this sample, make sure that the change notification privilege
            //is granted to scott.
            string constr = "User Id=scott;Password=tiger;Data Source=oracle";
            OracleConnection con = null;
            OracleDependency dep = null;

            try
            {
                con = new OracleConnection(constr);
                OracleCommand cmd = new OracleCommand("select * from emp", con);
                con.Open();
```

```

// Set the port number for the listener to listen for the notification
// request
OracleDependency.Port = 1005;

// Create an OracleDependency instance and bind it to an OracleCommand
// instance.
// When an OracleDependency instance is bound to an OracleCommand
// instance, an OracleNotificationRequest is created and is set in the
// OracleCommand's Notification property. This indicates subsequent
// execution of command will register the notification.
// By default, the notification request is using the Database Change
// Notification.
dep = new OracleDependency(cmd);

// Add the event handler to handle the notification. The
// OnMyNotification method will be invoked when a notification message
// is received from the database
dep.OnChange +=
    new OnChangeEventHandler(MyNotificationSample.OnMyNotificaton);

// The notification registration is created and the query result sets
// associated with the command can be invalidated when there is a
// change. When the first notification registration occurs, the
// notification listener is started and the listener port number
// will be 1005.
cmd.ExecuteNonQuery();

// Updating emp table so that a notification can be received when
// the emp table is updated.
// Start a transaction to update emp table
OracleTransaction txn = con.BeginTransaction();
// Create a new command which will update emp table
string updateCmdText =
    "update emp set sal = sal + 10 where empno = 7782";
OracleCommand updateCmd = new OracleCommand(updateCmdText, con);
// Update the emp table
updateCmd.ExecuteNonQuery();
//When the transaction is committed, a notification will be sent from
//the database
txn.Commit();
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
}

con.Close();
// Loop while waiting for notification
while(MyNotificationSample.IsNotified == false)
{
    Thread.Sleep(100);
}
}

public static void OnMyNotificaton(object src,
    OracleNotificationEventArgs arg)
{
    Console.WriteLine("Notification Received");
    DataTable changeDetails = arg.Details;
    Console.WriteLine("Data has changed in {0}",
        changeDetails.Rows[0]["ResourceName"]);
}

```

```
        MyNotificationSample.IsNotified = true;
    }
}
```

## Best Practice Guidelines and Performance Considerations

This section provides guidelines for working with Continuous Query Notification and the ODP.NET notification framework, and discusses the performance impacts. Every change notification registration consumes database memory, storage or network resources, or some combination thereof. The resource consumption further depends on the volume and size of the [invalidation message](#). In order to scale well with a large number of mid-tier clients, Oracle recommends that the client implement these best practices:

- Few and mostly read-only tables  
There should be few registered objects, and these should be mostly read-only, with very infrequent invalidations. If an object is extremely volatile, then a large number of invalidation notifications are sent, potentially requiring a lot of space (in memory or on disk) in the invalidation queue. This is also true if a large number of objects are registered.
- Few rows updated for each table  
Transactions should update (or insert or delete) only a small number of rows within the registered tables. Depending on database resources, a whole table could be invalidated if too many rows are updated within a single transaction, for a given table.  
  
This policy helps to contain the size of a single invalidation message, and reduces disk storage for the invalidation queue.

## OracleDataAdapter Safe Type Mapping

The ODP.NET `OracleDataAdapter` class provides the Safe Type Mapping feature to ensure that the following Oracle data types do not lose data when converted to their closely related .NET types in the `DataSet`:

- NUMBER
- DATE
- TimeStamp (refers to all TimeStamp objects)
- INTERVAL DAY TO SECOND

### Note

ODP.NET, Managed Driver and ODP.NET do not support Safe Type Mapping.

This section includes the following topics:

- [Comparison Between Oracle Data Types and .NET Types](#)
- [SafeMapping Property](#)

## Comparison Between Oracle Data Types and .NET Types

The following sections provide more details about the differences between the Oracle data types and the corresponding .NET types. In general, the Oracle data types allow a greater degree of precision than the .NET types do.

## Oracle NUMBER Type to .NET Decimal Type

The Oracle data type NUMBER can hold up to 38 precision, and the .NET Decimal type can hold up to 28 precision. If a NUMBER data type that has more than 28 precision is retrieved into a .NET Decimal type, it loses precision.

[Table 3-39](#) lists the maximum and minimum values for Oracle NUMBER and .NET Decimal types.

### Table 3-39 Oracle NUMBER to .NET Decimal Comparisons

| Value Limits | Oracle NUMBER                                   | .NET Decimal                            |
|--------------|-------------------------------------------------|-----------------------------------------|
| Maximum      | 9.99999999999999999999999999999999<br>99 e125   | 79,228,162,514,264,337,593,543,950,335  |
| Minimum      | -9.99999999999999999999999999999999<br>999 e125 | -79,228,162,514,264,337,593,543,950,335 |

## Oracle Date Type to .NET DateTime Type

The Oracle data type DATE can represent dates in BC whereas the .NET DateTime type cannot. If a DATE that goes to BC get retrieved into a .NET DateTime type, it loses data.

[Table 3-40](#) lists the maximum and minimum values for Oracle Date and .NET DateTime types.

### Table 3-40 Oracle Date to .NET DateTime Comparisons

| Value Limits | Oracle Date     | .NET DateTime                    |
|--------------|-----------------|----------------------------------|
| Maximum      | Dec 31, 9999 AD | Dec 31, 9999 AD 23:59:59.9999999 |
| Minimum      | Jan 1, 4712 BC  | Jan 1, 0001 AD 00:00:00.0000000  |

## Oracle TimeStamp Type to .NET DateTime Type

Similar to the DATE data type, the Oracle TimeStamp data type can represent a date in BC, and a .NET DateTime type cannot. If a TimeStamp that goes to BC is retrieved into a .NET DateTime type, it loses data. The Oracle TimeStamp type can represent values in units of e-9; the .NET DateTime type can represent only values in units of e-7. The Oracle TimeStamp with time zone data type can store time zone information, and the .NET DateTime type cannot.

[Table 3-41](#) lists the maximum and minimum values for Oracle TimeStamp and .NET DateTime types.

**Table 3-41 Oracle TimeStamp to .NET DateTime Comparisons**

| Value Limits | Oracle TimeStamp                   | .NET DateTime                    |
|--------------|------------------------------------|----------------------------------|
| Maximum      | Dec 31, 9999 AD 23:59:59.999999999 | Dec 31, 9999 AD 23:59:59.9999999 |
| Minimum      | Jan 1, 4712 BC 00:00:00.000000000  | Jan 1, 0001 AD 00:00:00.0000000  |

**Oracle INTERVAL DAY TO SECOND to .NET TimeSpan**

The Oracle data type INTERVAL DAY TO SECOND can hold up to 9 precision, and the .NET TimeSpan type can hold up to 7 precision. If an INTERVAL DAY TO SECOND data type that has more than 7 precision is retrieved into a .NET TimeSpan type, it loses precision. The Oracle INTERVAL DAY TO SECOND type can represent values in units of e-9, and the .NET TimeSpan type can represent only values in units of e-7.

[Table 3-42](#) lists the maximum and minimum values for Oracle INTERVAL DAY TO SECOND and .NET DateTime types.

**Table 3-42 Oracle INTERVAL DAY TO SECOND to .NET TimeSpan Comparisons**

| Value Limits | Oracle INTERVAL DAY TO SECOND | .NET TimeSpan              |
|--------------|-------------------------------|----------------------------|
| Maximum      | +999999999 23:59:59.999999999 | +10675199 02:48:05.4775807 |
| Minimum      | -999999999 23:59:59.999999999 | -10675199 02:48:05.4775808 |

## SafeMapping Property

The OracleDataAdapter Safe Type Mapping feature prevents data loss when populating Oracle data for any of these types into a .NET DataSet. By setting the SafeMapping property appropriately, these types can be safely represented in the DataSet, as either of the following:

- .NET byte[] in Oracle format
- .NET String

By default, Safe Type Mapping is disabled.

## Using Safe Type Mapping

To use the Safe Type Mapping feature, the OracleDataAdapter.SafeMapping property must be set with a hash table of key-value pairs. The key-value pairs must map database table column names (of type string) to a .NET type (of type Type). ODP.NET supports Safe Type Mapping to byte[] and String types. Any other type mapping causes an exception.

In situations where the column names are not known at design time, an asterisk ("\*") can be used to map all occurrences of database types to a safe .NET type. If both the valid column name and the asterisk are present, the column name is used.

**Note**

- Database table column names are case-sensitive.
- Column names in the hash table that correspond to invalid column names are ignored.

Safe Type Mapping as a string is more readable without further conversion. Converting certain Oracle data types to a string requires extra conversion, which can be slower than converting it to a byte[]. Conversion of .NET strings back to ODP.NET types relies on the formatting information of the session.

**SafeTyping Example**

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class SafeMappingSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";

        // In this SELECT statement, EMPNO, HIREDATE and SALARY must be
        // preserved using safe type mapping.
        string cmdstr = "SELECT EMPNO, ENAME, HIREDATE, SAL FROM EMP";

        // Create the adapter with the selectCommand txt and the connection string
        OracleDataAdapter adapter = new OracleDataAdapter(cmdstr, constr);

        // Get the connection from the adapter
        OracleConnection connection = adapter.SelectCommand.Connection;

        // Create the safe type mapping for the adapter
        // which can safely map column data to byte arrays, where
        // applicable. By executing the following statement, EMPNO, HIREDATE AND
        // SALARY columns will be mapped to byte[]
        adapter.SafeMapping.Add("*", typeof(byte[]));

        // Map HIREDATE to a string
        // If the column name in the EMP table is case-sensitive,
        // the safe type mapping column name must be case-sensitive.
        adapter.SafeMapping.Add("HIREDATE", typeof(string));

        // Map EMPNO to a string
        // If the column name in the EMP table is case-sensitive,
        // the safe type mapping column name must also be case-sensitive.
        adapter.SafeMapping.Add("EMPNO", typeof(string));
        adapter.SafeMapping.Add("SAL", typeof(string));

        // Create and fill the DataSet using the EMP
        DataSet dataset = new DataSet();
        adapter.Fill(dataset, "EMP");

        // Get the EMP table from the dataset
        DataTable table = dataset.Tables["EMP"];
```

```
// Get the first row from the EMP table
DataRow row = table.Rows[0];

// Print out the row info
Console.WriteLine("EMPNO Column: type = " + row["EMPNO"].GetType() +
    "; value = " + row["EMPNO"]);
Console.WriteLine("ENAME Column: type = " + row["ENAME"].GetType() +
    "; value = " + row["ENAME"]);
Console.WriteLine("HIREDATE Column: type = " + row["HIREDATE"].GetType() +
    "; value = " + row["HIREDATE"]);
Console.WriteLine("SAL Column: type = " + row["SAL"].GetType() +
    "; value = " + row["SAL"]);
    }
}
```

## OracleDataAdapter Requery Property

The `OracleDataAdapter Requery` property controls whether or not queries are reexecuted for `OracleDataAdapter Fill` calls after the initial `Fill` call.

The `OracleDataAdapter Fill` method allows appending or refreshing data in the `DataSet`. When appending the `DataSet` using the same query with subsequent `Fill` calls, reexecuting the query may not be desirable.

When the `Requery` property is set to `true`, each subsequent `Fill` call reexecutes the query and fills the `DataSet`. This is an expensive operation, and if the reexecution is not required, set `Requery` to `false`. If any of the `SelectCommand` properties or associated parameters must be changed, `Requery` must be set to `true`.

When the `Requery` property is set to `false`, the `DataSet` has all the data as a snapshot at a particular time. The query is executed only for the first `Fill` call; subsequent `Fill` calls fetch the data from a cursor opened with the first execution of the query. This feature is supported only for forward-only fetches. `Fill` calls that try to fetch rows before the last fetched row raise an exception. The connection used for the first `Fill` call must be available for subsequent `Fill` calls.

When filling a `DataSet` with an `OracleRefCursor` object, the `Requery` property can be used in a similar manner. When the `Requery` property is set to `false`, both the connection used for the first `Fill` call and the `OracleRefCursor` object must be available for the subsequent `Fill` calls.

## Guaranteeing Uniqueness in Updating DataSet to Database

This section describes how the `OracleDataAdapter` object configures the `PrimaryKey` and `Constraints` properties of the `DataTable` object which guarantee uniqueness when the `OracleCommandBuilder` object is updating `DataSet` changes to the database.

Using the `OracleCommandBuilder` object to dynamically generate DML statements to be executed against the database is one of the ways to reconcile changes made in a single `DataTable` object with the database.

In this process, the `OracleCommandBuilder` object must not be allowed to generate DML statements that may affect (update or delete) more than a single row in the database when reconciling a single `DataRow` change. Otherwise the `OracleCommandBuilder` could corrupt data in the database.

To guarantee that each `DataRow` object change affects only a single row, there must be a set of `DataColumn` objects in the `DataTable` for which all rows in the `DataTable` have a unique set of values. The set of `DataColumn` objects indicated by the properties `DataTable.PrimaryKey` and `DataTable.Constraints` meets this requirement. The `OracleCommandBuilder` object determines uniqueness in the `DataTable` by checking if the `DataTable.PrimaryKey` is not a null value or if there exists a `UniqueConstraint` object in the `DataTable.Constraints` collection.

This discussion first explains what constitutes uniqueness in `DataRow` objects and then explains how to maintain that uniqueness while updating, through the `DataTable` property configuration.

This section includes the following topics:

- [What Constitutes Uniqueness in DataRow Objects?](#)
- [Configuring PrimaryKey and Constraints Properties](#)
- [Updating Without PrimaryKey and Constraints Configuration](#)

### What Constitutes Uniqueness in DataRow Objects?

This section describes the minimal conditions that must be met to guarantee uniqueness of `DataRow` objects. The condition of uniqueness must be guaranteed before the `DataTable.PrimaryKey` and `DataTable.Constraints` properties can be configured, as described in the next section.

Uniqueness is guaranteed in a `DataTable` object if any one of the following is true:

- All the columns of the primary key are in the select list of the `OracleDataAdapter.SelectCommand` property.
- All the columns of a unique constraint are in the select list of the `OracleDataAdapter.SelectCommand` property, with at least one involved column having a NOT NULL constraint defined on it.
- All the columns of a unique index are in the select list of the `OracleDataAdapter.SelectCommand` property, with at least one of the involved columns having a NOT NULL constraint defined on it.
- A ROWID is present in the select list of the `OracleDataAdapter.SelectCommand` property.

**Note**

A set of columns, on which a unique constraint has been defined or a unique index has been created, requires at least one column that cannot be null for the following reason: if all the columns of the column set can be null, then multiple rows could exist that have a NULL value for each column in the column set. This would violate the uniqueness condition that each row has a unique set of values for the column set.

## Configuring PrimaryKey and Constraints Properties

If the minimal conditions described in "[What Constitutes Uniqueness in DataRow Objects?](#)" are met, then the `DataTable.PrimaryKey` or `DataTable.Constraints` properties can be set.

After these properties are set, the `OracleCommandBuilder` object can determine uniqueness in the `DataTable` by checking the `DataTable.PrimaryKey` property or the presence of a `UniqueConstraint` object in the `DataTable.Constraints` collection. Once uniqueness is determined, the `OracleCommandBuilder` object can safely generate DML statements to update the database.

The `OracleDataAdapter.FillSchema` method attempts to set these properties according to this order of priority:

1. If the primary key is returned in the select list, it is set as the `DataTable.PrimaryKey` property.
2. If a set of columns that meets the following criteria is returned in the select list, it is set as the `DataTable.PrimaryKey` property.

Criteria: The set of columns has a unique constraint defined on it or a unique index created on it, with each column having a NOT NULL constraint defined on it.

3. If a set of columns that meets the following criteria is returned in the select list, a `UniqueConstraint` object is added to the `DataTable.Constraints` collection, but the `DataTable.PrimaryKey` property is not set.

Criteria: The set of columns has a unique constraint defined on it or a unique index created on it, with at least one column having a NOT NULL constraint defined on it.

4. If a ROWID is part of the select list, it is set as the `DataTable.PrimaryKey` property.

Additionally, the `OracleDataAdapter.FillSchema` method performs as follows:

- Setting the `DataTable.PrimaryKey` property implicitly creates a `UniqueConstraint` object.
- If a column is part of the `DataTable.PrimaryKey` property or the `UniqueConstraint` object, or both, it will be repeated for each occurrence of the column in the select list.

## Updating Without PrimaryKey and Constraints Configuration

If the `DataTable.PrimaryKey` or `Constraints` properties have not been configured, for example, if the application has not called the `OracleDataAdapter.FillSchema` method, the `OracleCommandBuilder` object directly checks the select list of the `OracleDataAdapter.SelectCommand` property to determine if it guarantees uniqueness in the `DataTable`. However this check results in a database round-trip to retrieve the metadata for the `SELECT` statement of the `OracleDataAdapter.SelectCommand`.

Note that `OracleCommandBuilder` object cannot update a `DataTable` created from PL/SQL statements because they do not return any key information in their metadata.

## Globalization Support

ODP.NET globalization support enables applications to manipulate culture-sensitive data appropriately. This feature ensures proper string format, date, time, monetary, numeric, sort order, and calendar conventions depending on the Oracle globalization settings.

### Note

- ODP.NET, Managed Driver and ODP.NET Core are not `NLS_LANG` sensitive. They are only .NET locale sensitive.
- ODP.NET, Managed Driver and ODP.NET Core do not support thread-based globalization.

### See Also

["OracleGlobalization Class"](#)

This section includes the following:

- [Globalization Settings](#)
- [Globalization-Sensitive Operations](#)

## Globalization Settings

An `OracleGlobalization` object can be used to represent the following:

- [Client Globalization Settings](#)
- [Session Globalization Settings](#)
- [Thread-Based Globalization Settings](#)

## Client Globalization Settings

Client globalization settings are derived from the Oracle globalization setting (`NLS_LANG`) in the Windows registry of the local computer. The client globalization parameter settings are read-only and remain constant throughout the lifetime of the application. These settings can be obtained by calling the `OracleGlobalization.GetClientInfo` static method.

The following example retrieves the client globalization settings:

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class ClientGlobalizationSample  
{  
    static void Main()
```

```

    {
        OracleGlobalization ClientGlob = OracleGlobalization.GetClientInfo();

        Console.WriteLine("Client machine language: " + ClientGlob.Language);
        Console.WriteLine("Client charset: " + ClientGlob.ClientCharacterSet);
    }
}

```

The properties of the `OracleGlobalization` object provide the Oracle globalization value settings.

## Session Globalization Settings

Session globalization parameters are initially identical to client globalization settings. Unlike client settings, session globalization settings can be updated. However, they can be obtained only after establishing a connection against the database. The session globalization settings can be obtained by calling the `GetSessionInfo` method on the `OracleConnection` object. Invoking this method returns an instance of an `OracleGlobalization` class whose properties represent the globalization settings of the session.

When the `OracleConnection` object establishes a connection, it implicitly opens a session whose globalization parameters are initialized with those values specified by the client computer's Oracle globalization (or (NLS)) registry settings. The session settings can be updated and can change during its lifetime.

The following example changes the date format setting on the session:

```

// C#

using System;
using Oracle.DataAccess.Client;

class SessionGlobalizationSample
{
    static void Main()
    {
        OracleConnection con = new OracleConnection();

        con.ConnectionString = "User Id=scott;Password=tiger;Data Source=oracle;";
        con.Open();

        OracleGlobalization SessionGlob = con.GetSessionInfo();

        // SetSessionInfo updates the Session with the new value
        SessionGlob.DateFormat = "YYYY/MM/DD";
        con.SetSessionInfo(SessionGlob);
        Console.WriteLine("Date Format successfully changed for the session");

        // Close and Dispose OracleConnection object
        con.Close();
        con.Dispose();
    }
}

```

## Thread-Based Globalization Settings

Thread-based globalization parameter settings are specific to each thread. Initially, these settings are identical to the client globalization parameters, but they can be changed as specified by the application. When ODP.NET Types are converted to and from strings, the thread-based globalization parameters are used, if applicable.

Thread-based globalization parameter settings are obtained by invoking the `GetThreadInfo` static method of the `OracleGlobalization` class. The `SetThreadInfo` static method of the `OracleGlobalization` class can be called to set the thread's globalization settings.

ODP.NET classes and structures rely solely on the `OracleGlobalization` settings when manipulating culture-sensitive data. They do not use .NET thread culture information. If the application uses only .NET types, `OracleGlobalization` settings have no effect. However, when conversions are made between ODP.NET types and .NET types, `OracleGlobalization` settings are used where applicable.

#### ① Note

Changes to the `System.Threading.Thread.CurrentCulture` property do not impact the `OracleGlobalization` settings of the thread or the session, or the reverse.

The following example shows how the thread's globalization settings are used by the ODP.NET Types:

```
// C#

using System;
using Oracle.DataAccess.Types;
using Oracle.DataAccess.Client;

class ThreadBasedGlobalizationSample
{
    static void Main(string[] args)
    {
        // Set the thread's DateFormat for the OracleDate constructor
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.DateFormat = "YYYY-MON-DD";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleDate from a string using the DateFormat specified.
        OracleDate date = new OracleDate("1999-DEC-01");

        // Set a different DateFormat for the thread
        info.DateFormat = "MM/DD/YYYY";
        OracleGlobalization.SetThreadInfo(info);

        // Print "12/01/1999"
        Console.WriteLine(date.ToString());
    }
}
```

The `OracleGlobalization` object validates property changes made to it. If an invalid value is used to set a property, an exception is thrown. Note that changes made to the `Territory` and `Language` properties change other properties of the `OracleGlobalization` object implicitly.

#### ① See Also

*Oracle Database Globalization Support Guide* for more information on the properties affected by `Territory` and `Language` globalization settings

## Globalization-Sensitive Operations

This section lists ODP.NET types and operations that are dependent on or sensitive to globalization settings.

### Operations Dependent on Client Computer's Globalization Settings

The `OracleString` structure depends on the `OracleGlobalization` settings of the client computer. The client character set of the local computer is used when it converts a Unicode string to a `byte[]` in the `GetNonUnicode` method and when it converts a `byte[]` of ANSI characters to Unicode in the `OracleString` constructor that accepts a `byte[]`.

### Operations Dependent on Thread Globalization Settings

The thread globalization settings are used by ODP.NET types whenever they are converted to and from .NET string types, where applicable. Specific thread globalization settings are used in most cases, depending on the ODP.NET type, by the following:

- The `ToString` method
- The `Parse` static method
- Constructors that accept .NET string data
- Conversion operators to and from .NET strings

For example, the `OracleDate` type uses the `DateFormat` property of the thread globalization settings when the `ToString` method is invoked on it. This returns a `DATE` as a string in the format specified by the thread's settings.

The thread globalization settings also affect data that is retrieved into the `DataSet` as a string using Safe Type Mapping. If the type is format-sensitive, the strings are always in the format specified by the thread globalization settings.

For example, `INTERVAL DAY TO SECOND` data is not affected by thread settings because no format is applicable for this type. However, the `DateFormat` and `NumericCharacters` properties can impact the string representation of `DATE` and `NUMBER` types, respectively, when they are retrieved as strings into the `DataSet` through Safe Type Mapping.

#### ❗ See Also

- The remarks in [OracleGlobalization Class](#) for more details on the ODP.NET type methods that convert between ODP.NET types and .NET string types, and to identify which thread globalization settings are used for that particular method.
- [OracleDataAdapter Safe Type Mapping](#)
- [Oracle Data Provider for .NET Types Structures](#)

### Operations Sensitive to Session Globalization Parameters

Session globalization settings affect any data that is retrieved from or sent to the database as a string.

For example, if a DATE column is selected with the TO\_CHAR function applied on it, the DATE column data will be a string in the date format specified by the DateFormat property of the session globalization settings. Transmitting data in the other direction, the string data that is to be inserted into the DATE column, must be in the format specified by the DateFormat property of the session globalization settings.

## ODP.NET Driver Globalization Differences

### Default Session Time Zone

ODP.NET drivers set the default session time zone differently. While the session time zone for unmanaged ODP.NET uses an hour offset, managed ODP.NET and ODP.NET Core use the region identifier for setting their respective session time zone. As a result, managed and Core ODP.NET is sensitive to daylight savings in scenarios where the timestamp LTZ values have to be converted from or to the session time zone.

There are two methods to resolve this difference if needed. For ODP.NET, Unmanaged Driver, the application explicitly sets the region identifier with the environment variable ORA\_SDTZ. For example, set ORA\_SDTZ = <Region ID>. If ORA\_SDTZ variable is set, Oracle Client considers this value as the session time zone. The second method is to execute an alter session command to set the session time zone property to the region identifier.

### .NET Culture Info

As noted earlier, ODP.NET, Managed Driver and ODP.NET Core do not support thread-based globalization. ODP.NET, Unmanaged Driver does. As a result, managed ODP.NET and ODP.NET Core strings are insensitive to .NET culture information. As such, invoking the ToString() method on date/time related Oracle provider types (i.e. OracleDate, OracleTimestamp, etc.) will generate a string in the format of MM/dd/yyyy HH:mm:ss[.fffffffff] [timezone]. Whether the outputted string contains a fractional second and/or the timezone will depend on the Oracle provider type being used.

## Data Use Case Domains

Oracle AI Database 26ai introduces Data Use Case Domains, a dictionary object that belongs to a schema and encapsulates a set of optional properties and constraints for common values, such as credit card numbers or email addresses. After you define a use case domain, you can define table columns to be associated with that domain, thereby explicitly applying the domain's optional properties and constraints to those columns.

With Data Use Case Domains, you can define how you intend to use data centrally. They make it easier to ensure you handle values consistently across applications and improve data quality.

All ODP.NET provider types support using Data Use Case Domains, as well as retrieving Data Use Case Domains schema and name information using `OracleDataReader.GetSchemaTable()`. The `SchemaTable` has two columns, `DomainName` and `DomainSchema`, that stores this information.

## Annotations

Oracle Database annotations, a new Oracle AI Database 26ai feature, allow storing database object metadata. They comprise a name, commonly called a key, and an optional value. Both are freeform text fields. A schema object can have more than one annotation.

ODP.NET Core, managed, and unmanaged drivers all support Oracle Database annotations in table and view columns. ODP.NET materializes them as JSON formatted strings in those schema objects.

ODP.NET can retrieve database annotations using `OracleDataReader.GetSchemaTable`. The `SchemaTable` has one column, `Annotations`, that stores this information as JSON formatted string.

## OpenTelemetry

Modern computing has seen more distributed systems scaled and more services added, such as with microservices and serverless applications. With this growth, service ownership across the system is allocated to different individuals, or even organizations. It is increasingly difficult to observe how these services depend on each and affect other services without a unified observability framework. This becomes clear after a deployment or during an outage when issue identification requires speed and accuracy.

OpenTelemetry is such a unified observability framework. It is a popular open-source observability framework for instrumenting, generating, collecting, and exporting telemetry data. It provides a common specification and protocol so that multiple services can furnish a unified version of traces, metrics, and logs. OpenTelemetry relies on components that participate in the observability model to be instrumented, which means the code emits traces, metrics, and logs.

Numerous managed ODP.NET and ODP.NET Core APIs have been instrumented to support OpenTelemetry observability and standards. Developers and operators can then customize the ODP.NET metrics collected.

### ODP.NET OpenTelemetry Traces

Traces record the request paths taken either by an application or end user as they propagate through a multi-service architecture. Traces in OpenTelemetry are defined implicitly by their spans. A trace can be thought of as a directed acyclic graph of spans where the edges between spans are defined as parent/child relationships.

A span, or activity, represents an operation within a transaction. Each span encapsulates the following state:

- Display name
- ODP.NET NuGet version
- Start timestamp and duration
- Attributes – list of key-value pairs
- Events – a tuple (timestamp, name, attributes) and can number from zero or more
- The parent span identifier
- Links to causally related spans through `SpanContext`, which can number from zero or more

ODP.NET spans become child spans if the application creates a (parent) span before calling ODP.NET instrumented APIs.

ODP.NET OpenTelemetry publishes the following activity tags, or attributes.

**Table 3-43 ODP.NET OpenTelemetry activity tags**

| Attribute Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Activity.DisplayName      | Activity display name or the name of the operation being instrumented.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| db.name                   | Database being accessed by the command. The attribute value is the same as the OracleConnection DatabaseName property.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| db.odp.connection.id      | Gives each connection a unique identifier for diagnostic purposes. This identifier can be prefixed with a custom application generated string by setting the ConnectionIdPrefix property in OracleConnection or OracleCommand.                                                                                                                                                                                                                                                                                                                |
| db.odp.roundtrip.count    | Number of database server roundtrips the ODP.NET method makes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| db.odp.roundtrip.duration | Database server roundtrip time, which includes the time needed for ODP.NET processing, network sending and receiving, and database server processing.                                                                                                                                                                                                                                                                                                                                                                                         |
| db.odp.rows_affected      | Row count affected by the SQL DML (INSERT, UPDATE, and DELETE only) when using ExecuteNonQuery*, ExecuteReader*, or ExecuteScalar* methods. Does not return a value for stored procedures and anonymous PL/SQL.                                                                                                                                                                                                                                                                                                                               |
| db.odp.sql_id             | Oracle database SQL statement identifier value, equivalent to SQL_ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| db.odp.user.statement     | Redacted ODP.NET user-supplied command text which can differ from the database statement being executed, such as the case with stored procedures and XML commands.<br><br>This tag is instrumented only when the following two conditions are met: <ul style="list-style-type: none"> <li>• The internally executed statement is different from the user-supplied command text.</li> <li>• setDBStatementForText or SetDbStatementForStoredProcedure is set to true, depending on which is applicable, just like db.statement tag.</li> </ul> |
| db.response.returned_rows | Number of rows fetched per database round trip. This tag is active for SELECT statements only.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| db.statement              | Redacted database statement being executed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| db.system                 | Database name. Oracle is the attribute value for Oracle databases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

ODP.NET OpenTelemetry supports both dynamic and manual instrumentation. The next section describes how to set up each instrumentation method.

### Dynamic and Manual Instrumentation

ODP.NET OpenTelemetry requires an exporter, such Jaeger or Zipkin, to visualize and analyze traces. These exporters are available as NuGet packages and will also include the OpenTelemetry SDK as a NuGet dependency.

ODP.NET OpenTelemetry manual instrumentation has the following requirements:

- Oracle.ManagedDataAccess.OpenTelemetry package available from NuGet Gallery.
- Exporter NuGet package, such as Console or Zipkin, which is used for instrumentation visualization.
- OpenTelemetry SDK, which will be installed automatically with an exporter NuGet package.

Once the ODP.Net OpenTelemetry nuget package is installed, ODP.NET OpenTelemetry is enabled by invoking the `TracerProviderBuilder.AddOracleDataProviderInstrumentation` extension method upon application startup. It accepts various options for configuring OpenTelemetry instrumentation.

#### Code sample: Enabling ODP.NET OpenTelemetry instrumentation with default options

```
using OpenTelemetry.Trace;

Sdk.CreateTracerProviderBuilder()
.AddOracleDataProviderInstrumentation() // ODP.NET extension method
.AddConsoleExporter()
.Build();
```

#### Code sample: Enabling ODP.NET OpenTelemetry instrumentation with all options enabled

```
using OpenTelemetry.Trace;

Sdk.CreateTracerProviderBuilder()
.AddOracleDataProviderInstrumentation(o =>
{
    o.EnableConnectionLevelAttributes = true;
    o.RecordException = true;
    o.InstrumentOracleDataReaderRead = true;
    o.SetDbStatementForText = true;
})
.AddConsoleExporter()
.Build();
```

After enabling ODP.NET OpenTelemetry, whenever a provider instrumented API is called, OpenTelemetry traces will be generated and sent to the configured exporter.

By default, instrumentation for potentially sensitive data is disabled, such as for SQL statements.

A second manual instrumentation method allows enabling ODP.NET OpenTelemetry without adding the ODP.NET OpenTelemetry NuGet package and without calling the `AddOracleDataProviderInstrumentation()` extension method. It requires adding the `TracerProviderBuilder` call `AddSource("Oracle.ManagedDataAccess.Core")` for ODP.NET Core or `AddSource("Oracle.ManagedDataAccess")` for managed ODP.NET.

ODP.NET OpenTelemetry instrumentation will then be enabled using default options. The defaults must be used as there is no way to modify option values. Changing these values require using ODP.NET OpenTelemetry NuGet package directly.

`OpenTelemetry.Api` NuGet package is installed automatically if the application adds any OpenTelemetry exporter NuGet packages, such as `OpenTelemetry.Exporter.Console` or `OpenTelemetry.Exporter.Zipkin`. `OpenTelemetry.Api` is necessary to call the `AddSource()` method.

**Code sample: Enabling ODP.NET OpenTelemetry manual instrumentation via AddSource**

```
Sdk.CreateTracerProviderBuilder()  
    .AddSource("Oracle.ManagedDataAccess.Core")  
    .AddConsoleExporter()  
    .Build();
```

Through this instrumentation method, it is possible to enable and disable ODP.NET OpenTelemetry tracing programmatically at runtime dynamically. To enable, set `OracleConfiguration.OpenTelemetryTracing` to `true` (default). To disable, set it to `false`.

`OpenTelemetryTracing` is available as a managed ODP.NET .NET configuration file setting as well. As a .NET config setting, it is read upon app startup only. Changes to this setting's value after startup are ignored.

**Automatic Instrumentation**

OpenTelemetry automatic instrumentation enables ODP.NET tracing without requiring code changes. Existing .NET apps can turn on tracing without having to recompile.

To use it, add the `OpenTelemetry.AutoInstrumentation 1.7.0` NuGet package or higher to your project. Older package versions require setting environment variables to enable ODP.NET tracing. For example, the following environment variable settings turn on ODP.NET Core tracing using the console exporter.

```
OTEL_DOTNET_AUTO_TRACES_ADDITIONAL_SOURCES=Oracle.ManagedDataAccess.Core  
OTEL_DOTNET_AUTO_TRACES_CONSOLE_EXPORTER_ENABLED=true
```

ODP.NET automatic instrumentation is on by default when using a newer `OpenTelemetry.AutoInstrumentation` NuGet package.

**Instrumented ODP.NET APIs**

The list of managed ODP.NET and ODP.NET Core APIs that are instrumented to support OpenTelemetry is as follows. Every ODP.NET database round trip originating from one of these APIs is instrumented as well.

- `OracleCommand`
  - `ExecuteNonQuery()`
  - All `ExecuteNonQueryAsync` overloads
  - All `ExecuteReader` overloads
  - All `ExecuteReaderAsync` overloads
  - `ExecuteScalar()`
  - All `ExecuteScalarAsync` overloads
  - `ExecuteStream()`
  - `ExecuteToStream(Stream)`
  - `ExecuteXmlReader()`
  - All `ExecuteXmlReaderAsync` overloads

- `OracleConnection`
  - `Close()`
  - `Open()`
  - All `OpenAsync()` overloads
- `OracleDataAdapter`
  - All `Fill` overloads
- `OracleDataReader`
  - `Read()`
  - All `ReadAsync` overloads

[OpenTelemetry](#) documentation

## .NET Metrics

.NET Metrics are application numerical measurements collected at regular time intervals for the purposes of monitoring and alerting about application health. Typically, these metrics are delivered to a monitoring system. In an ODP.NET setting, metrics can monitor connection statistics, such as number of ODP.NET hard connections to the database, number of active connections, or number of free connections.

Starting with version 23.3.2, ODP.NET Core and managed ODP.NET support .NET Metrics. ODP.NET Core supports metrics on .NET (Core) for all operating systems ODP.NET Core is certified with. To use .NET Metrics, ODP.NET projects must include the NuGet package, `System.Diagnostics.DiagnosticSource` 6.0.0 or higher. This package includes the `System.Diagnostics.Metrics` APIs and allows ODP.NET code to be instrumented for rich data payload logging for consumption within the same process.

For metrics instrumentation, developers will associate the metric name `Oracle.ManagedDataAccess.Core` for ODP.NET Core or `Oracle.ManagedDataAccess` for managed ODP.NET to subscribe to and monitor ODP.NET measurements, such as for the `MeterListener` `MeterName` property.

For metrics collection, ODP.NET metrics is tightly integrated with .NET OpenTelemetry. This means that ODP.NET metrics can be published to and analyzed by the rich and expansive toolsets integrated with OpenTelemetry, such as Grafana and Prometheus. Developers can also use common .NET SDK tools, such as `dotnet-counters`. For example, to live monitor all metrics for all ODP.NET Core processes, execute the command:

```
dotnet-counters monitor "Oracle.ManagedDataAccess.Core"
```

You may indicate a specific process and metric to monitor:

```
dotnet-counters monitor -n <process name> <metrics source name>
```

You may identify the process by its identifier:

```
dotnet-counters monitor <metrics source name> -p <process id>
```

Unlike ODP.NET performance counters, there is no need to enable metrics explicitly. ODP.NET metrics counters instances are always available in-memory after an application starts. However, these metrics values are only published for active subscribers.

**Note**

.NET Metrics cannot be consumed by Windows Performance Monitor.

ODP.NET can flexibly collect and distinguish connection metrics at multiple granularity levels, including the:

- AppDomain level
- Connection string or pool manager level
- Database instance level

ODP.NET supports the following metric measurements and levels.

**Table 3-44 Metric Counters and Levels**

| <b>Metrics Counters</b>         | <b>Description</b>                                                                           | <b>Levels Supported</b> |
|---------------------------------|----------------------------------------------------------------------------------------------|-------------------------|
| HardConnects                    | Number of sessions established with database                                                 | All                     |
| HardDisconnects                 | Number of sessions severed from database                                                     | All                     |
| SoftConnects                    | Number of soft connects                                                                      | All                     |
| SoftDisconnects                 | Number of soft disconnects                                                                   | All                     |
| NumberOfActiveConnectionPools   | Number of active connection pools, which are pools with at least one connection              | All                     |
| NumberOfInactiveConnectionPools | Number of inactive connection pools, which are pools with zero connections                   | All                     |
| NumberOfActiveConnections       | Number of connections in use, also known as checked out connections                          | All                     |
| NumberOfFreeConnections         | Number of connections available for use in connection pool, also known as queued connections | All                     |
| NumberOfPooledConnections       | Number of pooled connections, which are the total of checked out and queued connections      | All                     |
| NumberOfNonPooledConnections    | Number of non-pooled active connections                                                      | All                     |
| NumberOfReclaimedConnections    | Number of implicitly garbage-collected connections                                           | All                     |
| NumberOfActiveHardConnections   | Number of opened database connections                                                        | All                     |
| NumberOfActiveSoftConnections   | Number of connections checked out from the pool                                              | All                     |

**Table 3-44 (Cont.) Metric Counters and Levels**

| Metrics Counters                     | Description                                                                                    | Levels Supported     |
|--------------------------------------|------------------------------------------------------------------------------------------------|----------------------|
| NumberOfActiveConnectionPoolGroups   | Number of pool groups (i.e., number of unique connection strings) with at least one connection | AppDomain level only |
| NumberOfInactiveConnectionPoolGroups | Number of pool groups (i.e., number of unique connection strings) with zero connections        | AppDomain level only |

.NET uses long metric level identifiers that are not easily human readable. They consist of a string with the application name, process id, and connection string. To make identifying the metric level easier, ODP.NET developers can customize the connection string identifier name in the `OraclePoolNameCollection.PoolNames` property. Managed ODP.NET developers also have the option to use the `<connectionPools>` section of the .NET configuration file. Developers will be able to configure a different pool name for each unique connection string.

Each cluster of Oracle Real Application Cluster (RAC) instances will use the same pool name configuration since all the instances in a cluster have an identical connection string.

## Debug Tracing

All ODP.NET providers include debug tracing support, which allows logging of all the ODP.NET activities into a trace file. Different levels of tracing are available.

Tracing can record the following information and more:

- Entry and exit information for the ODP.NET public methods
- User-provided SQL statements as well as SQL statements modified by the provider
- Connection pooling statistics such as enlistment and delistment
- Thread ID (entry and exit)
- HA Events and Load Balancing information
- Distributed Transactions
- Self-tuning information
- User-mode dumps upon unmanaged exceptions

The following properties enable and configure tracing for all ODP.NET providers:

- `TraceLevel` – specifies which ODP.NET details to write to the trace file
- `TraceFileLocation` – specifies the directory to write the trace to
- `TraceFileMaxSize` – specifies the maximum file size of each trace file
- `TraceOption` – specifies whether to use a separate trace file for each thread

By default, tracing is turned off (`TraceLevel = 0`). To enable tracing, set `TraceLevel` to the trace level you wish.

Managed ODP.NET and ODP.NET Core have the following trace levels:

- 1 = public APIs
- 2 = private APIs

- 4 = network APIs/data
- 8 = disables writing SQL statements and network packet contents

These values can be bitwise ORed. To enable all traces, set `TraceLevel` to 7.

Unmanaged ODP.NET has the following trace levels:

- 1 = Entry, exit, and SQL statement information
- 2 = Connection pooling statistics
- 4 = Distributed transactions (enlistment and delistment)
- 8 = User-mode dump creation upon unmanaged exception
- 16 = HA Event Information
- 32 = Load Balancing Information
- 64 = Self Tuning Information

These values can be bitwise ORed. To enable all traces, set `TraceLevel` to 127.

`TraceFileLocation` writes to a temporary operating system folder if no value is set.

- ODP.NET Core
  - Windows: *<Windows user temporary folder>\ODP.NET\core\trace*
  - Linux: *<current user temporary folder>/ODP.NET/core/trace*
  - macOS: *<macOS temporary folder>\ODP.NET\core\trace*
- ODP.NET, Managed Driver: *<Windows user temporary folder>\ODP.NET\managed\trace*
- ODP.NET, Unmanaged Driver: *<Windows user temporary folder>\ODP.NET\unmanaged\trace*

The Windows user temporary folder is determined by your local Windows settings, such as your Windows TMP or TEMP environment variable. Typically, it can be `C:\temp` or `C:\Users\<user name>\AppData\Local\Temp`.

`TraceFileMaxSize` defaults to 100 MB if no value is set. Administrators can use this setting to keep trace files down to a manageable size.

`TraceOption` will write all threads to a single trace file at a time by default (`TraceOption=0`).

ODP.NET will create an entry in the Windows event log where the trace was created anytime it creates a new trace file. An event log entry will be added every time in cases when `TraceFileLocation` changes, trace file size exceeds `TraceFileMaxSize`, `TraceLevel` changes, and `TraceOption` changes. In each of these cases, ODP.NET creates a new file and starts writing traces in the newly created file. ODP.NET Core does not support writing to the Windows event log.

To enable ODP.NET tracing, these trace properties must be set appropriately either in the `OracleConfiguration` class (all providers), in the .NET configuration file (managed and unmanaged ODP.NET), or in the Windows Registry (unmanaged ODP.NET).

ODP.NET begins writing to the trace file only after the `OracleConnection.Open()` call occurs.

### Dynamic Tracing

Starting with ODAC 19c, applications can change ODP.NET `OracleConfiguration` class trace settings during runtime. Most commonly, this feature would permit enabling and disabling tracing dynamically while applications continue to run. Dynamic tracing is useful for errors that

occur after applications are run for a considerable time. Customers can avoid collecting extremely large trace files and Oracle Support will find it easier to diagnose problems from more targeted trace files.

ODP.NET Core, managed, and unmanaged all support dynamic tracing.

To enable tracing at runtime, set `OracleConfiguration.TraceLevel` to the trace level desired. To disable tracing dynamically, set `OracleConfiguration.TraceLevel` to zero.

Only `OracleConfiguration` tracing properties can alter runtime tracing behavior. Windows Registry and .NET configuration file settings are only read when an application starts up.

As a general matter, tracing is not recommended for production use because writing to trace files affects performance. However, if a problem only occurs during production, use dynamic tracing to enable and disable tracing during the problem period to capture diagnostics for identifying the root cause.

## Database Application Migration: SQL Translation Framework

A key part of migrating non-Oracle database applications to an Oracle Database requires converting non-Oracle SQL statements to SQL statements that can be processed by an Oracle Database. SQL conversion is generally a manual and laborious process. To minimize the effort, Oracle Database 12c introduces SQL Translation Framework which takes non-Oracle SQL statements from client applications and then translates them at run-time for the Oracle Database to execute.

The SQL Translation Framework can be used to map non-Oracle stored procedure to Oracle stored procedures to ensure successful execution of those stored procedures when migrating to Oracle Database.

Currently, SQL Translation Framework is available for Sybase Adaptive Server Enterprise and Microsoft SQL Server. There is limited support for IBM DB2.

#### Note

SQL Translation Framework is only supported by ODP.NET, Unmanaged Driver. ODP.NET, Managed Driver and ODP.NET Core do not support this feature.

## The SQL Translation Profile

The SQL Translation Profile is a database object that contains the set of captured non-Oracle SQL statements, and their translations or translation errors. The SQL Translation Profile is used to review, approve, and modify translations. A profile is associated to a single translator. However, a translator can be used in one or more SQL Translation Profiles. Typically, there is

one SQL Translation Profile per application, otherwise applications can share translated queries. You can export profiles among various databases.

### 1. Configuring the SQL Translation Profile Name

The default translation profile name for SQL Translation Framework can be configured through the app/web/machine .NET configuration file. If configured, connections, by default will automatically be set to the specified profile when the connection is initially created.

### 2. Changing the SQL Translation Profile Name

ODP.NET supports setting the profile name through the .NET config file, logon trigger, or database service. ODP.NET does not support using ALTER SESSION from an application to set the profile name.

### 3. Forcing Translation

Applications are strictly prohibited to execute the following SQL which forces translation of all SQL's on the database:

```
ALTER SESSION SET events = '10601 trace name context forever, level 32'
```

### 4. Connection Related Error Mapping

Connection Related Error Mapping can be configured through the .NET configuration file. Please note that this error mapping strictly applies to errors which could be thrown before the connection is successfully established. Once the database connection is established successfully, then these error mapping will be completely ignored and further error translation will be provided through the error mapping configured in the database.

The rules to choose an error mapping section in the configuration file are as follows:

- a. ODP.NET uses the error mapping section which matches the configured userId, dataSource, and profile, where userId and dataSource matches the corresponding values in the connection string and profile matches the defaultProfile configuration setting.
- b. If no error mapping section is found from 4.a.), then ODP.NET uses the error mapping section which matches the userId, dataSource, and profile similar to 4.a.), but with the profile that matches with the defaultErrorMappingProfile configuration setting.
- c. If still no error mapping section is found, then ODP.NET uses the global mapping, that is, <ErrorMapping profile="\*">, if configured.

### 5. Stored Procedure Mapping.

Application must map their native stored procedure names to the corresponding Oracle stored procedure names on the translation profile in the database. The following procedure can be used to setup the mapping in the database.

```
DBMS_SQL_TRANSLATOR.REGISTER_SQL_TRANSLATION(
  PROFILE_NAME  VARCHAR2  IN
  SQL_TEXT      CLOB      IN
  TRANSLATED_TEXT CLOB      IN      DEFAULT
  ENABLE        BOOLEAN   IN      DEFAULT)
```

Example of stored procedure mapping:

```
DBMS_SQL_TRANSLATOR.REGISTER_SQL_TRANSLATION('profile_name',
  'native_sp_name',
  'oracle_sp_name');
```

## Allowed Logon Version Client Support

ODP.NET enables applications to specify the minimum authentication protocol that is to be used for a given application or for a given `OracleConnection` object, depending on where it's configured.

ODP.NET Supports the setting of

- `SqlNetAllowedLogonVersionClient` on the `OracleConnection` instance object
- `SqlNetAllowedLogonVersionClient` on the `OracleConfiguration` static object
- `SQLNET.ALLOWED_LOGON_VERSION` and `SQLNET.ALLOWED_LOGON_VERSION_CLIENT` in the `sqlnet.ora` file.

## ADO.NET Entity Framework and LINQ to Entities

This section describes ADO.NET Entity Framework and LINQ to Entities. Entity Framework is a framework for providing object-relational mapping service on data models.

This section contains these topics:

- [Overview of Entity Framework](#)
- [Language Integrated Query and Entity SQL](#)
- [Mapping Oracle Data Types to EDM Types](#)
- [Oracle Number Default Data Type Mapping and Customization](#)
- [Migrating Existing Entity Framework 5 Applications to Entity Framework 6](#)
- [Code First](#)
- [Unsupported Entity Framework Features](#)

### Note

ADO.NET Entity Framework and LINQ to Entities is not supported by ODP.NET Core.

## Overview of Entity Framework

ODP.NET includes support for the ADO.NET Entity Framework and LINQ to Entities. ODP.NET also supports Entity SQL.

Entity Framework is a framework for providing object-relational mapping service on data models. Entity Framework addresses the impedance mismatch between the relational database format and the client's preferred object format.

Entity Framework and LINQ provides productivity benefits for the .NET developer. It abstracts the database's data model from the application's data model. Working with object-relational data becomes easier with Entity Framework's tools. Oracle's integration with Entity Framework and LINQ enables Oracle .NET developers to take advantage of all these productivity benefits.

### Note

Binding scalar parameters is supported with ODP.NET and Entity Framework. In Entity Framework, parameter binding by name is supported. Binding by position is not supported.

Entity data models can be generated from Oracle database schemas. Schemas can be generated from entity data models. These Oracle entity data models can be queried and

manipulated using Visual Studio and ODP.NET. Oracle supports Code First, Database First, and Model First modeling approaches. Specifying filters on the Visual Studio Server Explorer data connection enables the Entity Data Model Wizard to also filter Oracle database objects that are fetched and displayed.

LINQ to Entities can perform queries on the Oracle Database using ODP.NET, including using LINQ to Entities built-in functions. INSERTs, UPDATEs, and DELETEs can be executed using Oracle stored procedures, or by using the `ObjectContext.SaveChanges` method.

ODP.NET supports function import of Oracle stored procedures that Entity Framework can then execute. These Oracle function imports can return a collection of scalar, complex, and entity types, including returning an Oracle implicit result set as an entity type. Implicit result set binding is supported using Oracle `REF CURSOR`.

#### ① See Also

- [Implicit REF CURSOR Binding](#).
- For a tutorial on how to use Entity Framework, Language Integrated Query (LINQ), and generate Data Definition Language (DDL) scripts using Model First, refer to: [Entity Framework, LINQ and Model-First for the Oracle Database](#)

## Language Integrated Query and Entity SQL

Language Integrated Query (LINQ) defines a set of operators that can be used to query, project, and filter data in arrays, enumerable classes, XML, relational databases, and other data sources. One form of LINQ, LINQ to Entities, allows querying of Entity Framework data sources. ODP.NET supports Entity Framework such that the Oracle database can participate in object-relational modeling and LINQ to Entities queries.

Entity SQL is a language that enables querying of Entity Framework conceptual models. It allows querying Entity Framework entities and relationships in a format that is similar to SQL. ODP.NET supports querying Oracle databases through Entity SQL.

LINQ and Entity SQL syntax are generally data source neutral.

## Mapping Oracle Data Types to EDM Types

The ODP.NET manifest file describes the primitive types, such as `VARCHAR2` and `Number`, and the Entity Data Model (EDM) types, such as `string` and `Int32`, that they map to. It also includes the facets for each EDM type.

ODP.NET does not support Time literals and canonical functions related to the Time type.

Oracle considers both `NULL` and empty strings to be `NULL` strings and are considered to be equal. Operations, such as `Equals()`, `Length()`, and `Trim()` on such strings will result in a `NULL` string.

[Table 4-1](#) maps the Oracle data types to their corresponding EDM types. The table also includes details about provider type attributes and the EDM type facets associated with each Oracle data type.

**Table 4-1 Mapping of Oracle Data Types and EDM Types**

| Oracle Data Types | EDM Types<br>(Primitive-TypeKind) | Provider Type Attributes:<br>Name and Value                                                                | EDM Type Facets                           |
|-------------------|-----------------------------------|------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| Bfile             | Binary                            | <ul style="list-style-type: none"> <li>Equal Comparable: False</li> <li>Order Comparable: False</li> </ul> | <a href="#">EDM Type Facets for Bfile</a> |
| Binary_Double     | Double                            | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | Not Applicable                            |
| Binary_Float      | Single                            | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | Not Applicable                            |
| Binary_Integer    | Int32                             | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | Not Applicable                            |
| Blob              | Binary                            | <ul style="list-style-type: none"> <li>Equal Comparable: False</li> <li>Order Comparable: False</li> </ul> | <a href="#">EDM Type Facets for Blob</a>  |
| Boolean           | Boolean                           | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | Not Applicable                            |
| Char              | String                            | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | <a href="#">EDM Type Facets for Char</a>  |
| Clob              | String                            | <ul style="list-style-type: none"> <li>Equal Comparable: False</li> <li>Order Comparable: False</li> </ul> | <a href="#">EDM Type Facets for Clob</a>  |
| Date              | DateTime                          | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | <a href="#">EDM Type Facets for Date</a>  |
| Float             | Decimal                           | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | <a href="#">EDM Type Facets for Float</a> |
| Int               | Int32                             | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | Not Applicable                            |

**Table 4-1 (Cont.) Mapping of Oracle Data Types and EDM Types**

| Oracle Data Types                                                        | EDM Types<br>(Primitive-TypeKind) | Provider Type Attributes:<br>Name and Value                                                                | EDM Type Facets                                            |
|--------------------------------------------------------------------------|-----------------------------------|------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| Interval Day To Second                                                   | Decimal                           | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | <a href="#">EDM Type Facets for Interval Day To Second</a> |
| Interval Year To Month                                                   | Decimal                           | <ul style="list-style-type: none"> <li>Equal Comparable: True</li> <li>Order Comparable: True</li> </ul>   | <a href="#">EDM Type Facets for Interval Year To Month</a> |
| Long                                                                     | String                            | <ul style="list-style-type: none"> <li>Equal Comparable: False</li> <li>Order Comparable: False</li> </ul> | <a href="#">EDM Type Facets for Long</a>                   |

## EDM Type Facets

The following sections enumerate the EDM type facets for the preceding Oracle data types. The first column of each table displays the EDM type facet names for the Oracle data type. Subsequent columns list the facet attribute names and displays their respective values.

### EDM Type Facets for Bfile

**Table 4-2 EDM Type Facets for Bfile**

| Facet name  | Attributes Name and Value                  |
|-------------|--------------------------------------------|
| MaxLength   | DefaultValue: 2147483648<br>Constant: True |
| FixedLength | DefaultValue: False<br>Constant: True      |

### EDM Type Facets for Blob

**Table 4-3 EDM Type Facets for Blob**

| Facet name  | Attributes Name and Value                  |
|-------------|--------------------------------------------|
| MaxLength   | DefaultValue: 2147483648<br>Constant: True |
| FixedLength | DefaultValue: False<br>Constant: True      |

## EDM Type Facets for Char

**Table 4-4 EDM Type Facets for Char**

| Facet Name  | Attributes Name and Value                                            |
|-------------|----------------------------------------------------------------------|
| MaxLength   | Minimum: 1<br>Maximum: 2000<br>DefaultValue: 2000<br>Constant: False |
| Unicode     | DefaultValue: False<br>Constant: True                                |
| FixedLength | DefaultValue: True<br>Constant: True                                 |

## EDM Type Facets for Clob

**Table 4-5 EDM Type Facets for Clob**

| Facet Name  | Attributes Name and Value                  |
|-------------|--------------------------------------------|
| MaxLength   | DefaultValue: 2147483647<br>Constant: True |
| Unicode     | DefaultValue: False<br>Constant: True      |
| FixedLength | DefaultValue: False<br>Constant: True      |

## EDM Type Facets for Date

**Table 4-6 EDM Type Facets for Date**

| Facet Name | Attributes Name and Value         |
|------------|-----------------------------------|
| Precision  | Constant: True<br>DefaultValue: 0 |

## EDM Type Facets for Float

**Table 4-7 EDM Type Facets for Float**

| Facet name | Attributes Name and Value                                        |
|------------|------------------------------------------------------------------|
| Precision  | Minimum: 0<br>Maximum: 126<br>DefaultValue: 0<br>Constant: False |

**Table 4-7 (Cont.) EDM Type Facets for Float**

| Facet name | Attributes Name and Value |
|------------|---------------------------|
| Scale      | Minimum: 0                |
|            | Maximum: 38               |
|            | DefaultValue: 0           |
|            | Constant: False           |

**EDM Type Facets for Interval Day To Second****Table 4-8 EDM Type Facets for Interval Day To Second**

| Facet name | Attributes Name and Value |
|------------|---------------------------|
| Precision  | Minimum: 1                |
|            | Maximum: 251              |
|            | DefaultValue: 251         |
|            | Constant: False           |
| Scale      | Minimum: 0                |
|            | Maximum: 9                |
|            | DefaultValue: 0           |
|            | Constant: False           |

**Note**

EDM types do not support TimeSpan.

Use `Decimal` to represent the total number of seconds. An application can obtain a `TimeSpan` by using the `TimeSpan.FromSeconds` static method.

**EDM Type Facets for Interval Year To Month****Table 4-9 EDM Type Facets for Interval Year To Month**

| Facet name | Attributes Name and Value |
|------------|---------------------------|
| Precision  | Minimum: 1                |
|            | Maximum: 250              |
|            | DefaultValue: 250         |
|            | Constant: False           |
| Scale      | Minimum: 0                |
|            | Maximum: 9                |
|            | DefaultValue: 0           |
|            | Constant: False           |

**EDM Type Facets for JSON****Table 4-10 EDM Type Facets for Json**

| Facet name  | Attributes Name and Value                        |
|-------------|--------------------------------------------------|
| MaxLength   | DefaultValue: 33,554,432 (32M)<br>Constant: True |
| Unicode     | DefaultValue: True<br>Constant: True             |
| FixedLength | DefaultValue: False<br>Constant: True            |

**EDM Type Facets for Long****Table 4-11 EDM Type Facets for Long**

| Facet name  | Attributes Name and Value                  |
|-------------|--------------------------------------------|
| MaxLength   | DefaultValue: 2147483647<br>Constant: True |
| Unicode     | DefaultValue: False<br>Constant: True      |
| FixedLength | DefaultValue: False<br>Constant: True      |

**EDM Type Facets for Long Raw****Table 4-12 EDM Type Facets for Long Raw**

| Facet name  | Attributes Name and Value                  |
|-------------|--------------------------------------------|
| MaxLength   | DefaultValue: 2147483647<br>Constant: True |
| FixedLength | DefaultValue: False<br>Constant: True      |

**EDM Type Facets for NChar****Table 4-13 EDM Type Facets for NChar**

| Facet name | Attributes Name and Value                                            |
|------------|----------------------------------------------------------------------|
| MaxLength  | Minimum: 1<br>Maximum: 1000<br>DefaultValue: 1000<br>Constant: False |

**Table 4-13 (Cont.) EDM Type Facets for NChar**

| Facet name  | Attributes Name and Value            |
|-------------|--------------------------------------|
| Unicode     | DefaultValue: True<br>Constant: True |
| FixedLength | DefaultValue: True<br>Constant: True |

**Note**

For NChar, the actual data is subject to the maximum byte limit of 2000.

The value of 1000 for Maximum and DefaultValue allows the EDM wizard to display columns of NCHAR(1000), where 1000 is the maximum number of characters allowed in DDL.

**EDM Type Facets for NClob****Table 4-14 EDM Type Facets for NClob**

| Facet name  | Attributes Name and Value                  |
|-------------|--------------------------------------------|
| MaxLength   | DefaultValue: 2147483647<br>Constant: True |
| Unicode     | DefaultValue: True<br>Constant: True       |
| FixedLength | DefaultValue: False<br>Constant: True      |

**EDM Type Facets for Number****Table 4-15 EDM Type Facets for Number**

| Facet name | Attributes Name and Value                                        |
|------------|------------------------------------------------------------------|
| Precision  | Minimum: 1<br>Maximum: 38<br>DefaultValue: 38<br>Constant: False |
| Scale      | Minimum: 0<br>Maximum: 38<br>DefaultValue: 0<br>Constant: False  |

**EDM Type Facets for NVarchar2**

**Table 4-16 EDM Type Facets for NVarchar2**

| Facet name  | Attributes Name and Value                                            |
|-------------|----------------------------------------------------------------------|
| MaxLength   | Minimum: 1<br>Maximum: 2000<br>DefaultValue: 2000<br>Constant: False |
| Unicode     | DefaultValue: True<br>Constant: True                                 |
| FixedLength | DefaultValue: False<br>Constant: True                                |

**Note**

For NVARCHAR2, the actual data is subject to the maximum byte limit of 4000.

The value of 2000 for Maximum and DefaultValue allows the EDM wizard to display columns of NVARCHAR2(2000), where 2000 is the maximum number of characters allowed in DDL.

**EDM Type Facets for Raw****Table 4-17 EDM Type Facets for Raw**

| Facet name  | Attributes Name and Value                      |
|-------------|------------------------------------------------|
| MaxLength   | Minimum: 1<br>Maximum: 2000<br>Constant: False |
| FixedLength | DefaultValue: False<br>Constant: True          |

**EDM Type Facets for ROWID****Table 4-18 EDM Type Facets for ROWID**

| Unicode     | DefaultValue: True<br>Constant: True       |
| FixedLength | DefaultValue: False<br>Constant: True      |

## Oracle Number Default Data Type Mapping and Customization

This section describes the default number mapping behavior and how to customize it for your application. You can configure a custom mapping in the .NET configuration file to override the default mapping for each Oracle NUMBER(*p*, *0*), which represents integer values.

Oracle NUMBER data types that represent integers do not have a matching .NET integer data type with exactly the same range of acceptable values. ODP.NET uses a default mapping that ensures any .NET integer type values can be stored within the Oracle database without requiring custom data type mapping. However, it is possible that Oracle NUMBER(*p*, *0*) column data can be larger than what a .NET data type can hold when retrieving values from the database.

For example, in Entity Framework 6, Oracle NUMBER(3, 0) has a default mapping to .NET Byte. Oracle NUMBER(3, 0) can store a value up to 999, while a .NET BYTE can store up to the value of 255. If you expect the Oracle data to exceed 255, modify the mapping to a larger numeric data type, such as a .NET Int16. Setting up this custom mapping allows you to consume the data in .NET without encountering an error. When such a custom mapping is used, be cautious not to insert a .NET Int16 value beyond what an Oracle NUMBER(3, 0) column can hold. Trying to insert Int16.MaxValue (i.e. 32,767) into a NUMBER(3, 0) column will cause an Oracle Database error.

## Entity Framework 6 Mapping and Customization

Managed and unmanaged ODP.NET Entity Framework 6 applications can set up custom data type mapping using a .NET configuration file. The mapping works with Code First, Database First, and Model First use cases. This format improves on the older version as it unifies how managed and unmanaged ODP.NET set their configuration values and supports auto-completion.

The following is an example of an edmMappings section for ODP.NET, Managed Driver:

```
<oracle.manageddataaccess.client>
  <version number="*">
    <edmMappings>
      <edmNumberMapping>
        <add NETType="bool" MinPrecision="1" MaxPrecision="1" DBType="Number" />
        <add NETType="byte" MinPrecision="2" MaxPrecision="3" DBType="Number" />
        <add NETType="int16" MinPrecision="4" MaxPrecision="5" DBType="Number" />
        <add NETType="int32" MinPrecision="6" MaxPrecision="10" DBType="Number" />
        <add NETType="int64" MinPrecision="11" MaxPrecision="19" DBType="Number" />
      </edmNumberMapping>
    </edmMappings>
  </version>
</oracle.manageddataaccess.client>
```

Where:

- DBType is the Oracle Database data type
- NETType is the .NET data type that the Oracle data type maps to
- MinPrecision is the minimum range the Oracle data type will map to the .NET type
- MaxPrecision is the maximum range the Oracle data type will map to the .NET type

The following is an example of an edmmappings section for ODP.NET, Unmanaged Driver. It is exactly same format as the managed driver with the exception of the opening and closing tags.

```
<oracle.unmanageddataaccess.client>
  <version number="*">
    <edmMappings>
      <edmNumberMapping>
        <add NETType="bool" MinPrecision="1" MaxPrecision="1" DBType="Number" />
        <add NETType="byte" MinPrecision="2" MaxPrecision="3" DBType="Number" />
        <add NETType="int16" MinPrecision="4" MaxPrecision="5" DBType="Number" />
        <add NETType="int32" MinPrecision="6" MaxPrecision="10" DBType="Number" />
        <add NETType="int64" MinPrecision="11" MaxPrecision="19" DBType="Number" />
      </edmNumberMapping>
    </edmMappings>
  </version>
</oracle.unmanageddataaccess.client>
```

## New Default Mappings

For Entity Framework 6, ODP.NET 12.1.0.2 introduces new default mappings that apply to Code First, Database First, and Model First scenarios. These changes were necessary to support Code First interoperability.

- .NET Booleans map to Oracle Number(1,0) and vice-versa by default
- .NET Bytes map to Oracle Number(2,0) and Number(3,0) and vice-versa by default

This default behavior can be changed by providing an alternative data type mapping by configuring the section of the .NET config file.

Starting with ODP.NET version 23 and Oracle AI Database 26ai, Oracle Boolean columns map to .NET Booleans in Database First scenarios while .NET Booleans remain mapped to Oracle Number(1) in Code First scenarios.

To override the default Code First mapping, specify the Entity Framework Fluent API `HasColumnType("boolean")` for the entity property.

## Data Type Mapping and Customization Process

To enable custom mapping, add the mapping information to the .NET config file *prior* to EDM creation.

If the EDM was created already before providing the mapping information, then you can *modify* the mappings either through the Visual Studio tools or manually. Using Visual Studio, go to the EDM Model Browser page. Right-click on the table(s) requiring new data type mapping and select **Table Mapping** from the pop-up menu. The **Mapping Details** window will appear usually at the bottom of your screen. Update **Column Mappings** as desired.

If you need to *add* or *delete* mappings, find the **Type** values in the CSDL mapping section of your project's existing EDMX file. Add or delete those **Type** values to the .NET data types you want the application to use. In the example below, the property name types for B00LC0L and BYTEC0L are added to the CSDL and mapped to Boolean and Byte, respectively.

Example Mapping Before CSDL Customization:

```
<Property Name="INT16C0L" Type="Int16" Nullable="false" />
```

Example Mapping After CSDL Customization:

```
<Property Name="B00LC0L" Type="Boolean" Nullable="false" />
<Property Name="BYTEC0L" Type="Byte" Nullable="false" />
<Property Name="INT16C0L" Type="Int16" Nullable="false" />
```

You can employ combinations of these customization possibilities depending on your planned mapping changes. If *many* tables and *many* columns require mapping changes, it is most efficient to delete the EDMX file and regenerate the data model. If a *few* tables and *many* columns require changes, then delete the affected tables, save the EDMX file, and select **Update Model from Database...** to include those tables again. If only a *single* table and *one or two* columns require changes, then modify the EDMX either manually or by using the **Mapping Details** window.

### Note

When using the EDM wizard to create a complex type from a function import, any custom EDM type mappings specified will not be applied automatically. The EDM wizard uses the default type mappings. Developers must then manually edit the resulting complex type. Developers begin this process after the complex type is generated. Any type declaration (field, property, constructor parameter, etc.) in the complex object which has an undesired type mapping, such as Decimal rather than Boolean, should be manually edited to the desired type.

## StoreGeneratedPattern Enumeration

The following sections describe the Identity attribute and the Virtual column.

### Identity Attribute

Oracle Database 12c (12.1) and later versions support table or view Identity attribute columns. Oracle has three Identity attribute types. When the EDM wizard generates a data model from an Oracle Identity attribute-containing table or view, ODP.NET will set the value of StoreGeneratedPattern to Identity in the .edmx file for any of three Oracle Identity types. The Identity attribute-associated column will use the server-generated value during INSERT; hence, application developers no longer need to create a sequence nor trigger. If the .NET application attempts to set the Identity attribute itself, this value will be ignored.

### Virtual Column

Oracle Database versions can store expressions directly in base tables as Virtual columns, also known as Generated columns. Virtual columns cannot be inserted into or updated. ODP.NET will not automatically set StoreGeneratedPattern to Computed in the EF model for Virtual columns. To avoid errors, application developers need to add or change the value of StoreGeneratedPattern to Computed for Virtual columns after the model generation. Once done, Virtual columns are excluded from INSERTs and UPDATES upon calling SaveChanges().

## Resolving Compilation Errors When Using Custom Mapping

If the custom mapping in a .NET configuration file has changed, then regenerate the data model to solve compilation errors introduced by the changes.

Under certain scenarios, custom mapping may cause compilation errors when a project that uses custom mapping is loaded by Visual Studio. One specific scenario is when Visual Studio opens a project with an existing custom mapping that now generates errors when those errors did not exist before. You may use the following workaround for such scenarios:

1. Open Visual Studio Help, About Microsoft Visual Studio. Click **OK** to exit the dialog box. Alternatively, open the to-be-used connection in Server Explorer.
2. Compile the project again to eliminate the compilation errors.

## Mapping Boolean and Guid Parameters in Custom INSERT, UPDATE, and DELETE Stored Procedures

When using your custom INSERT, UPDATE, or DELETE stored procedure in Stored Procedure Mapping, the following error might occur:

Error 2042: Parameter Mapping specified is not valid.

This can happen if a Number parameter has been mapped to a Boolean attribute, or if a RAW parameter has been mapped to a Guid attribute.

The solution is to manually add Precision="1" for the Number parameter, and MaxLength="16" for the RAW parameter of your stored procedure in the SSDL.

# Migrating Existing Entity Framework 5 Applications to Entity Framework 6

To migrate existing Database First Entity Framework 5 applications to Entity Framework 6, use the following instructions. The first four steps are generic to all Entity Framework applications. The last four steps are specific to Oracle deployments.

1. Uninstall Entity Framework 5 in Visual Studio Package Manager Console. For example,  
`Uninstall-Package EntityFramework`

2. Install Entity Framework 6 in Package Manager Console. For example,  
`Install-Package EntityFramework -Version 6.0.2`

This step adds Entity Framework 6 to the `configSections` entry and adds a new section called `entityFramework`.

3. Delete the following namespaces from your application:

```
// C#  
using System.Data.EntityClient;  
using System.Data.Objects;
```

4. Add the following namespaces to your application:

```
// C#  
using System.Data.Entity.Core.EntityClient;  
using System.Data.Entity.Core.Objects;
```

5. Add the Oracle Entity Framework 6 provider configuration information to the .NET config file in the providers section. Modify the ODP.NET version if using a version besides 6.121.2.0. If you installed the ODP.NET NuGet package, you can skip this step as the NuGet install has already added made this change.

```
<provider invariantName="Oracle.DataAccess.Client"  
type="Oracle.DataAccess.EntityFramework.EFOracleProviderServices,Oracle.DataAccess.En  
tityFramework, Version=6.121.2.0, Culture=neutral,  
PublicKeyToken=89b483f429c47342" />
```

```
<provider invariantName="Oracle.ManagedDataAccess.Client"  
type="Oracle.ManagedDataAccess.EntityFramework.EFOracleProviderServices,Oracle.Manage  
dDataAccess.EntityFramework, Version=6.121.2.0, Culture=neutral,  
PublicKeyToken=89b483f429c47342" />
```

6. Add the `Oracle.ManagedDataAccess.EntityFramework` or `Oracle.DataAccess.EntityFramework` assembly as a reference to the project.
7. Modify the Oracle data type to .NET data type mappings as required by your application. See "[Entity Framework 6 Mapping and Customization](#)" for more details.
8. Rebuild the application.

## Code First

Using the Entity Framework Code First modeling path, developers define the application domain model using source code rather than working directly with a designer or an XML-based configuration file. The classes defined within the source code become the model. The Code First model path offers an alternative to the existing Entity Framework Database First and Model First paths. Within Code First, the classes defined in code that comprise the model are

known as Plain Old CLR Objects (POCOs). This name derives from the fact that these classes have no dependency upon Entity Framework itself and are independent of it.

Oracle's support for the Code First modeling path enables .NET developers to take advantage of Oracle Database benefits.

 **See Also**  
[Configuring for Entity Framework Code First](#)

## Mapping of .NET Types to Oracle Types

When using the Code First path, the model is defined by the application's classes and properties. The property data types need to be mapped to the Oracle Database table data types. The following table lists the default mapping of supported .NET types to Oracle types as well as how to map a String property to non-default Oracle types:

**Table 4-25 Mapping of .NET Data Types to Oracle Data Types**

| .NET Data Type | Oracle Data Type | Mapping Method                                                                                                                                                                                        |
|----------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Boolean        | number(1, 0)     | Default<br><br>Note: The default mapping of Boolean/Byte types may be specified in the EDM Mapping configuration. Reference the EDM Mapping sections in the documentation for additional information. |

| Decimal        | number(18, 2)            | Default                                                                                                                                                                                          |
| Single         | binary_float             | Default                                                                                                                                                                                          |
| Double         | binary_double            | Default                                                                                                                                                                                          |
| Guid           | raw(16)                  | Default                                                                                                                                                                                          |
| DateTime       | date                     | Default                                                                                                                                                                                          |
| DateTimeOffset | timestamp with time zone | Default                                                                                                                                                                                          |
| String         | nclob                    | Default                                                                                                                                                                                          |
| String         | clob                     | Set Unicode to false using IsUnicode() fluent API                                                                                                                                                |
| String         | nvarchar2                | Set Max Length to <= 2000 using HasMaxLength() fluent API or MaxLength data annotation                                                                                                           |
| String         | varchar2                 | Set Max Length to <= 4000 using HasMaxLength() fluent API or MaxLength data annotation and set Unicode to false using IsUnicode() fluent API                                                     |
| String         | nchar                    | Set Max Length to <= 1000 using HasMaxLength() fluent API or MaxLength annotation and Set Column Type to NCHAR using HasColumnType() fluent API or Column data annotation                        |
| String         | char                     | Set Max Length to <= 2000 using HasMaxLength() fluent API or MaxLength annotation and Set Column Type to CHAR using HasColumnType() fluent API or Column data annotation                         |
| String         | Long                     | Set Column Type to LONG using HasColumnType() fluent API or Column data annotation<br><br>Note: The long data type is deprecated and not recommended.                                            |
| String         | rowid                    | Set Column Type to ROWID using HasColumnType() fluent API or Column data annotation                                                                                                              |

**Table 4-25 (Cont.) Mapping of .NET Data Types to Oracle Data Types**

| .NET Data Type | Oracle Data Type | Mapping Method                                                                       |
|----------------|------------------|--------------------------------------------------------------------------------------|
| String         | urowid           | Set Column Type to UROWID using HasColumnType() fluent API or Column data annotation |

**Note**

The character based columns, namely, CHAR, NCHAR, VARCHAR2, NVARCHAR2 will be created using character semantics to be able to store the specified Max Length amount of characters. However, due to the Oracle database limit, these columns can store only up to 4000 bytes. As such, these columns may not be able to store 4000 characters even if Max Length is set to 4000 characters since one character may require multiple number of bytes of storage, depending on the data and the database character set. If the character data can be longer than 4000 bytes, it may be more appropriate to use CLOB or NCLOB column.

**Influencing the Oracle Data Type Characteristics**

The type mappings listed in the previous table represent the mappings that occur by default or what is known as convention in Entity Framework. As illustrated with the String type, you can influence the resulting Oracle Data Type for a property as well as characteristics of that data type. There are two Entity Framework methods to influence the resulting Oracle Data Type: Data Annotations and the Code First Fluent API. Data Annotations permit you to explicitly mark a class property with one or more attributes, whereas the Code First Fluent API permits you to use code rather than attributes to achieve the same goal. For additional information regarding the use of Data Annotations and the Code First Fluent API refer to the Microsoft Entity Framework documentation.

The following table illustrates the available functionality:

**Table 4-26 Mapping of Data Annotations and the Code First Fluent APIs**

| Data Annotation | Fluent API   | Purpose                                                    | Applies To       |
|-----------------|--------------|------------------------------------------------------------|------------------|
| Key             | HasKey       | Set a property as the Primary Key.                         | All Scalar Types |
| Required        | IsRequired   | Set the database column as NOT NULL.                       | All              |
| MaxLength       | HasMaxLength | Specifies the maximum length of the property.              | String           |
| NotMapped       | Ignore       | Indicates the property is not mapped to a database column. | All              |

**Table 4-26 (Cont.) Mapping of Data Annotations and the Code First Fluent APIs**

| Data Annotation  | Fluent API         | Purpose                                                                                                                                                                                                                                                                                                                  | Applies To    |
|------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| ConcurrencyCheck | IsConcurrencyToken | Indicates the column should be used for optimistic concurrency checking.<br><br>Note: Do not use with an unbounded (no maximum length specified) string property as this will create a LOB column. Use of a LOB column in the concurrency check will result in an <code>ORA-00932: inconsistent datatypes error</code> . | All           |
| TimeStamp        | IsRowVersion       | Indicates to create the column as a rowversion column.                                                                                                                                                                                                                                                                   | Not Supported |
| Column           | HasColumnType      | Indicates the provider-specific type to use for the database column.<br><br>Note: Must be a legal compatible type. For example a <code>Date</code> property is not legal to map to a number column. Use the <code>TypeName</code> property with the <code>Column Data Annotation</code> to specify the type.             | All           |
| N/A              | IsUnicode          | Indicates to create the column as an N-type, that is, <code>nvarchar2</code> or <code>nclob</code> . Default is <code>true</code> .<br><br>Note: There is no Data Annotation equivalent for <code>IsUnicode</code> .                                                                                                     | String        |
| N/A              | HasPrecision       | Indicates the precision and scale for a decimal property.<br><br>Note: There is no Data Annotation equivalent for <code>HasPrecision</code> .                                                                                                                                                                            | Decimal       |

## Code First Migrations

The Oracle Data Provider for .NET supports Code First Migrations functionality. The use of Code First Migrations with Oracle Database is supported through the Package Manager Console window migrations commands. For information on these commands, refer to the Microsoft Code First Migrations documentation:

<https://docs.microsoft.com/en-us/ef/ef6/modeling/code-first/migrations/>

Code First Migrations utilizes a table known as the Migration History table for tracking migration operations as well as model changes. ODP.NET creates this table, by default, in the user schema specified in the context connection string. This table is named

**\_\_MigrationHistory**.

This table can be created in another user schema besides the user specified in the context connection string. This is accomplished through a process known as Migration History Table Customization, which is described in the following Microsoft documentation.

<https://docs.microsoft.com/en-us/ef/ef6/modeling/code-first/migrations/history-customization>

#### Note

- Changing the user schema for the table is the only supported customization.
- Code First Automatic Migrations is limited to working with the dbo schema only. Due to this limitation it is recommended to use code-based migrations, that is, add explicit migrations through the Add-Migration command.

## Code First Migrations With No Supporting Code Migration File

When using Code First Migrations with ODP.NET, the migration history table may be dropped if no supporting code migration file existed prior to updating the database. Developers should ensure the supporting code migration file has been added prior to updating the database.

The following steps can remove the migration history table:

1. Execute application to create database objects
2. **Enable-Migrations** in the Package Manager Console
3. Make code change to POCO
4. **Update-Database** in the Package Manager Console

The following steps ensure the code migration file is created:

1. Execute application to create database objects
2. **Enable-Migrations** in the Package Manager Console
3. Make code change to POCO
4. **Add-Migration** in the Package Manager Console. This step will create the necessary code migration file.
5. **Update-Database** in the Package Manager Console

## Code First Database Initialization

ODP.NET supports the following Code First Database Initializer methods:

- `CreateDatabaseIfNotExists` (default if none specified)
- `DropCreateDatabaseAlways`
- `DropCreateDatabaseIfModelChanges`

- NullDatabaseInitializer
- MigrateDatabaseToLatestVersion

Due to differences in how Oracle and SQL Server define a database, database initialization actions work on all of the Oracle objects in the model. An Oracle Database is not created or dropped, rather the objects that compose the model are considered to be the database for these operations.

## Oracle Database Object Creation

In order to support the client application, ODP.NET will create and maintain the required database objects. The following are the database objects created and maintained by the provider:

- Table
- Table Column
- Primary Key
- Foreign Key
- Index
- Sequence
- Trigger

For objects which directly relate to a client application object, namely, a table which represents an application class and a table column which represents a class property, the object names used are those provided by the client. These object names must conform to the object identifier length limits for Oracle Database. For example, if a class name length exceeds the valid object identifier length in Oracle Database then the `ORA-00972: identifier is too long` exception will be raised at object creation time.

For the remaining objects, ODP.NET utilizes a name generation algorithm if the supplied name length exceeds the database identifier length limit. If the supplied name length does not exceed the database limit the name is used as-is. In all cases, the object name is created as a quoted identifier in order to preserve case and any special characters which may be part of the identifier.

In cases where the provider generates a name to comply with database identifier length limits, the name is composed of the following underscore separated elements:

- A substring of the original name (from the first character)
- A numeric suffix value calculated from the original name

The following example illustrates the results of the name generation algorithm using a simple POCO in the client application:

```
public class LongSamplePocoTestClassName
{
    [Key]
    public int Id { get; set; }

    [MaxLength(64)]
    public string Name { get; set; }
}
```

The default name for the Primary Key for the resulting table will be:

`PK_LongSamplePocoTestClassNames`

As this name contains 31 characters (single byte per character), it violates the database identifier restrictions in Oracle Database 12.1 and earlier versions. In this example, we will assume we are using a pre-12.2 database version. Newer Oracle database versions support up to 128 bytes. The rewritten Primary Key name will resemble the following value:

```
PK_LongSamplePocoTes_730795129
```

The algorithm is designed to utilize as many characters as possible from the original name such that the new name does not violate the identifier length restrictions.

### Controlling Table Name and Owner

Through the use of Data Annotations or the Entity Framework Fluent API you may control the table name, as well as the table owner. For example, you may choose to explicitly set the table name to conform to your organization's naming standards or if you do not wish to, use the name Entity Framework provides. The `Table` Data Annotation is used to control both the table name and the owner. When using the Fluent API, the `.ToTable` method is used to control the table name and the owner within the `OnModelCreating` override in your class which derives from `DbContext`.

The following examples use an incomplete class definition to illustrate these actions.

Setting the table name using a Data Annotation:

```
[Table("Employee")]  
public class Employee
```

Setting the table name using the Fluent API:

```
protected override void OnModelCreating(DbModelBuilder modelBuilder)  
{  
    modelBuilder.Entity<Employee>().ToTable("Employee");  
}
```

Setting the table name and the owner using a Data Annotation:

```
[Table("Employee ", Schema="TESTUSER")]  
public class Employee
```

Setting the table name and the owner using the Fluent API:

```
protected override void OnModelCreating(DbModelBuilder modelBuilder)  
{  
    modelBuilder.Entity<Employee>().ToTable("Employee", "TESTUSER");  
}
```

#### Note

When using Data Annotations or the Fluent API as above to set the owner, it is required to also set the name.

### Setting the Default Table Owner

Rather than set the table owner for each user table, Entity Framework 6 and higher allows you to set the default owner to be used. This is done by invoking the `HasDefaultSchema` method within the `OnModelCreating` override in your class, which derives from `DbContext`.

For example, the following code will cause all user tables to be created within the `TESTUSER` schema by default:

```
protected override void OnModelCreating(DbModelBuilder modelBuilder)
{
    modelBuilder.HasDefaultSchema("TESTUSER");
}
```

**Note**

The owner name is case-sensitive.

**See Also**

*Oracle AI Database Administrator's Guide.*

## Using the Default Connection Factory

The default connection factory allows ODP.NET connections to be created by providing an Oracle connection string to the DbContext constructor. For example, the following entry could be used to configure the ODP.NET, Managed Driver default connection factory:

```
<defaultConnectionFactory
type="Oracle.ManagedDataAccess.EntityFramework.OracleConnectionFactory,
Oracle.ManagedDataAccess.EntityFramework,
Version=6.121.2.0,
Culture=neutral,
PublicKeyToken=89b483f429c47342" />
```

When using the default connection factory, the application supplies an Oracle connection string to the DbContext base constructor as follows:

```
public class TestContext : DbContext
{
    public TestContext()
        : base("<connection string>")
    {
    }
}
```

Where <connection string> is the ODP.NET connection string. This allows the application to connect to the database using code similar to the following:

```
using (var ctx = new TestContext())
{
    ...
}
```

For additional information please see the Microsoft documentation for the IDbConnectionFactory interface:

<https://docs.microsoft.com/en-us/dotnet/api/system.data.entity.infrastructure.idbconnectionfactory>

## Unsupported Entity Framework Features

The following items are not supported by the current release of the provider:

- Mapping Code First Insert, Update, Delete operations to Stored Procedures
- TimeStamp/RowVersion properties
- Custom Configuration
- Spatial Types
- Table-valued functions
- Connection Resiliency
- Oracle synonyms

The `OracleMigrationSqlGenerator` class and its members can be overridden to allow applications to generate custom SQL. However, Oracle does not support any issues caused by customer code that overrides any of the `OracleMigrationSqlGenerator` implementation. Only issues that can be reproduced without overriding `OracleMigrationSqlGenerator` are supported.

# 5

## Oracle Data Provider for .NET Entity Framework Core

Oracle Data Provider for .NET (ODP.NET) Entity Framework (EF) Core is a database provider that allows Entity Framework Core to be used with Oracle databases.

Entity Framework Core is a cross-platform Microsoft object-relational mapper that enables .NET developers to work with relational databases using .NET objects.

ODP.NET EF Core consists of a single 100% managed code dynamic-link library, `Oracle.EntityFrameworkCore.dll`, available via a NuGet package.

### Note

ODP.NET EF Core does not support Oracle UDTs, REFs, and Object Tables.

This section contains these topics:

- [Oracle Entity Framework Core 9 Features](#)
- [Oracle Entity Framework Core 8 Features](#)
- [Oracle Entity Framework Core 7 Features](#)
- [Application Programming Interface](#)
- [Sample Code](#)
- [Using ODP.NET Core Classes](#)
- [Logging](#)
- [Migrations](#)
- [Scaffolding Or Reverse Engineering](#)
- [Identifier Name Length and Uniqueness](#)
- [Using Large Character or Binary Data Types](#)
- [Performance Considerations](#)
- [Artificial Intelligence Vector Data Types](#)
- [Breaking Changes](#)

## Oracle Entity Framework Core 9 Features

Oracle supports the EF Core 9 features described on this page. This page notes the differences from standard EF Core 9 functionality and Oracle's support.

More details about each of these features standard functionality are described on the [What's New in EF Core 9 web page](#).

## Vector Similarity Search

Oracle EF Core 9 supports `VectorDistance`, `VectorEmbedding`, and `ToVector` EF functions with dense Oracle Database vectors. Default vector type mappings change from .NET string to primitive array types.

Starting with Oracle EF Core 23.8, Oracle Database sparse vectors are supported as well. This release also supports a native `OracleVector` provider type for dense vectors and `OracleSparseVector` provider type for sparse vectors for use with EF Core.

## Complex types: GroupBy and ExecuteUpdate

Complex types gain new Oracle EF Core support in two ways: grouping by a complex type instance and updating by using `ExecuteUpdate`.

## Prune Unneeded SQL Elements

In earlier EF Core releases, generated SQL contained unnecessary elements. Oracle EF Core 9 prunes these unnecessary tables and projection columns. This results in more compact and sometimes more efficient SQL.

In table pruning, unneeded tables in SQL JOINS are removed.

In projection pruning, unneeded projection columns in subqueries are eliminated.

## Force or Prevent Query Parameterization

Oracle EF Core can use the `EF.Constant` or `EF.Parameter` methods to direct the generated query to use a parameter value (`EF.Constant`) or parameter variable (`EF.Parameter`). Oracle EF Core 9 introduces `EF.Parameter` support.

## Inlined Uncorrelated Subqueries

In EF Core 8, an `IQueryable` interface referenced in another LINQ is executed in a separate database round trip. This results in multiple round trips and slows performance.

Oracle EF Core 9 enables the sub-query (`IQueryable`) and the LINQ executions in a single round trip.

## Queries Using Count != 0 Optimization

In Oracle EF Core 8, LINQ queries could be translated to use the SQL `COUNT` function. In EF Core 9, these LINQ queries will use the more efficient SQL `EXISTS`.

## New ToHashSetAsync<T> Methods

Oracle EF Core adds an asynchronous version of `Enumerable.ToHashSet<T>`. This method returns query results as a `HashSet`.

## Improved Data Seeding

Oracle EF Core has an easy way to populate a database with an initial data set. This is known as data seeding. `DbContextOptionsBuilder` introduces new `UseSeeding` and `UseAsyncSeeding` methods that are executed when the `DbContext` initializes during an `EnsureCreated` or `EnsureCreatedAsync` operation.

### Auto-Compiled Models and MSBuild Integration

Compiled EF Core models enhance app startup time for large models with hundreds of entity types. Previously, compiled models were generated manually using the command line. EF Core then was directed to use them with the `UseModel` method.

Oracle EF Core 9 can detect and use compiled models automatically, eliminating the need for `UseModel`. Moreover, if entity types or `DbContext` are changed, MSBuild automatically updates the compiled model when the model project is built.

### Make Existing Model Building Conventions More Extensible

Oracle EF Core 9 makes it easier to extend some of the public model-building conventions, such as the property mapping code.

### Update `ApplyConfigurationsFromAssembly` to Call Non-Public Constructors

The `ApplyConfigurationsFromAssembly` method can now be instantiated from a non-public constructor, as well as the public, parameterless form of this constructor has improved error messages during failed instantiations.

### Not Supported Features

The Oracle EF Core 9 provider does not support the following features:

- Protection against concurrent migrations, also known as database lock during migrations
- Read-only primitive collections

# Oracle Entity Framework Core 8 Features

Oracle supports the EF Core 8 features described on this page. This page notes the differences from standard EF Core 8 functionality and Oracle's support.

More details about each of these features standard functionality are described on the [What's New in EF Core 8.0 web page](#).

## JSON Columns

Oracle database includes comprehensive JSON document and column support, including binary JSON storage and JSON Relational Duality.

EF Core provides support for JSON columns that allows the mapping and modifying of aggregates built from .NET types to JSON documents. LINQ queries can act upon the aggregates, which will translate to the necessary query constructs to perform operations on the JSON.

Oracle EF Core 8 JSON column support includes:

- JSON column mapping
- Queries into JSON columns
- JSON column data updates
- Translate element access into JSON arrays

Oracle Database 21c and higher support JSON columns. Oracle EF Core 8 will map aggregate types to NCLOB columns instead of JSON columns when connected to earlier Oracle database versions.

## Math Translations

Concrete .NET types, such as double and float, recently introduced generic math interfaces. They mirrored existing functionality in .NET Math and MathF classes.

Oracle EF Core 8 translates calls to these generic math APIs in LINQ using existing Oracle SQL translations for Math and MathF. Developers can choose between math APIs, such as either `Math.Sin` or `double.Sin`.

Oracle EF Core support all math translations except for `DegreesToRadians` and `RadiansToDegrees`.

## Value Objects Using Complex Types

Oracle EF Core 8 support complex types, also known as object types. They are structured to hold multiple values, such as an address.

Complex types must be configured in the model using either mapping attributes "[ComplexType]" or by calling the "ComplexProperty" API in `OnModelCreating`.

Complex types do not map to their own tables. Instead, they are saved inline to the table columns. This matches the table sharing behavior of owned types.

## Model Building - Discriminator Columns Maximum Length

In Oracle EF Core 8, string discriminator columns in table-per-hierarchy inheritance mapping are now configured with a maximum length. This length is calculated as the smallest Fibonacci number covering all defined discriminator values.

### Raw SQL Queries for Unmapped Types

Oracle EF Core 8 has added raw SQL queries returning any mappable CLR type, without including that type in the EF model. Queries using unmapped types are executed using `SqlQuery` or `SqlQueryRaw`.

### Lazy-Loading Enhancements

Oracle EF Core 8 adds the following lazy-loading features:

- Lazy-loading for no-tracking queries
- Explicit loading from untracked entities
- Opt-out of lazy-loading for specific navigations

### Access to Tracked Entities

Oracle EF Core 8 supports new APIs for applications to lookup tracked entities by their primary, alternate, or foreign key. These APIs are accessed through the `LocalView<TEntity>` of the entity type.

### Not Supported Features

The following feature is not supported by the Oracle EF Core 8 provider:

- Primitive Collections

## Oracle Entity Framework Core 7 Features

Oracle Entity Framework Core 7 supports .NET 6 and 7 runtimes. It supports connecting to Oracle Database 12.2 and higher.

Oracle supports the EF Core 7 features described on this page. This page notes the differences from standard EF Core 7 functionality and Oracle's support. More details about each of these features standard functionality are described on the [What's New in EF Core 7.0 web page](#).

### Stored Procedure Mapping

Using Oracle PL/SQL stored procedures to perform entity insert, update, and delete operations are supported. [Table 5-2](#) lists the supported parameter data types. Oracle PL/SQL packages and functions are not currently supported.

#### Note

The `HasRowsAffectedReturnValue()` API is not supported.

### Query Enhancements

Oracle EF Core improves the following LINQ query translations:

- `GroupBy` as final operator
- `GroupJoin` as final operator
- `GroupBy` entity type

- Subqueries don't reference ungrouped columns from outer query
- Read-only collections can be used for Contains
- Translations of string aggregate functions, `string.Join` and `string.Concat`
- Translation of `string.IndexOf`
- Translation of `GetType` for entity types
- Filtered Include on hidden navigations

### Model Building Conventions

Oracle EF Core now supports model building that allow applications to remove or replace any model building conventions and to add new conventions.

### Model Building Enhancements

New enhancements in model building are supported with the following features and limitations:

- Mapping attribute for composite keys
- `DeleteBehavior` mapping attribute
- Properties mapped to different column names
- Unidirectional many-to-many relationships
- Entity splitting
- Descending Indexes are only supported for code first, and not for scaffolding.
- `ITableIndex.IsDescending` property, which returns a Boolean indicating whether the index is descending or not, is not supported.

### Custom Reverse Engineering Templates

Oracle EF Core 7 provider supports scaffolding customization of a generated EF model.

### New and Improved Interceptors and Events

Enhancements to interceptors which enable interception, modification, and/or suppression of EF Core operations are supported. These new improvements include interception for:

- New entity instance creation and population
- LINQ expression tree modification before query compilation
- Handling optimistic concurrency
- Connections before checking the connection string is populated
- After the result set has been consumed, but before the result set is closed
- `DbConnection` creation
- `DbCommand` after initialization

The new events include:

- Right before an entity is tracked or changes state
- Before and after changes are detected to entities and properties

### DbContext API and Behavior Enhancements

Improvements to `DbContext` and related classes are supported.

- Suppressor for uninitialized DbSet properties
- Distinguish cancellation from failure in logs
- New IProperty and INavigation overloads for EntityEntry methods
- EntityEntry for shared-type entity types
- ContextInitialized is now logged as Debug
- IEntityEntryGraphIterator is publicly usable

### Improved Value Generation

Improvements to the automatic generation of values for key properties are supported.

- Value generation for domain-driven design guarded types
- Sequence-based key generation

For sequence-based key generation, Oracle EF Core 7 provider introduces a new fluent API, `UseSequence()`, which can configure the default values of a key property to be generated using a database sequence.

### Migrations Tooling Improvements

Improvements when using the EF Core Migrations command-line tools are supported.

This includes the `UseOracle()` method which now accepts a null connection string so that the connection string can be assigned at a later time without encountering an exception. It also includes being able to detect when migration tools are running.

### First-Class Windows Forms Data Binding

The new data binding experiences introduced in Windows Forms which integrates well with EF Core are supported by the Oracle EF Core 7 provider.

### Not Supported Features

The following features are not supported by the Oracle EF Core 7 provider.

- Mapping to and from JSON columns
- Bulk updates
- Faster SaveChanges
- TPC inheritance mapping
- Performance enhancements for proxies

## Application Programming Interface

ODP.NET EF Core supports standard EF Core application programming interfaces. The provider contains additional extension methods specific to the provider.

- [DatabaseFacade Class](#)
- [DbContextOptionsBuilder Class](#)
- [IQueryingEnumerable Interface](#)
- [MigrationBuilder Class](#)
- [ModelBuilder Class](#)

- [OracleSQLCompatibility Enumeration](#)
- [Database Functions \(EF.Functions\) for Vectors](#)

## DatabaseFacade Class

ODP.NET EF Core contains additional extension methods and changes to method default behavior for the DatabaseFacade class.

- [DatabaseFacade.IsOracle](#)
- [DatabaseFacade.EnsureCreated](#)
- [DatabaseFacade.EnsureCreated\(string\[\]\)](#)
- [DatabaseFacade.EnsureDeleted](#)
- [DatabaseFacade.EnsureDeleted\(string\[\]\)](#)

### DatabaseFacade.IsOracle

This method returns true if ODP.NET is the currently used database provider.

```
// C#  
public static bool IsOracle()
```

Returns a bool value.

#### Note

The provider is only known after the provider is set in the DbContext.

### DatabaseFacade.EnsureCreated

This property ensures that the tables for the schema defined in the current context exists.

#### Declaration

```
// C#  
public static bool EnsureCreated()
```

#### Return Value

A bool

#### Remarks

If any of the tables in the schema exist, then no action is taken. Pre-existing tables are not checked for compatibility with the EF Core context model.

If none of the tables in the schema exist, then all the defined context model objects are created.

If the user/schema specified in the connection string does not exist, then an error is thrown and no action is taken to create the user/schema. The administrator must create the user/schema and assign the appropriate privileges prior to using this method.

The return value is `true` if all the objects defined in the context are created. It is `false` if any of the tables for the schema already exist.

### Exception

`NotSupportedException()` is thrown when a non-existent user/schema is specified in the connection string.

*Type:* `NotSupportedException()`

*Message:* Required user does not exist or invalid user name/password provided

## DatabaseFacade.EnsureCreated(string[])

This property ensures that the tables for the specified schemas in the string array exist.

### Declaration

```
// C#  
public static bool EnsureCreated (string[] schemas)
```

### Parameters

- `schemas` – List of schemas to check for the EF Core context's pre-existing tables. Schema names are case-sensitive.

### Return Value

A `bool`

### Remarks

If any of the tables in the string array schema list exists, then no action is taken. Pre-existing tables are not checked for compatibility with the EF Core context model.

If none of the tables in the string array schema list exist, then all the defined context model objects are created.

If the user/schema specified in the connection string does not exist, then an error is thrown and no action is taken to create the user/schema. The administrator must create the user/schema and assign the appropriate privileges prior to using this method.

If the schemas passed to this method does not include the user/schema specified in the connection string, then that schema is implicitly added to the array of schemas.

If the array of schemas is null or length zero, then the `DatabaseFacade.EnsureCreated()` API is called.

The return value is `true` if all the objects defined in the context are created. It is `false` if any of the tables for the schema already exist.

### Exception

`NotSupportedException()` is thrown when a non-existent user/schema is specified in the connection string.

*Type:* `NotSupportedException()`

*Message:* Required user does not exist or invalid user name/password provided

### Sample Code

```
using (var db = DbContext())
{
    db.Database.EnsureCreated(new string[]{"SCOTT", "HR", "EFUser"});
}
```

## DatabaseFacade.EnsureDeleted

This property ensures that all the schema user's created objects are deleted.

### Declaration

```
// C#
public static bool EnsureDeleted()
```

### Return Value

A bool

### Remarks

If none of the EF Core context model objects exist, no action is taken. If any of the objects exist, then all the user/schema objects are dropped, except for Oracle data dictionary objects.

**Warning:** The dropped objects include schema objects outside of the EF Core context model, as long as the user/schema has privileges to drop those objects.

If the schema defined in the current context does not exist, then no action is taken.

The return value is `true` if an attempt is made to drop all user created objects related to the schema in the current context. It is `false` if the schema specified in the connection string does not exist.

## DatabaseFacade.EnsureDeleted(string[])

This property ensures that the user/schema objects for the specified schemas in the string array are deleted.

### Declaration

```
// C#
public static bool EnsureCreated (string[] schemas)
```

### Parameters

- `schemas` – List of schemas to drop user generated objects. Schema names are case-sensitive.

### Return Value

A bool

### Remarks

If any of the objects exist, then all the user/schema objects are dropped, except for Oracle data dictionary objects. If none of the EF Core context model objects exist, no action is taken. If the schemas passed to this method does not include the user/schema specified in the connection string, then that schema is implicitly added to the array of schemas.

**Warning:** The dropped objects include schema objects outside of the EF Core context model, as long as the user/schema has privileges to drop those objects.

If the specified schemas do not exist, then no action is taken.

The return value is true if an attempt is made to drop all user created objects that the user has privilege to in the specified schemas. It is false if the schema specified in the connection string does not exist.

### Sample Code

```
using (var db = DbContext())
{
    db.Database.EnsureDeleted(new string[]{"SCOTT", "HR", "EFUser"});
}
```

## DbContextOptionsBuilder Class

ODP.NET EF Core contains additional extension methods and changes to method default behavior for the DbContextOptionsBuilder class.

- [DbContextOptionsBuilder.UseOracle](#)
- [UseOracle\(string connectionString\)](#)
- [UseOracle\(DbContextOptionsBuilder, Action<OracleDbContextOptionsBuilder> oracleOptionsAction = null\)](#)
- [UseOracleSQLCompatibility\(enum version\)](#)

## DbContextOptionsBuilder.UseOracle

This extension method sets the provider and database connection configuration to connect to Oracle Database. Developers can set any connection string attributes that are available in ODP.NET Core. The available method overloads that can be called are as follows:

- `UseOracle(string connectionString)`
- `UseOracle(string connectionString, Action<OracleDbContextOptionsBuilder> oracleOptionsAction = null)`
- `UseOracle(DbConnection connection, Action<OracleDbContextOptionsBuilder> oracleOptionsAction = null)`
- `DbContextOptionsBuilder<TContext> UseOracle<TContext>(string connectionString, Action<OracleDbContextOptionsBuilder> oracleOptionsAction = null)`
- `DbContextOptionsBuilder<TContext> UseOracle<TContext>(DbConnection connection, Action<OracleDbContextOptionsBuilder> oracleOptionsAction = null)`
- `UseOracle(DbContextOptionsBuilder, Action<OracleDbContextOptionsBuilder> oracleOptionsAction = null)`

## UseOracle(string connectionString)

This extension method sets the provider and database connection configuration. Developers can set any connection string attributes that are available in ODP.NET Core.

### Declaration

```
// C#
optionsBuilder.UseOracle(@"User Id=blog;Password=<password>;Data Source=pdborcl;");
```

## UseOracle(DbContextOptionsBuilder, Action<OracleDbContextOptionsBuilder> oracleOptionsAction = null)

The following extension configures the EF Core context to connect to an Oracle database without initially setting any `DbConnection` nor connection string. The `DbConnection` or connection string must be set before the `DbContext` attempts to connect to a database. To set the connection using, use `RelationalDatabaseFacadeExtensions.SetDbConnection` or `RelationalDatabaseFacadeExtensions.SetConnectionString`.

### Declaration

```
// C#  
public static DbContextOptionsBuilder UseOracle(this DbContextOptionsBuilder,  
Action<OracleDbContextOptionsBuilder>)
```

### Parameters

- `DbContextOptionsBuilder` - The builder being used to configure the context
- `Action<OracleDbContextOptionsBuilder>` - An optional action to allow additional Oracle specific configuration

### Return Value

The options builder so that further configuration can be chained.

### Sample Code

```
// C# - Setting up the DB context  
protected override void OnConfiguring(DbContextOptionsBuilder optionsBuilder) =>  
optionsBuilder.UseOracle();  
// Using the DB context  
using (var context = new DbContext())  
{  
context.Database.SetDbConnection(new OracleConnection(<connection string>));  
}
```

#### ① Note

- `optionsBuilder` is of type `DbContextOptionsBuilder`.
- Do not use Oracle built-in accounts to store Entity Framework Migrations.

## UseOracleSQLCompatibility(enum version)

This extension method specifies the database version generated SQL and functionality to be compatible with.

With Oracle EF Core 21.12.1 and higher, `UseOracleSQLCompatibility` extension method now takes an enumeration type as an argument rather than a string value.

The valid enum values that can be used are:

- `OracleSQLCompatibility.DatabaseVersion19`
- `OracleSQLCompatibility.DatabaseVersion21`

- `OracleSQLCompatibility.DatabaseVersion23`

By default, the SQL compatibility value will be `OracleSQLCompatibility.DatabaseVersion21`. So generated SQL will be compatible with database version 21. If using Oracle EF Core 8 with `OracleSQLCompatibility.DatabaseVersion21`, JSON database columns are supported. Otherwise, aggregate types will map to NCL0B columns in the database instead of JSON.

Using `OracleSQLCompatibility.DatabaseVersion23`, the .NET bool type will map to Oracle BOOLEAN column type rather than NUMBER(1) by default. To map .NET bools to NUMBER(1) by default, use `OracleSQLCompatibility.DatabaseVersion21` or lower.

The default enumeration value matches the ODP.NET version. For ODP.NET 21c, the default is `OracleSQLCompatibility.DatabaseVersion21`.

The following example shows how to set `UseOracleSQLCompatibility`.

```
// C#
optionsBuilder.UseOracle("User Id=hr;Password=<password>;Data Source = inst1", b =>
b.UseOracleSQLCompatibility(OracleSQLCompatibility.DatabaseVersion19));
```

#### Note

- `optionsBuilder` is of type `DbContextOptionsBuilder`.
- This extension method exists for EF Core 8 only.

## IQueryingEnumerable Interface

This section includes:

- [IQueryingEnumerable.ToQueryString Extension Method](#)

## IQueryingEnumerable.ToQueryString Extension Method

A string representation of the Oracle SQL query used. This extension method will generate SQL that can be run in Oracle Database and Oracle Autonomous Database.

To execute the generated SQL programmatically, developers can adapt the following C# pseudo-code for their specific requirements. The pseudo-code demonstrates how to generate the script using `ToQueryString()` on a sample LINQ query, and then how to execute the script with an `OracleCommand`, depending on the database version backing the application.

```
using System.Data;
using Microsoft.EntityFrameworkCore;
using Oracle.ManagedDataAccess.Client;

class ToQueryStringPseudoCode
{
    static void Main(string[] args)
    {
        using (ModelContext db = new ModelContext())
        {
            //sample LINQ to convert query string from
            string name = "Name";
            var query = db.Set<Instructor>().Where(c => c.Name == name);
            string sqltext = query.ToQueryString();
        }
    }
}
```

```

        //'sqltext' can be used directly with OracleCommand
        OracleConnection con = new OracleConnection("<Connection String>");
        con.Open();
        OracleCommand cmd = con.CreateCommand();
        cmd.CommandText = sqltext;
        OracleDataReader reader;
        reader = cmd.ExecuteReader();

        //verifying the result set
        while (reader.Read())
        {
            Console.WriteLine($"{reader[0]}, {reader[1]}, {reader[2]}, {reader[3]}");
        }
        con.Close();
    }
}
}

```

## MigrationBuilder Class

### MigrationBuilder.IsOracle Extension Method

Returns true if the MigrationBuilder object uses ODP.NET as its database provider.

#### Declaration

```
public static bool IsOracle(this MigrationBuilder)
```

#### Parameters

- MigrationBuilder object

#### Return Value

A bool.

#### Sample Code

```

var migrationBuilder = new MigrationBuilder("Oracle.EntityFrameworkCore");
bool b_oracle = migrationBuilder.IsOracle(); //returns true for ODP.NET

```

## ModelBuilder Class

ODP.NET EF Core contains additional extension methods and changes to method default behavior for the ModelBuilder class.

- [ModelBuilder UseIdentityColumn\(\) and UseOracleIdentityColumn\(\)](#)

## ModelBuilder UseIdentityColumn() and UseOracleIdentityColumn()

This extension method specifies whether the column is an identity column or have it associated with a sequence and a trigger to have a server generated column value, depending on the value passed to UseOracleSQLCompatibility(). By default, columns do not have this extension method enabled.

```

// C #
protected override void OnModelCreating(ModelBuilder modelBuilder)
{

```

```
modelBuilder.Entity<Blog>().Property(p => p.Id).UseIdentityColumn();  
}
```

For EF Core 3.1 and higher versions, use `UseIdentityColumn`. For EF Core 3.1 Core and lower versions, you can use `UseOracleIdentityColumn`. Starting with EF Core 5, `UseOracleIdentityColumn` is no longer available to use with Oracle EF Core. These two methods have identical functionality. For the remainder of this section, the term `UseIdentityColumn` is synonymous with `UseOracleIdentityColumn`.

## OracleSQLCompatibility Enumeration

The `OracleSQLCompatibility` enum is used to specify database version the generated SQL should be compatible with. It is also used to determine the type mappings for .NET types.

There are currently 3 possible values of `SQLCompatibility` that can be set in the application using `UseOracleSQLCompatibility()` API.

- `OracleSQLCompatibility.DatabaseVersion19`
- `OracleSQLCompatibility.DatabaseVersion21`
- `OracleSQLCompatibility.DatabaseVersion23`

If using Oracle EF Core 8 with `OracleSQLCompatibility.DatabaseVersion21`, JSON database columns are supported. Otherwise, aggregate types will map to NCLOB columns in the database instead of JSON.

Using `OracleSQLCompatibility.DatabaseVersion23`, the .NET bool type will map to Oracle `BOOLEAN` column type rather than `NUMBER(1)` by default. To map .NET bools to `NUMBER(1)` by default, use `OracleSQLCompatibility.DatabaseVersion21` or lower.

The default enumeration value matches the ODP.NET version. For ODP.NET 21c, the default is `OracleSQLCompatibility.DatabaseVersion21`.

## Database Functions (EF.Functions) for Vectors

EF Core providers can have custom C# methods that invoke database functions. These methods can be used in LINQ as `EF.Functions` extension methods. ODP.NET provides a number of them for vector data management. These vector methods can be used in EF Core 9 and higher with Oracle EF Core version 23.6 or higher. Vector features require connecting to Oracle AI Database 26ai or higher and setting `OracleSQLCompatibility` to be `DatabaseVersion23` or higher.

- [VectorDistance](#)
- [VectorEmbedding](#)
- [ToVector](#)

### VectorDistance

This method calculates the distance between the two given vectors.

#### Declaration

```
// C# - 2 overloaded methods  
public static double VectorDistance(object expression1, object expression2)  
public static double VectorDistance(object expression1, object expression2, string  
metric)
```

### Parameters

expression1 and expression2 represent the two vectors for which the distance is to be calculated.

metric is a string which indicates the metric used to calculate the distance.

### Return Value

System.Double that is the distance between the two vectors in the metric format

### Exception

- If any argument value is null, then an `ArgumentNullException` is thrown.
- If any argument value is empty string, then an `ArgumentException` is thrown.
- If any invalid argument value is passed, then an `OracleException` is thrown with the database error message.

### Remarks

This method uses the Oracle `VECTOR_DISTANCE` database function.

Both vector parameters must have the same number of dimensions and vector format. This is a `VECTOR_DISTANCE` function requirement. They can be column expressions, variables, or inline strings.

The possible distance metric values are:

- Cosine (Default)
- Dot
- Euclidean
- Euclidean\_Squared
- Hamming
- Jaccard
- Manhattan

If you want to use the metric parameter as a variable, then you must enclose it in the `EF.Constant()` method because the metric argument in the `VECTOR_DISTANCE` database function is not a string, but a metric expression.

### Sample Code

```
var query1 = (from t in ctx.AIData
              where t.Id == 10
              select EF.Functions.VectorDistance(t.V, vector, "Cosine")).ToList();

var distanceType= "Cosine";
var query2 = (from t in ctx.AIData
              where t.Id == 10
              select EF.Functions.VectorDistance(t.V, vector,
EF.Constant(distanceType))).ToList();
```

**① See Also**

Oracle SQL VECTOR\_DISTANCE database function

## VectorEmbedding

This method returns the input string's vector embedding using the specified model.

**Declaration**

```
// C#  
public static object VectorEmbedding(string modelName, object expression)
```

**Parameters**

modelName is the importing embedding model to generate the vector embedding from.

expression is the value from which to generate the embedding.

**Return Value**

System.Object that is the provided expression's embedding in a vector format.

**Exception**

- If any argument value is null, then an `ArgumentNullException` is thrown.
- If any argument value is empty string, then an `ArgumentException` is thrown.
- If any invalid argument value is passed, then an `OracleException` is thrown with the database error message.

**Remarks**

This method uses the Oracle VECTOR\_EMBEDDING database function.

The modelName should be the same as what is in the database. The model needs to be loaded in the database prior to using this EF Core method.

modelName can be an inline string or variable. If it is a variable, enclose it in the `EF.Constant()` method to prevent parameterization. modelName is an expression, not a string in the VECTOR\_EMBEDDING database function.

The expression argument can be a column, variable, or inline string.

**Sample Code**

```
string keyword = "cars";  
var query1 = (from t in ctx.AIData  
              select EF.Functions.VectorEmbedding("doc_model",  
keyword)).Take(1).ToList();  
  
var modelName = "doc_model"  
var query2 = (from t in ctx.AIData  
              select EF.Functions.VectorEmbedding(EF.Constant(modelName),  
keyword)).Take(1).ToList();
```

**① See Also**

Oracle SQL VECTOR\_EMBEDDING database function

## ToVector

This method converts a vector from one format to another format.

**Declaration**

```
// C# - 3 overloaded methods
public static object ToVector(object expression)
public static object ToVector(object expression, long dimensions)
public static object ToVector(object expression, long dimensions, string format)
```

**Parameters**

expression is the vector to be converted to a different vector format.

dimensions is a numeric value for the number of dimensions for the new vector.

format is the vector numeric format to convert the vector to.

**Return Value**

System.Object that is the in the specified vector numeric format.

**Exception**

- If any argument value is null, then an `ArgumentNullException` is thrown.
- If any argument value is empty string, then an `ArgumentException` is thrown.
- If any invalid argument value is passed, then an `OracleException` is thrown with the database error message.

**Remarks**

This method uses the Oracle `T0_VECTOR` database function.

expression could be a column, variable, or inline string in vector format.

The number of dimensions can alternatively be specified as zero (0). In this case, the dimension number is determined by expression.

The possible vector format values are:

- Binary
- Int8
- Float32
- Float64
- \*

This is the target vector numeric format to convert the vector to. If format value is not specified or is an asterisk (\*), the format used is `Float32`.

To use dimensions or format as variables, enclose them in the `EF.Constant()` method.

Oracle SQL TO\_VECTOR database function

## Sample Code

This code sample demonstrates code necessary to create a blogging context of Blogs and Posts objects.

EF Core will create database schema tables mapping to these two objects. When the application is run, it will add a new blog entry to the Blogs table, then retrieve that entry back to the application.

```
// C#
using Oracle.EntityFrameworkCore;
using System.Collections.Generic;
using Microsoft.EntityFrameworkCore;

namespace OracleBlog
{
    class Program
    {
        public class BloggingContext : DbContext
        {
            public DbSet<Blog> Blogs { get; set; }
            public DbSet<Post> Posts { get; set; }
            protected override void OnConfiguring(DbContextOptionsBuilder optionsBuilder)
            {
                optionsBuilder.UseOracle(@"User Id=blog;Password=<password>;Data
Source=pdborcl;");
            }
        }
        public class Blog
        {
            public int BlogId { get; set; }
            public string Url { get; set; }
            public List<Post> Posts { get; set; }
        }
        public class Post
        {
            public int PostId { get; set; }
            public string Title { get; set; }
            public string Content { get; set; }
            public int BlogId { get; set; }
            public Blog Blog { get; set; }
        }
        static void Main(string[] args)
        {
            using (var db = new BloggingContext())
            {
                var blog = new Blog { Url = "https://blogs.example.com" };
                db.Blogs.Add(blog);
                db.SaveChanges();
            }
            using (var db = new BloggingContext())
            {
                var blogs = db.Blogs;
            }
        }
    }
}
```

```
    }  
  }  
}
```

Additional ODP.NET EF Core sample code is available on GitHub, including stored procedure and dependency injection examples.

<https://github.com/oracle/dotnet-db-samples/tree/master/samples/ef-core>

## Using ODP.NET Core Classes

Developers can use the `OracleConfiguration` class and other ODP.NET Core classes in Entity Framework Core to access ODP.NET Core-specific functionality, such as the TNS ADMIN location or tracing settings.

The ODP.NET Core assembly will already be part of any Oracle EF Core project since it is a dependency of `Oracle.EntityFrameworkCore`. Most commonly, developers will add the ODP.NET Core namespace to the project:

```
// C#  
using Oracle.ManagedDataAccess.Client;
```

Then, add the desired `OracleConfiguration` property settings. These properties should be set prior to any EF Core code as `OracleConfiguration` settings must be made prior to opening an ODP.NET connection. The below example turns on tracing and sets a TNS ADMIN location which should contain the application's `tnsnames.ora` and `sqlnet.ora` files:

```
// C#  
static void Main(string[] args)  
{  
    OracleConfiguration.TraceFileLocation = @"D:\traces";  
    OracleConfiguration.TraceLevel = 7;  
    OracleConfiguration.TnsAdmin = @"D:\tnsadmin";  
  
    <Start Entity Framework Core code>  
}
```

Oracle EF Core applications can use all the properties and behavior available in ODP.NET Core.

## Logging

Oracle EF Core integrates directly with EF Core logging mechanisms. Oracle EF Core logs are filtered using `DbLoggerCategory` class and `LogLevel` enumeration.

The following `DbLoggerCategory` properties can be used to filter the logs:

- `Database`
- `Database.Command`
- `Database.Connection`
- `DbLoggerCategory.Infrastructure`
- `Migrations`
- `Model`
- `Model.Validation`

- Query
- Scaffolding
- Update

The following `LogLevel` properties are available:

- **Debug:** Displays entry and exit traces. Also displays key Oracle EF Core activities and metadata, such as SQL executed, table and column metadata, and mappings.
- **Error:** Displays error related information, including the stack trace.
- **None**

To setup logging using `DebugLoggerProvider`, include the `Microsoft.Extensions.Logging.Debug.dll` assembly in your project. Similarly to setup logging using `ConsoleLoggerProvider`, include the `Microsoft.Extensions.Logging.Console.dll` assembly in your project. Next, add the following namespace in your project:

```
using Microsoft.Extensions.Logging;
```

Next, configure the `DbContext` to use the logger factory.

```
protected override void OnConfiguring(DbContextOptionsBuilder optionsBuilder)
{
    optionsBuilder.UseOracle(@<connection string>)
        .UseLoggerFactory(_myLoggerFactory);
}
```

Finally, set the `DbLoggerCategory` and `LogLevel` properties that you would like to be written to the log. In an `EnsureCreated` scenario, you can create the following `LoggerFactory`:

```
public static readonly ILoggerFactory _myLoggerFactory
    = LoggerFactory.Create(builder =>
    {
        builder
            .AddFilter((category, level) =>
                category == DbLoggerCategory.Database.Name &&
                // Filter the logs based on DbLoggerCategory. Comment this line above if you do not want
                // to filter logs based on DbLoggerCategory.
                level >= LogLevel.Trace
                // Filter the logs based on LogLevel. All levels greater than or equal to "Trace" will
                // be enabled. Comment this line above if you do not want to filter logs based on LogLevel.
            )
            .AddDebug();
    });
```

In a migrations scenario, you can create the following `LoggerFactory`:

```
public static readonly ILoggerFactory _myLoggerFactory
    = LoggerFactory.Create(builder =>
    {
        builder
            .AddFilter((category, level) =>
                category == DbLoggerCategory.Database.Command.Name &&
                // Filter the logs based on DbLoggerCategory. Comment this line above if you do not want
                // to filter logs based on DbLoggerCategory.
                level >= LogLevel.Trace
                // Filter the logs based on LogLevel. All levels greater than or equal to "Trace" will
            )
    });
```

```

be enabled. Comment this line above if you do not want to filter logs based on LogLevel.
)
    .AddConsole();
});

```

In Scaffolding scenario, use the `-verbose` option to generate traces.

```
Scaffold-DbContext .. -verbose
```

## Migrations

By convention, ODP.NET EF Core maps an appropriate database data type based on the .NET data type and its characteristics. This table shows the default mappings. Fluent APIs/Annotations can be used to map the .NET types to any valid Oracle data type.

This table shows the default mappings. Fluent APIs and Data Annotations can be used to map the .NET types to any valid Oracle data type.

**Table 5-1 ODP.NET Entity Framework Core Migrations Data Type Default Mappings**

| .NET Type Alias | .NET Data Type        | Required Fluent API(s)* | Oracle Database Data Type       |
|-----------------|-----------------------|-------------------------|---------------------------------|
| bool            | System.Boolean        | None                    | BOOLEAN or<br>NUMBER(1)         |
| sbyte           | System.Sbyte          | None                    | NUMBER(3)                       |
| byte            | System.Byte           | None                    | NUMBER(3)                       |
| short/int16     | System.Int16          | None                    | NUMBER(5)                       |
| ushort/uint16   | System.UInt16         | None                    | NUMBER(5)                       |
| int/int32       | System.Int32          | None                    | NUMBER(10)                      |
| uint32          | System.UInt32         | None                    | NUMBER(10)                      |
| decimal         | System.Decimal        | None                    | NUMBER(18,2)                    |
| long/int64      | System.Int64          | None                    | NUMBER(19)                      |
| uint64          | System.UInt64         | None                    | NUMBER(20)                      |
| float           | System.Float          | None                    | BINARY_FLOAT                    |
| double          | System.Double         | None                    | BINARY_DOUBLE                   |
| DateTime        | System.DateTime       | None                    | TIMESTAMP(7)                    |
| DateTimeOffset  | System.DateTimeOffset | None                    | TIMESTAMP(7) WITH<br>TIME ZONE  |
| TimeSpan        | System.TimeSpan       | None                    | INTERVAL DAY(8) TO<br>SECOND(7) |
| char            | System.Char           | None                    | NVARCHAR2(1)                    |
| byte[]          | System.Byte[]         | None                    | RAW(2000)                       |
| byte[]          | System.Byte[]         | HasMaxLength(x <= 2000) | RAW(x)                          |
| byte[]          | System.Byte[]         | HasMaxLength(x > 2000)  | BLOB                            |
| string          | System.String         | None                    | NVARCHAR2(2000)                 |

**Table 5-1 (Cont.) ODP.NET Entity Framework Core Migrations Data Type Default Mappings**

| .NET Type Alias | .NET Data Type | Required Fluent API(s)*                                                        | Oracle Database Data Type |
|-----------------|----------------|--------------------------------------------------------------------------------|---------------------------|
| string          | System.String  | IsUnicode(false) &&<br>IsFixedLength(false)<br>) &&<br>HasMaxLength(x > 4000)  | CLOB                      |
| string          | System.String  | IsUnicode(true) &&<br>IsFixedLength(false)<br>) &&<br>HasMaxLength(x > 2000)   | NCLOB                     |
| string          | System.String  | IsUnicode(false) &&<br>IsFixedLength(false)<br>) &&<br>HasMaxLength(x <= 4000) | VARCHAR2(size)            |
| string          | System.String  | IsUnicode(true) &&<br>IsFixedLength(false)<br>) &&<br>HasMaxLength(x <= 2000)  | NVARCHAR2(size)           |
| string          | System.String  | IsUnicode(false) &&<br>IsFixedLength(true)<br>&&<br>HasMaxLength(x < 2000)     | CHAR(size)                |
| string          | System.String  | IsUnicode(true) &&<br>IsFixedLength(true)<br>&&<br>HasMaxLength(x < 1000)      | NCHAR(size)               |
| string          | System.String  | HasColumnType("VECTOR(dimension, OR(dimension, type))")                        | VECTOR(dimension, type)   |
| guid            | System.Guid    | None                                                                           | RAW(16)                   |

\* Corresponding data annotations can also be used instead of the specified fluent APIs.

NCHAR and NVARCHAR2 use character length semantics. The number of characters for columns with one of these data types depend on the character set, NLS\_NCHAR\_CHARACTERSET. ODP.NET Entity Framework Core defaults to a 2-byte character set, which allows a maximum of 2000 characters for NCHAR and NVARCHAR2 columns. If a [MaxLength(4000)] data annotation or fluent API equivalent is used for a string entity property, ODP.NET will map the property to an NCLOB type because the specified length is greater than 2000 characters.

For example, if a NVARCHAR2(4000) column on the database NLS\_NCHAR\_CHARACTERSET or if the NVARCHAR2 column has a maximum 32 KB length (i.e. MAX\_STRING\_SIZE = EXTENDED), the string entity property can use the [Column] data annotation or a fluent API equivalent to map to an N-character data type, rather than mapping to the default NLOB. Here's an example of using such an annotation:

```
[Column("Name", TypeName = "NVARCHAR2(4000)")]
string EmployeeName
```

Applications may prefer N-character data types over NLOBs as they require no additional server roundtrips to fetch and update data.

### Synonyms

EF Core migrations can generate arbitrary Oracle schema objects using the RelationalDatabaseFacadeExtensions class, such as using the ExecuteSqlRaw method to perform DDL on those objects. For example, to create a synonym for the Blogs table sample, the following code snippet can be used:

```
private static void SetupDatabase()
{
    using (var db = new BloggingContext())
    {
        db.Database.EnsureDeleted();
        if (db.Database.EnsureCreated())
        {

            //other code

            #region Synonym
            db.Database.ExecuteSqlRaw(
                " create synonym s for \"Blogs\";");
            #endregion

            db.SaveChanges();
        }
    }
}
```

## Scaffolding Or Reverse Engineering

ODP.NET EF Core supports scaffolding the following tables and views:

- Relational tables and views
- Materialized views

By convention, ODP.NET EF Core maps an appropriate .NET data type based on the Oracle Database data type and its characteristics.

When scaffolding, developers may wish to change the default data type mappings between Oracle Database and .NET. When modifying .NET CLR types of the generated entity's property, remove the auto-generated HasColumnType() Fluent API in the model. For example, an Oracle NUMBER(4) is scaffolded to a .NET Byte data type by default. If the .NET CLR data type is changed to .NET Short or Int16 data type, then an invalid cast exception at runtime may occur until the HasColumnType("NUMBER(4)") has been removed.

**Data Type Mapping**

This table shows the default mappings.

**Table 5-2 ODP.NET Entity Framework Core Reverse Engineering Data Type Default Mappings**

| Oracle Database Data Type     | .NET Type Alias | .NET Data Type        |
|-------------------------------|-----------------|-----------------------|
| NUMBER(1)                     | bool            | System.Boolean        |
| NUMBER(2) to NUMBER(4)        | byte            | System.Byte           |
| NUMBER(5)                     | short/int16     | System.Int16          |
| NUMBER(6) to NUMBER(10)       | int/int32       | System.Int32          |
| NUMBER(11) to NUMBER(19)      | long/int64      | System.Int64          |
| NUMBER(>19)                   | decimal         | System.Decimal        |
| NUMBER(p,s)                   | decimal         | System.Decimal        |
| NUMBER                        | decimal         | System.Decimal        |
| BINARY_FLOAT                  | float           | System.Float          |
| BINARY_DOUBLE                 | double          | System.Double         |
| BOOLEAN                       | bool            | System.Boolean        |
| TIMESTAMP                     | DateTime        | System.DateTime       |
| TIMESTAMP WITH TIMEZONE       | DateTimeOffset  | System.DateTimeOffset |
| TIMESTAMP WITH LOCAL TIMEZONE | DateTime        | System.DateTime       |
| DATE                          | DateTime        | System.DateTime       |
| INTERVAL DAY TO SECOND        | TimeSpan        | System.TimeSpan       |
| INTERVAL YEAR TO MONTH        | string          | System.String         |
| VARCHAR2                      | string          | System.String         |
| JSON                          | string          | System.String         |
| NVARCHAR2                     | string          | System.String         |
| CHAR                          | string          | System.String         |
| NCHAR                         | string          | System.String         |
| CLOB                          | string          | System.String         |
| NCLOB                         | string          | System.String         |
| RAW                           | byte[]          | System.Byte[]         |
| BLOB                          | byte[]          | System.Byte[]         |
| XMLTYPE                       | string          | System.String         |
| ROWID                         | string          | System.String         |
| UROWID                        | string          | System.String         |
| LONG                          | string          | System.String         |
| BFILE                         | byte[]          | System.Byte[]         |
| LONG RAW                      | byte[]          | System.Byte[]         |
| VECTOR                        | string          | System.String         |

Scaffolding Tables from Another Schema

Developers can scaffold tables from other schemas other than the user/schema they are connected with. The connected user requires privileges to access the other schema's objects. Once these privileges are granted, developers can use the Package Manager Console (PMC) tools for Entity Framework Core to perform the scaffolding operation. For example:

```
Scaffold-DbContext "User Id=scott;Password=<password>;Data Source=myhost:1521/mydb;"
Oracle.EntityFrameworkCore -Schemas HR -Tables EMPLOYEES
```

Developers can use the -Schemas and -Tables parameters to specify which schemas and tables/views to scaffold for an Entity Framework Core model. If connecting with one user/schema to create tables from a second schema, the user must have at least SELECT privileges for that second schema.

The following table displays the ODP.NET Entity Framework Core behavior when the -Schemas and/or -Tables parameter is specified or left as default while scaffolding a pre-existing model using the Package Manager Console command, Scaffold-DbContext. All sample command excerpts below use Scaffold-DbContext syntax. Similar functionality is available using the EF Core tools command, dotnet ef dbcontext scaffold.

Table 5-3 Schema and Table Filter Mapping

| Mapping of Schema and Table Filters | No Schema Filter                                                            | Schema Filter                                                                                                                                                                                     |
|-------------------------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Table Filter                     | Generates all tables/views within current user/schema<br><i>Box 1</i>       | Generates all tables/views in specified user(s)/schema(s)<br><i>Box 2</i>                                                                                                                         |
| Table Filter                        | Generates specified tables/views within current user/schema<br><i>Box 3</i> | Generates specified tables/views within current schema <i>and</i> all tables/views in specified user(s)/schema(s)<br><br>Filtered results include combined <i>Box 2</i> and <i>Box 3</i> results. |

It is possible to scaffold tables/views in other schemas by appending the schema name in front: -Tables <schema>.<table/view>

For example, the following snippet would scaffold three tables in three different schemas:

```
-Tables SCHEMA1.TABLEA, SCHEMA2.TABLEB, SCHEMA3.TABLEC
```

If the schema or table name contains any special characters, such as a period, then use brackets to delimit the schema and table names when using the -Tables option.

```
-Tables [SCHEMA1].[TABLEA]
```

Scaffolding Views

Oracle supports scaffolding database relational and materialized views only. These views can be either read-only or updatable. Use the -Tables parameter to specify the views to scaffold. If the parameter is left blank (default), all the user tables, relational views, and materialized views will be scaffolded.

## Customizing Data Type Mapping

If default data type mappings are not the best fit for the .NET application, the scaffolded data type mappings can be changed. For example, the NUMBER(1) maps to a .NET bool by default. If the column data contains numbers other than Boolean values, a better mapping would be to a .NET byte.

To customize mappings, Oracle EF Core apps should use reverse engineering templates, or T4 text templates. These templates provide an alternative mapping Oracle EF Core can use during scaffolding. A common set of alternative data type mappings are in the table below. They are a more complementary match between Oracle database types and .NET types for scaffolding.

**Table 5-4 ODP.NET Entity Framework Core Scaffolding Default and Alternative Data Type Mappings**

| Oracle Database Data Type | Default .NET Type Alias | More Complementary .NET Type Alias |
|---------------------------|-------------------------|------------------------------------|
| NUMBER(1)                 | bool                    | byte                               |
| NUMBER(2) to NUMBER(4)    | byte                    | Int16                              |
| NUMBER(5)                 | Int16                   | Int32                              |
| NUMBER(6) to NUMBER(10)   | Int32                   | Int64                              |
| NUMBER(10) to NUMBER(19)  | Int64                   | Decimal                            |

One advantage of the more complementary .NET data types is they can store all possible values of the mapped Oracle Database data types.

## Using T4 Templates for Data Type Mapping Customization

Standard .NET T4 templates provide the data type mapping customization information for EF Core scaffolding. To use the template, follow these steps.

1. Install the EF Core templates package. For example, you can incorporate the package using the .NET CLI command:

```
dotnet new install Microsoft.EntityFrameworkCore.Templates
```

2. Add the Oracle EF Core default templates to your project. This too can be done with the .NET CLI as seen here:

```
dotnet new ef-templates
```

You should now see a new project directory Code-Templates/EFCore with two files, DbContext.t4 and EntityType.t4. The DbContext.t4 template is used to scaffold a DbContext class for the database. The EntityType.t4 template is used to scaffold entity type classes for each table and view in the database. We will use the EntityType.t4 template in the next step.

3. Using the EntityType.t4 template, any CLR Type can be mapped to a specific Oracle database type. The template snippet maps the NUMBER(1) column Col1 to a .NET short data type instead of .NET bool default type:

```
//Specify the store type custom mapping to your chosen the CLR type
var clrType = (property.Name == "Col1" && property.GetColumnType() ==
"NUMBER(1)")
? typeof(short)
```

```

        : property.ClrType;

//Add any required 'usings' for the clrType
usings.AddRange(code.GetRequiredUsings(clrType));

        var needsNullable = Options.UseNullableReferenceTypes && property.IsNullable
&& !clrType.IsValueType;
        var needsInitializer = Options.UseNullableReferenceTypes && !
property.IsNullable && !clrType.IsValueType;
        #>
        public <#> code.Reference(clrType) #><#> needsNullable ? "?" : "" #> <#>
property.Name #> { get; set; }<#> needsInitializer ? " = null!;" : "" #>
        <#>
        firstProperty = false;

```

The newly added template overrides Oracle EF Core's default type mapping.

Oracle provides sample T4 text templates developers can use as is or customize on the Oracle .NET GitHub sample code site. Snippets can be copied directly into an application's T4 text template with a minimum of customization.

The property name in the template is what scaffolding generates as per the standard property naming scheme. In the above example, the database column, COL1, becomes the Col1 .NET property name. In the below example, the database column C01\_SMALLINT becomes the property name C01SmallInt.

```

var clrType = (property.Name == "C01SmallInt" && property.GetColumnType() ==
"NUMBER(38)")
    ? typeof(short)
    : property.ClrType;

```

An easy way to determine the .NET type name is to perform scaffolding without a template.

If altering some property aspects, such as the CLR Type, ensure the appropriate altered variable is used when printing the property as seen in the example clrType reference, not property.clrType.

```

public <#> code.Reference(clrType) #><#> needsNullable ? "?" : "" #> <#>
property.Name #> { get; set; }<#> needsInitializer ? " = null!;" : "" #>

```

### Using T4 Templates to Preserve Legacy Mapping Behavior

Default data type mappings can change based on new data types introduced in .NET or Oracle database. For example, Oracle EF Core 23ai scaffolds NUMBER(1) columns to Boolean data types and then expects only Boolean values to be used. When a non-Boolean value is used, then an error, such as "System.InvalidOperationException: No coercion operator is defined between types 'System.Nullable`1[System.Int16]' and 'System.Boolean'" occurs.

If you are upgrading from Oracle EF Core 21c to 23ai, and your database uses NUMBER(1) columns for legacy .NET numeric types like byte, short, or int, then you can use a T4 template to preserve the previous behavior and avoid unwanted HasColumnType("NUMBER(1)") fluent API generation. To do this, follow the first two steps from the [Using T4 Templates for Data Type Mapping Customization](#).

For the third step, open the CodeTemplates/EFCore/DbContext.t4 file. Find the location where propertyFluentApiCalls is initialized and replace it with the following code:

```

``t4
var storeType = property.GetColumnType();
var clrType = property.ClrType;
var isBoolOrNullableBool = clrType == typeof(bool) || clrType == typeof(bool?);
var propertyFluentApiCalls = property.GetFluentApiCalls(annotationCodeGenerator)
?.FilterChain(c =>
!(Options.UseDataAnnotations && c.IsHandledByDataAnnotations)
&& !(c.Method == "IsRequired" && Options.UseNullableReferenceTypes && !
property.ClrType.IsValueType)
&& !(c.Method == "HasColumnType" && storeType == "NUMBER(1)" && isBoolOrNullableBool));

```

Save the `DbContext.t4` file.

This T4 template change detects if a column is `NUMBER(1)`. If so, it skips adding `.HasColumnType("NUMBER(1)")` for `bool` and `bool?` data types only. No other fluent API calls are modified.

For subsequent scaffold operations, the `NUMBER(1)` column will no longer generate an error as the legacy mapping is restored. The legacy mapping can also be restored without modifying the T4 text template. The developer would need to manually remove the `.HasColumnType("NUMBER(1)")` method from the entity definition scaffolding generated. The removal has to be repeated each time scaffolding occurs.

## Identifier Name Length and Uniqueness

Oracle Database limit identifier names, such as table names, column names, and primary key names, to 128 bytes. Oracle Entity Framework Core will automatically truncate identifier names that are too long to this specified length, except for table names. This prevents both the user and Entity Framework Core from creating identifiers beyond the maximum character limit of the Oracle Database and receiving an "ORA-00972: IDENTIFIER IS TOO LONG" error" in most instances.

If the identifiers use multi-byte characters, the maximum identifier length may require a setting with character expansion ratio in mind to assure that all identifiers can be created in the Oracle database. For example, if the Oracle database character set is UTF8, a single character may require up to 4 bytes. Thus, to guarantee that all identifiers can be created in an Oracle database that does not support long identifiers, the `RelationalAnnotationNames.MaxIdentifierLength` field can be set to 32 bytes (i.e. 128 bytes divided by 4). By default, Oracle EF Core `MaxIdentifierLength` has a value of 128.

Even if your EF Core model does not use identifier names longer than what your database version supports, you should consider setting `MaxIdentifierLength` to a lower value. ODP.NET and Entity Framework Core auto-generate schema object names from models. They may, on occasion, append additional characters to the names, which could exceed the maximum number of characters the database permits. By setting the `MaxIdentifierLength`, you prevent EF Core from causing the ORA-00972 error inadvertently.

## Using Large Character or Binary Data Types

By default, .NET `byte[]` maps to `RAW(2000)` and .NET `string` maps to `NVARCHAR(2000)`. But if your application deals with data that larger than 2000 bytes, you can use the `Column` or the `MaxLength` data annotations or the associated fluent API to create `BLOB` and `CLOB` columns in the database, respectively.

```
// This annotation will force a BLOB column to be created.  
[Column("BLOB_COLUMN", TypeName = "BLOB")]  
public byte[] BYTE_TYPE { get; set; }
```

```
// This annotations will force a NCLOB column to be created.  
[MaxLength(65536)]  
public string NCLOB_TYPE { get; set; }
```

Without these annotations, you may hit errors, such as “ORA-01460: unimplemented or unreasonable conversion requested” or “ORA-12899: value too large for column” when modifying the data.

## Performance Considerations

EF Core application performance is most optimal for binding character-based data when the .NET `String` entity property bind data type and the database column data type `Unicode` support match. If the mapping is done properly, then the application will bind the string entity property value properly as `NVARCHAR2` for a `NVARCHAR2` column or bind it as `VARCHAR2` for a `VARCHAR2` column. If the types are mismatched, then additional processing is incurred on the server side, slowing down performance.

To avoid performance related issues due to this mismatch, one of the following can be done:

- If the table already exists, use scaffolding to generate the entity classes corresponding to the relational database tables. Doing so generates the correct fluent API for each table column.
- If the entity classes exist without the corresponding database tables, use migrations to generate the corresponding database columns for the string entity properties, which will honor the `IsUnicode()` or `HasColumnType()` fluent APIs that are invoked.
- If manually creating the entity classes corresponding to the database tables, correctly map each string entity property to the `NVARCHAR2` or `VARCHAR2` column type using the appropriate `IsUnicode()` or `HasColumnType()` fluent API to avoid mismatches.

Other considerations:

- If both `IsUnicode()` and `HasColumnType()` fluent APIs are used, then the `HasColumnType()` fluent API takes precedence.
- For migrations, the .NET `String` entity property maps to `NVARCHAR2` by default. For scaffolding, both `VARCHAR2` and `NVARCHAR2` columns map to .NET `string`.
- If the database column type is `VARCHAR2`, then the `IsUnicode(false)` or `HasColumnType("VARCHAR2(<length>)")` fluent API should be used to correctly map the string entity property to the `VARCHAR2` column. This avoids the performance degradation problem.
- If a string entity property is associated with a `NVARCHAR2` column, no invocations of `IsUnicode()` nor `HasColumnType()` fluent APIs are needed. Alternatively, `IsUnicode(true)` or

`HasColumnType("NVARCHAR2(<length>")` fluent APIs can be invoked to bind the data as `NVARCHAR2`.

- In Oracle.EntityFrameworkCore 2.19.70 and earlier versions, string entity property values were always bound as `VARCHAR2` while executing LINQ queries. The behavior changed starting with Oracle EF Core 2.19.80. The string entity property values are now bound based on the mapping specified for entity string property. An application that performed optimally with Oracle EF Core 2.19.70 can degrade in performance when upgrading to a later Oracle EF Core version.
- If you encounter a new performance problem after an Oracle EF Core upgrade, verify the string entity properties associated with `VARCHAR2` columns have not set either `IsUnicode(false)` nor `HasColumnType("VARCHAR2(<length>")` fluent APIs nor equivalent data annotations. If so, add one of these fluent API so that the character-based data are bound using the correct type.

## Artificial Intelligence Vector Data Types

Starting with version 23.8, Oracle EF Core supports developing both dense and sparse Oracle Database vectors with `VectorDistance`, `VectorEmbedding`, and `ToVector` EF functions.

ODP.NET natively supports dense vectors in .NET and EF Core with the `OracleVector` data type. Sparse vectors are supported using the `OracleSparseVector` data type. These data types are mapped by default to Oracle Database `DENSE` and `SPARSE` format vectors, respectively.

Entity Framework Core 9 or higher is required for the vector data type support.

In Oracle EF Core 23.7, only dense vectors were supported and the default vector mappings were to primitive array types that included `short[]`, `float[]`, `double[]`, and `byte[]`.

In prior releases, vector data types were mapped to .NET strings.

The following table shows the .NET common language runtime (CLR) data types that Oracle Database vectors map to by default and the possible alternative mappings.

**Table 5-5 Oracle Vector EF Core Data Type Mapping**

| Oracle Database Data Type      | Default CLR Mapping             | Alternative CLR Mapping                                                                      |
|--------------------------------|---------------------------------|----------------------------------------------------------------------------------------------|
| DENSE vector (fixed format)    | <code>OracleVector</code>       | <code>short[]</code> , <code>float[]</code> , <code>double[]</code> , or <code>byte[]</code> |
| DENSE vector (flexible format) | <code>OracleVector</code>       | None                                                                                         |
| SPARSE vector (all formats)    | <code>OracleSparseVector</code> | None                                                                                         |

A fixed vector format is a database vector with a specific numeric format, such as `VECTOR(100, FLOAT64)`, `VECTOR(*, FLOAT32)`, or `VECTOR(24, BINARY)`. The number of dimensions can vary.

A flexible vector format can store any numeric format, such as `VECTOR(3, *)`, `VECTOR(*, *)`, or `VECTOR(100, *, SPARSE)`. The number of dimensions can vary as well.

### Migrations

When an Oracle EF Core model contains `OracleVector` or `OracleSparseVector` data types, they are mapped to Oracle Database vectors only when the `HasColumnType()` fluent API or corresponding data annotation is specified. Migrations are also allowed if entity properties are the ones defined in the alternative CLR mapping column as documented in the above table.

For sparse vectors, application must declare the complete vector column type in `HasColumnType()`, such as `HasColumnType("VECTOR(3,FLOAT64, sparse)")`.

### Scaffolding

By default, Oracle Database dense vectors in any numeric format map to `OracleVector` and sparse vectors in any numeric format will map to `OracleSparseVector` for EF Core scaffolding.

Fixed dense vectors mapping can be customized to map to primitive array types, including `short[]`, `float[]`, `double[]`, and `byte[]`.

### Code Sample

The following EF Core code sample demonstrates how to use ODP.NET vector types with EF Core, LINQ, and EF.Functions.

```
/*
This Oracle EF Core Code First sample shows how to create and use a database
schema with Oracle vector columns. It does the following:
1. Creates two tables, one with dense vectors and the other with sparse vectors.
It uses native ODP.NET vectors, OracleVector and OracleSparseVector.
2. Inserts two rows into each table.
3. Shows various vector EF function use cases by executing LINQ commands on the tables.
Note: Native ODP.NET vector types require the Oracle.ManagedDataAccess.Types namespace.
Requires EF Core 9 or higher.
*/

using System;
using System.Linq;
using Microsoft.EntityFrameworkCore;
using Oracle.ManagedDataAccess.Types;

namespace OracleVectorSample
{
    class Program
    {
        static void Main(string[] args)
        {
            using (var ctx = new ModelContext())
            {
                ctx.Database.EnsureDeleted();
                ctx.Database.EnsureCreated();

                short[] shortdataD = [1, 2, 3];
                float[] floatdataD = [1.1f, 2.2f, 3.3f];
                double[] doubledataD = [3.3, 2.2, 1.1];
                string stringdataD = "[3,2,1]";

                OracleVector shortVecD = new OracleVector(shortdataD);
                OracleVector floatVecD = new OracleVector(floatdataD);

```

## Breaking Changes

### Application Programming Interface Changes

- Oracle EF Core UseOracleSQLCompatibility extension method

In EF Core 6 and higher versions with Oracle EF Core version 23, UseOracleSQLCompatibility extension method now takes an enumeration type as an argument rather than a string value. This extension method's default value will be the same as the Oracle EF Core version. For example, if you are using Oracle EF Core 23, then its value will be OracleSQLCompatibility.DatabaseVersion23.

This default assumes the app is using the same database version as the Oracle EF Core version, that is, Oracle AI Database 26ai with Oracle 23ai client. If they are not the same version, then the developer should modify the enumeration value to match the database version they are connecting to. This ensures fewer compatibility errors and allows Oracle EF Core to use the latest Oracle AI Database features.

[UseOracleSQLCompatibility\(enum version\)](#)

### Desupported APIs

The desupported APIs are as follows:

- modelBuilder.UseOracleIdentityColumn Extension Method

Starting with EF Core 5, ODP.NET EF Core desupports UseOracleIdentityColumn.

Developers should call the modelBuilder.UseIdentityColumn extension method instead,

which provides identical functionality. `UseOracleIdentityColumn` remains supported for EF Core 3.1 and earlier releases.

- `ModelBuilder` and `PropertyBuilder` `ForOracleUseSequenceHiLo` Extension Method  
Starting with EF Core 5, ODP.NET EF Core desupports `ForOracleUseSequenceHiLo`. Developers should call the `ModelBuilder.UseHiLo` extension method instead, which provides identical functionality. `ForOracleUseSequenceHiLo` remains supported for EF Core 3.1 and earlier releases.
- `Oracle.EntityFrameworkCore.Migrations.Operations.OracleCreateUserOperation` Class  
Starting with Oracle EF Core 21c, the `OracleCreateUserOperation` class is desupported. Developers should call the `MigrationBuilder.Sql` method instead with a `CREATE USER` SQL statement to create a user if they are using the desupported API directly.
- `Oracle.EntityFrameworkCore.Migrations.Operations.OracleDropUserOperation` Class  
Starting with Oracle EF Core 21c, the `OracleDropUserOperation` class is desupported. Developers should call the `MigrationBuilder.Sql` method instead with a `DROP USER` SQL statement to drop a user if they are using the desupported API directly.

## OracleAccessToken Class

An `OracleAccessToken` object stores Oracle Identity and Access Management(IAM) and Microsoft Entra ID OAuth information required for token authentication.

### Class Inheritance

`System.Object`

`Oracle.DataAccess.OracleAccessToken`

Declaration

```
// C#
public sealed class OracleAccessToken
```

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

Example 6-1 Using OracleAccessToken Constructor and Event

```
// C#
public class OracleAccessToken
{
    //Constructor for OAuth
    public OracleAccessToken(char[] token);

    // Constructor
    public OracleAccessToken(char[] dbToken, char[] privateKey);

    // Event to get refreshed token before expiry
    public event OracleRefreshAccessTokenEventHandler RefreshAccessToken;
}
```

- [OracleAccessToken Event](#)

OracleAccessToken Members

OracleAccessToken members are listed in the following tables.

OracleAccessToken Constructor

OracleAccessToken constructors are listed in [OracleAccessToken Constructors](#).

Table 6-1 OracleAccessToken Constructor

| Constructor                                    | Description                                                                          |
|------------------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">OracleAccessToken Constructors</a> | OracleAccessToken constructors instantiate new instances of OracleAccessToken class. |

## OracleAccessToken Event

OracleAccessToken event is listed in [OracleAccessToken Event](#).

**Table 6-2 OracleAccessToken Event**

| Event                                    | Description                                                                                                       |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">RefreshAccessToken Event</a> | Triggered 60 seconds before the signature token expiration time so that application can provide a refreshed token |

## OracleAccessToken Constructors

OracleAccessToken constructors instantiate new instances of OracleAccessToken class.

### Overload List:

- [OracleAccessToken\(char\)](#)

This constructor creates an OracleAccessToken object with the access token provided by the application.

- [OracleAccessToken\(char, char\)](#)

This constructor creates an OracleAccessToken object with the signature token and private key provided by the application. Only Signature token type will be supported through this class.

- [OracleAccessToken Members](#)

## OracleAccessToken(char)

This constructor creates an OracleAccessToken object with the access token provided by the application.

### Declaration

```
// C#  
public OracleAccessToken(char[] token);
```

### Exceptions

ArgumentNullException is raised if token is passed in as null.

### Description

The char[] passed by the application for the access token will be cleared by ODP.NET. Applications should not depend on this char[] once this constructor is called.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAccessToken Class](#)
- [OracleAccessToken Members](#)

## OracleAccessToken(char, char)

This constructor creates an OracleAccessToken object with the signature token and private key provided by the application. Only Signature token type will be supported through this class.

### Declaration

```
// C#  
public OracleAccessToken(char[] dbToken, char[] privateKey);
```

### Exceptions

- ArgumentNullException is raised if any parameters are passed in as null.
- ArgumentException is thrown if the provided token is invalid.

### Description

The char[] passed by the application for the signature token and private key will be cleared by ODP.NET. Applications should not depend on these char[] once this constructor is called.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAccessToken Class](#)
- [OracleAccessToken Members](#)

## RefreshAccessToken Event

This event is triggered 60 seconds before the database token expiration time so that application can provide a refreshed token.

### Declaration

```
// C#  
public event OracleRefreshAccessTokenEventHandler RefreshAccessToken;
```

Description

The event handler receives an `OracleRefreshAccessTokenEventArgs` object in which the application should set the refreshed database token and private key, or access token. The event handler is not called unless a connection has been made with the token, and the token has been found to be valid.

# OracleClientFactory Class

An `OracleClientFactory` object allows applications to instantiate ODP.NET classes in a generic way.

Class Inheritance

Declaration

```
// C#
public sealed class OracleClientFactory : DbProviderFactory
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET Core      | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;

class FactorySample
{
    static void Main()
    {
        string constr = "user id=scott;password=tiger;data source=oracle";

        DbProviderFactory factory =
            DbProviderFactories.GetFactory("Oracle.DataAccess.Client");

        DbConnection conn = factory.CreateConnection();

        try
        {
            conn.ConnectionString = constr;
            conn.Open();

            DbCommand cmd = factory.CreateCommand();
            cmd.Connection = conn;
            cmd.CommandText = "select * from emp";

            DbDataReader reader = cmd.ExecuteReader();
            while (reader.Read())
                Console.WriteLine(reader["EMPNO"] + " : " + reader["ENAME"]);
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.Message);
            Console.WriteLine(ex.StackTrace);
        }
    }
}
```

## OracleClientFactory Members

OracleClientFactory members are listed in the following tables.

### OracleClientFactory Field

The OracleClientFactory field is listed in [Table 6-3](#)

**Table 6-3 OracleClientFactory Field**

| Property                 | Description                                       |
|--------------------------|---------------------------------------------------|
| <a href="#">Instance</a> | Gets an instance of the OracleClientFactory class |

### OracleClientFactory Constructor

The OracleClientFactory constructor is listed in [Table 6-4](#)

**Table 6-4 OracleClientFactory Constructor**

| Property                                        | Description                                              |
|-------------------------------------------------|----------------------------------------------------------|
| <a href="#">OracleClientFactory Constructor</a> | Instantiates a new instance of OracleClientFactory class |

### OracleClientFactory Public Properties

The OracleClientFactory public properties are listed in [Table 6-5](#).

**Table 6-5 OracleClientFactory Public Properties**

| Property                                      | Description                                                                 |
|-----------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">CanCreateDataSourceEnumerator</a> | Indicates whether or not the CreateDataSourceEnumerator method is supported |

### OracleClientFactory Public Methods

OracleClientFactory Public Methods are listed in [Table 6-6](#).

**Table 6-6 OracleClientFactory Public Method**

| Method                                        | Description                                                                                        |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">CreateCommand</a>                 | Returns a DbCommand object that represents an OracleCommand object                                 |
| <a href="#">CreateCommandBuilder</a>          | Returns a DbCommandBuilder object that represents an OracleCommandBuilder object                   |
| <a href="#">CreateConnection</a>              | Returns a DbConnection object that represents an OracleConnection object                           |
| <a href="#">CreateConnectionStringBuilder</a> | Returns a DbConnectionStringBuilder object that represents an OracleConnectionStringBuilder object |
| <a href="#">CreateDataAdapter</a>             | Returns a DbDataAdapter object that represents an OracleDataAdapter object                         |

**Table 6-6 (Cont.) OracleClientFactory Public Method**

| Method                                     | Description                                                                                                                                                 |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CreateDataSource</a>           | Creates a new OracleDataSource object using the provided connection string<br><i>Not available in ODP.NET, Unmanaged Driver and ODP.NET, Managed Driver</i> |
| <a href="#">CreateDataSourceEnumerator</a> | Returns a DbDataSourceEnumerator object that represents an OracleDataSourceEnumerator object                                                                |
| <a href="#">CreateParameter</a>            | Returns a DbParameter object that represents an OracleParameter object                                                                                      |
| <a href="#">CreatePermission</a>           | Returns a CodeAccessPermission object that represents an OraclePermission object                                                                            |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)

## OracleClientFactory Field

The OracleClientFactory field is listed in [Table 6-7](#)

**Table 6-7 OracleClientFactory Field**

| Property                 | Description                                       |
|--------------------------|---------------------------------------------------|
| <a href="#">Instance</a> | Gets an instance of the OracleClientFactory class |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## Instance

The Instance field gets an instance of the OracleClientFactory class. This can be used to retrieve strongly typed data objects.

**Declaration**

```
// C#  
public static readonly OracleClientFactory Instance
```

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

# OracleClientFactory Constructor

The OracleClientFactory constructor creates a new instances of the OracleClientFactory class.

**Declaration**

```
// C#
public OracleClientFactory();
```

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

# OracleClientFactory Public Properties

The OracleClientFactory public properties are listed in [Table 6-8](#).

**Table 6-8 OracleClientFactory Public Properties**

| Property                                      | Description                                                                 |
|-----------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">CanCreateDataSourceEnumerator</a> | Indicates whether or not the CreateDataSourceEnumerator method is supported |

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

# CanCreateDataSourceEnumerator

This property indicates whether or not the CreateDataSourceEnumerator method is supported.

**Declaration**

```
// C#
public override bool CanCreateDataSourceEnumerator { get; }
```

**Property Value**

Returns true.

**Remarks**

ODP.NET supports the `OracleDataSourceEnumerator` object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## OracleClientFactory Public Methods

The `OracleClientFactory` public method is listed in [Table 6-9](#).

**Table 6-9 OracleClientFactory Public Method**

| Method                                        | Description                                                                                                                                                              |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CreateCommand</a>                 | Returns a <code>DbCommand</code> object that represents an <code>OracleCommand</code> object                                                                             |
| <a href="#">CreateCommandBuilder</a>          | Returns a <code>DbCommandBuilder</code> object that represents an <code>OracleCommandBuilder</code> object                                                               |
| <a href="#">CreateConnection</a>              | Returns a <code>DbConnection</code> object that represents an <code>OracleConnection</code> object                                                                       |
| <a href="#">CreateConnectionStringBuilder</a> | Returns a <code>DbConnectionStringBuilder</code> object that represents an <code>OracleConnectionStringBuilder</code> object                                             |
| <a href="#">CreateDataAdapter</a>             | Returns a <code>DbDataAdapter</code> object that represents an <code>OracleDataAdapter</code> object                                                                     |
| <a href="#">CreateDataSource</a>              | Creates a new <code>OracleDataSource</code> object using the provided connection string<br><i>Not available in ODP.NET, Unmanaged Driver and ODP.NET, Managed Driver</i> |
| <a href="#">CreateDataSourceEnumerator</a>    | Returns a <code>DbDataSourceEnumerator</code> object that represents an <code>OracleDataSourceEnumerator</code> object                                                   |
| <a href="#">CreateParameter</a>               | Returns a <code>DbParameter</code> object that represents an <code>OracleParameter</code> object                                                                         |
| <a href="#">CreatePermission</a>              | Returns a <code>CodeAccessPermission</code> object that represents an <code>OraclePermission</code> object                                                               |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## CreateCommand

This method returns a DbCommand object that represents an OracleCommand object.

### Declaration

```
// C#  
public override DbCommand CreateCommand();
```

### Return Value

A DbCommand object that represents an OracleCommand object.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## CreateCommandBuilder

This method returns a DbCommandBuilder object that represents an OracleCommandBuilder object.

### Declaration

```
// C#  
public override DbCommandBuilder CreateCommandBuilder();
```

### Return Value

A DbCommandBuilder object that represents an OracleCommandBuilder object.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## CreateConnection

This method returns a DbConnection object that represents an OracleConnection object.

### Declaration

```
// C#  
public override DbConnection CreateConnection();
```

### Return Value

A DbConnection object that represents an OracleConnection object.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## CreateConnectionStringBuilder

This method returns a DbConnectionStringBuilder object that represents an OracleConnectionStringBuilder object.

### Declaration

```
// C#  
public override DbConnectionStringBuilder CreateConnectionStringBuilder();
```

### Return Value

A DbConnectionStringBuilder object that represents an OracleConnectionStringBuilder object.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## CreateDataAdapter

This method returns a DbDataAdapter object that represents an OracleDataAdapter object.

**Declaration**

```
// C#  
public override DbDataAdapter CreateDataAdapter();
```

**Return Value**

A `DbDataAdapter` object that represents an `OracleDataAdapter` object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## CreateDataSource

This method creates a new `OracleDataSource` object using the provided connection string.

**Declaration**

```
// C#  
OracleDataSource CreateDataSource(string connectionString)
```

**Parameters**

- *connectionString*  
The connection string to connect to the database

**Return Value**

An `OracleDataSource` object ready to create database connections and commands.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)
- ["OracleDataSourceEnumerator Class"](#)

## CreateDataSourceEnumerator

This method returns a `DbDataSourceEnumerator` object that represents an `OracleDataSourceEnumerator` object.

**Declaration**

```
// C#  
public override DbDataSourceEnumerator CreateDataSourceEnumerator();
```

**Return Value**

A DbDataSourceEnumerator object that represents an OracleDataSourceEnumerator object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)
- ["OracleDataSourceEnumerator Class"](#)

## CreateParameter

This method returns a DbParameter object that represents an OracleParameter object.

**Declaration**

```
// C#  
public override DbParameter CreateParameter();
```

**Return Value**

A DbParameter object that represents an OracleParameter object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

## CreatePermission

This method returns a CodeAccessPermission object that represents an OraclePermission object.

**Declaration**

```
// C#  
public override System.Security.CodeAccessPermission CreatePermission(  
    System.Security.Permissions.PermissionState state);
```

Parameter

- `state`  
A `PermissionState` object.

Return Value

A `CodeAccessPermission` object that represents an `OraclePermission` object.

Remarks

This method enables users, writing provider-independent code, to get a `CodeAccessPermission` instance that represents an `OraclePermission` object.

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleClientFactory Class](#)
- [OracleClientFactory Members](#)

# OracleCommand Class

An `OracleCommand` object represents a SQL command, a stored procedure, or a table name. The `OracleCommand` object is responsible for formulating the request and passing it to the database. If results are returned, `OracleCommand` is responsible for returning results as an `OracleDataReader`, a `.NET XmlReader`, a `.NET Stream`, a scalar value, or as output parameters.

Class Inheritance

Declaration

```
// C#
public sealed class OracleCommand : DbCommand, ICloneable
```

Requirements

| Provider | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver      | ODP.NET Core                 |
|----------|---------------------------|------------------------------|------------------------------|
| Assembly | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll | Oracle.ManagedDataAccess.dll |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

The execution of any transaction-related statements from an `OracleCommand` is not recommended because it is not reflected in the state of the `OracleTransaction` object represents the current local transaction, if one exists.

`ExecuteXmlReader`, `ExecuteStream`, and `ExecuteToStream` methods are only supported for XML operations.

`ExecuteReader` and `ExecuteScalar` methods are not supported for XML operations.

To minimize the number of open server cursors, `OracleCommand` objects should be explicitly disposed.

### Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleCommandSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        string cmdQuery = "select ename, empno from emp";

        // Create the OracleCommand
        OracleCommand cmd = new OracleCommand(cmdQuery);

        cmd.Connection = con;
        cmd.CommandType = CommandType.Text;

        // Execute command, create OracleDataReader object
        OracleDataReader reader = cmd.ExecuteReader();

        while (reader.Read())
        {
            // output Employee Name and Number
        }
    }
}
```

```
        Console.WriteLine("Employee Name : " + reader.GetString(0) + " , " +  
            "Employee Number : " + reader.GetDecimal(1));  
    }  
  
    // Clean up  
    reader.Dispose();  
    cmd.Dispose();  
    con.Dispose();  
}  
}
```

## OracleCommand Members

OracleCommand members are listed in the following tables.

### OracleCommand Constructors

OracleCommand constructors are listed in [Table 6-10](#).

**Table 6-10 OracleCommand Constructors**

| Constructor                                | Description                                                     |
|--------------------------------------------|-----------------------------------------------------------------|
| <a href="#">OracleCommand Constructors</a> | Instantiates a new instance of OracleCommand class (Overloaded) |

### OracleCommand Static Methods

The OracleCommand static method is listed in [Table 6-11](#).

**Table 6-11 OracleCommand Static Method**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

### OracleCommand Properties

OracleCommand properties are listed in [Table 6-12](#).

**Table 6-12 OracleCommand Properties**

| Property                                | Description                                                                                                                                                 |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddRowid</a>                | Adds the ROWID as part of the select list                                                                                                                   |
| <a href="#">AddToStatementCache</a>     | Causes executed statements to be cached, when the property is set to <code>true</code> and statement caching is enabled                                     |
| <a href="#">ArrayBindCount</a>          | Specifies if the array binding feature is to be used and also specifies the maximum number of array elements to be bound in the <code>Value</code> property |
| <a href="#">ArrayBindRowsAffected</a>   | Returns the number of affected rows for each iteration while executing a DML using array binding                                                            |
| <a href="#">BindByName</a>              | Specifies the binding method in the collection                                                                                                              |
| <a href="#">CommandText</a>             | Specifies the SQL statement or stored procedure to run against the Oracle database or the XML data used to store changes to the Oracle database             |
| <a href="#">CommandTimeout</a>          | Specifies the number of seconds the command is allowed to execute before terminating the execution with an exception                                        |
| <a href="#">CommandType</a>             | Specifies the command type that indicates how the <code>CommandText</code> property is to be interpreted                                                    |
| <a href="#">Connection</a>              | Specifies the <code>OracleConnection</code> object that is used to identify the connection to execute a command                                             |
| Container                               | Inherited from <code>System.ComponentModel.Component</code>                                                                                                 |
| <a href="#">DesignTimeVisible</a>       | Specifies whether or not the <code>OracleCommand</code> object is visible on designer controls.                                                             |
| <a href="#">FetchSize</a>               | Specifies the size of <code>OracleDataReader</code> 's internal cache to store result set data                                                              |
| <a href="#">FetchSqlId</a>              | Indicates whether or not to fetch the <code>SQL_ID</code> of the executed statements<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                   |
| <a href="#">ImplicitRefCursors</a>      | Specifies an array of <code>OracleRefCursors</code> mapped to an implicit resultset returned by the stored procedure.                                       |
| <a href="#">InitialLOBFetchSize</a>     | Specifies the amount of data that the <code>OracleDataReader</code> initially fetches for LOB columns                                                       |
| <a href="#">InitialLONGFetchSize</a>    | Specifies the amount of data that the <code>OracleDataReader</code> initially fetches for LONG and LONG RAW columns                                         |
| <a href="#">Notification</a>            | Indicates that there is a notification request for the command                                                                                              |
| <a href="#">NotificationAutoEnlist</a>  | Indicates whether or not to register for a continuous query notification with the database automatically when the command is executed                       |
| <a href="#">Parameters</a>              | Specifies the parameters for the SQL statement or stored procedure                                                                                          |
| <a href="#">RowSize</a>                 | Specifies the amount of memory needed by the <code>OracleDataReader</code> internal cache to store one row of data                                          |
| <a href="#">RowsToFetchPerRoundTrip</a> | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                 |
| Site                                    | Inherited from <code>System.ComponentModel.Component</code>                                                                                                 |

**Table 6-12 (Cont.) OracleCommand Properties**

| Property                           | Description                                                                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SqlId</a>              | Provides the SQL_ID corresponding to the last executed statement on the OracleCommand<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">Transaction</a>        | Specifies the OracleTransaction object in which the OracleCommand executes                                                                 |
| <a href="#">UpdatedRowSource</a>   | Specifies how query command results are applied to the row being updated                                                                   |
| <a href="#">UseEdmMapping</a>      | Indicates whether or not the command object utilizes the Entity Data Model mapping configuration values                                    |
| <a href="#">XmlCommandType</a>     | Specifies the type of XML operation on the OracleCommand                                                                                   |
| <a href="#">XmlQueryProperties</a> | Specifies the properties that are used when an XML document is created from the result set of a SQL query statement                        |
| <a href="#">XmlSaveProperties</a>  | Specifies the properties that are used when an XML document is used to save changes to the database                                        |

**OracleCommand Public Methods**

OracleCommand public methods are listed in [Table 6-13](#).

**Table 6-13 OracleCommand Public Methods**

| Public Method                        | Description                                                                                                                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Cancel</a>               | Attempts to cancel a command that is currently executing on a particular connection                                                                                               |
| <a href="#">Clone</a>                | Creates a copy of OracleCommand object                                                                                                                                            |
| CreateObjRef                         | Inherited from System.MarshalByRefObject                                                                                                                                          |
| <a href="#">CreateParameter</a>      | Creates a new instance of OracleParameter class                                                                                                                                   |
| <a href="#">Dispose</a>              | Releases any resources or memory allocated by the object                                                                                                                          |
| Equals                               | Inherited from System.Object (Overloaded)                                                                                                                                         |
| <a href="#">ExecuteNonQuery</a>      | Executes a SQL statement or a command using the XmlCommandType and CommandText properties and returns the number of rows affected                                                 |
| <a href="#">ExecuteNonQueryAsync</a> | Returns a Task-based asynchronous version of ExecuteNonQuery() (Overloaded).                                                                                                      |
| <a href="#">ExecuteReader</a>        | Executes a command (Overloaded)                                                                                                                                                   |
| <a href="#">ExecuteReaderAsync</a>   | Returns a Task-based asynchronous version of OracleCommand.ExecuteReader(), which fetches the result set as an OracleDataReader object. (Overloaded)                              |
| <a href="#">ExecuteScalar</a>        | Returns the first column of the first row in the result set returned by the query                                                                                                 |
| <a href="#">ExecuteScalarAsync</a>   | Returns a Task-based asynchronous version of OracleCommand.ExecuteScalar(), which returns the first column of the first row in the result set returned by the query. (Overloaded) |

Table 6-13 (Cont.) OracleCommand Public Methods

| Public Method                          | Description                                                                                                                                                                            |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ExecuteStream</a>          | Executes a command using the <code>XmlCommandType</code> and <code>CommandText</code> properties and returns the results in a new <code>Stream</code> object                           |
| <a href="#">ExecuteToStream</a>        | Executes a command using the <code>XmlCommandType</code> and <code>CommandText</code> properties and appends the results as an XML document to the existing <code>Stream</code>        |
| <a href="#">ExecuteXmlReader</a>       | Executes a command using the <code>XmlCommandType</code> and <code>CommandText</code> properties and returns the result as an XML document in a .NET <code>XmlTextReader</code> object |
| <a href="#">ExecuteXmlReaderAsync</a>  | Returns a Task-based asynchronous version of <code>OracleCommand.ExecuteXmlReader()</code> , which fetches the result set as an <code>XmlReader</code> object (Overloaded)             |
| <code>GetHashCode</code>               | Inherited from <code>System.Object</code>                                                                                                                                              |
| <code>GetLifetimeService</code>        | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                  |
| <code>GetType</code>                   | Inherited from <code>System.Object</code>                                                                                                                                              |
| <code>InitializeLifetimeService</code> | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                  |
| <a href="#">Prepare</a>                | <i>This method is a no-op</i>                                                                                                                                                          |
| <code>ToString</code>                  | Inherited from <code>System.Object</code>                                                                                                                                              |

## OracleCommand Constructors

`OracleCommand` constructors instantiate new instances of `OracleCommand` class.

#### Overload List:

- [OracleCommand\(\)](#)  
This constructor instantiates a new instance of `OracleCommand` class.
- [OracleCommand\(string\)](#)  
This constructor instantiates a new instance of `OracleCommand` class using the supplied SQL command or stored procedure, and connection to the Oracle database.
- [OracleCommand\(string, OracleConnection\)](#)  
This constructor instantiates a new instance of `OracleCommand` class using the supplied SQL command or stored procedure, and connection to the Oracle database.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## OracleCommand()

This constructor instantiates a new instance of `OracleCommand` class.

**Declaration**

```
// C#  
public OracleCommand();
```

**Remarks**

Default constructor.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## OracleCommand(string)

This constructor instantiates a new instance of `OracleCommand` class using the supplied SQL command or stored procedure, and connection to the Oracle database.

**Declaration**

```
// C#  
public OracleCommand(string cmdText);
```

**Parameters**

- *cmdText*  
The SQL command or stored procedure to be executed.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

# OracleCommand(string, OracleConnection)

This constructor instantiates a new instance of `OracleCommand` class using the supplied SQL command or stored procedure, and connection to the Oracle database.

## Declaration

```
// C#
public OracleCommand(string cmdText, OracleConnection OracleConnection);
```

## Parameters

- `cmdText`  
The SQL command or stored procedure to be executed.
- `OracleConnection`  
The connection to the Oracle database.

# OracleCommand Static Methods

The `OracleCommand` static method is listed in [Table 6-14](#).

Table 6-14 OracleCommand Static Method

| Method              | Description                                            |
|---------------------|--------------------------------------------------------|
| <code>Equals</code> | Inherited from <code>System.Object</code> (Overloaded) |

### See Also

# OracleCommand Properties

`OracleCommand` properties are listed in [Table 6-15](#).

**Table 6-15 OracleCommand Properties**

| Property                                | Description                                                                                                                                     |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddRowid</a>                | Adds the ROWID as part of the select list                                                                                                       |
| <a href="#">AddToStatementCache</a>     | Causes executed statements to be cached, when the property is set to true and statement caching is enabled                                      |
| <a href="#">ArrayBindCount</a>          | Specifies if the array binding feature is to be used and also specifies the maximum number of array elements to be bound in the Value property  |
| <a href="#">ArrayBindRowsAffected</a>   | Returns the number of affected rows for each iteration while executing a DML using array binding                                                |
| <a href="#">BindByName</a>              | Specifies the binding method in the collection                                                                                                  |
| <a href="#">CommandText</a>             | Specifies the SQL statement or stored procedure to run against the Oracle database or the XML data used to store changes to the Oracle database |
| <a href="#">CommandTimeout</a>          | Specifies the number of seconds the command is allowed to execute before terminating the execution with an exception                            |
| <a href="#">CommandType</a>             | Specifies the command type that indicates how the CommandText property is to be interpreted                                                     |
| <a href="#">Connection</a>              | Specifies the OracleConnection object that is used to identify the connection to execute a command                                              |
| Container                               | Inherited from System.ComponentModel.Component                                                                                                  |
| <a href="#">DesignTimeVisible</a>       | Specifies whether or not the OracleCommand object is visible on designer controls.                                                              |
| <a href="#">FetchSize</a>               | Specifies the size of OracleDataReader's internal cache to store result set data                                                                |
| <a href="#">FetchSqlId</a>              | Indicates whether or not to fetch the SQL_ID of the executed statements<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                    |
| <a href="#">ImplicitRefCursors</a>      | Specifies an array of OracleRefCursors mapped to an implicit resultset returned by the stored procedure.                                        |
| <a href="#">InitialLOBFetchSize</a>     | Specifies the amount of data that the OracleDataReader initially fetches for LOB columns                                                        |
| <a href="#">InitialLONGFetchSize</a>    | Specifies the amount that of data the OracleDataReader initially fetches for LONG and LONG RAW columns                                          |
| <a href="#">Notification</a>            | Indicates that there is a notification request for the command                                                                                  |
| <a href="#">NotificationAutoEnlist</a>  | Indicates whether or not to register for a continuous query notification with the database automatically when the command is executed           |
| <a href="#">Parameters</a>              | Specifies the parameters for the SQL statement or stored procedure                                                                              |
| <a href="#">RowSize</a>                 | Specifies the amount of memory needed by the OracleDataReader internal cache to store one row of data                                           |
| <a href="#">RowsToFetchPerRoundTrip</a> | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                     |
| Site                                    | Inherited from System.ComponentModel.Component                                                                                                  |

Table 6-15 (Cont.) OracleCommand Properties

| Property                           | Description                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SqlId</a>              | Provides the SQL_ID corresponding to the last executed statement on the OracleCommand                                           |
| <a href="#">Transaction</a>        | Specifies the OracleTransaction object in which the OracleCommand executes<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">UpdatedRowSource</a>   | Specifies how query command results are applied to the row being updated                                                        |
| <a href="#">UseEdmMapping</a>      | Indicates whether or not the command object utilizes the Entity Data Model mapping configuration values                         |
| <a href="#">XmlCommandType</a>     | Specifies the type of XML operation on the OracleCommand                                                                        |
| <a href="#">XmlQueryProperties</a> | Specifies the properties that are used when an XML document is created from the result set of a SQL query statement             |
| <a href="#">XmlSaveProperties</a>  | Specifies the properties that are used when an XML document is used to save changes to the database                             |

## AddRowid

This property adds the ROWID as part of the select list.

**Declaration**

```
// C#  
public bool AddRowid {get; set;}
```

**Property Value**

bool

**Remarks**

Default is false.

This ROWID column is hidden and is not accessible by the application. To gain access to the ROWIDs of a table, the ROWID must explicitly be added to the select list without the use of this property.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- ["LOB Support"](#) for further information on how this property used with LOBs

## AddToStatementCache

This property causes executed statements to be cached when the property is set to true and statement caching is enabled. If statement caching is disabled or if this property is set to false, the executed statement is not cached.

### Declaration

```
// C#  
public bool AddToStatementCache{get; set;}
```

### Return Value

Returns bool value. A value of true indicates that statements are being added to the cache, false indicates otherwise.

### Property Value

A bool value that indicates that the statements will be cached when they are executed, if statement caching is enabled.

### Remarks

Default is true.

AddToStatementCache is ignored if statement caching is disabled. Statement caching is enabled by setting the Statement Cache Size connection string attribute to a value greater than 0.

When statement caching is enabled, however, this property provides a way to selectively add statements to the cache.

### Example

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class AddToStatementCacheSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle;" +  
            "statement cache size=10";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
    }  
}
```

```
OracleCommand cmd = new OracleCommand("select * from emp", con);

if (cmd.AddToStatementCache)
    Console.WriteLine("Added to the statement cache:" + cmd.CommandText);
else
    Console.WriteLine("Not added to the statement cache:" + cmd.CommandText);

// The execution of "select * from emp" will be added to the statement cache
// because statement cache size is greater than 0 and OracleCommand's
// AddToStatementCache is true by default.
OracleDataReader readerEmp = cmd.ExecuteReader();

// Do not add "select * from dept" to the statement cache
cmd.CommandText = "select * from dept";
cmd.AddToStatementCache = false;

if (cmd.AddToStatementCache)
    Console.WriteLine("Added to the statement cache:" + cmd.CommandText);
else
    Console.WriteLine("Not added to the statement cache:" + cmd.CommandText);

// The execution of "select * from dept" will not be added to the
// statement cache because AddToStatementCache is set to false.
OracleDataReader readerDept = cmd.ExecuteReader();

// Clean up
con.Dispose();
}
```

## ArrayBindCount

This property specifies if the array binding feature is to be used and also specifies the number of array elements to be bound in the OracleParameter Value property.

### Declaration

```
// C#
public int ArrayBindCount {get; set;}
```

### Property Value

An int value that specifies number of array elements to be bound in the OracleParameter Value property.

## Exceptions

ArgumentException - The ArrayBindCount value specified is invalid.

## Remarks

Default = 0.

If ArrayBindCount is equal to 0, array binding is not used; otherwise, array binding is used and OracleParameter Value property is interpreted as an array of values. The value of ArrayBindCount must be specified to use the array binding feature.

If neither DbType nor OracleDbType is set, it is strongly recommended that you set ArrayBindCount before setting the OracleParameter Value property so that inference of DbType and OracleDbType from Value can be correctly done.

Array binding is not used by default.

If the XmlCommandType property is set to any value other than None, this property is ignored.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)
- ["Array Binding"](#)
- ["Value "](#)

## ArrayBindRowsAffected

This property returns the number of affected rows for each iteration while executing a DML using array binding.

### Declaration

```
// C#  
public long[] ArrayBindRowsAffected ;
```

### Property Value

A long type

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)
- ["Array Binding"](#)
- ["Value "](#)

## BindByName

This property specifies the binding method in the collection.

### Declaration

```
// C#  
public bool BindByName {get; set;}
```

### Property Value

Returns true if the parameters are bound by name; returns false if the parameters are bound by position.

### Remarks

Default = false.

BindByName is ignored under the following conditions:

- The value of the XmlCommandType property is Insert, Update, or Delete.
- The value of the XmlCommandType property is Query, but there are no parameters set on the OracleCommand.

If the XmlCommandType property is OracleXmlCommandType.Query and any parameters are set on the OracleCommand, the BindByName property must be set to true. Otherwise, the following OracleCommand methods throw an InvalidOperationException.

- ExecuteNonQuery
- ExecuteXmlReader
- ExecuteStream
- ExecuteToStream

**① See Also**

## CommandText

This property specifies the SQL statement or stored procedure to run against the Oracle database or the XML data used to store changes to the Oracle database.

**Declaration**

```
// C#  
public override string CommandText {get; set;}
```

**Property Value**

A string.

**Implements**

IDbCommand

**Remarks**

The default is an empty string.

When the CommandType property is set to StoredProcedure, the CommandText property is set to the name of the stored procedure. The command calls this stored procedure when an Execute method is called.

The effects of XmlCommandType values on CommandText are:

- XmlCommandType = None.  
CommandType property determines the contents of CommandText.
- XmlCommandType = Query.  
CommandText must be a SQL query. The SQL query should be a select statement. CommandType property is ignored.
- XmlCommandType property is Insert, Update, or Delete.  
CommandText must be an XML document. CommandType property is ignored.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)

## CommandTimeout

This property specifies the minimum number of seconds that the command is allowed to execute before terminating with an exception.

**Declaration**

```
// C#  
public override int CommandTimeout {get; set;}
```

**Property Value**

int

**Implements**

IDbCommand.CommandTimeout

**Exceptions**

InvalidArgument - The specified value is less than 0.

**Remarks**

Default is 0 seconds, which enforces no time limit.

When the specified timeout value expires before a command execution finishes, ODP.NET will begin the process of canceling the command. If cancellation is successful, then an exception is thrown with the message ORA-01013: user requested cancel of current operation. Other possible exceptions thrown after a command timeout expiration occurs include ORA-00936 and ORA-00604. If the command is executed in time without any errors, then no exceptions are thrown.

ODP.NET does not guarantee a command will be cancelled at the exact moment the timeout value is reached. The timeout value is the minimum time to allow a command to complete before the cancellation process begins. It is possible for commands to complete after the timeout value expires.

In a situation where multiple OracleCommand objects use the same connection, the timeout expiration on one of the OracleCommand objects may terminate any of the executions on the single connection. To make the timeout expiration of a OracleCommand cancel only its own command execution, simply use one OracleCommand for each connection if that OracleCommand sets the CommandTimeout property to a value greater than 0.

## CommandType

This property specifies the command type that indicates how the CommandText property is to be interpreted.

### Declaration

```
// C#  
public override CommandType CommandType {get; set;}
```

### Property Value

A CommandType.

### Exceptions

ArgumentException - The value is not a valid CommandType.

### Remarks

Default = CommandType.Text

If the value of the XmlCommandType property is not None, then the CommandType property is ignored. ODP.NET does not support the property value CommandType.TableDirect.

### ① See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## Connection

This property specifies the OracleConnection object that is used to identify the connection to execute a command.

### Declaration

```
// C#  
public OracleConnection Connection {get; set;}
```

**Property Value**

An OracleConnection object.

**Implements**

IDbCommand

**Remarks**

Default = null

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## DesignTimeVisible

This property specifies whether or not the OracleCommand object is visible on designer controls.

**Declaration**

```
// C#  
public override bool DesignTimeVisible { get; set; }
```

**Property Value**

A value that indicate whether or not OracleCommand object is visible in a control. The default is true.

**Remarks**

This property is used by developers to indicate whether or not OracleCommand object is visible in a control.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## FetchSize

This property specifies the size of OracleDataReader's internal cache to store result set data.

### Declaration

```
// C#  
public long FetchSize {get; set;}
```

### Property Value

A long that specifies the size (in bytes) of the `OracleDataReader`'s internal cache.

### Exceptions

`ArgumentException` - The `FetchSize` value specified is invalid.

### Remarks

Default = 131072.

The `FetchSize` property is inherited by the `OracleDataReader` that is created by a command execution returning a result set. The `FetchSize` property on the `OracleDataReader` object determines the amount of data the `OracleDataReader` fetches into its internal cache for each database round-trip.

If the `XmlCommandType` property is set to any value other than `None`, this property is ignored.

The `RowSize` and `FetchSize` properties handle UDT and `XMLType` data differently than other scalar data types. Because only a reference to the UDT and `XMLType` data is stored in the ODP.NET's internal cache, the `RowSize` property accounts for only the memory needed for the reference (which is very small) and not the actual size of the UDT and `XMLType` data. Thus, applications can inadvertently fetch a large number of UDT or `XMLType` instances from the database in a single database round-trip. This is because the actual size of UDT and `XMLType` data do not count against the `FetchSize`, and it would require numerous UDT and `XMLType` references to fill up the default cache size of 131072 bytes. Therefore, when fetching UDT or `XMLType` data, the `FetchSize` property must be appropriately configured to control the number of UDT and `XMLType` instances that are to be fetched, rather than the amount of the actual UDT and `XMLType` data to be fetched.

NOTE: For LOB and LONG data types, only the sizes specified in the `InitialLOBFetchSize` and `InitialLONGFetchSize` properties are accounted for by the `RowSize` property in addition to the metadata and reference information that is maintained by the cache for each LOB in the select list.

## FetchSqlId

This property indicates whether or not to fetch the `SQL_ID` of the executed statements.

**Declaration**

```
// C#  
public bool FetchSqlId {get; set;}
```

**Property Value**

A boolean value

**Remarks**

By default, the value of this property is false which means SQL\_ID would not be fetched for executed statements.

Set this property to true before executing a statement to be able to get the SQL\_ID corresponding to the statement being executed.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ImplicitRefCursors

This property returns an array of OracleRefCursors, where each OracleRefCursor maps to an implicit resultset returned by the stored procedure.

**Declaration**

```
// C#  
public OracleRefCursor[] ImplicitRefCursors {get; set;}
```

**Property Value**

An array of OracleRefCursors.

**Remarks**

This property is populated only when the stored procedure is executed through ExecuteNonQuery and it does not get populated in any other scenarios.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## InitialLOBFetchSize

This property specifies the amount of data that the `OracleDataReader` initially fetches for LOB columns.

### Declaration

```
// C#  
public int InitialLOBFetchSize {get; set;}
```

### Property Value

An `int` specifying the number of characters or bytes to fetch initially.

### Exceptions

`ArgumentException` - The `InitialLOBFetchSize` value specified is invalid.

### Remarks

The value of `InitialLOBFetchSize` specifies the initial amount of LOB data that is immediately fetched by the `OracleDataReader`. The property value specifies the number of characters for CLOB and NCLOB data, and the number of bytes for BLOB data.

The `InitialLOBFetchSize` value is used to determine the length of the LOB column data to fetch, if the LOB column is in the select list. If the select list does not contain a LOB column, the `InitialLOBFetchSize` value is ignored.

When `InitialLOBFetchSize` is set to -1, the entire LOB data is prefetched and stored in the fetch array.

Default = 0.

The maximum value supported for `InitialLOBFetchSize` is 2 GB.

`GetOracleBlob` and `GetOracleClob` methods can be used to retrieve any LOBs no matter the `InitialLOBFetchSize` value.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)
- ["Obtaining LOB Data"](#) for more information on setting `InitialLOBFetchSize` values

## InitialLONGFetchSize

This property specifies the amount of data that the `OracleDataReader` initially fetches for LONG and LONG RAW columns.

### Declaration

```
// C#  
public int InitialLONGFetchSize {get; set;}
```

### Property Value

An int specifying the amount.

### Exceptions

ArgumentException - The InitialLONGFetchSize value specified is invalid.

### Remarks

The maximum value supported for InitialLONGFetchSize is 32767. If this property is set to a higher value, the provider resets it to 32767.

The value of InitialLONGFetchSize specifies the initial amount of LONG or LONG RAW data that is immediately fetched by the OracleDataReader. The property value specifies the number of characters for LONG data and the number of bytes for LONG RAW. To fetch more than the specified InitialLONGFetchSize amount, one of the following must be in the select list:

- Primary key
- ROWID
- Unique columns - (defined as a set of columns on which a unique constraint has been defined or a unique index has been created, where at least one of the columns in the set has a NOT NULL constraint defined on it)

The InitialLONGFetchSize value is used to determine the length of the LONG and LONG RAW column data to fetch if one of the two is in the select list. If the select list does not contain a LONG or a LONG RAW column, the InitialLONGFetchSize value is ignored.

When InitialLONGFetchSize is set to -1, the entire LONG or LONG RAW data is prefetched and stored in the fetch array. Calls to GetString, GetChars, or GetBytes in OracleDataReader allow retrieving the entire data.

Default = 0.

Setting this property to 0 defers the LONG and LONG RAW data retrieval entirely until the application specifically requests it.

#### See Also

- [OracleCommand Class](#)
- [OracleCommand Members](#)
- ["Obtaining LONG and LONG RAW Data"](#) for further information

## Notification

This instance property indicates that there is a notification request for the command.

## Declaration

```
// C#  
public OracleNotificationRequest Notification {set; get;}
```

## Property Value

A notification request for the command.

## Remarks

When a changed notification is first registered, the client listener is started in order to receive any database notification. The listener uses the port number defined in the `OracleDependency.Port` static field. Subsequent change notification registrations use the same listener in the same client process and do not start another listener.

When `Notification` is set to an `OracleNotificationRequest` instance, a notification registration is created (if it has not already been created) when the command is executed. Once the registration is created, the properties of the `OracleNotificationRequest` instance cannot be modified. If the notification registration has already been created, the result set that is associated with the command is added to the existing registration.

When `Notification` is set to null, subsequent command executions do not require a notification request. If a notification request is not required, set the `Notification` property to null, or set the `NotificationAutoEnlist` property to false.

For Continuous Query Notification, a notification request can be used for multiple command executions. In that case, any query result set associated with different commands can be invalidated within the same registration.

When the `OracleDependency.OnChange` event is fired, if the ROWID column is explicitly included in the query (or `AddRowid` property is set to true), then the `Rowid` column contains ROWID values in the `DataTable` referenced by the `OracleNotificationEventArgs.Details` property. This behavior can be overridden by explicitly requesting for an inclusion and exclusion of ROWID values in the `OracleNotificationEventArgs` by setting the `OracleDependency.RowidInfo` to `OracleRowidInfo.Include` or `OracleRowidInfo.Exclude`, respectively.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)
- ["Continuous Query Notification Support"](#)
- [Continuous Query Notification Classes](#)

## NotificationAutoEnlist

This instance property indicates whether or not to register for a continuous query notification with the database automatically when the command is executed.

**Declaration**

```
// C#  
public bool NotificationAutoEnlist {set; get;}
```

**Property Value**

A bool value indicating whether or not to make a continuous query notification request automatically, when the command is executed. If NotificationAutoEnlist is set to true, and the Notification property is set appropriately, a continuous query notification request is registered automatically; otherwise, no continuous query notification registration is made.

Default value: true

**Remarks**

A notification request can be used for multiple command executions using the same OracleCommand instance. In that case, set the NotificationAutoEnlist property to true.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)
- ["Continuous Query Notification Support "](#)
- [Continuous Query Notification Classes](#)

## Parameters

This property specifies the parameters for the SQL statement or stored procedure.

**Declaration**

```
// C#  
public OracleParameterCollection Parameters {get;}
```

**Property Value**

OracleParameterCollection

**Implements**

IDbCommand

**Remarks**

Default value = an empty collection

The number of the parameters in the collection must be equal to the number of parameter placeholders within the command text, or an error is raised.

If the command text does not contain any parameter tokens (such as :1,:2), the values in the Parameters property are ignored.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## RowSize

This property specifies the amount of memory needed by the `OracleDataReader` internal cache to store one row of data.

### Declaration

```
// C#  
public long RowSize {get;}
```

### Property Value

A long that indicates the amount of memory (in bytes) that an `OracleDataReader` needs to store one row of data for the executed query.

### Remarks

Default value = 0

The `RowSize` property is set to a nonzero value after the execution of a command that returns a result set. This property can be used at design time or dynamically during runtime, to set the `FetchSize`, based on number of rows. For example, to enable the `OracleDataReader` to fetch `N` rows for each database round-trip, the `OracleDataReader` `FetchSize` property can be set dynamically to `RowSize * N`. Note that for the `FetchSize` to take effect appropriately, it must be set after `OracleCommand.ExecuteReader()` but before `OracleDataReader.Read()`.

ODP.NET now supports values up to 32K for `VARCHAR2`, `NVARCHAR2` or `RAW` type columns in its calculation of `RowSize` value.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)

## RowsToFetchPerRoundTrip

This property specifies the total number of rows to retrieve per database round trip.

### Declaration

```
// C#  
public Int64 RowsToFetchPerRoundTrip { get; set; }
```

**Property Type**

System.Int64

**Remarks**

This property has no default value. If it is not set, ODP.NET ignores this property.

The row data fetched in a single round trip applies to scalar types only, such as NUMBER and VARCHAR2 columns. If reference data types, such as LOBs, UDTs, and XMLType, exist in the result set, they are retrieved in separate round trips. These reference types can have their own fetch tuning parameters as reference type data sizes can vary in size from row to row, sometimes significantly.

RowsToFetchPerRoundTrip can be set before or after the OracleCommand executes on OracleConnection, OracleCommand, OracleDataReader, or OracleRefCursor. The value can also be changed after initial data fetches so that more or fewer rows are fetched on subsequent round trips. For OracleConfiguration, this property can only be set before the first connection opens.

## SqlId

This property provides the SQL\_ID corresponding to the last executed statement on the OracleCommand.

**Declaration**

```
// C#  
public string SqlId { get; }
```

**Property Value**

A string value

**Remarks**

If FetchSqlId was set to false then this property will return null.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## Transaction

This property specifies the `OracleTransaction` object in which the `OracleCommand` executes.

### Declaration

```
// C#  
public OracleTransaction Transaction {set; get;}
```

### Property Value

`OracleTransaction`

### Implements

`IDbCommand`

### Remarks

Default value = `null`

`Transaction` returns a reference to the transaction object associated with the `OracleCommand` connection object. Thus the command is executed in whatever transaction context its connection is currently in.

#### ① Note

When this property is accessed through an `IDbCommand` reference, its set accessor method is not operational.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## UpdatedRowSource

This property specifies how query command results are applied to the row to be updated.

### Declaration

```
// C#  
public override UpdateRowSource UpdatedRowSource {get; set;}
```

### Property Value

An `UpdateRowSource`.

### Implements

`IDbCommand`

**Exceptions**

ArgumentException - The UpdateRowSource value specified is invalid.

**Remarks**

Always returns UpdateRowSource,

Set accessor throws an ArgumentException if the value is other than UpdateRowSource.None.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## UseEdmMapping

This property Indicates whether or not the OracleCommand object utilizes the Entity Data Model mapping configuration values.

**Declaration**

```
// C#  
public bool UseEdmMapping
```

**Property Value**

A bool.

**Remarks**

Default is false.

The UseEdmMapping property allows user to explicitly specify that the OracleCommand object should use the Entity Data Model mapping configuration values. This enables use of Entity Framework Multiple Result Sets feature.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## XmlCommandType

This property specifies the type of XML operation on the OracleCommand.

**Declaration**

```
// C#  
public OracleXmlCommandType XmlCommandType {get; set;}
```

**Property Value**

An OracleXmlCommandType.

**Remarks**

Default value is None.

XmlCommandType values and usage:

- None - The CommandType property specifies the type of operation.
- Query - CommandText property must be set to a SQL select statement. The query is executed, and the results are returned as an XML document. The SQL select statement in the CommandText and the properties specified by the XmlQueryProperties property are used to perform the operation. The CommandType property is ignored.
- Insert, Update, or Delete - CommandText property is an XML document containing the changes to be made. The XML document in the CommandText and the properties specified by the XmlSaveProperties property are used to perform the operation. The CommandType property is ignored.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## XmlQueryProperties

This property specifies the properties that are used when an XML document is created from the result set of a SQL query statement.

**Declaration**

```
// C#  
public OracleXmlQueryProperties XmlQueryProperties {get; set;}
```

**Property Value**

OracleXmlQueryProperties.

**Remarks**

When a new instance of OracleCommand is created, an instance of OracleXmlQueryProperties is automatically available on the OracleCommand instance through the OracleCommand.XmlQueryProperties property.

A new instance of OracleXmlQueryProperties can be assigned to an OracleCommand instance. Assigning an instance of OracleXmlQueryProperties to the XmlQueryProperties of an

OracleCommand instance creates a new instance of the given OracleXmlQueryProperties instance for the OracleCommand. This way each OracleCommand instance has its own OracleXmlQueryProperties instance.

Use the default constructor to get a new instance of OracleXmlQueryProperties.

Use the OracleXmlQueryProperties.Clone() method to get a copy of an OracleXmlQueryProperties instance.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## XmlSaveProperties

This property specifies the properties that are used when an XML document is used to save changes to the database.

#### Declaration

```
// C#  
public OracleXmlSaveProperties XmlSaveProperties {get; set;}
```

#### Property Value

OracleXmlSaveProperties.

#### Remarks

When a new instance of OracleCommand is created, an instance of OracleXmlSaveProperties is automatically available on the OracleCommand instance through the OracleCommand.XmlSaveProperties property.

A new instance of OracleXmlSaveProperties can be assigned to an OracleCommand instance. Assigning an instance of OracleXmlSaveProperties to the XmlSaveProperties of an OracleCommand instance creates a new instance of the given OracleXmlSaveProperties instance for the OracleCommand. This way each OracleCommand instance has its own OracleXmlSaveProperties instance.

Use the default constructor to get a new instance of OracleXmlSaveProperties.

Use the OracleXmlSaveProperties.Clone() method to get a copy of an OracleXmlSaveProperties instance.

## OracleCommand Public Methods

OracleCommand public methods are listed in [Table 6-16](#).

**Table 6-16 OracleCommand Public Methods**

| Public Method                         | Description                                                                                                                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Cancel</a>                | Attempts to cancel a command that is currently executing on a particular connection                                                                                               |
| <a href="#">Clone</a>                 | Creates a copy of OracleCommand object                                                                                                                                            |
| CreateObjRef                          | Inherited from System.MarshalByRefObject                                                                                                                                          |
| <a href="#">CreateParameter</a>       | Creates a new instance of OracleParameter class                                                                                                                                   |
| <a href="#">Dispose</a>               | Releases any resources or memory allocated by the object                                                                                                                          |
| Equals                                | Inherited from System.Object (Overloaded)                                                                                                                                         |
| <a href="#">ExecuteNonQuery</a>       | Executes a SQL statement or a command using the XmlCommandType and CommandText properties and returns the number of rows affected                                                 |
| <a href="#">ExecuteNonQueryAsync</a>  | Returns a Task-based asynchronous version of ExecuteNonQuery() (Overloaded).                                                                                                      |
| <a href="#">ExecuteReader</a>         | Executes a command (Overloaded)                                                                                                                                                   |
| <a href="#">ExecuteReaderAsync</a>    | Returns a Task-based asynchronous version of OracleCommand.ExecuteReader(), which fetches the result set as an OracleDataReader object. (Overloaded)                              |
| <a href="#">ExecuteScalar</a>         | Returns the first column of the first row in the result set returned by the query                                                                                                 |
| <a href="#">ExecuteScalarAsync</a>    | Returns a Task-based asynchronous version of OracleCommand.ExecuteScalar(), which returns the first column of the first row in the result set returned by the query. (Overloaded) |
| <a href="#">ExecuteStream</a>         | Executes a command using the XmlCommandType and CommandText properties and returns the results in a new Stream object                                                             |
| <a href="#">ExecuteToStream</a>       | Executes a command using the XmlCommandType and CommandText properties and appends the results as an XML document to the existing Stream                                          |
| <a href="#">ExecuteXmlReader</a>      | Executes a command using the XmlCommandType and CommandText properties and returns the result as an XML document in a .NET XmlTextReader object                                   |
| <a href="#">ExecuteXmlReaderAsync</a> | Returns a Task-based asynchronous version of OracleCommand.ExecuteXmlReader(), which fetches the result set as an XmlReader object (Overloaded)                                   |
| GetHashCode                           | Inherited from System.Object                                                                                                                                                      |
| GetLifetimeService                    | Inherited from System.MarshalByRefObject                                                                                                                                          |
| GetType                               | Inherited from System.Object                                                                                                                                                      |
| InitializeLifetimeService             | Inherited from System.MarshalByRefObject                                                                                                                                          |

**Table 6-16 (Cont.) OracleCommand Public Methods**

| Public Method           | Description                               |
|-------------------------|-------------------------------------------|
| <a href="#">Prepare</a> | <i>This method is a no-op</i>             |
| ToString                | Inherited from <code>System.Object</code> |

## Cancel

This method attempts to cancel a command that is currently executing on a particular connection.

**Declaration**

```
// C#  
public override void Cancel();
```

**Implements**

```
IDbCommand.Cancel
```

**Remarks**

If cancellation of the command succeeds, an exception is thrown. If cancellation is not successful, no exception is thrown. If there is no command being executed at the time of the `Cancel` invocation, `Cancel` does nothing. Invoking the `Cancel` method does not guarantee that the command executing at the time will always be cancelled. The execution may complete before it can be terminated. In such cases, no exception is thrown.

Commands cancellation will stop the command execution stage or results fetching stage if it is a query. If these stages have completed, `Cancel` does nothing.

ODP.NET sends a cancellation message to the database server when the `Cancel` method is invoked. There may be a delay when cancelling a running PL/SQL program. This delay is specific to PL/SQL's design in how it handles command cancellations.

When managed ODP.NET or ODP.NET Core invokes `Cancel`, it is deterministic. That means the command executed by the `OracleCommand` object is the only command that could be canceled. Unmanaged ODP.NET `Cancel` is non-deterministic.

Non-determinism in unmanaged ODP.NET means that when multiple `OracleCommand` objects share the same connection, only one command can be executed on that connection at any one time. When it is invoked, the `Cancel` method attempts to cancel the statement currently running on the connection that the `OracleCommand` object is using to execute the command. However, when multiple `OracleCommand` objects execute statements on the same connection simultaneously, issuing a `Cancel` method invocation may cancel any of the issued commands. This is because the command designated for cancellation may complete before the `Cancel`

invocation is effective. If this happens, a command executed by a different `OracleCommand` could be cancelled instead.

There are several ways to avoid this non-deterministic situation that the `Cancel` method can cause:

- The application can create just one `OracleCommand` object for each connection. Doing so assures that the `Cancel` invocation only cancels commands executed by the `OracleCommand` object using a particular connection.
- Command executions in the application are synchronized between `OracleCommand` objects that use the same connection.

These suggestions do not apply if `Cancel` is not used in the application.

Because the termination on the currently running execution is non-deterministic, it is recommended that any *non-atomic* SQL or PL/SQL execution be started within a transaction. When the command execution successfully terminates with an exception of ORA-01013: user requested cancel of current operation, the transaction can be rolled back for data integrity. Other possible exceptions thrown after a command cancellation occurs include ORA-00936 and ORA-00604. Examples of non-atomic execution are collections of DML command executions that are executed one-by-one and multiple DML commands that are part of a PL/SQL stored procedure or function.

### Example

```
// C#

// This example shows how command executions can be cancelled in a
// deterministic way even if multiple commands are executed on a single
// connection. This is accomplished by synchronizing threads through events.
// Since the Cancel method terminates the currently running operation on the
// connection, threads must be serialized if multiple threads are using the
// same connection to execute server round-trip incurring operations.
// Furthermore, the example shows how the execution and cancel threads should
// be synchronized so that nth iteration of the command execution does not
// inappropriately cancel the (n+1)th command executed by the same thread.

using System;
using System.Data;
using Oracle.DataAccess.Client;
using System.Threading;

class CancelSample
{
    private OracleCommand cmd;
    Thread t1, t2;
    // threads signal following events when assigned operations are completed

    private AutoResetEvent ExecuteEvent = new AutoResetEvent(false);
    private AutoResetEvent CancelEvent = new AutoResetEvent(false);
    private AutoResetEvent FinishedEvent = new AutoResetEvent(false);
    AutoResetEvent[] ExecuteAndCancel = new AutoResetEvent[2];

    // Default constructor
    CancelSample()
    {
        cmd = new OracleCommand("select * from all_objects",
            new OracleConnection("user id=scott;password=tiger;data source=oracle"));
        ExecuteAndCancel[0] = ExecuteEvent;
        ExecuteAndCancel[1] = CancelEvent;
    }
}
```

```
// Constructor that takes a particular command and connection
CancelSample(string command, OracleConnection con)
{
    cmd = new OracleCommand(command, con);
    ExecuteAndCancel[0] = ExecuteEvent;
    ExecuteAndCancel[1] = CancelEvent;
}

// Execution of the command
public void Execute()
{
    OracleDataReader reader = null;
    try
    {
        Console.WriteLine("Execute.");
        reader = cmd.ExecuteReader();
        Console.WriteLine("Execute Done.");
        reader.Close();
    }
    catch(Exception e)
    {
        Console.WriteLine("The command has been cancelled.", e.Message);
    }
    Console.WriteLine("ExecuteEvent.Set()");
    ExecuteEvent.Set();
}

// Canceling of the command
public void Cancel()
{
    try
    {
        // cancel query if it takes longer than 100 ms to finish execution
        System.Threading.Thread.Sleep(100);
        Console.WriteLine("Cancel.");
        cmd.Cancel();
    }
    catch (Exception e)
    {
        Console.WriteLine(e.ToString());
    }
    Console.WriteLine("Cancel done.");
    Console.WriteLine("CancelEvent.Set()");
    CancelEvent.Set();
}

// Execution of the command with a potential of cancelling
public void ExecuteWithinLimitedTime()
{
    for (int i = 0; i < 5; i++)
    {
        Monitor.Enter(typeof(CancelSample));
        try
        {
            Console.WriteLine("Executing " + this.cmd.CommandText);
            ExecuteEvent.Reset();
            CancelEvent.Reset();
            t1 = new Thread(new ThreadStart(this.Execute));
            t2 = new Thread(new ThreadStart(this.Cancel));
            t1.Start();
            t2.Start();
        }
        finally
        {
            Monitor.Exit(typeof(CancelSample));
        }
    }
}
```

```

    }
    finally
    {
        WaitHandle.WaitAll(ExecuteAndCancel);
        Monitor.Exit(typeof(CancelSample));
    }
}
FinishedEvent.Set();
}
[MTAThread]
static void Main()
{
    try
    {
        AutoResetEvent[] ExecutionCompleteEvents = new AutoResetEvent[3];

        // Create the connection that is to be used by three commands
        OracleConnection con = new OracleConnection("user id=scott;" +
            "password=tiger;data source=oracle");
        con.Open();

        // Create instances of CancelSample class
        CancelSample test1 = new CancelSample("select * from all_objects", con);
        CancelSample test2 = new CancelSample("select * from all_objects, emp",
            con);
        CancelSample test3 = new CancelSample("select * from all_objects, dept",
            con);

        // Create threads for each CancelSample object instance
        Thread t1 = new Thread(new ThreadStart(test1.ExecuteWithinLimitedTime));
        Thread t2 = new Thread(new ThreadStart(test2.ExecuteWithinLimitedTime));
        Thread t3 = new Thread(new ThreadStart(test3.ExecuteWithinLimitedTime));

        // Obtain a handle to an event from each object
        ExecutionCompleteEvents[0] = test1.FinishedEvent;
        ExecutionCompleteEvents[1] = test2.FinishedEvent;
        ExecutionCompleteEvents[2] = test3.FinishedEvent;

        // Start all threads to execute three commands using a single connection
        t1.Start();
        t2.Start();
        t3.Start();

        // Wait for all three commands to finish executing/canceling before
        //closing the connection
        WaitHandle.WaitAll(ExecutionCompleteEvents);
        con.Close();
    }
    catch (Exception e)
    {
        Console.WriteLine(e.ToString());
    }
}
}

```

- [OracleCommand Class](#)
- [OracleCommand Members](#)
- <http://msdn.microsoft.com/library> for detailed information about this Microsoft .NET Framework feature

## Clone

This method creates a copy of an `OracleCommand` object.

### Declaration

```
// C#  
public object Clone();
```

### Return Value

An `OracleCommand` object.

### Implements

`ICloneable`

### Remarks

The cloned object has the same property values as that of the object being cloned.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## CreateParameter

This method creates a new instance of `OracleParameter` class.

### Declaration

```
// C#  
public OracleParameter CreateParameter();
```

### Return Value

A new `OracleParameter` with default values.

**Implements**

IDbCommand

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## Dispose

This method releases any resources or memory allocated by the object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

**Remarks**

The Dispose method also closes the OracleCommand object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteNonQuery

This method executes a SQL statement or a command using the XmlCommandType and CommandText properties and returns the number of rows affected.

**Declaration**

```
// C#  
public override int ExecuteNonQuery();
```

**Return Value**

The number of rows affected.

**Implements**

IDbCommand

## Exceptions

InvalidOperationException - The command cannot be executed.

## Remarks

ExecuteNonQuery returns the number of rows affected, for the following:

- If the command is UPDATE, INSERT, or DELETE and the XmlCommandType property is set to OracleXmlCommandType.None.
- If the XmlCommandType property is set to OracleXmlCommandType.Insert, OracleXmlCommandType.Update, OracleXmlCommandType.Delete.

For all other types of statements, the return value is -1.

ExecuteNonQuery is used for either of the following:

- Catalog operations (for example, querying the structure of a database or creating database objects such as tables).
- Changing the data in a database without using a DataSet, by executing UPDATE, INSERT, or DELETE statements.
- Changing the data in a database using an XML document.

Although ExecuteNonQuery does not return any rows, it populates any output parameters or return values mapped to parameters with data.

If the XmlCommandType property is set to OracleXmlCommandType.Query then ExecuteNonQuery executes the select statement in the CommandText property, and if successful, returns -1. The XML document that is generated is discarded. This is useful for determining if the operation completes successfully without getting the XML document back as a result.

If the XmlCommandType property is set to OracleXmlCommandType.Insert, OracleXmlCommandType.Update, or OracleXmlCommandType.Delete, then the value of the CommandText property is an XML document. ExecuteNonQuery saves the changes in that XML document to the table or view that is specified in the XmlSaveProperties property. The return value is the number of rows that are processed in the XML document. Also, each row in the XML document could affect multiple rows in the database, but the return value is still the number of rows in the XML document.

## Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class ExecuteNonQuerySample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleCommand cmd = new OracleCommand(
            "select sal from emp where empno=7934", con);

        object sal = cmd.ExecuteScalar();
    }
}
```

```
Console.WriteLine("Employee sal before update: " + sal);

cmd.CommandText = "update emp set sal = sal + .01 where empno=7934";

// Auto-commit changes
int rowsUpdated = cmd.ExecuteNonQuery();

if (rowsUpdated > 0)
{
    cmd.CommandText = "select sal from emp where empno=7934";
    sal = cmd.ExecuteScalar();
    Console.WriteLine("Employee sal after update: " + sal);
}

// Clean up
cmd.Dispose();
con.Dispose();
}
}
```

### Requirements

For XML support, this method requires Oracle9i XML Developer's Kits (Oracle XDK) or later, to be installed in the database. Oracle XDK can be downloaded from Oracle Technology Network (OTN).

## ExecuteNonQueryAsync

### Overload List:

ExecuteNonQueryAsync returns a Task-based asynchronous version of ExecuteNonQuery().

- [ExecuteNonQueryAsync\(\)](#)

This method returns an asynchronous version of ExecuteNonQuery(), which executes the command against its connection object and returns the number of rows affected.

- [ExecuteNonQueryAsync\(CancellationTokencancellationToken\)](#)

This method returns an asynchronous version of ExecuteNonQuery(), which executes the command against its connection object and returns the number of rows affected with a CancellationTokencancellationToken.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteNonQueryAsync()

This method returns an asynchronous version of `ExecuteNonQuery()`, which executes the command against its connection object and returns the number of rows affected.

**Declaration**

```
// C#  
public Task<int> int ExecuteNonQueryAsync();
```

**Return Value**

A Task object.

**Implements**

DbCommand

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteNonQueryAsync(CancellationToken cancellationToken)

This method returns an asynchronous version of `ExecuteNonQuery()`, which executes the command against its connection object and returns the number of rows affected with a `CancellationToken`.

**Declaration**

```
// C#  
public override Task<int> int ExecuteNonQueryAsync(CancellationToken cancellationToken);
```

**Return Value**

A Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Implements**

DbCommand

## Exceptions

InvalidOperationException - The command cannot be executed.

## Example

```
using Oracle.ManagedDataAccess.Client;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main()
        {
            string connection = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";
            OracleConnection oc = new OracleConnection(connection);
            await oc.OpenAsync(CancellationToken.None);
            Console.WriteLine("Connection opened successfully");

            OracleCommand cmd = oc.CreateCommand();
            cmd.CommandText = "insert into tab1 values(1)";
            Task task = cmd.ExecuteNonQueryAsync(CancellationToken.None);
            await task;
            Console.WriteLine("Query executed");
            oc.Close();
        }
    }
}
```

## ExecuteReader

### Overload List:

ExecuteReader executes a command specified in the CommandText.

- [ExecuteReader\(\)](#)  
This method executes a command specified in the CommandText and returns an OracleDataReader object.
- [ExecuteReader\(CommandBehavior\)](#)  
This method executes a command specified in the CommandText and returns an OracleDataReader object, using the specified CommandBehavior value.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteReader()

This method executes a command specified in the `CommandText` and returns an `OracleDataReader` object.

**Declaration**

```
// C#  
public OracleDataReader ExecuteReader();
```

**Return Value**

An `OracleDataReader`.

**Implements**

`IDbCommand`

**Exceptions**

`InvalidOperationException` - The command cannot be executed.

**Remarks**

When the `CommandType` property is set to `CommandType.StoredProcedure`, the `CommandText` property should be set to the name of the stored procedure.

The specified command executes this stored procedure when `ExecuteReader` is called. If parameters for the stored procedure consist of `REF CURSOR` objects, behavior differs depending on whether `ExecuteReader()` or `ExecuteNonQuery()` is called. If `ExecuteReader()` is invoked, `REF CURSOR` objects can be accessed through the `OracleDataReader` that is returned. If more than one `REF CURSOR` is returned from a single execution, subsequent `REF CURSOR` objects can be accessed sequentially by the `NextResult` method on the `OracleDataReader`. If the `ExecuteNonQuery` method is invoked, the output parameter value can be cast to a `OracleRefCursor` type and the `OracleRefCursor` object then can be used to either populate a `DataSet` or create an `OracleDataReader` object from it. This approach provides random access to all the `REF CURSOR` objects returned as output parameters.

The value of 100 is used for the `FetchSize`. If 0 is specified, no rows are fetched. For further information, see ["Obtaining LONG and LONG RAW Data"](#).

If the value of the `XmlCommandType` property is set to `OracleXmlCommandType.Insert`, `OracleXmlCommandType.Update`, `OracleXmlCommandType.Delete`, or `OracleXmlCommandType.Query` then the `ExecuteReader` method throws an `InvalidOperationException`.

### Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class ExecuteReaderSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleCommand cmd = new OracleCommand("select ename from emp", con);

        OracleDataReader reader = cmd.ExecuteReader();

        while (reader.Read())
        {
            Console.WriteLine("Employee Name : " + reader.GetString(0));
        }

        // Clean up
        reader.Dispose();
        cmd.Dispose();
        con.Dispose();
    }
}
```

## ExecuteReader(CommandBehavior)

This method executes a command specified in the CommandText and returns an OracleDataReader object, using the specified behavior.

### Declaration

```
// C#
public OracleDataReader ExecuteReader(CommandBehavior behavior);
```

### Parameters

- *behavior*  
The expected behavior.

### Return Value

An `OracleDataReader`.

### Implements

`IDbCommand`

### Exceptions

`InvalidOperationException` - The command cannot be executed.

### Remarks

A description of the results and the effect on the database of the query command is indicated by the supplied *behavior* that specifies command behavior.

For valid `CommandBehavior` values and for the command behavior of each `CommandBehavior` enumerated type, read the .NET Framework documentation.

When the `CommandType` property is set to `CommandType.StoredProcedure`, the `CommandText` property should be set to the name of the stored procedure. The command executes this stored procedure when `ExecuteReader()` is called.

If the stored procedure returns stored REF CURSORS, read the section on `OracleRefCursors` for more details. See "[OracleRefCursor Class](#)".

The value of 100 is used for the `FetchSize`. If 0 is specified, no rows are fetched. For more information, see "[Obtaining LONG and LONG RAW Data](#)".

If the value of the `XmlCommandType` property is set to `OracleXmlCommandType.Insert`, `OracleXmlCommandType.Update`, `OracleXmlCommandType.Delete`, or `OracleXmlCommandType.Query` then the `ExecuteReader` method throws an `InvalidOperationException`.

#### See Also

## ExecuteReaderAsync

### Overload List:

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.

- [ExecuteReaderAsync\(\)](#)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.

- [ExecuteReaderAsync\(CancellationToken cancellationToken\)](#)  
This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.
- [ExecuteReaderAsync\(CommandBehavior behavior\)](#)  
This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.
- [ExecuteReaderAsync\(CommandBehavior behavior, CancellationToken cancellationToken\)](#)  
This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.

### Example (Using all overloads)

```
using Oracle.ManagedDataAccess.Client;
using System;
using System.Data;
using System.Threading;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main()
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";
            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationToken.None);

            OracleCommand cmd = oc.CreateCommand();
            cmd.CommandText = "select * from demo_table";

            OracleDataReader reader;

            reader = await cmd.ExecuteReaderAsync();
            while (await reader.ReadAsync(CancellationToken.None))
            {
                Console.WriteLine(reader.GetValue(0));
            }

            reader = await cmd.ExecuteReaderAsync(CancellationToken.None);
            while (await reader.ReadAsync(CancellationToken.None))
            {
                Console.WriteLine(reader.GetValue(0));
            }

            reader = await cmd.ExecuteReaderAsync(CommandBehavior.Default);
            while (await reader.ReadAsync(CancellationToken.None))
            {
                Console.WriteLine(reader.GetValue(0));
            }

            reader = await cmd.ExecuteReaderAsync(CommandBehavior.Default,
            CancellationToken.None);
            while (await reader.ReadAsync(CancellationToken.None))
            {
```

```
        Console.WriteLine(reader.GetValue(0));  
    }  
} }  
}
```

## ExecuteReaderAsync()

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.

### Declaration

```
// C#  
public Task<OracleDataReader> ExecuteReaderAsync();
```

### Return Value

`Task<OracleDataReader>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

`DbCommand`

### Exceptions

`InvalidOperationException` - The command cannot be executed.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)

## ExecuteReaderAsync(CancellationToken cancellationToken)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.

### Declaration

```
// C#  
public Task<OracleDataReader> ExecuteReaderAsync(CancellationToken cancellationToken);
```

**Parameters**

cancellationToken - The input cancellation token which can be used by the application to cancel the task before command timeout occurs.

**Return Value**

Task<OracleDataReader> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Implements**

DbCommand

**Exceptions**

InvalidOperationException - The command cannot be executed.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteReaderAsync(CommandBehavior behavior)

This method returns a Task-based asynchronous version of OracleCommand.ExecuteReader(), which fetches the result set as an OracleDataReader object.

**Declaration**

```
// C#  
public Task<OracleDataReader> ExecuteReaderAsync(CommandBehavior behavior);
```

**Parameters**

behavior - the expected behavior. Provides a description of the results of the query and its effect on the database.

**Return Value**

Task<OracleDataReader> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Implements**

DbCommand

**Exceptions**

InvalidOperationException - The command cannot be executed.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- [OracleCommand Members](#)

## ExecuteReaderAsync(CommandBehavior behavior, CancellationToken cancellationToken)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteReader()`, which fetches the result set as an `OracleDataReader` object.

### Declaration

```
// C#  
public Task<OracleDataReader> ExecuteReaderAsync(CommandBehavior behavior,  
CancellationToken cancellationToken);
```

### Parameters

- `behavior` - the expected behavior. Provides a description of the results of the query and its effect on the database.
- `cancellationToken` - the input cancellation token which can be used by the application to cancel the task before command timeout occurs.

### Return Value

`Task<OracleDataReader>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

`DbCommand`

### Exceptions

`InvalidOperationException` - The command cannot be executed.

### ① See Also

- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteScalar

This method executes the query using the connection, and returns the first column of the first row in the result set returned by the query.

## Declaration

```
// C#  
public override object ExecuteScalar();
```

## Return Value

An object which represents the value of the first row, first column.

## Implements

IDbCommand

## Exceptions

InvalidOperationException - The command cannot be executed.

## Remarks

Extra columns or rows are ignored. ExecuteScalar retrieves a single value (for example, an aggregate value) from a database. This requires less code than using the ExecuteReader() method, and then performing the operations necessary to generate the single value using the data returned by an OracleDataReader.

If the query does not return any row, it returns null.

The ExecuteScalar method throws an InvalidOperationException, if the value of the XmlCommandType property is set to one of the following OracleXmlCommandType values: Insert, Update, Delete, Query.

## Example

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class ExecuteScalarSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        OracleCommand cmd = new OracleCommand("select count(*) from emp", con);  
  
        object count = cmd.ExecuteScalar();  
  
        Console.WriteLine("There are {0} rows in table emp", count);  
  
        // Clean up  
        cmd.Dispose();  
        con.Dispose();  
    }  
}
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteStream

This method executes a command using the `XmlCommandType` and `CommandText` properties and returns the result as an XML document in a new `Stream` object.

**Declaration**

```
// C#  
public Stream ExecuteStream();
```

**Return Value**

A `Stream`.

**Remarks**

The behavior of `ExecuteStream` varies depending on the `XmlCommandType` property value:

- `XmlCommandType = OracleXmlCommandType.None`  
`ExecuteStream` throws an `InvalidOperationException`.
- `XmlCommandType = OracleXmlCommandType.Query`  
`ExecuteStream` executes the select statement in the `CommandText` property, and if successful, returns an `OracleClob` object containing the XML document that was generated. `OracleClob` contains Unicode characters.  
  
If the SQL query does not return any rows, then `ExecuteStream` returns an `OracleClob` object containing an empty XML document.
- `XmlCommandType = OracleXmlCommandType.Insert, OracleXmlCommandType.Update, or OracleXmlCommandType.Delete`.  
  
The value of the `CommandText` property is an XML document. `ExecuteStream` saves the data in that XML document to the table or view that is specified in the `XmlSaveProperties` property and an empty `OracleClob` is returned.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)
- *Oracle XML DB Developer's Guide*
- <http://www.oracle.com/technetwork/index.html>

## ExecuteToStream

This method executes a command using the `XmlCommandType` and `CommandText` properties and appends the result as an XML document to the existing `Stream` provided by the application.

### Declaration

```
// C#  
public void ExecuteToStream(Stream outputStream);
```

### Parameters

- `outputStream`  
A `Stream`.

### Remarks

The behavior of `ExecuteToStream` varies depending on the `XmlCommandType` property value:

- `XmlCommandType = OracleXmlCommandType.None`  
`ExecuteToStream` throws an `InvalidOperationException`.
- `XmlCommandType = OracleXmlCommandType.Query`  
`ExecuteToStream` executes the select statement in the `CommandText` property, and if successful, appends the XML document that was generated to the given `Stream`.  
If the SQL query does not return any rows, then nothing is appended to the given `Stream`.  
The character set of the appended data is Unicode.
- `XmlCommandType = OracleXmlCommandType.Insert`, `OracleXmlCommandType.Update`, or `OracleXmlCommandType.Delete`  
The value of the `CommandText` property is an XML document. `ExecuteToStream` saves the changes in that XML document to the table or view that is specified in the `XmlSaveProperties` property. Nothing is appended to the given `Stream`.

## ExecuteScalarAsync

### Overload List:

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteScalar()`, which returns the first column of the first row in the result set returned by the query.

- [ExecuteScalarAsync\(\)](#)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteScalar()`, which returns the first column of the first row in the result set returned by the query.

- [ExecuteScalarAsync\(CancellationToken cancellationToken\)](#)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteScalar()` with input `CancellationToken`, which returns the first column of the first row in the result set returned by the query.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteScalarAsync()

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteScalar()`, which returns the first column of the first row in the result set returned by the query.

### Declaration

```
// C#  
public Task<object> ExecuteScalarAsync();
```

### Return Value

`Task<object>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

`DbCommand`

### Exceptions

`InvalidOperationException` - The command cannot be executed.

### Remarks

This will call into the `ExecuteScalarAsync` implementation with argument `'cancellationToken'` passed as `CancellationToken.None`.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteScalarAsync(CancellationToken cancellationToken)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteScalar()`, which returns the first column of the first row in the result set returned by the query.

### Declaration

```
// C#  
public override Task<object> ExecuteScalarAsync(CancellationToken cancellationToken);
```

### Parameters

`cancellationToken` - The input cancellation token which can be used by the application to cancel the task before command timeout occurs.

### Return Value

`Task<object>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

`DbCommand`

### Exceptions

`InvalidOperationException` - The command cannot be executed.

### Example

```
using Oracle.ManagedDataAccess.Client;  
using System.Threading;  
  
namespace AsyncApp  
{  
    class AsyncDemo  
    {  
        static async Task Main()  
        {  
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";  
            OracleConnection oc = new OracleConnection(connectionString);  
            await oc.OpenAsync(CancellationToken.None);  
  
            OracleCommand cmd = oc.CreateCommand();  
            cmd.CommandText = "select * from demo_table";  
  
            var value = await cmd.ExecuteScalarAsync(CancellationToken.None);  
        }  
    }  
}
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteXmlReader

This method executes the command using the `XmlCommandType` and `CommandText` properties and returns the result as an XML document in a .NET `XmlTextReader` object.

**Declaration**

```
// C#  
public XmlReader ExecuteXmlReader();
```

**Return Value**

An `XmlReader`.

**Remarks**

The behavior of `ExecuteXmlReader` varies depending on the `XmlCommandType` property value:

- `XmlCommandType = OracleXmlCommandType.None`  
`ExecuteStream` and `ExecuteToStream` throw an `InvalidOperationException`.
- `XmlCommandType = OracleXmlCommandType.Query`  
`ExecuteXmlReader` executes the select statement in the `CommandText` property, and if successful, returns a .NET `XmlTextReader` object containing the XML document that was generated.  
  
If the XML document is empty, which can happen if the SQL query does not return any rows, then an empty .NET `XmlTextReader` object is returned.
- `XmlCommandType = OracleXmlCommandType.Insert`, `OracleXmlCommandType.Update`, or `OracleXmlCommandType.Delete`.

The value of the `CommandText` property is an XML document, and `ExecuteXmlReader` saves the changes in that XML document to the table or view that is specified in the `XmlSaveProperties` property. An empty .NET `XmlTextReader` object is returned.

**See Also**

## ExecuteXmlReaderAsync

### Overload List:

The method `ExecuteXmlReaderAsync` returns a Task-based asynchronous version of `OracleCommand.ExecuteXmlReader()`, which fetches the result set as an `XmlReader` object.

- [ExecuteXmlReaderAsync\(\)](#)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteXmlReader()`, which fetches the result set as an `XmlReader` object.

- [ExecuteXmlReaderAsync\(CancellationToken\)](#)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteXmlReader()`, which fetches the result set as an `XmlReader` object.

### Example (includes overloads)

```
using Oracle.ManagedDataAccess.Client;
using System;
using System.Threading;
using System.Xml;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main()
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";
            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationToken.None);

            OracleCommand cmd = oc.CreateCommand();
            cmd.CommandText = "select * from demo_table";

            XmlReader reader;

            reader = await cmd.ExecuteXmlReaderAsync();
            while (reader.Read())
            {
                Console.WriteLine(reader.Value);
            }

            reader = await cmd.ExecuteXmlReaderAsync(CancellationToken.None);
            while (reader.Read())
            {
                Console.WriteLine(reader.Value);
            }
        }
    }
}
```

## ExecuteXmlReaderAsync()

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteXmlReader()`, which fetches the result set as an `XmlReader` object.

**Declaration**

```
// C#  
public Task<XmlReader> ExecuteXmlReaderAsync();
```

**Return Value**

`Task<XmlReader>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Implements**

`DbCommand`

**Exceptions**

`InvalidOperationException` - The command cannot be executed.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ExecuteXmlReaderAsync(CancellationTokens)

This method returns a Task-based asynchronous version of `OracleCommand.ExecuteXmlReader()`, which fetches the result set as an `XmlReader` object.

**Declaration**

```
// C#  
public Task<XmlReader> ExecuteXmlReaderAsync(CancellationToken cancellationToken);
```

**Parameter**

*cancellationToken* - The input cancellation token which can be used by the application to cancel the task before command timeout occurs.

**Return Value**

Task<XmlReader> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Implements**

DbCommand

**Exceptions**

InvalidOperationException - The command cannot be executed.

**See Also**

## OracleCommandBuilder Class

An OracleCommandBuilder object provides automatic SQL generation for the OracleDataAdapter when updates are made to the database.

**Class Inheritance**

System.Object

System.MarshalByRefObject

System.ComponentModel.Component

System.Data.Common.DbCommandBuilder

Oracle.DataAccess.Client.OracleCommandBuilder

**Declaration**

```
// C#  
public sealed class OracleCommandBuilder : DbCommandBuilder
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Remarks

OracleCommandBuilder automatically generates SQL statements for single-table updates when the SelectCommand property of the OracleDataAdapter is set. An exception is thrown if the DataSet contains multiple tables. The OracleCommandBuilder registers itself as a listener for RowUpdating events whenever its DataAdapter property is set. Only one OracleDataAdapter object and one OracleCommandBuilder object can be associated with each other at one time.

To generate INSERT, UPDATE, or DELETE statements, the OracleCommandBuilder uses ExtendedProperties within the DataSet to retrieve a required set of metadata. If the SelectCommand is changed after the metadata is retrieved (for example, after the first update), the RefreshSchema method should be called to update the metadata.

OracleCommandBuilder first looks for the metadata from the ExtendedProperties of the DataSet; if the metadata is not available, OracleCommandBuilder uses the SelectCommand property of the OracleDataAdapter to retrieve the metadata.

## Example

The following example performs an update on the EMP table. It uses the OracleCommandBuilder object to create the UpdateCommand for the OracleDataAdapter object when OracleDataAdapter.Update() is called.

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleCommandBuilderSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        string cmdstr = "SELECT empno, sal from emp";

        // Create the adapter with the selectCommand txt and the
        // connection string
        OracleDataAdapter adapter = new OracleDataAdapter(cmdstr, constr);
```

```
// Create the builder for the adapter to automatically generate
// the Command when needed
OracleCommandBuilder builder = new OracleCommandBuilder(adapter);

// Create and fill the DataSet using the EMP
DataSet dataset = new DataSet();
adapter.Fill(dataset, "EMP");

// Get the EMP table from the dataset
DataTable table = dataset.Tables["EMP"];

// Indicate DataColumn EMPNO is unique
// This is required by the OracleCommandBuilder to update the EMP table
table.Columns["EMPNO"].Unique = true;

// Get the first row from the EMP table
DataRow row = table.Rows[0];

// Update the salary
double sal = double.Parse(row["SAL"].ToString());
row["SAL"] = sal + .01;

// Now update the EMP using the adapter
// The OracleCommandBuilder will create the UpdateCommand for the
// adapter to update the EMP table
adapter.Update(dataset, "EMP");

Console.WriteLine("Row updated successfully");
}
}
```

## OracleCommandBuilder Members

OracleCommandBuilder members are listed in the following tables.

### OracleCommandBuilder Constructors

OracleCommandBuilder constructors are listed in [Table 6-17](#).

**Table 6-17 OracleCommandBuilder Constructors**

| Constructor                                       | Description                                                            |
|---------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">OracleCommandBuilder Constructors</a> | Instantiates a new instance of OracleCommandBuilder class (Overloaded) |

**OracleCommandBuilder Static Methods**

OracleCommandBuilder static methods are listed in [Table 6-18](#).

**Table 6-18 OracleCommandBuilder Static Methods**

| Method                           | Description                                                                                                                                                                               |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DeriveParameters</a> | Queries for the parameters of a stored procedure or function, represented by a specified OracleCommand, and populates the OracleParameterCollection of the command with the return values |
| Equals                           | Inherited from System.Object (Overloaded)                                                                                                                                                 |

**OracleCommandBuilder Properties**

OracleCommandBuilder properties are listed in [Table 6-19](#).

**Table 6-19 OracleCommandBuilder Properties**

| Property                         | Description                                                                                                                                              |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Container                        | Inherited from System.ComponentModel.Component                                                                                                           |
| <a href="#">CaseSensitive</a>    | Indicates whether or not double quotes are used around Oracle object names when generating SQL statements                                                |
| <a href="#">CatalogLocation</a>  | <i>Not Supported</i>                                                                                                                                     |
| <a href="#">CatalogSeparator</a> | <i>Not Supported</i>                                                                                                                                     |
| <a href="#">ConflictOption</a>   | <i>Not Supported</i>                                                                                                                                     |
| <a href="#">DataAdapter</a>      | Indicates the OracleDataAdapter for which the SQL statements are generated                                                                               |
| <a href="#">QuotePrefix</a>      | Specifies the beginning character or characters used to specify database objects whose names contain special characters such as spaces or reserved words |
| <a href="#">QuoteSuffix</a>      | Specifies the ending character or characters used to specify database objects whose names contain special characters such as spaces or reserved words    |
| <a href="#">SchemaSeparator</a>  | Specifies the character to be used for the separator between the schema identifier and other identifiers                                                 |
| Site                             | Inherited from System.ComponentModel.Component                                                                                                           |

**OracleCommandBuilder Public Methods**

OracleCommandBuilder public methods are listed in [Table 6-20](#).

**Table 6-20 OracleCommandBuilder Public Methods**

| Public Method                      | Description                                                                                                                                    |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| CreateObjRef                       | Inherited from System.MarshalByRefObject                                                                                                       |
| Dispose                            | Inherited from System.ComponentModel.Component                                                                                                 |
| Equals                             | Inherited from System.Object (Overloaded)                                                                                                      |
| <a href="#">GetDeleteCommand</a>   | Gets the automatically generated OracleCommand object that has the SQL statement (CommandText) perform deletions on the database (Overloaded)  |
| GetHashCode                        | Inherited from System.Object                                                                                                                   |
| <a href="#">GetInsertCommand</a>   | Gets the automatically generated OracleCommand object that has the SQL statement (CommandText) perform insertions on the database (Overloaded) |
| GetLifetimeService                 | Inherited from System.MarshalByRefObject                                                                                                       |
| GetType                            | Inherited from System.Object                                                                                                                   |
| <a href="#">GetUpdateCommand</a>   | Gets the automatically generated OracleCommand object that has the SQL statement (CommandText) perform updates on the database (Overloaded)    |
| InitializeLifetimeService          | Inherited from System.MarshalByRefObject                                                                                                       |
| <a href="#">QuotedIdentifier</a>   | Returns the correct quoted form of the provided unquoted identifier, with any embedded quotes in the identifier properly escaped               |
| <a href="#">RefreshSchema</a>      | Refreshes the database schema information used to generate INSERT, UPDATE, or DELETE statements                                                |
| <a href="#">UnquotedIdentifier</a> | Returns the correct unquoted form of the provided quoted identifier, removing any escape notation for quotes embedded in the identifier        |
| ToString                           | Inherited from System.Object                                                                                                                   |

**OracleCommandBuilder Events**

The OracleCommandBuilder event is listed in [Table 6-21](#).

**Table 6-21 OracleCommandBuilder Events**

| Event Name | Description                                    |
|------------|------------------------------------------------|
| Disposed   | Inherited from System.ComponentModel.Component |

**See Also**

## OracleCommandBuilder Constructors

OracleCommandBuilder constructors create new instances of the OracleCommandBuilder class.

### Overload List:

- [OracleCommandBuilder\(\)](#)

This constructor creates an instance of the OracleCommandBuilder class.

- [OracleCommandBuilder\(OracleDataAdapter\)](#)

This constructor creates an instance of the OracleCommandBuilder class and sets the DataAdapter property to the provided OracleDataAdapter object.

### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## OracleCommandBuilder()

This constructor creates an instance of the OracleCommandBuilder class.

### Declaration

```
// C#  
public OracleCommandBuilder();
```

### Remarks

Default constructor.

### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## OracleCommandBuilder(OracleDataAdapter)

This constructor creates an instance of the OracleCommandBuilder class and sets the DataAdapter property to the provided OracleDataAdapter object.

### Declaration

```
// C#  
public OracleCommandBuilder(OracleDataAdapter da);
```

Parameters

- da*  
The `OracleDataAdapter` object provided.

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

OracleCommandBuilder Static Methods

OracleCommandBuilder static methods are listed in [Table 6-22](#).

Table 6-22 OracleCommandBuilder Static Methods

| Method                           | Description                                                                                                                                                                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DeriveParameters</a> | Queries for the parameters of a stored procedure or function, represented by a specified <code>OracleCommand</code> , and populates the <code>OracleParameterCollection</code> of the command with the return values |
| <code>Equals</code>              | Inherited from <code>System.Object</code> (Overloaded)                                                                                                                                                               |

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

DeriveParameters

This method queries for the parameters of a stored procedure or function, represented by a specified `OracleCommand`, and populates the `OracleParameterCollection` of the command with the return values.

Declaration

```
// C#  
public static void DeriveParameters(OracleCommand command);
```

Parameters

- command*

The command that represents the stored procedure or function for which parameters are to be derived.

### Exceptions

`InvalidOperationException` - The `CommandText` is not a valid stored procedure or function name, the `CommandType` is not `CommandType.StoredProcedure`, or the `Connection.State` is not `ConnectionState.Open`.

### Remarks

When `DeriveParameters` is used to populate the `Parameter` collection of an `OracleCommand` Object that represents a stored function, the return value of the function is bound as the first parameter (at position 0 of the `OracleParameterCollection`).

`DeriveParameters` can only be used for stored procedures or functions, not for anonymous PL/SQL blocks.

`DeriveParameters` incurs a database round-trip to retrieve parameter metadata prior to executing the stored procedure/function. It should only be used during design time. To avoid unnecessary database round-trips in a production environment, the `DeriveParameters` method itself should be replaced with the explicit parameter settings that were returned by the `DeriveParameters` method at design time.

`DeriveParameters` can only preserve the case of the stored procedure or function name if it is encapsulated by double-quotes. For example, if the stored procedure in the database is named `GetEmployees` with mixed-case, the `CommandText` property on the `OracleCommand` object must be set appropriately as in the following example:

```
cmd.CommandText = "\"GetEmployees\"";
```

Stored procedures and functions in a package must be provided in the following format:

```
<package name>.<procedure or function name>
```

For example, to obtain parameters for a stored procedure named `GetEmployees` (mixed-case) in a package named `EmpProcedures` (mixed-case), the name provided to the `OracleCommand` is:

```
"\"EmpProcedures\".\"GetEmployees\""
```

`DeriveParameters` cannot be used for object type methods.

The derived parameters contain all the metadata information that is needed for the stored procedure to execute properly. The application must provide the value of the parameters before execution, if required. The application may also modify the metadata information of the parameters before execution. For example, the `Size` property of the `OracleParameter` may be modified for PL/SQL character and string types to optimize the execution of the stored procedure.

The output values of derived parameters return as .NET Types by default. To obtain output parameters as provider types, the `OracleDbType` property of the parameter must be set explicitly by the application to override this default behavior. One quick way to do this is to set the `OracleDbType` to itself for all output parameters that should be returned as provider types.

The `BindByName` property of the supplied `OracleCommand` is left as is, but the application can change its value.

If the specified stored procedure or function is overloaded, the first overload is used to populate the parameters collection.

```
// Database Setup
/*
connect scott/tiger@oracle
CREATE OR REPLACE PROCEDURE MyOracleStoredProc (arg_in IN VARCHAR2,
  arg_out OUT VARCHAR2) IS
BEGIN
  arg_out := arg_in;
END;
/
*/

// C#
using System;
using System.Data;
using Oracle.DataAccess.Client;

class DeriveParametersSample
{
  static void Main()
  {
    // Create the PL/SQL Stored Procedure MyOracleStoredProc as indicated in
    // the preceding Database Setup

    string constr = "User Id=scott;Password=tiger;Data Source=oracle";
    OracleConnection con = new OracleConnection(constr);
    con.Open();

    // Create an OracleCommand
    OracleCommand cmd = new OracleCommand("MyOracleStoredProc", con);
    cmd.CommandType = CommandType.StoredProcedure;

    // Derive Parameters
    OracleCommandBuilder.DeriveParameters(cmd);
    Console.WriteLine("Parameters Derived");

    // Prints "Number of Parameters for MyOracleStoredProc = 2"
    Console.WriteLine("Number of Parameters for MyOracleStoredProc = {0}",
      cmd.Parameters.Count);

    // The PL/SQL stored procedure MyOracleStoredProc has one IN and
    // one OUT parameter. Set the Value for the IN parameter.
    cmd.Parameters[0].Value = "MyText";

    // The application may modify the other OracleParameter properties also
    // This sample uses the default Size for the IN parameter and modifies
    // the Size for the OUT parameter

    // The default size for OUT VARCHAR2 is 4000
    // Prints "cmd.Parameters[1].Size = 4000"
    Console.WriteLine("cmd.Parameters[1].Size = " + cmd.Parameters[1].Size);

    // Set the Size for the OUT parameter
    cmd.Parameters[1].Size = 6;

    // Execute the command
    cmd.ExecuteNonQuery();

    // Prints "cmd.Parameters[1].Value = MyText"
    Console.WriteLine("cmd.Parameters[1].Value = " + cmd.Parameters[1].Value);

    con.Close();
    con.Dispose();
  }
}
```

```
}
}
```

| Site                             | Inherited from System.ComponentModel.Component                                                                                                           |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## CaseSensitive

This property indicates whether or not double quotes are used around Oracle object names (for example, tables or columns) when generating SQL statements.

### Declaration

```
// C#  
bool CaseSensitive {get; set;}
```

### Property Value

A bool that indicates whether or not double quotes are used.

### Remarks

Default = false

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## CatalogLocation

This property is not supported.

### Declaration

```
// C#  
public override CatalogLocation CatalogLocation {get; set;}
```

### Exceptions

NotSupportedException - This property is not supported.

### Remarks

This property is not supported.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## CatalogSeparator

This property is not supported.

**Declaration**

```
// C#  
public override string CatalogSeparator {get; set;}
```

**Exceptions**

NotSupportedException - This property is not supported.

**Remarks**

This property is not supported.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## ConflictOption

This property is not supported.

**Declaration**

```
// C#  
public override string ConflictOption {get; set;}
```

**Exceptions**

NotSupportedException - This property is not supported.

**Remarks**

This property is not supported.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## DataAdapter

This property indicates the `OracleDataAdapter` object for which the SQL statements are generated.

### Declaration

```
// C#  
OracleDataAdapter DataAdapter {get; set;}
```

### Property Value

An `OracleDataAdapter` object.

### Remarks

Default = null

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## QuotePrefix

This property specifies the beginning character or characters used to specify database objects whose names contain special characters such as spaces or reserved words.

### Declaration

```
// C#  
public override string QuotePrefix {get; set;}
```

### Property Value

The beginning character or characters to use. The default value is "\".

### Remarks

This property is independent of any `OracleConnection` or `OracleCommand` objects.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## QuoteSuffix

This property specifies the ending character or characters used to specify database objects whose names contain special characters such as spaces or reserved words.

### Declaration

```
// C#  
public override string QuoteSuffix {get; set;}
```

### Property Value

The ending character or characters to use. The default value is "\".

### Remarks

This property is independent of any `OracleConnection` or `OracleCommand` objects.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## SchemaSeparator

This property specifies the character to be used for the separator between the schema identifier and other identifiers.

### Declaration

```
// C#  
public override string SchemaSeparator {get; set; }
```

### Property Value

The character to be used as the schema separator.

### Exceptions

`NotSupportedException` - The input value is not a dot (.).

## Remarks

The default schema separator is a dot (.). The only acceptable value for this property is a dot (.).

This property is independent of any `OracleConnection` or `OracleCommand` objects.

## Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;

class SchemaSeperatorSample
{
    static void Main(string[] args)
    {
        try
        {
            OracleCommandBuilder cmdBuilder = new OracleCommandBuilder();

            //schemaSeparator is dot(.)
            Console.WriteLine("schemaSeparator is {0}",
                             cmdBuilder.SchemaSeparator);

            //set the schemaseparator, only '.' is allowed.
            cmdBuilder.SchemaSeparator = ".";

            // the only acceptable value for this property is a dot (.)
            // Hence the following line will throw NotSupportedException
            cmdBuilder.SchemaSeparator = "!";
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.Message);
            Console.WriteLine(ex.StackTrace);
        }
    }
}
```

## OracleCommandBuilder Public Methods

`OracleCommandBuilder` public methods are listed in [Table 6-24](#).

**Table 6-24 OracleCommandBuilder Public Methods**

| Public Method                     | Description                                                                                                                                    |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| CreateObjRef                      | Inherited from System.MarshalByRefObject                                                                                                       |
| Dispose                           | Inherited from System.ComponentModel.Component                                                                                                 |
| Equals                            | Inherited from System.Object (Overloaded)                                                                                                      |
| <a href="#">GetDeleteCommand</a>  | Gets the automatically generated OracleCommand object that has the SQL statement (CommandText) perform deletions on the database (Overloaded)  |
| GetHashCode                       | Inherited from System.Object                                                                                                                   |
| <a href="#">GetInsertCommand</a>  | Gets the automatically generated OracleCommand object that has the SQL statement (CommandText) perform insertions on the database (Overloaded) |
| GetLifetimeService                | Inherited from System.MarshalByRefObject                                                                                                       |
| GetType                           | Inherited from System.Object                                                                                                                   |
| <a href="#">GetUpdateCommand</a>  | Gets the automatically generated OracleCommand object that has the SQL statement (CommandText) perform updates on the database (Overloaded)    |
| InitializeLifetimeService         | Inherited from System.MarshalByRefObject                                                                                                       |
| <a href="#">QuoteIdentifier</a>   | Returns the correct quoted form of the provided unquoted identifier, with any embedded quotes in the identifier properly escaped               |
| <a href="#">RefreshSchema</a>     | Refreshes the database schema information used to generate INSERT, UPDATE, or DELETE statements                                                |
| <a href="#">UnquoteIdentifier</a> | Returns the correct unquoted form of the provided quoted identifier, removing any escape notation for quotes embedded in the identifier        |
| ToString                          | Inherited from System.Object                                                                                                                   |

## GetDeleteCommand

Gets the automatically generated OracleCommand object that has the SQL statement (CommandText) perform deletions on the database

**Overload List**

- [GetDeleteCommand\(\)](#)

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform deletions on the database when an application calls `Update()` on the `OracleDataAdapter`.

- [GetDeleteCommand\(bool\)](#)

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform deletions on the database when an application calls `Update()` on the `OracleDataAdapter`.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## GetDeleteCommand()

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform deletions on the database when an application calls `Update()` on the `OracleDataAdapter`.

### Declaration

```
// C#  
public OracleCommand GetDeleteCommand();
```

### Return Value

An `OracleCommand`.

### Exceptions

`ObjectDisposedException` - The `OracleCommandBuilder` object is already disposed.

`InvalidOperationException` - Either the `SelectCommand` or the `DataAdapter` property is null, or the primary key cannot be retrieved from the `SelectCommand` property of the `OracleDataAdapter`.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## GetDeleteCommand(bool)

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform deletions on the database when an application calls `Update()` on the `OracleDataAdapter`.

### Declaration

```
// C#  
public OracleCommand GetDeleteCommand(bool useColumnsForParameterNames);
```

### Parameters

- `useColumnsForParameterNames`

If true, the method generates parameter names matching column names if possible. If false, the method binds parameters by position.

### Return Value

An `OracleCommand`.

### Exceptions

`ObjectDisposedException` - The `OracleCommandBuilder` object is already disposed.

`InvalidOperationException` - Either the `SelectCommand` or the `DataAdapter` property is null, or the primary key cannot be retrieved from the `SelectCommand` property of the `OracleDataAdapter`.

### Remarks

If the `bool` is true, the method generates parameter names matching column names if possible. If false, the method binds parameters by position.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## GetInsertCommand

Gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform insertions on the database

### Overload List

- [GetInsertCommand\(\)](#)

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform insertions on the database when an application calls `Update()` on the `OracleDataAdapter`.

- [GetInsertCommand\(bool\)](#)

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform insertions on the database when an application calls `Update()` on the `OracleDataAdapter`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## GetInsertCommand()

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform insertions on the database when an application calls `Update()` on the `OracleDataAdapter`.

**Declaration**

```
// C#  
public OracleCommand GetInsertCommand();
```

**Return Value**

An `OracleCommand`.

**Exceptions**

`ObjectDisposedException` - The `OracleCommandBuilder` object is already disposed.

`InvalidOperationException` - Either the `SelectCommand` or the `DataAdapter` property is null, or the primary key cannot be retrieved from the `SelectCommand` property of the `OracleDataAdapter`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## GetInsertCommand(bool)

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform insertions on the database when an application calls `Update()` on the `OracleDataAdapter`.

**Declaration**

```
// C#  
public OracleCommand GetInsertCommand(bool useColumnsForParameterNames);
```

**Parameters**

- `useColumnsForParameterNames`

If true, the method generates parameter names matching column names if possible. If false, the method binds parameters by position.

### Return Value

An `OracleCommand`.

### Exceptions

`ObjectDisposedException` - The `OracleCommandBuilder` object is already disposed.

`InvalidOperationException` - Either the `SelectCommand` or the `DataAdapter` property is null, or the primary key cannot be retrieved from the `SelectCommand` property of the `OracleDataAdapter`.

### Remarks

If the `bool` is true, the method generates parameter names matching column names if possible. If false, the method binds parameters by position.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)

## GetUpdateCommand

Gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform updates on the database

### Overload List

- [GetUpdateCommand\(\)](#)  
This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform updates on the database when an application calls `Update()` on the `OracleDataAdapter`.
- [GetUpdateCommand\(bool\)](#)  
This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform updates on the database when an application calls `Update()` on the `OracleDataAdapter`.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## GetUpdateCommand()

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform updates on the database when an application calls `Update()` on the `OracleDataAdapter`.

### Declaration

```
// C#  
public OracleCommand GetUpdateCommand();
```

### Return Value

An `OracleCommand`.

### Exceptions

`ObjectDisposedException` - The `OracleCommandBuilder` object is already disposed.

`InvalidOperationException` - Either the `SelectCommand` or the `DataAdapter` property is null, or the primary key cannot be retrieved from the `SelectCommand` property of the `OracleDataAdapter`.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## GetUpdateCommand(bool)

This method gets the automatically generated `OracleCommand` object that has the SQL statement (`CommandText`) perform updates on the database when an application calls `Update()` on the `OracleDataAdapter`.

### Declaration

```
// C#  
public OracleCommand GetUpdateCommand(bool useColumnsForParameterNames);
```

### Parameters

- `useColumnsForParameterNames`

If true, the method generates parameter names matching column names if possible. If false, the method binds parameters by position.

### Return Value

An `OracleCommand`.

### Exceptions

`ObjectDisposedException` - The `OracleCommandBuilder` object is already disposed.

InvalidOperationException - Either the SelectCommand or the DataAdapter property is null, or the primary key cannot be retrieved from the SelectCommand property of the OracleDataAdapter.

### Remarks

If the bool is true, the method generates parameter names matching column names if possible. If false, the method binds parameters by position.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## QuoteIdentifier

This method returns the correct quoted form of the provided unquoted identifier, with any embedded quotes in the identifier properly escaped.

### Declaration

```
// C#  
public override string QuoteIdentifier(string unquotedIdentifier);
```

### Parameters

- *UnquotedIdentifier*  
An unquoted identifier string.

### Return Value

The quoted version of the identifier. Embedded quotes within the identifier are properly escaped.

### Exceptions

ArgumentNullException - The input parameter is null.

### Remarks

This method is independent of any OracleConnection or OracleCommand objects.

### Example

```
// C#  
  
using System;  
using System.Data;  
using System.Data.Common;  
using Oracle.DataAccess.Client;  
  
class QuoteIdentifierSample  
{  
    static void Main(string[] args)
```

```
{
    OracleCommandBuilder builder = new OracleCommandBuilder();
    string quoteIdentifier = builder.QuoteIdentifier("US\"ER");

    //quoteIdentifier for "US\"ER" is (\\"US\\"ER\\")
    Console.WriteLine("quoteIdentifier is {0}" , quoteIdentifier);
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## RefreshSchema

This method refreshes the database schema information used to generate INSERT, UPDATE, or DELETE statements.

#### Declaration

```
// C#
public override void RefreshSchema();
```

#### Remarks

An application should call RefreshSchema whenever the SelectCommand value of the OracleDataAdapter object changes.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommandBuilder Class](#)
- [OracleCommandBuilder Members](#)

## UnquoteIdentifier

This method returns the correct unquoted form of the provided quoted identifier, removing any escape notation for quotes embedded in the identifier.

#### Declaration

```
// C#
public override string UnquoteIdentifier(string quotedIdentifier);
```

#### Parameters

- *quotedIdentifier*  
The quoted string identifier.

### Return Value

The unquoted identifier, with escape notation for any embedded quotes removed.

### Exceptions

ArgumentNullException - The input parameter is null.

ArgumentException - The input parameter is empty.

### Remarks

This method is independent of any OracleConnection or OracleCommand objects.

### Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;

class UnQuoteIdentifierSample
{
    static void Main(string[] args)
    {
        //create an OracleCommandBuilder object.
        OracleCommandBuilder builder = new OracleCommandBuilder();

        string identifier = "US\"ER";
        Console.WriteLine("Identifier is {0}", identifier);

        // quote the identifier
        string quoteIdentifier = builder.QuoteIdentifier(identifier);

        //quoteIdentifier of "US\"ER" is (\\"US\\"ER\\")
        Console.WriteLine("QuotedIdentifier is {0}" , quoteIdentifier);
        string unquoteIdentifier = builder.UnquoteIdentifier(quoteIdentifier);

        //And its unquoteIdentifier is US\"ER
        Console.WriteLine("UnquotedIdentifier is {0}" , unquoteIdentifier);
    }
}
```

# OracleConfiguration Class

An OracleConfiguration is a static class for setting ODP.NET configuration data using a single programming interface.

Class Inheritance

System.Object  
  
Oracle.ManagedDataAccess.Client.OracleConfiguration

Declaration

```
// C#  
public sealed class OracleConfiguration
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Note

Unmanaged ODP.NET implements the OracleConfiguration debug tracing properties only.

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#

using System;
using Oracle.ManagedDataAccess.Client;

namespace ODP_Core_Config_API
{
    class odp_core_config
    {
        static void Main(string[] args)
        {
            // This sample demonstrates how to use ODP.NET Core Configuration API

            // Add connect descriptors and net service names entries.
            OracleConfiguration.OracleDataSources.Add("orclpdb",
                "(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<hostname or IP>)(PORT=1521))

## OracleConfiguration Members

OracleConfiguration members are listed in the following tables.

### OracleConfiguration Methods

OracleConfiguration methods are listed in [Table 6-26](#).

**Table 6-26 OracleConfiguration Methods**

| Method                                                   | Description                                                                                                                  |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DisableConnectionStringAllowedProperties</a> | Disables connection configuration restriction<br><i>Not available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">EnableConnectionStringAllowedProperties</a>  | Accepts an allowed connection configuration parameter list (Overloaded)<br><i>Not available in ODP.NET, Unmanaged Driver</i> |

**OracleConfiguration Connection Properties**

OracleConfiguration Connection properties are listed in [Table 6-27](#).

**Table 6-27 OracleConfiguration Connection Properties**

| Property                                     | Description                                                                                                                                                                    |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ConfigurationProviders</a>       | Enables one or more centralized configuration providers<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                   |
| <a href="#">DatabaseCharset</a>              | Sets the CHAR database character set at the process level and is used to optimize connection establishment<br><i>Not available in ODP.NET, Unmanaged Driver</i>                |
| <a href="#">DatabaseNCharset</a>             | Sets the NCHAR database character set at the process level and is used to optimize connection establishment<br><i>Not available in ODP.NET, Unmanaged Driver</i>               |
| <a href="#">DatabaseEditionName</a>          | Specifies the Oracle edition name for the connection object                                                                                                                    |
| <a href="#">DefaultSDUSize</a>               | Specifies the session data unit size (SDU) for Oracle networking communication between client and server                                                                       |
| <a href="#">DisableOOB</a>                   | Specifies whether to enable Oracle Net Services to send or receive out-of-band break messages using urgent data provided by the underlying protocol                            |
| <a href="#">DrpcConnectionClass</a>          | Specifies a logical name that identifies the DRCP connection pool that the ODP.NET connection will use                                                                         |
| <a href="#">HostnameDefaultServiceIsHost</a> | Specifies whether to default the service name to the hostname in Oracle Easy Connect Naming so that the service name does not need to be specified                             |
| <a href="#">NamesDirectoryPath</a>           | Specifies the naming method order used for client name resolution lookups                                                                                                      |
| <a href="#">OciCompartment</a>               | Gets or sets the Oracle Cloud Identifier (OCID) of the target database's compartment at the process level                                                                      |
| <a href="#">OciConfigurationFile</a>         | Gets or sets the configuration file location at the process level where the OCI token authentication values can be found.<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">OciDatabase</a>                  | Gets or sets the target database's Oracle Cloud Identifier (OCID) at the process level                                                                                         |
| <a href="#">OciIamUrl</a>                    | Gets or sets the URL end point at the process level for getting the database token                                                                                             |

**Table 6-27 (Cont.) OracleConfiguration Connection Properties**

| Property                                               | Description                                                                                                                                                                                                           |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OciProfile</a>                             | Gets or sets the OCI profile at the process level to use from the token authentication configuration file.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                       |
| <a href="#">OciTenacy</a>                              | Gets or sets the Oracle Cloud Identifier (OCID) of the IAM user's cloud tenancy at the process level for retrieving the database token                                                                                |
| <a href="#">OracleDataSources</a>                      | Returns a collection of TNS entries added through OracleConfiguration                                                                                                                                                 |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the InvalidCastException and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">TAUsePooledConnections</a>                 | Indicates whether to use pre-existing connections from the pool for failover<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                     |
| <a href="#">TcpConnectTimeout</a>                      | Specifies the time, in seconds, for a client to establish a TCP connection (PROTOCOL=tcp in the TNS connect address) to the database server before it can time out                                                    |
| <a href="#">TimeZoneFileLocation</a>                   | Specifies the time zone file directory                                                                                                                                                                                |
| <a href="#">TnsAdmin</a>                               | Specifies the tnsnames.ora and/or sqlnet.ora directory location                                                                                                                                                       |
| <a href="#">UseSNI</a>                                 | Specifies whether to use Server Name Indication (SNI)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                            |

**OracleConfiguration Secure Connection Properties**

OracleConfiguration Secure Connection Properties are listed in [Table 6-28](#).

**Table 6-28 OracleConfiguration Secure Connection Properties**

| Property                                        | Description                                                                                                                                                    |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AllowUncPaths</a>                   | Allows or disallows ODP.NET access to configuration files with Universal Naming Convention location paths<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">PasswordAuthentication</a>          | Sets the process level PASSWORD_AUTH parameter value                                                                                                           |
| <a href="#">SEPSWalletLocation</a>              | Specifies the Secure External Password Store wallet location, typically used for PKCS #12 wallet files                                                         |
| <a href="#">SEPSWalletPassword</a>              | Stores the password to decrypt the PKCS #12 wallet located in the Secure External Password Store                                                               |
| <a href="#">SqlNetAllowWeakCrypto</a>           | Allows or disallows weaker encryption and checksum algorithms for database connections                                                                         |
| <a href="#">SqlNetAllowedLogonVersionClient</a> | Specifies the minimum authentication protocol that is to be used when authenticating against the Oracle database for a given application                       |

**Table 6-28 (Cont.) OracleConfiguration Secure Connection Properties**

| Property                                        | Description                                                                                                                                                                    |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SqlNetAuthenticationServices</a>    | Enables one or more authentication services, such as TCP/IP with SSL                                                                                                           |
| <a href="#">SqlNetCloudUser</a>                 | Specifies an user name for web server HTTP basic authentication                                                                                                                |
| <a href="#">SqlNetCryptoChecksumClient</a>      | Specifies the checksum client behavior                                                                                                                                         |
| <a href="#">SqlNetCryptoChecksumTypesClient</a> | Specifies the crypto-checksum algorithms the client can use                                                                                                                    |
| <a href="#">SqlNetEncryptionClient</a>          | Specifies the encryption client behavior                                                                                                                                       |
| <a href="#">SqlNetEncryptionTypesClient</a>     | Specifies encryption algorithms that the client can use                                                                                                                        |
| <a href="#">SqlNetIgnoreANOEncrytionForTCPS</a> | Specifies whether to disable double encryption and double checksumming under certain conditions<br><i>Not available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">SqlNetWalletOverride</a>            | Specifies whether the client overrides the strong authentication credential with the stored wallet password credential for the database connection                             |
| <a href="#">SqlNetURI</a>                       | Specifies the WebSocket universal resource identifier                                                                                                                          |
| <a href="#">SSLCertificateThumbprint</a>        | Specifies the TLS/SSL certificate thumbprint in the certificate store for the ODP.NET connection to use                                                                        |
| <a href="#">SSLServerDNMatch</a>                | Enforces the database server distinguished name (DN) matches its service name                                                                                                  |
| <a href="#">SSLVersion</a>                      | Enforces the connection to use a specific SSL/TLS version                                                                                                                      |
| <a href="#">TLSExcludeVersion</a>               | Indicates which SSL/TLS versions connections should not be enabled for<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                    |
| <a href="#">TLSVersion</a>                      | Enforces the connection to use a specific SSL/TLS version<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                 |
| <a href="#">TokenAuthentication</a>             | Sets the value for TOKEN_AUTH parameter at the process level                                                                                                                   |
| <a href="#">TokenLocation</a>                   | Gets or sets the token location directory at the process level where the access token , or database token and private key files, are present for ODP.NET token authentication. |
| <a href="#">UseMITKerberos</a>                  | Specifies whether to use MIT Kerberos or Kerberos.NET<br><i>Only available in ODP.NET, Managed Driver</i>                                                                      |
| <a href="#">WalletLocation</a>                  | Specifies the location of wallets                                                                                                                                              |
| <a href="#">WalletPassword</a>                  | Stores the password to decrypt the PKCS #12 wallet<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                        |

**OracleConfiguration Command Properties**

OracleConfiguration Command properties are listed in [Table 6-29](#).

**Table 6-29 OracleConfiguration Command Properties**

| Property                                         | Description                                                                                                                                                                      |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddOracleTypesDeserialization</a>    | Adds ODP.NET-specific data types to the “allow” list to permit deserialization into DataSet or DataTable                                                                         |
| <a href="#">BindByName</a>                       | Specifies whether the binding method used for the parameter collection is by name or by position                                                                                 |
| <a href="#">CommandTimeout</a>                   | Specifies the number of seconds the command is allowed to execute before terminating the execution with an exception                                                             |
| <a href="#">GetDecimalRetainTrailingZeros</a>    | Specifies whether to retain trailing zeros from an Oracle NUMBER in a .NET Decimal                                                                                               |
| <a href="#">MapVectorColumnAsClob</a>            | Specifies whether to retrieve vector types as native vectors or CLOB/VARCHAR2 in .NET<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                       |
| <a href="#">ProviderTypeNLSSensitiveToString</a> | Specifies whether to honor the data type's NLS format when the ToString() method is called<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                  |
| <a href="#">UseClientInitiatedCQN</a>            | Specifies whether to use Client Initiated Continuous Query Notification (CICQN) or traditional Continuous Query Notification (CQN) that does not rely on a persistent connection |

**OracleConfiguration Directories Properties**

OracleConfiguration Directories properties are listed in [Table 6-30](#).

**Table 6-30 OracleConfiguration Directories Properties**

| Property                                        | Description                                                                                                                                                                        |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DefaultAdminContext</a>             | Specifies the default directory entry that contains a LDAP Oracle Context from which connect identifiers can be created, modified, or looked up                                    |
| <a href="#">DirectoryServers</a>                | Lists the host names and port numbers of the primary and alternate LDAP directory servers                                                                                          |
| <a href="#">DirectoryServerType</a>             | Specifies the directory server type used, such as Oracle Internet Directory or Microsoft Active Directory                                                                          |
| <a href="#">LdapAdmin</a>                       | Specifies the ldap.ora directory location                                                                                                                                          |
| <a href="#">NamesLdapAuthenticateBind</a>       | Specifies whether the LDAP naming adapter should attempt to authenticate using a specified wallet when it connects to the LDAP directory to resolve the name in the connect string |
| <a href="#">NamesLdapAuthenticateBindMethod</a> | Specifies the authentication method the client LDAP naming adapter should use while connecting to the LDAP directory to resolve connect string names                               |
| <a href="#">NamesLdapConnTimeout</a>            | Specifies the non-blocking connection timeout to the LDAP server                                                                                                                   |

**OracleConfiguration High Availability Properties**

OracleConfiguration High Availability properties are listed in [Table 6-31](#).

**Table 6-31 OracleConfiguration High Availability Properties**

| Property                                              | Description                                                                                                                                                                                                                         |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ChunkMigrationConnectionTimeout</a>       | This setting pauses the connection request until the migration completes or fails to migrate in the specified time, then connect to the correct shard with the data requested.<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">DbNotificationAddress</a>                 | Specifies the address that the provider listens to for all notifications sent by the database for continuous query notification feature.                                                                                            |
| <a href="#">DbNotificationPort</a>                    | Specifies the port number that the provider listens to for all notifications sent by the database for continuous query notification, Fast Connection Failover, and/or Runtime Connection Load Balancing features                    |
| <a href="#">DistributedTransactionRecoveryAddress</a> | Specifies the machine name or IP address the OraMTS recovery service runs on to resolve database in-doubt transactions                                                                                                              |
| <a href="#">DistributedTransactionRecoveryPort</a>    | Specifies the port the OraMTS recovery service listens on to resolve database in-doubt transactions                                                                                                                                 |
| <a href="#">DistributedTransactionTimeToLive</a>      | Specifies the time the transaction can remain inactive after it has been detached or delisted from the database                                                                                                                     |
| <a href="#">HAEvents</a>                              | Enables the application to receive Fast Connection Failover events for maintaining application high availability                                                                                                                    |
| <a href="#">MaxCallsPerRequestBoundary</a>            | Specifies the maximum request size, or ODP.NET calls, beyond which Application Continuity replay will be disabled                                                                                                                   |
| <a href="#">OnsConfigFile</a>                         | Specifies the configuration file to define Oracle Notification Service (ONS) behavior                                                                                                                                               |
| <a href="#">OnsMode</a>                               | Specifies the ONS daemon mode as either local or remote                                                                                                                                                                             |
| <a href="#">OnsProtocol</a>                           | Defines whether the ONS connection uses TCP/IP or TCP/IP with SSL/TLS                                                                                                                                                               |
| <a href="#">OnsWalletLocation</a>                     | Specifies the directory location of the ONS wallets                                                                                                                                                                                 |
| <a href="#">OracleOnsServers</a>                      | Returns a collection of logical ONS servers added through OracleConfiguration                                                                                                                                                       |
| <a href="#">ServiceRelocationConnectionTimeout</a>    | Specifies the time to wait before retrying connecting to a service that becomes unavailable.                                                                                                                                        |

**OracleConfiguration Performance Properties**

OracleConfiguration Performance properties are listed in [Table 6-32](#).

**Table 6-32 OracleConfiguration Performance Properties**

| Property                              | Description                                                                                                             |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <a href="#">FetchSize</a>             | Specifies the total memory size, in bytes, that the provider allocates to cache data fetched in one database round-trip |
| <a href="#">LoadBalancing</a>         | Enables the application to receive runtime connection load balancing information                                        |
| <a href="#">MaxStatementCacheSize</a> | Specifies the maximum number of statements that can be cached when self-tuning is enabled                               |

**Table 6-32 (Cont.) OracleConfiguration Performance Properties**

| Property                                | Description                                                                                                                 |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Pipelining</a>              | Enables asynchronous execution on the database server side                                                                  |
| <a href="#">PerformanceCounters</a>     | Specifies the ODP.NET connection performance counters to publish so that they can be monitored                              |
| <a href="#">ReceiveBufferSize</a>       | Specifies the buffer space limit for receive operations of sessions                                                         |
| <a href="#">RowsToFetchPerRoundTrip</a> | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">SelfTuning</a>              | Specifies whether self-tuning is enabled for an ODP.NET application                                                         |
| <a href="#">SendBufferSize</a>          | Specifies the buffer space limit for send operations of sessions                                                            |
| <a href="#">StatementCacheSize</a>      | Specifies the number of cursors or statements to be cached for each database connection                                     |
| <a href="#">TcpNoDelay</a>              | Preempts delays in buffer flushing within the TCP/IP protocol stack                                                         |

**OracleConfiguration Diagnostics and Tracing Properties**

OracleConfiguration Diagnostics and Tracing properties are listed in [Table 6-33](#).

**Table 6-33 OracleConfiguration Diagnostics and Tracing Properties**

| Property                             | Description                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ConnectionIdPrefix</a>   | Identifies a particular application's connections by appending its string to the connection identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>   |
| <a href="#">OpenTelemetryTracing</a> | Specifies whether to dynamically enable or disable ODP.NET OpenTelemetry tracing instrumentation or not.<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">PoolNames</a>            | Specifies a string to identify the monitored connection pool more easily                                                                                      |
| <a href="#">Program</a>              | Specifies the application program name<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                   |
| <a href="#">SuppressErrorURL</a>     | Shows or suppresses the Oracle Database Error Messages URL for the specific error with more information on its cause and resolution                           |
| <a href="#">TraceFileLocation</a>    | Specifies the destination directory to output provider traces                                                                                                 |
| <a href="#">TraceFileMaxSize</a>     | Specifies the maximum file size of each trace file                                                                                                            |
| <a href="#">TraceLevel</a>           | Specifies the generated trace level to trace ODP.NET calls and diagnose provider issues                                                                       |
| <a href="#">TraceOption</a>          | Specifies whether to generate a single trace file or multiple trace files for multithreaded applications                                                      |

## OracleConfiguration Methods

OracleConfiguration methods are listed in [Table 6-34](#).

**Table 6-34 OracleConfiguration Methods**

| Method                                                   | Description                                                                                                                  |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DisableConnectionStringAllowedProperties</a> | Disables connection configuration restriction<br><i>Not available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">EnableConnectionStringAllowedProperties</a>  | Accepts an allowed connection configuration parameter list (Overloaded)<br><i>Not available in ODP.NET, Unmanaged Driver</i> |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DisableConnectionStringAllowedProperties

This method disables connection configuration restriction.

**Declaration**

```
// C#  
public static void DisableConnectionStringAllowedProperties()
```

**Exceptions**

None.

**Remarks**

When invoked, any prior list of allowed parameters is discarded. Connections are no longer subject to configuration restrictions.

Connection configuration restriction can be enabled again by calling an `EnableConnectionStringAllowedProperties` method. Calling this method does not impact existing connection pools until `ClearPool()` or `ClearAllPools()` is called.

## EnableConnectionStringAllowedProperties

**Overload List:**

- [EnableConnectionStringAllowedProperties\(string, bool\)](#)  
This method accepts an allowed connection configuration parameter list in a JSON string format.
- [EnableConnectionStringAllowedProperties\(FileInfo, bool\)](#)  
This method accepts a file path to an allowed parameter list in a JSON file.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## EnableConnectionStringAllowedProperties(string, bool)

This method accepts an allowed connection configuration parameter list in a JSON string format.

**Declaration**

```
// C#
public static void EnableConnectionStringAllowedProperties(string allowList, bool
enforceOnAlias)
```

**Parameters**

- *allowList*  
Allowed parameters list in JSON string format
- *enforceOnAlias*  
Whether to enforce the allowed parameters list on TNS aliases

**Exceptions**

None.

## Remarks

ODP.NET will check the connection string Data Source if any disallowed parameters are included. If so, the request will not be allowed to connect.

Applications can invoke this `EnableConnectionStringAllowedProperties` method anytime during runtime with a new allowed list. The new settings will apply to new non-pooled connections and new connection pools created henceforth.

For existing connection pools, the new settings are applied after `ClearPool()` or `ClearAllPools()` is invoked.

### See Also

## EnableConnectionStringAllowedProperties(FileInfo, bool)

This method accepts a file path to an allowed parameter list in a JSON file.

### Declaration

```
// C#
public static void EnableConnectionStringAllowedProperties(FileInfo jsonFile, bool
enforceOnAlias)
```

### Parameters

- *jsonFile*  
Specifies the JSON allowed parameters file path.
- *enforceOnAlias*  
Whether to enforce the allowed parameters list on TNS aliases

### Exceptions

**OracleException** – If Universal Naming Convention (UNC) file paths are not allowed and the file path is configured with a UNC file path.

**OracleException** – An **OracleException** (ORA-50124: Configuration file is required to be named as {0}) is thrown if the file path contains a file name other than `ODPConnectionStringAllowedProperties.json`.

**InvalidOperationException** – If this method is invoked with a different JSON file path than used earlier after at least one connection has been opened.

**Remarks**

The JSON file parameter of type FileInfo can be set to the directory that contains the ODPConnectionStringAllowedProperties.json file or to the full file path with that JSON file. If a file name is supplied, it must be ODPConnectionStringAllowedProperties.json.

ODP.NET will check the connection string Data Source if any disallowed parameters are included. If so, the request will not be allowed to connect.

If the application calls the EnableConnectionStringAllowedProperties method before the first connection is created, then ODP.NET tries to open and read the ODPConnectionStringAllowedProperties.json file. Failure to open or read the file throws an exception.

The application cannot invoke the EnableConnectionStringAllowedProperties method, which takes a different JSON file location after a valid connection has been opened. However, the application may invoke the method again with the same file path and a different enforceOnAlias value. The Boolean parameter will be applied as configured.

The application can update the JSON file contents during runtime. ODP.NET proactively tries to read the file once it is saved.

## OracleConfiguration Connection Properties

OracleConfiguration Connection properties are listed in [Table 6-35](#).

**Table 6-35 OracleConfiguration Connection Properties**

| Property                               | Description                                                                                                                                                      |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ConfigurationProviders</a> | Enables one or more centralized configuration providers<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                     |
| <a href="#">DatabaseCharset</a>        | Sets the CHAR database character set at the process level and is used to optimize connection establishment<br><i>Not available in ODP.NET, Unmanaged Driver</i>  |
| <a href="#">DatabaseNCharset</a>       | Sets the NCHAR database character set at the process level and is used to optimize connection establishment<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">DatabaseEditionName</a>    | Specifies the Oracle edition name for the connection object                                                                                                      |
| <a href="#">DisableOOB</a>             | Specifies whether to enable Oracle Net Services to send or receive out-of-band break messages using urgent data provided by the underlying protocol              |

Table 6-35 (Cont.) OracleConfiguration Connection Properties

| Property                                               | Description                                                                                                                                                                                                           |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DrpcConnectionClass</a>                    | Specifies a logical name that identifies the DRCP connection pool that the ODP.NET connection will use                                                                                                                |
| <a href="#">HostnameDefaultServiceIsHost</a>           | Specifies whether to default the service name to the hostname in Oracle Easy Connect Naming so that the service name does not need to be specified                                                                    |
| <a href="#">NamesDirectoryPath</a>                     | Specifies the naming method order used for client name resolution lookups                                                                                                                                             |
| <a href="#">OciCompartment</a>                         | Gets or sets the Oracle Cloud Identifier (OCID) of the target database's compartment at the process level                                                                                                             |
| <a href="#">OciConfigurationFile</a>                   | Gets or sets the configuration file location at the process level where the OCI token authentication values can be found.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                        |
| <a href="#">OciDatabase</a>                            | Gets or sets the target database's Oracle Cloud Identifier (OCID) at the process level                                                                                                                                |
| <a href="#">OciIamUrl</a>                              | Gets or sets the URL end point at the process level for getting the database token                                                                                                                                    |
| <a href="#">OciProfile</a>                             | Gets or sets the OCI profile at the process level to use from the token authentication configuration file.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                       |
| <a href="#">OciTenancy</a>                             | Gets or sets the Oracle Cloud Identifier (OCID) of the IAM user's cloud tenancy at the process level for retrieving the database token                                                                                |
| <a href="#">OracleDataSources</a>                      | Returns a collection of TNS entries added through OracleConfiguration                                                                                                                                                 |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the InvalidCastException and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">TAFUsePooledConnections</a>                | Indicates whether to use pre-existing connections from the pool for failover<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                     |
| <a href="#">TcpConnectTimeout</a>                      | Specifies the time, in seconds, for a client to establish a TCP connection (PROTOCOL=tcp in the TNS connect address) to the database server before it can time out                                                    |
| <a href="#">TimeZoneFileLocation</a>                   | Specifies the time zone file directory                                                                                                                                                                                |
| <a href="#">TnsAdmin</a>                               | Specifies the tnsnames.ora and/or sqlnet.ora directory location                                                                                                                                                       |
| <a href="#">UseSNI</a>                                 | Specifies whether to use Server Name Indication (SNI)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                            |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- [OracleConfiguration Members](#)

## ConfigurationProviders

This property enables one or more centralized configuration providers.

**Declaration**

```
// C#  
public static string ConfigurationProviders { get; set; }
```

**Property Type**

System.String

**Exception**

- **ArgumentException:** Thrown when ConfigurationProviders contains an invalid configuration provider, or None is used with another provider, or the string is otherwise not properly formatted.
- **ArgumentNullExcpetion:** Thrown when ConfigurationProviders is set to null

**Remarks**

This property allows applications to enforce restrictions on which providers can be used.

**Table 6-36 ConfigurationProviders Values**

| Value      | Description                                                      |
|------------|------------------------------------------------------------------|
| All        | Enables all configuration providers. This is the default value.  |
| None       | Disables all configuration providers                             |
| Azure      | Enables Azure App configuration provider                         |
| AzureVault | Enables Azure Vault Configuration provider                       |
| OCIObject  | Enables Oracle Cloud Infrastructure (OCI) Configuration provider |
| OCIVault   | Enables OCI Vault Configuration provider                         |
| File       | Enable local file provider                                       |

The values are case-insensitive.

These values must be set prior to opening a connection with a centralized configuration provider. They cannot be modified after a connection is opened. The values are not verified until a URL is used upon the connection open.

Any combination of configuration providers can be enabled.

```
OracleConfiguration.ConfigurationProviders = "File, OCIObject";
```

Optionally, the list of providers can be enclosed in parentheses. For example, the following code sample enables Azure App configuration provider and OCI Configuration provider.

```
OracleConfiguration.ConfigurationProviders = "(Azure, OCIObject)";
```

Duplicate values are ignored, such as (Azure, OCIObject, Azure), and do not create an exception.

Using None in a list with other providers throws an exception, such as (All, None) or (None, OCIVault).

Setting the value to empty parentheses ( ) will be the same as using None. However, using an empty string is invalid, and will result in an error when the value is verified.

Using All in a list with other providers enables all providers, such as (File, Azure, All).

For JSON-based providers, the providers used within the JSON config must also be enabled. For example, if the file provider uses an OCI Vault URL to store the password, both File and OCIVault must be enabled.

This setting can also be used in sqlnet.ora or .NET configuration file. The precedence order, from highest to lowest, is:

1. OracleConfiguration.ConfigurationParameters
2. .NET Config
3. sqlnet.ora

Alternatively, instead of using a string value, use the OracleConfigurationProvider enumeration and bitwise the enums to enable multiple providers. Only OracleConfiguration.ConfigurationProviders property allows this. Sqlnet.ora CONFIGURATION\_PROVIDERS and .NET configuration file ConfigurationProviders do not support using this enumeration. They only support string values. Here is a code sample using ConfigurationProviders to enable the Azure App Configuration, OCI Object, and Azure Vault providers.

```
OracleConfiguration.ConfigurationProviders = OracleConfigurationProvider.Azure |  
OracleConfigurationProvider.OCIObject | OracleConfigurationProvider.AzureVault;
```

## DatabaseCharset

This property sets the CHAR database character set at the process level and is used to optimize connection establishment.

**Declaration**

```
// C#  
public static OracleDatabaseCharset DatabaseCharset {set;}
```

**Remarks**

The default value is `OracleDatabaseCharset.AL32UTF8`.

When the application provides the actual CHAR database character set to connect with, the connection can be established in an optimized way with fewer roundtrips. If the property contains a non-matching character set value, connection establishment follows a traditional, less optimized process.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)
- [OracleDatabaseCharset Enumeration](#)

## DatabaseNCharset

This property sets the NCHAR database character set at the process level and is used to optimize connection establishment.

**Declaration**

```
// C#  
public static OracleDatabaseNCharset DatabaseNCharset {set;}
```

**Remarks**

The default value is `OracleDatabaseNCharset.AL16UTF16`.

When the application provides the actual NCHAR database character set to connect with, the connection can be established in an optimized way with fewer roundtrips. If the property contains a non-matching character set value, connection establishment follows a traditional, less optimized process.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)
- [OracleDatabaseNCharset Enumeration](#)

## DatabaseEditionName

This property specifies the Oracle edition name for the connection object. This property is used with the Oracle Edition-Based Redefinition feature.

### Declaration

```
// C#  
public static string DatabaseEditionName { get; set; }
```

### Property Type

System.String

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DisableOOB

This property specifies whether to enable Oracle Net Services to send or receive out-of-band break messages using urgent data provided by the underlying protocol. Default is false.

### Declaration

```
// C#  
public static bool DisableOOB { get; set; }
```

### Property Type

System.Boolean

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DrcpConnectionClass

This property specifies a logical name that identifies the DRCP connection pool that the ODP.NET connection will use. It will be used as a default if the DrcpConnectionClass property on the OracleConnection object is not set. It will be ignored for non-DRCP connections. Default value is null.

**Declaration**

```
// C#  
public static string DrcpConnectionClass { get; set; }
```

**Property Type**

System.String

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## HostnameDefaultServiceIsHost

This property specifies whether to default the service name to the hostname in Oracle Easy Connect Naming so that the service name does not need to be specified.

**Declaration**

```
// C#  
public static bool HostnameDefaultServiceIsHost { get; set; }
```

**Property Type**

System.Boolean

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## MapVectorColumnAsClob

This property specifies whether to retrieve vector types as native vectors or CLOB/VARCHAR2 in .NET.

**Declaration**

```
// C#  
public static bool MapVectorColumnAsClob { get; set; }
```

**Property Type**

System.Boolean

### Remarks

When false (default), then native vector type for vector data is retrieved from the database. When true, then CLOB or VARCHAR2 for vector data is retrieved from the database.

The property allows easier migration from earlier ODP.NET versions that did not support a native vector data type to be upgraded with a simple code change and continue the existing behavior of using a CLOB or VARCHAR2 data type.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## NamesDirectoryPath

This property specifies the naming method order used for client name resolution lookups.

### Declaration

```
// C#  
public static string NamesDirectoryPath { get; set; }
```

### Property Type

System.String

### Example

```
C#  
OracleConfiguration.NamesDirectoryPath = "(tnsnames, ldap)";
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OciCompartment

This property gets or sets the Oracle Cloud Identifier (OCID) of the target database's compartment at the process level.

### Declaration

```
// C#  
public static string OciCompartment { get; set; }
```

**Property Type**

System.String

**Remarks**

This property is optional by default. This property is mandatory if the `OciDatabase` property is set.

If `OciCompartment` is not set, then ODP.NET requests access to all the cloud tenancy's databases identified in the `OciTenancy` property.

There is no default value for this property.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OciConfigurationFile

This property gets or sets the configuration file location at the process level where the OCI token authentication values can be found.

**Declaration**

```
// C#  
public static string OciConfigurationFile { get; set; }
```

**Property Type**

System.String

**Remarks**

This parameter is applicable to the OCI API key and OCI interactive authentication flows only and is optional.

The file names do not need to be specified since ODP.NET uses the standard file names.

If this parameter is not set, then ODP.NET uses the OCI config file in the default location: `C:/<user-profile>/.oci/config`. If the parameter is not set and the default configuration file is not found, then the user is prompted on the console to provide a region id for the OCI interactive authentication flow. A list of possible region ids will be displayed to the user. In the case of the OCI API key flow, the user will see an error.

On Windows, the Oracle `HOME` and `USERPROFILE` environment variables are used for the default directory location if they are set. Otherwise, Oracle `HOME` and `HOMEDRIVE` environment variables are used.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OciDatabase

This property gets or sets the target database's Oracle Cloud Identifier (OCID) at the process level.

**Declaration**

```
// C#  
public static string OciCompartment { get; set; }
```

**Property Type**

System.String

**Remarks**

This property is optional.

If it is not set, then ODP.NET requests access to all the cloud compartment's databases identified in the `OciCompartment` property. If `OciCompartment` property is also not set, then ODP.NET requests access to all the tenancy's databases specified in the `OciTenancy` property.

There is no default value for this property.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OciIamUrl

This property gets or sets the URL end point at the process level for getting the database token.

**Declaration**

```
// C#  
public static string OciIamUrl { get; set; }
```

**Property Type**

System.String

**Remarks**

This is a mandatory property for IAM alternate password use. If not set in that usage scenario, ODP.NET raises an error.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OciProfile

This property gets or sets the OCI profile at the process level to use from the token authentication configuration file.

**Declaration**

```
// C#  
public static string OciProfile { get; set; }
```

**Property Type**

System.String

**Remarks**

This parameter is applicable to the OCI API key and OCI interactive authentication flows only and is optional.

ODP.NET uses the DEFAULT profile if no profile value is set.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OciTenacy

This property gets or sets the Oracle Cloud Identifier (OCID) of the IAM user's cloud tenancy at the process level for retrieving the database token.

**Declaration**

```
// C#  
public static string OciTenacy { get; set; }
```

**Property Type**

System.String

**Remarks**

This is a mandatory property for IAM alternate password use. If not set in that usage scenario, ODP.NET raises an error.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)

## OracleDataSources

This property returns a collection of TNS entries added through OracleConfiguration.

**Declaration**

```
// C#  
public static OracleDataSourceCollection OracleDataSources
```

**Property**

Type:Oracle.ManagedDataAccess.Client.OracleDataSourceCollection

Returns a static OracleDataSourceCollection object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)
- [OracleDataSourceCollection Class](#)

## SuppressGetDecimalInvalidCastException

This property specifies whether to suppress the InvalidCastException and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal.

**Declaration**

```
// C#  
public static bool SuppressGetDecimalInvalidCastException {get; set;}
```

**Property Type**

System.Boolean

**Remarks**

Oracle NUMBER has a maximum of 38 precision. .NET Decimal has a maximum of 28 or 29 precision. When the `OracleDataReader.GetDecimal()`, `GetValue()`, or `OracleDataAdapter.Fill()` method is called for an Oracle NUMBER value that cannot be represented as a .NET Decimal, then ODP.NET throws an `InvalidCastException` because not all the precision can be preserved when converting the number to a .NET Decimal.

This behavior occurs when `SuppressGetDecimalInvalidCastException` is set to false, which is the default value.

When `SuppressGetDecimalInvalidCastException` is set to true, the resulting .NET Decimal is rounded off to 28 or 29 precision, allowing as much of the value to be represented without throwing an exception. If the resulting rounded number is larger than can be stored in a .NET Decimal, then an exception will be thrown, such as the number  $1 \times 10^{32}$ .

By using `OracleConfiguration.SuppressGetDecimalInvalidCastException`, this ODP.NET setting becomes enabled globally for the app. It can be overridden at the `OracleConnection`, `OracleDataReader`, or `OracleDataAdapter` level, which each has its own `SuppressGetDecimalInvalidCastException` property.

## TAFUsePooledConnections

This property indicates whether to use pre-existing connections from the pool for failover.

**Declaration**

```
// C#  
public static bool TAFUsePooledConnections
```

**Remarks**

By default, the property is set to true. An application can set this property to false to ensure ODP.NET always creates a new connection is created for failover.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TcpConnectTimeout

This property specifies the time, in seconds, for a client to establish a TCP connection (PROTOCOL=tcp in the TNS connect address) to the database server before it can time out. Default value is 20 seconds.

**Declaration**

```
// C#  
public static string TcpConnectTimeout { get; set; }
```

**Property Type**

System.String

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TimeZoneFileLocation

This property specifies the time zone file directory.

**Declaration**

```
// C#  
public string TimeZoneFileLocation {get; set;}
```

**Property Type**

System.String

**Remarks**

Countries and regions can alter when they observe daylight saving time or other changes for their time zones. Oracle publishes new time zone files to keep databases updated. Administrators then deploy these files to the database and clients to keep them in sync. Mismatched time zone settings between server and client can cause errors, such as ORA-01882: timezone region not found.

ODP.NET has built-in time zone settings that are up to date when it was published. To incorporate new settings, an administrator deploys the time zone file to a directory location and

sets `TimeZoneFileLocation` to that location before the ODP.NET app opens its first connection.

This property only accepts a directory location, not a file name.

ODP.NET will use the highest time zone file version among those in the directory and the ODP.NET embedded time zone file.

The backslash (\) is a special character in .NET that represents the beginning of an escape sequence. To specify a directory location, use any one of the following formats in .NET to correctly represent backslashes in a directory location:

```
// C#
OracleConfiguration.TimeZoneFileLocation= "D:\\oracle\\client\\timezoneloc";
OracleConfiguration.TimeZoneFileLocation= @"D:\oracle\client\timezoneloc";
OracleConfiguration.TimeZoneFileLocation= "D:/oracle/client/timezoneloc";
```

### Exceptions

`ArgumentException` - if a file is specified along with a directory.

`ArgumentException` - if an incorrect or empty directory is specified.

## TnsAdmin

This property specifies the `tnsnames.ora` and/or `sqlnet.ora` directory location.

### Declaration

```
// C#
public static string TnsAdmin { get; set; }
```

### Property Type

`System.String`

The backslash (\) is a special character in .NET that represents the beginning of an escape sequence. To specify a directory location, use any one of the following formats in .NET so that backslashes are correctly represented in a directory location:

```
// C#
OracleConfiguration.TnsAdmin = "D:\\oracle\\client\\admin";
OracleConfiguration.TnsAdmin = @"D:\oracle\client\admin";
OracleConfiguration.TnsAdmin = "D:/oracle/client/admin";
```

**① See Also**

## UseSNI

This property specifies whether to use Server Name Indication (SNI).

**Declaration**

```
// C#  
bool UseSNI { get; set;}
```

**Property Type**

System.Boolean

**Remarks**

Default is false. False disables using SNI.

When UseSNI is set to true, the following configuration rules must be obeyed. Any deviation will disable SNI automatically.

- Only the following CONNECT\_DATA names can be used.
  - ServiceName
  - Server
  - InstanceName
  - ColocationTag
- The CONNECT\_DATA name values can only contain alphanumeric, underscore, hyphen, or period characters.
- No more than two consecutive period characters
- No hyphen character before or after a period
- No hyphen at the beginning or end of the CONNECT\_DATA name values above
- No period at the beginning or end of the CONNECT\_DATA name values above

## OracleConfiguration Secure Connection Properties

OracleConfigurationSecure Connection properties are listed in [Table 6-37](#).

**Table 6-37 OracleConfiguration Secure Connection Properties**

| Property                                         | Description                                                                                                                                                    |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AllowUncPaths</a>                    | Allows or disallows ODP.NET access to configuration files with Universal Naming Convention location paths<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">OciCompartment</a>                   | Gets or sets the Oracle Cloud Identifier (OCID) of the target database's compartment at the process level                                                      |
| <a href="#">OciDatabase</a>                      | Gets or sets the target database's Oracle Cloud Identifier (OCID) at the process level                                                                         |
| <a href="#">OciIamUrl</a>                        | Gets or sets the URL end point at the process level for getting the database token                                                                             |
| <a href="#">OciTenacy</a>                        | Gets or sets the Oracle Cloud Identifier (OCID) of the IAM user's cloud tenancy at the process level for retrieving the database token                         |
| <a href="#">PasswordAuthentication</a>           | Sets the process level PASSWORD_AUTH parameter value                                                                                                           |
| <a href="#">SEPSWalletLocation</a>               | Specifies the Secure External Password Store wallet location, typically used for PKCS #12 wallet files                                                         |
| <a href="#">SEPSWalletPassword</a>               | Stores the password to decrypt the PKCS #12 wallet located in the Secure External Password Store                                                               |
| <a href="#">SqlNetAllowWeakCrypto</a>            | Allows or disallows weaker encryption and checksum algorithms for database connections                                                                         |
| <a href="#">SqlNetAllowedLogonVersionClient</a>  | Specifies the minimum authentication protocol that is to be used when authenticating against the Oracle database for a given application                       |
| <a href="#">SqlNetAuthenticationServices</a>     | Enables one or more authentication services, such as TCP/IP with SSL                                                                                           |
| <a href="#">SqlNetCloudUser</a>                  | Specifies an user name for web server HTTP basic authentication                                                                                                |
| <a href="#">SqlNetCryptoChecksumClient</a>       | Specifies the checksum client behavior                                                                                                                         |
| <a href="#">SqlNetCryptoChecksumTypesClient</a>  | Specifies the crypto-checksum algorithms the client can use                                                                                                    |
| <a href="#">SqlNetEncryptionClient</a>           | Specifies the encryption client behavior                                                                                                                       |
| <a href="#">SqlNetEncryptionTypesClient</a>      | Specifies encryption algorithms that the client can use                                                                                                        |
| <a href="#">SqlNetIgnoreANOEncryptionForTCPS</a> | Specifies whether to disable double encryption and double checksumming under certain conditions<br><i>Not available in ODP.NET, Unmanaged Driver</i>           |
| <a href="#">SqlNetWalletOverride</a>             | Specifies whether the client overrides the strong authentication credential with the stored wallet password credential for the database connection             |
| <a href="#">SqlNetURI</a>                        | Specifies the WebSocket universal resource identifier                                                                                                          |
| <a href="#">SSLCertificateThumbprint</a>         | Specifies the TLS/SSL certificate thumbprint in the certificate store for the ODP.NET connection to use                                                        |
| <a href="#">SSLServerDNMatch</a>                 | Enforces the database server distinguished name (DN) matches its service name                                                                                  |

**Table 6-37 (Cont.) OracleConfiguration Secure Connection Properties**

| Property                            | Description                                                                                                                                                                    |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SSLVersion</a>          | Enforces the connection to use a specific SSL/TLS version<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                 |
| <a href="#">TLSExcludeVersion</a>   | Indicates which SSL/TLS versions connections should not be enabled for<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                    |
| <a href="#">TLSVersion</a>          | Enforces the connection to use a specific SSL/TLS version<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                 |
| <a href="#">TokenAuthentication</a> | Sets the value for TOKEN_AUTH parameter at the process level                                                                                                                   |
| <a href="#">TokenLocation</a>       | Gets or sets the token location directory at the process level where the access token , or database token and private key files, are present for ODP.NET token authentication. |
| <a href="#">UseMITKerberos</a>      | Specifies whether to use MIT Kerberos or Kerberos.NET<br><i>Only available in ODP.NET, Managed Driver</i>                                                                      |
| <a href="#">WalletLocation</a>      | Specifies the location of wallets                                                                                                                                              |
| <a href="#">WalletPassword</a>      | Stores the password to decrypt the PKCS #12 wallet<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                        |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## AllowUncPaths

This property allows or disallows ODP.NET access to configuration files with Universal Naming Convention location paths.

**Declaration**

```
// C#
public static bool AllowUncPaths { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

For ODP.NET to access configuration files, such as sqlnet.ora, on local network machines, users can specify Universal Naming Convention (UNC) paths.

The AllowUncPaths property enables or disables ODP.NET's ability to use these UNC paths.

The property default is true. When true, ODP.NET is allowed to access configuration files specified with UNC path locations.

When false, ODP.NET throws an ORA-50121 error when it tries to access any configuration file that uses an UNC path.

Server Message Block coercion attacks use UNC paths to have a target machine authenticate an attacker's computer. If successful, then the attacker copies that authentication to gain access to another system. Disabling UNC paths prevents this attack from being used.

An UNC patch consists of a double backslash, followed by a server name, host name, or IP address. Next is another backslash, followed by the share name. After that is a directory separator character with the directory name. This continues for additional subdirectories. An optional file name can be included at the end. Here's an example: `\MyHostName\MyShare\MyDirectory\MyFile.txt`

## PasswordAuthentication

This property sets the process level PASSWORD\_AUTH parameter value. The possible values are `OciToken` and `PasswordVerifier`. The default value is `PasswordVerifier`, which indicates the typical database username and password can be used for authentication.

### Declaration

```
// C#  
public static OraclePasswordAuth PasswordAuthentication { get; set; }
```

### Property Type

An `OraclePasswordAuth` enumeration

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)

## SEPSWalletLocation

This property specifies the Secure External Password Store wallet location, typically used for PKCS #12 wallet files.

**Declaration**

```
// C#  
public static string OracleConfiguration.SEPSWalletLocation { get; set; }
```

**Property Type**

System.String

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SEPSWalletPassword

This property stores the password to decrypt the PKCS #12 wallet located in the Secure External Password Store.

**Declaration**

```
// C#  
public static OracleOpaqueString SEPSWalletPassword { get; set; }
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetAllowedLogonVersionClient

This property specifies the minimum authentication protocol that is to be used when authenticating against the Oracle database for a given application.

**Declaration**

```
// C#  
public OracleAllowedLogonVersionClient SqlNetAllowedLogonVersionClient { set; }
```

**Property Type**

OracleAllowedLogonVersionClient

**Values**

An OracleAllowedLogonVersionClient enumeration value.

### Example

```
// C#
OracleConfiguration.SqlNetAllowedLogonVersionClient =
OracleAllowedLogonVersionClient.Version12a;
```

### Remarks

The default is `OracleAllowedLongVersionClient.12`.

#### See Also

- *Oracle Database Net Services Reference* to better understand the minimum authentication protocol that is to be used when authenticating against the Oracle database for a given application.
- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)
- [OracleAllowedLogonVersionClient Enumeration](#)

## SqlNetAllowWeakCrypto

This property allows or disallows weaker encryption and checksum algorithms for database connections.

### Declaration

```
// C#
public static bool SqlNetAllowWeakCrypto { get; set; }
```

### Property Type

System.Boolean

### Remarks

When this parameter is true, ODP.NET can use weaker encryption and checksum algorithms to connect to Oracle database. When false, only stronger algorithms will be allowed to used for connections.

Default is true.

Encryption algorithms that ODP.NET supports and are considered weak:

- 3DES 112-bit
- 3DES 168-bit

No supported ODP.NET checksum algorithms are considered weak.

All other supported encryption and checksum algorithms are considered strong.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetAuthenticationServices

This property enables one or more authentication services, such as TCP/IP with SSL.

**Declaration**

```
// C#  
public static string SqlNetAuthenticationServices { get; set; }
```

**Property Type**

System.String

Default value is NONE.

Valid Values: All, Kerberos5, NTS, TCPS, or NONE.

**Note**

ODP.NET Core does not currently support the Kerberos5 value.

**Example**

```
//C#  
con.SqlNetAuthenticationServices = "(nts, tcps)";
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetCloudUser

This property specifies an user name for web server HTTP basic authentication.

**Declaration**

```
// C#  
public static string SqlNetCloudUser { get; set; }
```

**Property Type**

System.String

Default: none

**Remarks**

When you use a secure websocket protocol, the client uses this user as the user name for authentication. The password for this user should be stored in a wallet using mkstore utility commands.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetCryptoChecksumClient

This property specifies the checksum client behavior.

**Declaration**

```
// C#  
public static string SqlNetCryptoChecksumClient { get; set; }
```

**Property Type**

System.String

Default value is accepted.

Valid Values:

- accepted - to enable the security service if required or requested by the database.
- rejected - to disable the security service, even if required by the database.
- requested - to enable the security service if the database allows it.
- required - to enable the security service and disallow the connection if the database is not enabled for the security service.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetCryptoChecksumTypesClient

This property specifies the crypto-checksum algorithms the client can use.

### Declaration

```
// C#  
public static string SqlNetCryptoChecksumTypesClient { get; set; }
```

### Property Type

System.String

Valid Values:

- SHA1
- SHA256
- SHA384
- SHA512

### Example

```
C#  
OracleConfiguration.SqlNetCryptoChecksumTypesClient = "(SHA1, SHA256, SHA512)";
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetEncryptionClient

This property specifies the encryption client behavior.

### Declaration

```
// C#  
public static string SqlNetEncryptionClient { get; set; }
```

### Property Type

System.String

Default value is accepted.

Valid Values:

- accepted - to enable the security service if required or requested by the database.
- rejected - to disable the security service, even if required by the database.
- requested - to enable the security service if the database allows it.

- required - to enable the security service and disallow the connection if the database is not enabled for the security service.

#### 📘 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetEncryptionTypesClient

This property specifies encryption algorithms that the client can use.

### Declaration

```
// C#  
public static string SqlNetEncryptionTypesClient { get; set; }
```

### Property Type

System.String

Valid Values:

- AES128
- AES192
- AES256
- 3DES112
- 3DES168

### Example

```
C#  
OracleConfiguration.SqlNetEncryptionTypesClient = "(aes128, aes192)";
```

#### 📘 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## SqlNetIgnoreANOEncryptionForTCPS

This property specifies whether to disable double encryption and double checksumming under certain conditions.

**Declaration**

```
// C#  
public static bool SqlNetIgnoreANOEncryptionForTCPS { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

When true and the connection uses TCPS (TLS), this property attempts to downgrade the Oracle Native Network Encryption (Advanced Networking Option) and checksumming from REQUIRED and REQUESTED to ACCEPTED. This setting indicates the intent to avoid double encryption and/or double data integrity when it's not desired. In those situations, ODP.NET will try to use TCPS only.

This property's default value is false. When false, ODP.NET will permit double encryption and double data integrity if they are enabled.

The parameter is ignored in either of these two scenarios:

- Transport is not TCPS
- NNE (ANO) encryption and/or checksumming level is not set to REQUIRED or REQUESTED

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetWalletOverride

This property specifies whether the client overrides the strong authentication credential with the stored wallet password credential for the database connection.

**Declaration**

```
// C#  
public static bool SqlNetWalletOverride { get; set; }
```

**Property Type**

System.Boolean

**Description**

Default is false. By setting this value to true, ODP.NET uses the stored wallet password credential to connect.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SqlNetURI

This property specifies the WebSocket universal resource identifier.

**Declaration**

```
// C#  
public static string SqlNetURI { get; set; }
```

**Property Type**

System.String

This property is Request-URI of the HTTP GET method. It identifies the endpoint of the WebSocket connection, both to allow multiple domains to be served from one IP address and to allow multiple WebSocket endpoints to be served by a single server.

When setting the URI in unmanaged ODP.NET, it cannot begin with a forward slash character. For managed ODP.NET and ODP.NET Core, the forward slash at the beginning of the URI is optional.

Default value is sqlnet.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SSLCertificateThumbprint

This property specifies the TLS/SSL certificate thumbprint in the certificate store for the ODP.NET connection to use.

**Declaration**

```
// C#  
public static string SSLCertificateThumbprint { get; set; }
```

**Remarks**

When there are multiple certificates possible for ODP.NET to use from the certificate store, specifying the thumbprint tells ODP.NET which certificate to connect the user with. This avoids the user from performing certificate selection manually, such as via a graphical interface. Users can select a certificate manually using the `OracleConnection.AllowCertificateSelectionUI` property.

ODP.NET supports certificates through thumbprint only. It supports the SHA1 and SHA2 algorithms.

ODP.NET expects thumbprints in the format of <Algorithm>:<Hash>. For example,

- SHA1:1B:11:01:5E:D1:7C:20:B2:62:39:3E:04:7B:83:47:DE:70:2E:4E:44
- SHA256:CD:C6:8B:0D:36:FE:20:0E:7F:86:5F:94:0B:4D:EC:EE:1B:C0:D1:09

Or

- SHA1:1B11015ED17C20B262393E047B8347DE702E4E44
- SHA256:CDC68B0D36FE200E7F865F940B4DECEE1BC0D109

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## SSLServerDNMatch

This property enforces the database server distinguished name (DN) matches its service name. Default value is false.

### Declaration

```
// C#  
public static bool SSLServerDNMatch { get; set; }
```

### Property Type

System.Boolean

Valid Values:

- true - to enforce a match. If the DN matches the service name, then the connection succeeds. If the DN does not match the service name, then the connection fails.
- false - to not enforce a match. If the DN does not match the service name, then the connection is successful, but an error is logged to the sqlnet.log file.

## SSLVersion

This property enforces the connection to use a specific SSL/TLS version.

**Declaration**

```
// C#  
public static string SSLVersion { get; set; }
```

**Property Type**

System.String

**Description**

Supported values are: undetermined |1.2|TLSv1.2|1.3|TLSv1.3. To specify more than one SSL/TLS version, enclose the version numbers between parentheses and separate the values with a comma. For example, (1.2,1.3).

Starting with ODP.NET 23.9, you can specify a minimum TLS version by appending the plus (+) sign after the version, such as 1.2+ or TLSv1.2+. This value indicates to use TLS 1.2 or higher, whichever highest version the database server supports.

In some cases, apps may want to set a minimum TLS version, but not support one or more higher versions. To identify excluded versions, set the TLSExcludeVersion property on OracleConfiguration, OracleConnection, or equivalent.

The default value is an undetermined version. An undetermined version means ODP.NET is allowed to use any TLS version, this property is allowed to specify. An exception will be thrown for invalid value.

This property overrides the SSL\_VERSION parameter.

**Example**

```
OracleConfiguration.SSLVersion = 1.2+;
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TLSExcludeVersion

This property indicates which SSL/TLS versions connections should not be enabled for.

**Declaration**

```
// C#  
public static string TLSExcludeVersion { get; set; }
```

**Property Type**

System.String

### Description

The `TLSVersion` or `SSLVersion` properties sets the supported connection SSL/TLS versions. `TLSExcludeVersion` sets the versions that the app connections cannot use.

Typically, `TLSExcludeVersion` is used when the TLS/SSL version has a minimum value set, such as `TLSv1.2+`, and the app wants to prevent connections from using a version above the minimum value, such as `TLS 1.3`.

Supported exclusion values are: `1.2|TLSv1.2|1.3|TLSv1.3`. To specify more than one SSL/TLS version to exclude, enclose the version numbers between parentheses and separate the values with a comma. For example, `(1.2,1.3)`.

This property has no default value.

An exception will be thrown for invalid value.

This property overrides the `TLS_EXCLUDE_VERSION` parameter, including the full connect descriptor and Easy Connect Plus configuration.

## TLSVersion

This property enforces the connection to use a specific SSL/TLS version.

### Declaration

```
// C#  
public static string TLSVersion { get; set; }
```

### Property Type

`System.String`

### Description

Supported values are: `undetermined|1.2|TLSv1.2|1.3|TLSv1.3`. To specify more than one SSL/TLS version, enclose the version numbers between parentheses and separate the values with a comma. For example, `(1.2,1.3)`.

Starting with ODP.NET 23.9, you can specify a minimum TLS version by appending the plus (+) sign after the version, such as `1.2+` or `TLSv1.2+`. This value indicates to use TLS 1.2 or higher, whichever highest version the database server supports.

In some cases, apps may want to set a minimum TLS version, but not support one or more higher versions. To identify excluded versions, set the `TLSExcludeVersion` property on `OracleConfiguration`, `OracleConnection`, or equivalent.

The default value is an undetermined version. An undetermined version means ODP.NET is allowed to use any TLS version, this property is allowed to specify. An exception will be thrown for invalid value.

This property overrides the SSL\_VERSION parameter.

### Example

```
OracleConfiguration.TLSVersion = 1.2+;
```

## TokenAuthentication

This property sets the value for TOKEN\_AUTH parameter at the process level. The possible values for this property include OracleTokenAuth.OciToken, OracleTokenAuth.Disabled, OracleTokenAuth.OAuth and so on.

### Declaration

```
// C#
public static OracleTokenAuth TokenAuthentication { get; set; }
```

**Table 6-38 OracleTokenAuth Members**

| Member Name          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Disabled             | Default value. Token authentication is DISABLED.                                                                                                                                                                                                                                                                                                                                                                                                       |
| OAuth                | Token authentication enabled for Microsoft Entra ID.                                                                                                                                                                                                                                                                                                                                                                                                   |
| OciApiKey            | Token authentication using OCI_API_KEY authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                                       |
| OciInstancePrincipal | Token authentication using OCI_INSTANCE_PRINCIPAL authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                            |
| OciDelegationToken   | Token authentication using OCI_DELEGATION_TOKEN authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                              |
| OciInteractive       | Token authentication using OCI_INTERACTIVE authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                                   |
| OciDefault           | Token authentication using the most appropriate method depending on the application environment. ODP.NET first attempts to retrieve the token using the OCI API key. If that fails, then ODP.NET checks whether it is in a Cloud Shell environment to attempt to get the token using delegation token authentication flow. Lastly, it attempts to use the instance principal authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i> |

**Table 6-38 (Cont.) OracleTokenAuth Members**

| Member Name | Description                                                                |
|-------------|----------------------------------------------------------------------------|
| OciToken    | Token authentication is enabled for Oracle Identity and Access Management. |

## TokenLocation

This property gets or sets the token location directory at the process level where the access token, or database token and private key files, are present for ODP.NET token authentication. The file names do not need to be specified.

**Declaration**

```
// C#  
public static string TokenLocation { get; set; }
```

**Property Value**

A directory location.

**Exceptions**

None.

**Description**

This property is mandatory for OAuth file-based access tokens, but optional for database tokens.

In the access token case, this property can be the directory where the file “token” is, or the full-path specification of the token file.

For OCI IAM PoP tokens, a file’s full-path specification can be specified if it does not have the standard name, “token”. A file name does not need to be specified when it uses this standard, fixed name. Bearer token default token location is an empty string.

**Note**

Only managed ODP.NET and ODP.NET Core can use this property.

**Remarks**

Applications can override the default location of signature token and private key by setting a new custom location through this property.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## UseMITKerberos

This property specifies whether to use MIT Kerberos or Kerberos.NET.

**Declaration**

```
// C#  
public static bool UseMITKerberos { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

This property only applies to managed ODP.NET as it can use either MIT Kerberos or Kerberos.NET.

When set to true (default), managed ODP.NET will use MIT Kerberos. MIT Kerberos must be installed separately.

When set to false, it uses the Oracle.ManagedDataAccess.Kerberos NuGet package and Kerberos.NET. Oracle recommends using Kerberos.NET.

The option to use managed ODP.NET with Kerberos.NET became available in ODP.NET 23.9.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## WalletLocation

This property specifies the location of wallets. Wallets are certificates, keys, and trustpoints processed by SSL/TLS.

**Declaration**

```
// C#  
public static string WalletLocation { get; set; }
```

**Property Type**

System.String

### Remarks

Microsoft Certificate Store (MCS) and file system wallets are supported.

This property can accept file path or URL values that contain the wallet file.

It supports single sign-on files (.sso file extension) and PKCS #12 files (.p12 file extension). Since wallet location is a directory location, not file location, ODP.NET chooses the file to use based on the criteria:

- When the wallet password is not supplied:
  - Reads the .sso file, if present
  - Reads the .p12 file, if present
- When the wallet password is supplied:
  - Reads the .p12 file, if present

#### Note

MCS wallets are supported only on Windows operating systems.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## WalletPassword

This property stores the password to decrypt the PKCS #12 wallet.

### Declaration

```
// C#  
public static OracleOpaqueString WalletPassword {get; set;}
```

### Property Value

The password to decrypt the encrypted PKCS #12 wallet.

### Remarks

Wallet passwords support the same functionality as traditional ODP.NET passwords.

Since PKCS #12 files are encrypted, apps must provide the wallet password as an `OracleOpaqueString`. When the wallet password is provided through the `OracleConfiguration.WalletPassword` or the `OracleConnection.WalletPassword` class property, ODP.NET loads the associated PKCS #12 file as designated by the wallet location. Alternately, if no password is provided, then ODP.NET loads the associated SSO file.

Changing the `WalletPassword` for an existing connection pool does not create a new pool. Only setting the property or unsetting it creates a new pool.

### Note

The `OracleConfiguration.WalletPassword` is associated with the `OracleConfiguration.WalletLocation` and the `OracleConnection.WalletPassword` is associated with the `OracleConnection.WalletLocation`.

### Example

```
//Create OracleOpaqueString for wallet password
string walletPassword = "<WALLET PASSWORD>";
OracleOpaqueString opaPwd = new OracleOpaqueString();
foreach (char c in walletPassword)
    opaPwd.AppendChar(c);
opaPwd.MakeReadOnly();

//Create and open connection
OracleConnection conn = new OracleConnection("user id=HR; password=<PASSWORD>");
conn.WalletLocation = "C:\\wallet\\location\\";
conn.WalletPassword = opaPwd;
conn.Open();
```

## AddOracleTypesDeserialization

This static method adds ODP.NET-specific data types to the “allow” list to permit deserialization into DataSet or DataTable.

**Declaration**

```
// C#
public static void AddOracleTypesDeserialization();
```

**Remarks**

In newer .NET versions, the allowed DataSet and DataTable data types that can be deserialized are now restricted for security reasons. This change applies to .NET 5, plus .NET Core and .NET Framework updates. If application DataSets and DataTables use Oracle data types with one of these new .NET versions, use the AddOracleTypesDeserialization method to add ODP.NET-specific data types to the “allow” list so that they can be deserialized. If an attempt is made to deserialize ODP.NET-specific types without adding them to the “allow” list, an ODP.NET type initializer exception will be encountered.

If other software that is part of the application adds data types to the allow list as well, be careful not to overwrite the ODP.NET allowed types. Be sure to only append to the allow list, not overwrite it. If overwriting does occur, call AddOracleTypesDeserialization method afterwards to add the ODP.NET types back to the list.

The ODP.NET AddOracleTypesDeserialization method call itself appends to the allow list. It does not overwrite existing entries.

This property is available in ODP.NET 19.10 and higher. It has also been backported to the latest ODP.NET 18c, 12.2, and 12.1 patches.

### Example

```
// C#
// Sample demonstrating loading an XML file with Oracle data types into DataSet

using System.Data;
using Oracle.ManagedDataAccess.Client;

class OracleTypeDeserializationSample
{
    static void Main()
    {
        OracleConfiguration.AddOracleTypesDeserialization();
        DataSet ds = new DataSet();
        ds.ReadXml("dsch1.xml");
    }
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## BindByName

This property specifies whether the binding method used for the parameter collection is by name or by position. Default value (false) is bind by position.

### Declaration

```
// C#
public static bool BindByName { get; set; }
```

### Property Type

System.Boolean

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## CommandTimeout

This property specifies the number of seconds the command is allowed to execute before terminating the execution with an exception. Default value is 0 seconds, which results in no time limit.

**Declaration**

```
// C#  
public static int CommandTimeout { get; set; }
```

**Property Type**

System.Int32.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## GetDecimalRetainTrailingZeros

This property specifies whether to retain trailing zeros from an Oracle NUMBER in a .NET Decimal.

**Declaration**

```
// C#  
public static bool GetDecimalRetainTrailingZeros { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

Starting with ODP.NET 19.11, Oracle NUMBER column values retrieved as .NET Decimals retain a trailing zero if the number of digits on the right hand side of the decimal point is odd in number when this property is set to true.

The default value is false.

This property can be used whenever retrieving data into a .NET Decimal, including the following scenarios:

- `OracleDataReader.GetDecimal();`
- `OracleDecimal.Value`
- Parameter output value of type `Decimal`
- JSON data with `Decimal` in it
- UDT with `Decimal` attribute

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## ProviderTypeNLSSensitiveToString

This property specifies whether to honor the data type's NLS format when the ToString() method is called.

**Declaration**

```
// C#  
public static bool ProviderTypeNLSSensitiveToString { get; set; }
```

**Property Value**

System.Boolean

**Remarks**

Default value is true. When true, ODP.NET honors the database session NLS format when ToString() is called for the provider type.

Prior to version 23.6, ODP.NET returned data in a default format that ignored the database session's NLS format. If you wish to use this earlier behavior, set the property to false.

This property applies to the following provider types: OracleDate, OracleDecimal, OracleTimeStamp, OracleTimeStampLTZ, and OracleTimeStampTZ.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)
- [OracleDataSourceCollection Class](#)

## UseClientInitiatedCQN

This property specifies whether to use Client Initiated Continuous Query Notification (CICQN) or traditional Continuous Query Notification (CQN) that does not rely on a persistent connection.

**Declaration**

```
// C#  
public static bool UseClientInitiatedCQN {get; set;}
```

**Remarks**

When set to true, ODP.NET creates and uses a separate connection to receive server-initiated database change notifications. This is known as CICQN. This single connection aggregates all notifications for the pool, but the connection does not count toward the Min Pool Size nor the Max Pool Size limits. For managed ODP.NET, if there are five connection pools using CICQN, then ODP.NET will then have five additional connections, one per pool.

If false (default), then ODP.NET will use traditional CQN to receive the database change notifications. The client creates a listening end point (i.e. IP address and port) that does not rely on a database connection to continuously exist.

CICQN is commonly used in cloud scenarios or if firewalls between the database and client do not allow access to the client port. Otherwise, traditional CQN is used.

ODP.NET CICQN requires Oracle Database 19c or higher.

UseClientInitiatedCQN must be set to its intended value prior to opening a database connection.

## OracleConfiguration Directories Properties

OracleConfiguration Directories properties are listed in [Table 6-40](#) .

**Table 6-40 OracleConfiguration Directories Properties**

| Property                                        | Description                                                                                                                                                                        |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DefaultAdminContext</a>             | Specifies the default directory entry that contains a LDAP Oracle Context from which connect identifiers can be created, modified, or looked up                                    |
| <a href="#">DirectoryServers</a>                | Lists the host names and port numbers of the primary and alternate LDAP directory servers                                                                                          |
| <a href="#">DirectoryServerType</a>             | Specifies the directory server type used, such as Oracle Internet Directory or Microsoft Active Directory                                                                          |
| <a href="#">LdapAdmin</a>                       | Specifies the ldap.ora directory location                                                                                                                                          |
| <a href="#">NamesLdapAuthenticateBind</a>       | Specifies whether the LDAP naming adapter should attempt to authenticate using a specified wallet when it connects to the LDAP directory to resolve the name in the connect string |
| <a href="#">NamesLdapAuthenticateBindMethod</a> | Specifies the authentication method the client LDAP naming adapter should use while connecting to the LDAP directory to resolve connect string names                               |
| <a href="#">NamesLdapConnTimeout</a>            | specifies the non-blocking connection timeout to the LDAP server                                                                                                                   |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DefaultAdminContext

This property specifies the default directory entry that contains a LDAP Oracle Context from which connect identifiers can be created, modified, or looked up.

**Declaration**

```
// C#  
public static string DefaultAdminContext { get; set; }
```

**Property Type**

System.String

**Values**

Valid distinguished name

**Example**

```
// C#  
OracleConfiguration.DefaultAdminContext=@"o=OracleSoftware,c=US";
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DirectoryServers

This property lists the host names and port numbers of the primary and alternate LDAP directory servers.

**Declaration**

```
// C#  
public static string DirectoryServers { get; set; }
```

**Property Type**

System.String

Use the following format to list the host names and port numbers:

<HOST>:<PORT>[:<TLS/SSL PORT>]

### Example

```
// C#
OracleConfiguration.DirectoryServers="(ldap-server1:389, ldap-server2:400:636)";
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DirectoryServerType

This property specifies the directory server type used, such as Oracle Internet Directory or Microsoft Active Directory.

### Declaration

```
// C#
public static string DirectoryServerType { get; set; }
```

### Property Type

System.String

### Values

- *oid* for Oracle Internet Directory
- *ad* for Microsoft Active Directory

### Example

```
// C#
OracleConfiguration.DirectoryServerType=@"oid";
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## LdapAdmin

This property specifies the `ldap.ora` directory location.

### Declaration

```
// C#
public static string LdapAdmin { get; set; }
```

**Property Type**

System.String

The LdapAdmin setting works in conjunction with the TnsAdmin setting to determine the ldap.ora search order.

**Example**

```
// C#  
OracleConfiguration.LdapAdmin=@"D:\user\ldap\";
```

**Remarks**

ODP.NET will search for ldap.ora using the location search order as listed in [Oracle Configuration Files](#) for ODP.NET Core and in [Oracle Client Configuration File Settings](#) for managed ODP.NET.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## NamesLdapAuthenticateBind

This property specifies whether the LDAP naming adapter should attempt to authenticate using a specified wallet when it connects to the LDAP directory to resolve the name in the connect string.

**Declaration**

```
// C#  
public static bool NamesLdapAuthenticateBind { get; set; }
```

**Property Type**

System.Boolean

If the parameter is set to true, then the LDAP connection is authenticated using a wallet whose location must be specified in the OracleConfiguration.WalletLocation property.

If the parameter is set to false, then the LDAP connection is established using an anonymous bind.

Default value is false.

**Example**

```
// C#  
OracleConfiguration.NamesLdapAuthenticateBind = true;
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## NamesLdapAuthenticateBindMethod

This property specifies the authentication method the client LDAP naming adapter should use while connecting to the LDAP directory to resolve connect string names.

**Declaration**

```
// C#  
public static string NamesLdapAuthenticateBindMethod { get; set; }
```

**Property Type**

System.String

**Remarks**

The simple authentication method over LDAPS (LDAP over TLS connection) is supported.

Store the directory entry distinguished name and password in an Oracle wallet. When the client connects to the LDAP server, it is authenticated using the credentials stored in this wallet. The wallet must contain client certificates. Its trust store must contain the certificates issued by the certificate authority of the LDAP server.

The parameter value is a string (ldaps\_simple\_auth).

The LDAP naming adapter uses the `oracle.ldap.client.dn` and `oracle.ldap.client.password` entries from the wallet for authenticating to the LDAP server. If these entries are not present, then the client attempts an anonymous authentication using TLS or LDAPS.

**Default**

none

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## NamesLdapConnTimeout

This property specifies the non-blocking connection timeout to the LDAP server.

**Declaration**

```
// C#
public static Int32 NamesLdapConnTimeout { get; set; }
```

**Property Type**

System.Int32

This property sets the time to wait (in seconds) for a LDAP server connection before a time out error can occur.

The minimum value is -1, which indicates no connection timeout. The default value is 15 seconds.

**Example**

```
// C#
OracleConfiguration.NamesLdapConnTimeout = -1;
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OracleConfiguration High Availability Properties

OracleConfiguration High Availability properties are listed in [Table 6-41](#).

**Table 6-41 OracleConfiguration High Availability Properties**

| Property                                              | Description                                                                                                                                                                                                                         |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ChunkMigrationConnectionTimeout</a>       | This setting pauses the connection request until the migration completes or fails to migrate in the specified time, then connect to the correct shard with the data requested.<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">DbNotificationAddress</a>                 | Specifies the address that the provider listens to for all notifications sent by the database for continuous query notification feature                                                                                             |
| <a href="#">DbNotificationPort</a>                    | Specifies the port number that the provider listens to for all notifications sent by the database for continuous query notification, Fast Connection Failover, and/or Runtime Connection Load Balancing features                    |
| <a href="#">DistributedTransactionRecoveryAddress</a> | Specifies the machine name or IP address the OraMTS recovery service runs on to resolve database in-doubt transactions                                                                                                              |
| <a href="#">DistributedTransactionRecoveryPort</a>    | Specifies the port the OraMTS recovery service listens on to resolve database in-doubt transactions                                                                                                                                 |
| <a href="#">DistributedTransactionTimeToLive</a>      | Specifies the time the transaction can remain inactive after it has been detached or delisted from the database                                                                                                                     |

**Table 6-41 (Cont.) OracleConfiguration High Availability Properties**

| Property                                           | Description                                                                                                       |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">HAEvents</a>                           | Enables the application to receive Fast Connection Failover events for maintaining application high availability  |
| <a href="#">MaxCallsPerRequestBoundary</a>         | Specifies the maximum request size, or ODP.NET calls, beyond which Application Continuity replay will be disabled |
| <a href="#">OnsConfigFile</a>                      | Specifies the configuration file to define Oracle Notification Service (ONS) behavior                             |
| <a href="#">OnsMode</a>                            | Specifies the ONS daemon mode as either local or remote                                                           |
| <a href="#">OnsProtocol</a>                        | Defines whether the ONS connection uses TCP/IP or TCP/IP with SSL/TLS                                             |
| <a href="#">OnsWalletLocation</a>                  | Specifies the directory location of the ONS wallets                                                               |
| <a href="#">OracleOnsServers</a>                   | Returns a collection of logical ONS servers added through OracleConfiguration                                     |
| <a href="#">ServiceRelocationConnectionTimeout</a> | Specifies the time to wait before retrying connecting to a service that becomes unavailable.                      |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## ChunkMigrationConnectionTimeout

In sharding, a connection request to a specific shard can occur while data is migrating from the original shard to a new one. This setting will pause the connection request until the migration completes or fails to migrate in the specified time, then connect to the correct shard with the data requested.

**Declaration**

```
// C#
public static int ChunkMigrationConnectionTimeout {get;set;}
```

**Property Value**

The maximum time, in seconds, for a pooled connection request to pause waiting for a chunk migration or split partitionset for a particular chunk.

**Remarks**

If a specific shard connection request occurs while data is migrating to a new shard or being split and moved to a new shard through a split partitionset operation, then this setting pauses the connection request until the data migration completes or fails in the specified time. It then connects to the correct shard with the data requested.

Default is 120 seconds. This setting requires connection pooling to be enabled.

ODP.NET reads the chunk migration connection timeout setting only upon pool creation. A new timeout setting will not be used until a new pool is created.

This setting is in effect if

- write access is required and a chunk is read-only, or
- during a chunk migration or split partitionset, the chunk becomes unavailable to read.

If the connection requires only read-only access, then this setting will not be used unless the chunk becomes unavailable.

If the connection requires write access and the chunk does not become writable or available before the chunk migration connection timeout expires, then a new connection will be created. If the connection cannot be created, then an `OracleException` will occur.

During chunk migration or split partitionset, an ODP.NET connection request obeys only the chunk migration connection timeout. All other connection timeout values, such as `OracleConnection.ConnectionTimeout`, are ignored.

Oracle recommends setting the ODP.NET chunk migration connection timeout to a value greater than the chunk move server timeout. One way to set this server timeout is using the Global Data Services Control Utility (GDSCCTL) `move chunk` command's timeout option. This server-side timeout only applies to chunk migrations, not split partitionset.

The `OracleConnection ChunkMigrationConnectionTimeout` property inherits from the `OracleConfiguration ChunkMigrationConnectionTimeout` property. The `OracleConnection` property can be separately set to override the property set in the `OracleConfiguration` class.

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DbNotificationAddress

This property specifies the address that the provider listens to for all notifications sent by the database for continuous query notification feature.

### Declaration

```
// C#  
public static string DbNotificationAddress { get; set; }
```

### Property Type

`System.String`

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DbNotificationPort

This property specifies the port number that the provider listens to for all notifications sent by the database for continuous query notification, Fast Connection Failover, and/or Runtime Connection Load Balancing features. A value of -1 allows directs the provider to use a random port.

**Declaration**

```
// C#  
public static int DbNotificationPort { get; set; }
```

**Property Type**

System.Int32.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DistributedTransactionRecoveryAddress

This property specifies the machine name or IP address the OraMTS recovery service runs on to resolve database in-doubt transactions.

**Declaration**

```
// C#  
public static string DistributedTransactionRecoveryAddress { get; set; }
```

**Property Type**

System.String

**Remarks**

The default value is the local machine name.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DistributedTransactionRecoveryPort

This property specifies the port the OraMTS recovery service listens on to resolve database in-doubt transactions.

**Declaration**

```
// C#  
public static int DistributedTransactionRecoveryPort { get; set; }
```

**Property Type**

System.Int32

**Remarks**

The default value is 2030.

The port must be between 1 and 65535, or the default will be used.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## DistributedTransactionTimeToLive

This property specifies the time the transaction can remain inactive after it has been detached or delisted from the database.

**Declaration**

```
// C#  
public static int DistributedTransactionTimeToLive { get; set; }
```

**Property Type**

System.Int32

**Property Value**

The unit of time is seconds.

**Remarks**

The default value is 120 seconds.

The time to live must be between 1 and `int.MaxValue`, or the default will be used.

Once this time expires, the transaction is automatically terminated by the provider.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## HAEvents

This property enables the application to receive Fast Connection Failover events for maintaining application high availability. Default is true.

**Declaration**

```
// C#  
public static bool HAEvents { get; set; }
```

**Property Type**

`System.Boolean`

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## MaxCallsPerRequestBoundary

This property specifies the maximum request size, or ODP.NET calls, beyond which Application Continuity replay will be disabled.

**Declaration**

```
// C#  
public static int MaxCallsPerRequestBoundary { get; set; }
```

**Property Type**

`System.Int32`

### Remarks

In Application Continuity, ODP.NET stores all the driver calls that occur between request boundaries, generally when connections are checked out and in. Having this call record is what makes session restoration possible after a failover. For long-running connections, more calls to restore mean more memory is necessary to retain all the changes between request boundaries. ODP.NET allows you to disable session replay when this memory usage becomes too high by setting a maximum number of calls to retain between request boundaries.

If the property value is set to 100, replay will be disabled for any request with more than 100 calls. Disabling replay applies only to the connection request that exceeds the limit. Other connection requests below the limit remain enabled and can be recovered after a failover. Replay will be re-enabled at the next BeginRequest call on the same connection.

By default, the property value is `Int32.MaxValue`.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OnsConfigFile

This property specifies the configuration file to define Oracle Notification Service (ONS) behavior. The file specified should contain the same local port and remote port values as specified in the `ons.config` file used by the local ONS daemon. This will enable the application to receive events from the local ONS daemon.

### Declaration

```
// C#  
public static string OnsConfigFile { get; set; }
```

### Property Type

`System.String`

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OnsMode

This property specifies the ONS daemon mode as either "local" or "remote".

For local configuration, configure and make available ONS on the node where ODP.NET is running so that ODP.NET can receive events directly from the local ONS daemon.

Remote configuration is used when the application directly receives ONS events from the ONS daemons running on remote machines. One of the advantages of this configuration is that no ONS daemon is needed on the client end and; therefore, there is no need to manage this process.

#### Declaration

```
// C#  
public static OnsConfigMode OnsMode { get; set; }
```

#### Property Type

System.String

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OnsProtocol

This property defines whether the ONS connection uses TCP/IP or TCP/IP with SSL/TLS.

#### Declaration

```
// C#  
public static string OnsProtocol { get; set; }
```

#### Property Type

System.String

#### Usage Notes

Valid values are TCP or TCPS. Default value is TCP.

#### Example

```
OracleConfiguration.OnsProtocol=TCPS
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OnsWalletLocation

This property specifies the directory location of the ONS wallets. Wallets are certificates, keys, and trustpoints processed by SSL/TLS.

### Declaration

```
// C#  
public static string OnsWalletLocation { get; set; }
```

### Property Type

System.String

### Usage Notes

Default value is none.

### Example

```
OracleConfiguration.OnsWalletLocation=@"D:\user\wallets\"
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OracleOnsServers

This property returns a collection of logical ONS servers added through OracleConfiguration.

### Declaration

```
// C#  
public static OracleOnsServerCollection OracleOnsServers
```

### Property

Type:Oracle.ManagedDataAccess.Client.OracleOnsServerCollection

Returns a static OracleOnsServerCollection object.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)
- [OracleDataSourceCollection Class](#)

## ServiceRelocationConnectionTimeout

This property specifies the time to wait before retrying connecting to a service that becomes unavailable. Default value is 90 seconds. Whenever a database service becomes unavailable, such as due to a service being relocated, an application can encounter numerous connectivity errors during this time. To avoid unnecessary connection attempts to an unavailable service which will result in an error, the driver will block any connection attempts until the service is up or until this property's specified time limit expires from the time when the service DOWN event was received, whichever comes first.

### Declaration

```
// C#  
public static string ServiceRelocationConnectionTimeout { get; set; }
```

### Property Type

System.String

#### ① See Also

- [OracleConfiguration Members](#)

## OracleConfiguration Performance Properties

OracleConfiguration Performance properties are listed in [Table 6-42](#).

**Table 6-42 OracleConfiguration Performance Properties**

| Property                              | Description                                                                                                             |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DefaultSDUSize</a>        | Specifies the session data unit size (SDU) for Oracle networking communication between client and server                |
| <a href="#">FetchSize</a>             | Specifies the total memory size, in bytes, that the provider allocates to cache data fetched in one database round-trip |
| <a href="#">LoadBalancing</a>         | Enables the application to receive runtime connection load balancing information                                        |
| <a href="#">MaxStatementCacheSize</a> | Specifies the maximum number of statements that can be cached when self-tuning is enabled                               |
| <a href="#">Pipelining</a>            | Enables asynchronous execution on the database server side                                                              |
| <a href="#">PerformanceCounters</a>   | Specifies the ODP.NET connection performance counters to publish so that they can be monitored                          |
| <a href="#">ReceiveBufferSize</a>     | Specifies the buffer space limit for receive operations of sessions                                                     |

**Table 6-42 (Cont.) OracleConfiguration Performance Properties**

| Property                                | Description                                                                                                                 |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">RowsToFetchPerRoundTrip</a> | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">SelfTuning</a>              | Specifies whether self-tuning is enabled for an ODP.NET application                                                         |
| <a href="#">SendBufferSize</a>          | Specifies the buffer space limit for send operations of sessions                                                            |
| <a href="#">StatementCacheSize</a>      | Specifies the number of cursors or statements to be cached for each database connection                                     |
| <a href="#">TcpNoDelay</a>              | Preempts delays in buffer flushing within the TCP/IP protocol stack                                                         |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)

## DefaultSDUSize

This property specifies the session data unit size (SDU) for Oracle networking communication between client and server.

**Declaration**

```
// C#
public static int DefaultSDUSize { get; set; }
```

**Remarks**

Before sending data across the network, ODP.NET or Oracle database buffers and encapsulates data into the SDU. They send the data stored in this buffer when the buffer is full, flushed, or when database server tries to read data. When large amounts of data are being transmitted or when the message size is consistent, adjusting the size of the SDU buffers can improve performance, network utilization, or memory consumption.

The default value is 65536 bytes, equivalent to 64 KB.

ODP.NET and Oracle database can each set its own SDU size. The actual SDU size used is negotiated at connect time. The smaller of the two values is chosen. Oracle AI Database 26ai uses a 64 KB SDU size. Earlier database releases set their default SDU size to 8 KB.

The OracleConfiguration SDU size can only be set before the first connection is established globally in the the .NET domain.

The OracleConnection SDU size can only be set before the connection is established. Moreover, the OracleConnection SDU size for a connection pool can only be set one time. All follow on set attempts are ignored for that pool.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## FetchSize

This property specifies the total memory size, in bytes, that the provider allocates to cache data fetched in one database round-trip. Default value is 131072.

**Declaration**

```
// C#  
public static int FetchSize { get; set; }
```

**Property Type**

System.Int32

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## LoadBalancing

This property enables the application to receive runtime connection load balancing information. Default is true.

**Declaration**

```
// C#  
public static bool LoadBalancing { get; set; }
```

**Property Type**

System.Boolean

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## MaxStatementCacheSize

This property specifies the maximum number of statements that can be cached when self-tuning is enabled. Default value is 100.

### Declaration

```
// C#  
public static int MaxStatementCacheSize { get; set; }
```

### Property Type

System.Int32

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## PerformanceCounters

This property specifies the ODP.NET connection performance counters to publish so that they can be monitored.

### Declaration

```
// C#  
public static Int64 PerformanceCounters { get; set; }
```

### Property Type

System.Int64

### Remarks

ODP.NET enables monitoring many different connection counters, including pooled and non-pooled connections. These counters can be monitored individually or together. Developers can set which counters to monitor prior to application startup using the PerformanceCounters property.

By default, performance counters are not enabled.

#### ① See Also

- [Connection Performance Counters](#) for more information on setting up and configuring counters.
- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## Pipelining

This property enables asynchronous execution on the database server side.

### Declaration

```
// C#  
public static bool Pipelining { get; set; }
```

### Property Type

System.Boolean

### Description

Default is false.

To enable pipelining, that is, database server asynchronous execution; set this property to true, and enable asynchronous ODP.NET, that is, client side asynchronous execution as well. Pipelining can only be enabled if async ODP.NET is enabled.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## ReceiveBufferSize

This property specifies the buffer space limit for receive operations of sessions.

### Declaration

```
// C#  
public static int ReceiveBufferSize{get; set; }
```

### Property Type

System.Int32

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## RowsToFetchPerRoundTrip

This property specifies the total number of rows to retrieve per database round trip.

**Declaration**

```
// C#  
public static Int64 RowsToFetchPerRoundTrip { get; set; }
```

**Property Type**

System.Int64

**Remarks**

This property has no default value. If it is not set, then ODP.NET ignores this property.

The row data fetched in a single round trip applies to scalar types only, such as NUMBER and VARCHAR2 columns. If reference data types, such as LOBs, UDTs, and XMLType, exist in the result set, they are retrieved in separate round trips. These reference types can have their own fetch tuning parameters as reference type data sizes can vary in size from row to row, sometimes significantly.

RowsToFetchPerRoundTrip can be set before or after the OracleCommand executes on OracleConnection, OracleCommand, OracleDataReader, or OracleRefCursor. The value can also be changed after initial data fetches so that more or fewer rows are fetched on subsequent round trips. For OracleConfiguration, this property can only be set before the first connection opens.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SelfTuning

This property specifies whether self-tuning is enabled for an ODP.NET application. By default, self-tuning (true) is enabled.

**Declaration**

```
// C#  
public static bool SelfTuning { get; set; }
```

**Property Type**

System.Boolean

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## SendBufferSize

This property specifies the buffer space limit for send operations of sessions.

### Declaration

```
// C#  
public static int SendBufferSize { get; set; }
```

### Property Type

System.Int32

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## StatementCacheSize

This property specifies the number of cursors or statements to be cached for each database connection. This setting corresponds to the connection string Statement Cache Size attribute. A value greater than zero enables statement caching. Default value is zero.

### Declaration

```
// C#  
public static int StatementCacheSize { get; set; }
```

### Property Type

System.Int32

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TcpNoDelay

This property preempts delays in buffer flushing within the TCP/IP protocol stack. Default value is true.

### Declaration

```
// C#  
public static bool TcpNoDelay { get; set; }
```

**Property Type**

System.Boolean

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OracleConfiguration Diagnostics and Tracing Properties

OracleConfiguration Diagnostics and Tracing properties are listed in [Table 6-43](#).

**Table 6-43 OracleConfiguration Diagnostics and Tracing Properties**

| Property                             | Description                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ConnectionIdPrefix</a>   | Identifies a particular application's connections by appending its string to the connection identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>   |
| <a href="#">OpenTelemetryTracing</a> | Specifies whether to dynamically enable or disable ODP.NET OpenTelemetry tracing instrumentation or not.<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">PoolNames</a>            | Specifies a string to identify the monitored connection pool more easily                                                                                      |
| <a href="#">Program</a>              | Specifies the application program name<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                   |
| <a href="#">SuppressErrorURL</a>     | Shows or suppresses the Oracle Database Error Messages URL for the specific error with more information on its cause and resolution                           |
| <a href="#">TraceFileLocation</a>    | Specifies the destination directory to output provider traces                                                                                                 |
| <a href="#">TraceFileMaxSize</a>     | Specifies the maximum file size of each trace file                                                                                                            |
| <a href="#">TraceLevel</a>           | Specifies the generated trace level to trace ODP.NET calls and diagnose provider issues                                                                       |
| <a href="#">TraceOption</a>          | Specifies whether to generate a single trace file or multiple trace files for multithreaded applications                                                      |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## ConnectionStringPrefix

This property is used to identify a particular application's connections by appending its string to the connection identifier. The identifier and prefix can be used to uniquely identify the application connections for tracing and diagnosis purposes.

### Declaration

```
// C#  
public static string ConnectionIdPrefix { set; }
```

### Property Value

System.String

### Remarks

The property value is an 8-byte identifier limited to alphanumeric characters and underscore (\_).

#### 📘 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OpenTelemetryTracing

This property specifies whether to dynamically enable or disable ODP.NET OpenTelemetry tracing instrumentation or not.

### Declaration

```
// C#  
public static bool OpenTelemetryTracing { get; set; }
```

### Property Type

Bool

### Remarks

Default value is true.

This property can be changed at runtime to dynamically turn off and on ODP.NET OpenTelemetry tracing. When this OracleConfiguration property is explicitly set to a value, it overrides the OpenTelemetryTracing value set in the .NET configuration file.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## PoolNames

This property specifies a string to identify the monitored connection pool more easily.

**Declaration**

```
// C#  
public static OraclePoolNameCollection PoolNames { get; }
```

**Property Type**

OraclePoolNameCollection class instance

**Remarks**

OraclePoolNameCollection class exposes Add and Remove methods to add or remove pool name for each unique connection string. Example:

```
OracleConfiguration.PoolNames.Add("PoolA", "<unique connection string>");
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## Program

This property specifies the application program name.

**Declaration**

```
// C#  
public static string Program {get; set}
```

**Property Value**

This property stores the name identifying the client program.

**Remarks**

This name is also stored in the PROGRAM column of V\$SESSION on the database server. By default, the application/process name obtained from .NET is used. The app can assign different value or reset to the default by assigning a null value.

The string is returned regardless of the connection state. This property cannot be changed after the first successfully opened connection.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)
- [OracleDataSourceCollection Class](#)

## SuppressErrorURL

This property shows or suppresses the Oracle Database Error Messages URL for the specific error with more information on its cause and resolution.

### Declaration

```
// C#  
public static bool SuppressErrorURL { get; set; }
```

### Property Type

System.Boolean

### Remarks

The default value is false.

When set to true, ODP.NET exception messages will only contain an error code, for example, ORA-12345, and a brief description. This is the same behavior as earlier ODP.NET versions.

When set to false, ODP.NET exception messages will include the error code, description, and an URL to the Oracle Database Error Messages website for the particular error code. This specific error code web page includes more information, such as the possible error cause and actions to resolve it.

The error URLs are not appended for ODP specific errors (ORA-50000 - ORA 50999)

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TraceFileLocation

This property specifies the destination directory to output provider traces.

**Declaration**

```
// C#  
public static string TraceFileLocation { get; set; }
```

**Property Type**

System.String

**Remarks**

On Windows, the default TraceFileLocation is <Windows user temporary folder>\ODP.NET\core\trace. On Linux, the default is <current user temporary folder>/ODP.NET/core/trace. If you modify the trace file location, then do not use a write-protected directory, such as C:\ on Windows. Write-protection may prevent ODP.NET from being able to write a trace file to that particular directory location.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TraceFileMaxSize

This property specifies the maximum file size of each trace file.

**Declaration**

```
// C#  
public static int TraceFileMaxSize { get; set; }
```

**Property Type**

System.Int32

**Remarks**

Administrators can maintain reasonably sized trace files by using this property to enforce a maximum size that any individual ODP.NET trace file can be. The TraceFileMaxSize value is in megabytes. If no value is set, TraceFileMaxSize defaults to a value of 100, which is 100 megabytes (MB).

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TraceLevel

This property specifies the generated trace level to trace ODP.NET calls and diagnose provider issues. Errors will always be traced. Default value is 0 indicating tracing is disabled.

### Declaration

```
// C#  
public static int TraceLevel { get; set; }
```

### Property Type

System.Int32

Valid Values:

- 1 = public APIs
- 2 = private APIs
- 4 = network APIs/data
- 8 = disables writing SQL statements and network packet contents

These values can be bitwise ORed. To enable all traces, set TraceLevel to 7. Use TraceLevel 8 if you require SQL statements and network packet contents to be excluded from the trace.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## TraceOption

This property specifies whether to generate a single trace file or multiple trace files for multithreaded applications. Default value is 0 indicating single trace file for all application threads.

### Declaration

```
// C#  
public static int TraceOption { get; set; }
```

### Property Type

System.Int32

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConfiguration Class](#)
- [OracleConfiguration Members](#)

## OracleConfigurationProvider Class

The OracleConfigurationProvider class contains enumerated values that specify the ODP.NET centralized configuration providers that the application is allowed to use.

### Class Inheritance

System.Object

Oracle.ManagedDataAccess.OracleConfigurationProvider

### Declaration

```
// C#  
public sealed class OracleConfigurationProvider : IComparable
```

### Requirements

| Provider              | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | See <a href="#">System Requirements</a> |

### Remarks

OracleConfigurationProvider is technically a class but is functionally an enumeration that has a predefined list of possible values. You use the bitwise OR operator '|' to combine multiple enum values.

This class is only applicable to the OracleConfiguration.OracleConfigurationProviders property; It cannot be in sqlnet.ora nor .NET configuration files.

| Member Name | Description                                                      |
|-------------|------------------------------------------------------------------|
| None        | Disables all configuration providers                             |
| Azure       | Enables Azure App configuration provider                         |
| OCIObject   | Enables Oracle Cloud Infrastructure (OCI) Configuration provider |

| Member Name | Description                                                     |
|-------------|-----------------------------------------------------------------|
| File        | Enable local file provider                                      |
| AzureVault  | Enables Azure Vault Configuration provider                      |
| OCIVault    | Enables OCI Vault Configuration provider                        |
| All         | Enables all configuration providers. This is the default value. |

The property default value of All will remain constant in future ODP.NET versions. The configuration providers list supported by All may increase in the future.

### Thread Safety

This class only has public static methods, so it is entirely thread safe.

#### ① See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

## OracleConnection Class

An OracleConnection object represents a connection to an Oracle database.

#### ① Note

The OracleConnection class has been extended and modified in the Oracle.ManagedDataAccess.Azure and Oracle.ManagedDataAccess.Oci assemblies. They expose methods for ODP.NET to connect through Azure and Oracle Cloud Infrastructure token authentication, respectively.

### Class Inheritance

System.Object

System.MarshalByRefObject

System.ComponentModel.Component

System.Data.Common.DbConnection

Oracle.DataAccess.Client.OracleConnection

### Declaration

```
// C#  
public sealed class OracleConnection : DbConnection, IDbConnection, ICloneable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleConnectionSample
{
    static void Main()
    {
        // Connect
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Execute a SQL SELECT
        OracleCommand cmd = con.CreateCommand();
        cmd.CommandText = "select * from emp";
        OracleDataReader reader = cmd.ExecuteReader();

        // Print all employee numbers
        while (reader.Read())
            Console.WriteLine(reader.GetInt32(0));

        // Clean up
        reader.Dispose();
        cmd.Dispose();
        con.Dispose();
    }
}
```

## OracleConnection Members

OracleConnection members are listed in the following tables.

### OracleConnection Constructors

OracleConnection constructors are listed in [Table 6-44](#).

**Table 6-44 OracleConnection Constructors**

| Constructor                                   | Description                                                            |
|-----------------------------------------------|------------------------------------------------------------------------|
| <a href="#">OracleConnection Constructors</a> | Instantiates a new instance of the OracleConnection class (Overloaded) |

### OracleConnection Static Methods

The OracleConnection static methods are listed in [Table 6-45](#).

**Table 6-45 OracleConnection Static Methods**

| Method                                            | Description                                                                                                                                            |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ClearAllPools</a>                     | Clears all connections from all the connection pools                                                                                                   |
| <a href="#">ClearPool</a>                         | Clears the connection pool that is associated with the provided OracleConnection object                                                                |
| <a href="#">ClearInteractiveTokenCache</a>        | Clears the connection pool, Microsoft Entra ID, and OCI IAM access tokens from the ODP.NET cache.<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| Equals                                            | Inherited from System.Object (Overloaded)                                                                                                              |
| <a href="#">UnregisterCloudConfigNotification</a> | Unregisters an OracleConnection from receiving cloud provider change notifications<br><i>Not available in ODP.NET, Unmanaged Driver</i>                |

### OracleConnection Properties

OracleConnection properties are listed in [Table 6-46](#).

Table 6-46 OracleConnection Properties

| Property                                        | Description                                                                                                                                                                                                                         |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AccessToken</a>                     | Used to get or set <code>OracleAccessToken</code> on the connection                                                                                                                                                                 |
| <a href="#">ActionName</a>                      | Specifies the action name for the connection                                                                                                                                                                                        |
| <a href="#">AllowCertificateSelectionUI</a>     | Indicates whether to allow the user to select a specific TLS/SSL certificate via a graphical interface for their database connection when using a MCS wallet location<br><i>Not Available in ODP.NET, Unmanaged Driver</i>          |
| <a href="#">AutoCommit</a>                      | Specifies whether to commit each SQL statement implicitly or only until an explicit commit occurs                                                                                                                                   |
| <a href="#">AutoProxy</a>                       | Enables using a HTTPS proxy server for the ODP.NET connection                                                                                                                                                                       |
| <a href="#">BindByName</a>                      | Specifies the binding method in the collection<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                 |
| <a href="#">ChunkMigrationConnectionTimeout</a> | This setting pauses the connection request until the migration completes or fails to migrate in the specified time, then connect to the correct shard with the data requested.<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">ClientId</a>                        | Specifies the client identifier for the connection                                                                                                                                                                                  |
| <a href="#">ClientInfo</a>                      | Specifies the client information for the connection                                                                                                                                                                                 |
| <a href="#">ClientTimeZoneFileVersion</a>       | Returns the highest time zone file version in the <code>TimeZoneFileLocation</code> directory and embedded in ODP.NET                                                                                                               |
| <a href="#">CommandTimeout</a>                  | Specifies the number of seconds the command is allowed to execute before terminating the execution with an exception<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                           |
| <a href="#">ConnectionIdPrefix</a>              | Identifies a particular application's connections by appending its string to the connection identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                         |
| <a href="#">ConnectionString</a>                | Specifies connection information or URL used to connect to an Oracle database                                                                                                                                                       |
| <a href="#">ConnectionTimeout</a>               | Indicates the maximum amount of time that the <code>Open</code> method can take to obtain a pooled connection before the request is terminated                                                                                      |
| <a href="#">ConnectionType</a>                  | Determines whether a particular connection object is associated with a TimesTen database connection, an Oracle database connection, or no physical connection<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>   |
| Container                                       | Inherited from <code>System.ComponentModel.Component</code>                                                                                                                                                                         |
| <a href="#">Credential</a>                      | Used to get or set an <code>OracleCredential</code> object on the connection                                                                                                                                                        |

Table 6-46 (Cont.) OracleConnection Properties

| Property                                    | Description                                                                                                                                                                  |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Database</a>                    | <i>Not Supported</i>                                                                                                                                                         |
| <a href="#">DatabaseCharset</a>             | Specifies the CHAR database character set on the connection and is used to optimize connection establishment<br><i>Not Available in ODP.NET, Unmanaged Driver</i>            |
| <a href="#">DatabaseNCharset</a>            | Specifies the NCHAR database character set on the connection and is used to optimize connection establishment<br><i>Not Available in ODP.NET, Unmanaged Driver</i>           |
| <a href="#">DatabaseDomainName</a>          | Specifies the name of the database domain to which the connection is set                                                                                                     |
| <a href="#">DatabaseEditionName</a>         | Sets or gets the edition name for the OracleConnection object                                                                                                                |
| <a href="#">DatabaseMaxIdentifierLength</a> | Specifies the maximum identifier length the connection supports                                                                                                              |
| <a href="#">DatabaseName</a>                | Specifies the name of the database to which the connection is set                                                                                                            |
| <a href="#">DatabaseTimeZoneFileVersion</a> | Returns the database's time zone file version                                                                                                                                |
| <a href="#">DataSource</a>                  | Specifies the Oracle Net Services Name, Connect Descriptor, or an easy connect naming that identifies the database to which to connect                                       |
| <a href="#">DRCPConnectionClass</a>         | Specifies a logical name that identifies the DRCP connection pool that the ODP.NET connection will use                                                                       |
| <a href="#">DRCPPurity</a>                  | Specifies whether an application can reuse a pooled session (Pooled) or must use a new session (New)                                                                         |
| <a href="#">FetchSize</a>                   | Specifies the total memory size, in bytes, that the provider allocates to cache data fetched in one database round-trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">HostName</a>                    | Specifies the name of the host to which the connection is set                                                                                                                |
| <a href="#">HttpsProxy</a>                  | Specifies the HTTPS proxy server                                                                                                                                             |
| <a href="#">HttpsProxyPort</a>              | Specifies the HTTPS proxy server port number                                                                                                                                 |
| <a href="#">InstanceName</a>                | Specifies the name of the instance to which the connection is set                                                                                                            |
| <a href="#">IsInTransaction</a>             | Specifies if the current application is in a transaction                                                                                                                     |
| <a href="#">IsNNEChecksummed</a>            | Indicates if the connection uses Oracle Database Native Network Encryption (NNE) checksumming<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">IsNNEEncrypted</a>              | Indicates if the connection uses Oracle Database Native Network Encryption (NNE).<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                       |

Table 6-46 (Cont.) OracleConnection Properties

| Property                                     | Description                                                                                                                                                                    |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">IsTLSEncrypted</a>               | Indicates if the connection uses TCPS, SSL, or TLS<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                        |
| <a href="#">KeepAlive</a>                    | Specifies whether to keep an idle connection alive.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                       |
| <a href="#">KeepAliveInterval</a>            | Specifies the time interval after an unacknowledged probe before a new probe is sent.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                     |
| <a href="#">KeepAliveTime</a>                | Specifies the idle time before a keepalive probe is sent.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                 |
| <a href="#">MaxStatementCacheSize</a>        | Specifies the maximum number of statements that can be cached when self-tuning is enabled<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                 |
| <a href="#">ModuleName</a>                   | Specifies the module name for the connection                                                                                                                                   |
| <a href="#">NamesDirectoryPath</a>           | Specifies the naming method order used for client name resolution lookups                                                                                                      |
| <a href="#">OciCompartment</a>               | Gets or sets the Oracle Cloud Identifier (OCID) of the target database's compartment                                                                                           |
| <a href="#">OciDatabase</a>                  | Gets or sets the target database's Oracle Cloud Identifier (OCID)                                                                                                              |
| <a href="#">OciIamUrl</a>                    | Gets or sets the URL end point for getting the database token                                                                                                                  |
| <a href="#">OciTenacy</a>                    | Gets or sets the Oracle Cloud Identifier (OCID) of the IAM user's cloud tenancy to retrieve the database token                                                                 |
| <a href="#">PasswordAuthentication</a>       | Sets the connection PASSWORD_AUTH parameter value                                                                                                                              |
| <a href="#">PDBName</a>                      | Used to set and get the name of the pluggable database to which the session is connected to                                                                                    |
| <a href="#">Pipelining</a>                   | Enables asynchronous execution on the database server side<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                |
| <a href="#">PoolName</a>                     | Specifies the name that uniquely identifies the pool in .NET metrics or performance counters.<br><i>Not available in ODP.NET, Unmanaged Driver and ODP.NET, Managed Driver</i> |
| <a href="#">ProviderName</a>                 | Specifies the ODP.NET provider type and version<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                           |
| <a href="#">ProviderNuGetVersion</a>         | Specifies the ODP.NET NuGet version number<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                |
| <a href="#">ProviderVersion</a>              | Specifies the ODP.NET assembly version                                                                                                                                         |
| <a href="#">RemoteConfigurationFiltering</a> | Specifies whether local configuration file access, such as to wallet and tnsnames.ora files, is allowed from centralized configuration providers                               |

Table 6-46 (Cont.) OracleConnection Properties

| Property                                           | Description                                                                                                                                        |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Roles</a>                              | Retrieves the <code>OracleRoleCollection</code> object associated with the connection.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>        |
| <a href="#">RowsToFetchPerRoundTrip</a>            | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                        |
| <a href="#">SDU</a>                                | Specifies the session data unit size (SDU) for Oracle networking communication between client and server                                           |
| <a href="#">ServerVersion</a>                      | Specifies the version number of the Oracle database to which the <code>OracleConnection</code> has established a connection                        |
| <a href="#">ServiceName</a>                        | Specifies the name of the service to which the connection is set                                                                                   |
| <a href="#">ServiceRelocationConnectionTimeout</a> | Specifies the time to wait before retrying connecting to a service that becomes unavailable<br><i>Not Available in ODP.NET, Unmanaged Driver</i>   |
| <a href="#">SessionlessTransactionOptions</a>      | Indicates the sessionless transaction options<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                 |
| <a href="#">SessionlessTransactionId</a>           | Returns the sessionless transaction identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                |
| Site                                               | Inherited from <code>System.ComponentModel.Component</code>                                                                                        |
| <a href="#">SqlNetAllowedLogonVersionClient</a>    | Specifies the minimum authentication protocol that is to be used for a given <code>OracleConnection</code> object                                  |
| <a href="#">SqlNetAuthenticationServices</a>       | This property enables one or more authentication services, such as TCP/IP with SSL.                                                                |
| <a href="#">SqlNetCryptoChecksumClient</a>         | Specifies the checksum client behavior.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                       |
| <a href="#">SqlNetCryptoChecksumTypesClient</a>    | Specifies the checksum algorithms the client can use.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                         |
| <a href="#">SqlNetEncryptionClient</a>             | Specifies the encryption client behavior<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                      |
| <a href="#">SqlNetEncryptionTypesClient</a>        | Specifies encryption algorithms that the client can use.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                      |
| <a href="#">SqlNetWalletOverride</a>               | Specifies whether the client overrides the strong authentication credential with the stored wallet password credential for the database connection |
| <a href="#">SSLCertificateThumbprint</a>           | Specifies the TLS/SSL certificate thumbprint in the certificate store for the ODP.NET connection to use                                            |
| <a href="#">SSLServerCertDN</a>                    | Sets the distinguished name (DN) string that will be used to validate the server certificate DN                                                    |

Table 6-46 (Cont.) OracleConnection Properties

| Property                                               | Description                                                                                                                                                                                                                                            |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SSLServerDNMatch</a>                       | Enables server certificate distinguished name (DN) validation                                                                                                                                                                                          |
| <a href="#">SSLVersion</a>                             | Enforces the connection to use a specific SSL/TLS version<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                         |
| <a href="#">State</a>                                  | Specifies the current state of the connection                                                                                                                                                                                                          |
| <a href="#">StatementCacheSize</a>                     | Specifies the current size of the statement cache associated with this connection                                                                                                                                                                      |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the <code>InvalidCastException</code> and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal<br><i>Not available in ODP.NET, Unmanaged Driver</i>                     |
| <a href="#">SwitchedConnection</a>                     | If the returned pooled connection changed its service name ( <code>ServiceName</code> ) or pluggable database ( <code>PDBName</code> ) in order to connect to the desired pluggable database, then this property will consider the connection switched |
| <a href="#">TAFMode</a>                                | Configures Transparent Application Failover behavior on the connection<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                            |
| <a href="#">TLSExcludeVersion</a>                      | Indicates which SSL/TLS versions connections should not be enabled for.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                           |
| <a href="#">TLSVersion</a>                             | Enforces the connection to use a specific SSL/TLS version<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                         |
| <a href="#">TnsAdmin</a>                               | Specifies the directory location of <code>tnsnames.ora</code> or <code>sqlnet.ora</code> , or both<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                |
| <a href="#">TokenAuthentication</a>                    | Sets the value for <code>TOKEN_AUTH</code> parameter for the connection<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                           |
| <a href="#">TokenLocation</a>                          | Gets or sets the token location path for the connection where the signature token and private key files are located<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                               |
| <a href="#">UseClientInitiatedCQN</a>                  | Specifies whether to use Client Initiated Continuous Query Notification (CICQN) or traditional Continuous Query Notification (CQN) that does not rely on a persistent connection<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                  |

Table 6-46 (Cont.) OracleConnection Properties

| Property                                            | Description                                                                                                                                                                                                                                                    |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">UseHourOffsetForUnsupportedTimezone</a> | Specifies whether the hour offset can be used for the session time zone, when the Oracle time zone region name that is associated with the .NET locale is not supported by the Oracle database being used<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">UseSNI</a>                              | Specifies whether to use Server Name Indication (SNI)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                     |
| <a href="#">WalletLocation</a>                      | Specifies the location of wallets. Wallets are certificates, keys, and trustpoints processed by SSL/TLS<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                   |
| <a href="#">WalletPassword</a>                      | Stores the password to decrypt the PKCS #12 wallet<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                        |

**OracleConnection Public Methods**

OracleConnection public methods are listed in [Table 6-47](#).

Table 6-47 OracleConnection Public Methods

| Public Method                               | Description                                                                                                                             |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">BeginRequest</a>                | Starts an explicit request boundary when using Application Continuity<br><i>Not available in ODP.NET, Unmanaged Driver</i>              |
| <a href="#">BeginSessionlessTransaction</a> | Starts a new sessionless transaction and returns its global transaction identifier<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">BeginTransaction</a>            | Begins a local transaction (Overloaded)                                                                                                 |
| <a href="#">ChangeDatabase</a>              | <i>Not Supported</i>                                                                                                                    |
| <a href="#">Clone</a>                       | Creates a copy of an OracleConnection object                                                                                            |
| <a href="#">Close</a>                       | Closes the database connection                                                                                                          |
| <a href="#">CreateCommand</a>               | Creates and returns an OracleCommand object associated with the OracleConnection object                                                 |
| CreateObjRef                                | Inherited from System.MarshalByRefObject                                                                                                |
| <a href="#">Commit()</a>                    | Commits the database transaction                                                                                                        |
| <a href="#">DisableReplay</a>               | Disables replay on the connection in Application Continuity<br><i>Not available in ODP.NET, Unmanaged Driver</i>                        |
| Dispose                                     | Inherited from System.ComponentModel.Component                                                                                          |
| <a href="#">EndRequest</a>                  | Indicates an ending explicit request boundary when using Application Continuity<br><i>Not available in ODP.NET, Unmanaged Driver</i>    |

Table 6-47 (Cont.) OracleConnection Public Methods

| Public Method                                | Description                                                                                                                                                  |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">EnlistDistributedTransaction</a> | Enables applications to explicitly enlist in a specified distributed transaction<br><i>Not supported in .NET Core</i>                                        |
| <a href="#">EnlistTransaction</a>            | Enables applications to enlist in a specified distributed transaction                                                                                        |
| Equals                                       | Inherited from System.Object (Overloaded)                                                                                                                    |
| <a href="#">FlushCache</a>                   | Flushes all updates and deletes made through REF objects retrieved using this connection<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| GetHashCode                                  | Inherited from System.Object                                                                                                                                 |
| GetLifetimeService                           | Inherited from System.MarshalByRefObject                                                                                                                     |
| <a href="#">GetSchema</a>                    | Returns schema information for the data source of the OracleConnection                                                                                       |
| <a href="#">GetSessionInfo</a>               | Returns or refreshes the property values of the OracleGlobalization object that represents the globalization settings of the session (Overloaded)            |
| GetType                                      | Inherited from System.Object                                                                                                                                 |
| InitializeLifetimeService                    | Inherited from System.MarshalByRefObject                                                                                                                     |
| <a href="#">Open</a>                         | Opens a database connection with the property settings specified by the ConnectionString                                                                     |
| <a href="#">OpenAsync</a>                    | Returns a Task-based asynchronous version of OracleConnection.Open (Overloaded)                                                                              |
| <a href="#">OpenWithNewClientSecret</a>      | Opens a new connection using a new Microsoft Entra ID client secret<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                     |
| <a href="#">OpenWithNewPassword</a>          | Opens a new connection with the new password (Overloaded)                                                                                                    |
| <a href="#">OpenWithNewPasswordAsync</a>     | A Task-based asynchronous version of OracleConnection.OpenWithNewPassword(), which opens a new connection with the new password. (Overloaded)                |
| <a href="#">OpenWithNewToken</a>             | This method can be used to open a new connection by providing the refreshed/updated access token directly to ODP.NET (Overloaded)                            |
| <a href="#">PurgeStatementCache</a>          | Flushes the Statement Cache by closing all open cursors on the database, when statement caching is enabled                                                   |
| <a href="#">ResumeSessionlessTransaction</a> | Resumes a sessionless transaction using the provided unique transaction identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                      |
| <a href="#">Rollback</a>                     | Rolls back the local transaction                                                                                                                             |
| <a href="#">Save(String)</a>                 | Creates a savepoint in the database                                                                                                                          |
| <a href="#">SetSessionInfo</a>               | Alters the session's globalization settings with the property values provided by the OracleGlobalization object                                              |

**Table 6-47 (Cont.) OracleConnection Public Methods**

| Public Method                                                        | Description                                                                                                                                                                                 |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SetShardingKey(OracleShardingKey, OracleShardingKey)</a> | Enables applications to set the sharding key and super sharding key before requesting a connection                                                                                          |
| <a href="#">SuspendSessionlessTransaction</a>                        | Suspends the active sessionless transaction immediately from the session.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                              |
| ToString                                                             | Inherited from System.Object                                                                                                                                                                |
| <a href="#">UseAzureTokenAuthentication</a>                          | Associates the Microsoft Entra ID token authentication settings with the OracleConnection object for use upon the next connection open<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">UseOciTokenAuthentication</a>                            | Associates the OCI IAM token authentication settings with the OracleConnection object for use upon the next connection open<br><i>Not available in ODP.NET, Unmanaged Driver</i>            |

**OracleConnection Events**

OracleConnection events are listed in [Table 6-48](#).

**Table 6-48 OracleConnection Events**

| Event Name                     | Description                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ConnectionOpen</a> | This event is triggered upon the OracleConnection.Open() method                                                               |
| Disposed                       | Inherited from System.ComponentModel.Component                                                                                |
| <a href="#">Failover</a>       | An event that is triggered when an Oracle failover occurs<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">HAEvent</a>        | An event that is triggered when an HA event occurs                                                                            |
| <a href="#">InfoMessage</a>    | An event that is triggered for any message or warning sent by the database                                                    |
| <a href="#">StateChange</a>    | An event that is triggered when the connection state changes                                                                  |

## OracleConnection Constructors

OracleConnection constructors instantiate new instances of the OracleConnection class.

**Overload List:**

- [OracleConnection\(\)](#)  
This constructor instantiates a new instance of the OracleConnection class using default property values.
- [OracleConnection\(string\)](#)  
This constructor instantiates a new instance of the OracleConnection class with the provided connection string.
- [OracleConnection\(string, OracleCredential\)](#)  
This constructor instantiates a new OracleConnection class instance using the provided connection string and OracleCredential class.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OracleConnection()

This constructor instantiates a new instance of the OracleConnection class using default property values.

**Declaration**

```
// C#  
public OracleConnection();
```

**Remarks**

The properties for OracleConnection are set to the following default values:

- ConnectionString = empty string
- ConnectionTimeout = 15 (default value of 0 is used for the implicit database connection)
- DataSource = empty string
- ServerVersion = empty string

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OracleConnection(string)

This constructor instantiates a new instance of the `OracleConnection` class with the provided connection string.

### Declaration

```
// C#  
public OracleConnection(string connectionString);
```

### Parameters

- *connectionString*  
The connection information used to connect to the Oracle database.

### Remarks

The `ConnectionString` property is set to the supplied *connectionString*. The `ConnectionString` property is parsed and an exception is thrown if it contains invalid connection string attributes or attribute values.

The properties of the `OracleConnection` object default to the following values unless they are set by the connection string:

- `ConnectionString` = empty string
- `ConnectionTimeout` = 15 (default value of 0 is used for the implicit database connection)
- `DataSource` = empty string
- `ServerVersion` = empty string

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OracleConnection(string, OracleCredential)

This constructor instantiates a new `OracleConnection` class instance using the provided connection string and `OracleCredential` class.

### Declaration

```
// C#  
public OracleConnection(string connectionString, OracleCredential orclCredential);
```

### Parameters

- *connectionString*  
connection string that does not contain any of user `id`, password, DBA Privilege, proxy user `id`, nor proxy password.

- `orclCredential`

OracleCredential object containing user credentials. If this parameter is passed as null then the behavior of OracleConnection will be same as OracleConnection with normal connection string.

### Remarks

Use this constructor to create a new OracleConnection object with an OracleCredential object containing user credentials and a connection string that does not contain any of user id, password, DBA Privilege, proxy user id, nor proxy password.

ODP.NET uses a modified connection pooling algorithm with OracleCredential, which is described in more detail in the section [Connection Pooling with OracleCredential](#).

### Exceptions

InvalidOperationException is raised when non-null OracleCredential object is used with a connection string containing any of user id, password, DBA Privilege, proxy user id, or proxy password.

## OracleConnection Static Methods

The OracleConnection static methods are listed in [Table 6-49](#).

**Table 6-49 OracleConnection Static Methods**

| Method                                            | Description                                                                                                                                            |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ClearAllPools</a>                     | Clears all connections from all the connection pools                                                                                                   |
| <a href="#">ClearPool</a>                         | Clears the connection pool that is associated with the provided OracleConnection object.                                                               |
| <a href="#">ClearInteractiveTokenCache</a>        | Clears the connection pool, Microsoft Entra ID, and OCI IAM access tokens from the ODP.NET cache.<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| Equals                                            | Inherited from System.Object (Overloaded)                                                                                                              |
| <a href="#">UnregisterCloudConfigNotification</a> | Unregisters an OracleConnection from receiving cloud provider change notifications<br><i>Not available in ODP.NET, Unmanaged Driver</i>                |

### ① See Also

- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ClearAllPools

This method clears all connections from all the connection pools.

### Declaration

```
// C#  
public static void ClearAllPools();
```

### Remarks

This call is analogous to calling `ClearPool` for all the connection pools that are created for the application.

For connection string URLs, this method removes all existing URLs from the ODP.NET cache. Upon the next connection attempt, ODP.NET will refresh the connection information from the centralized configuration provider.

### Exceptions

`InvalidOperationException` – No connection pool could be found for the application.

### Example

```
// C#  
// Sample demonstrating the use of ClearAllPools API in OracleConnection class  
  
using System;  
using Oracle.DataAccess.Client;  
  
class ClearAllPoolsSample  
{  
    static void Main()  
    {  
        Console.WriteLine("Running ClearAllPools sample..." );  
        // Set the connection string  
        string strConn = "User Id=scott;Password=tiger;Data Source=oracle;" +  
            "Min pool size=5;";  
        OracleConnection conn = new OracleConnection(strConn);  
  
        // Create another connection object with a different connection string  
        string strConnNew = "User Id=scott;Password=tiger;Data Source=oracle;";  
        OracleConnection connNew = new OracleConnection(strConnNew);  
  
        // Open the connections. Separate pools are created for conn and connNew  
        conn.Open();  
        connNew.Open();  
  
        // Clears the pools associated with conn and connNew  
        OracleConnection.ClearAllPools ();  
    }  
}
```

```
// cleanup
conn.Close();
connNew.Close();
Console.WriteLine("Done!");
}
}
```

- ["ClearPool"](#)

## ClearPool

This method clears the connection pool that is associated with the provided `OracleConnection` object.

### Declaration

```
// C#
public static void ClearPool(OracleConnection connection);
```

### Remarks

When this method is invoked, all idle connections are closed and freed from the pool. Currently used connections are not discarded until they are returned to the pool.

`ClearPool` does not automatically repopulate the pool with new connections. This prevents the pool from being repopulated with invalid connections if client remains unable to connect with the database server. Developers programmatically control when the pool is repopulated by calling `OracleConnection.Open()`, which will repopulate the pool with at least the Min Pool Size number of connections.

Connections created after this method invocation are not cleared unless another invocation is made.

Starting with ODP.NET 21c, `ClearPool` will now clear the pool even if ODP.NET is in the process of populating the pool to the Min Pool Size number of connections.

This method can be invoked with an `OracleConnection` object before opening the connection as well as after, provided the `ConnectionString` is properly set.

For connection string URLs, this method removes existing URLs from the ODP.NET cache. Upon the next connection attempt, ODP.NET will refresh the connection information from the centralized configuration provider.

### Exceptions

`InvalidOperationException` – Either the connection pool cannot be found or the provided connection string is invalid.

### Example

```
// C#
// Sample demonstrating the use of ClearPool API in OracleConnection class

using System;
using Oracle.DataAccess.Client;

class ClearPoolSample
{
    static void Main()
    {
        Console.WriteLine("Running ClearPool sample..." );
        // Set the connection string
        string strConn = "User Id=scott;Password=tiger;Data Source=oracle;" +
            "Min pool size=5;";
        OracleConnection conn = new OracleConnection(strConn);

        // Open the connection
        conn.Open();

        // Clears the connection pool associated with connection 'conn'
        OracleConnection.ClearPool (conn);

        // This connection will be placed back into the pool
        conn.Close ();

        // Open the connection again to create additional connections in the pool
        conn.Open();

        // Create a new connection object
        OracleConnection connNew = new OracleConnection(strConn);

        // Clears the pool associated with Connection 'connNew'
        // Since the same connection string is set for both the connections,
        // connNew and conn, they will be part of the same connection pool.
        // We need not do an Open() on the connection object before calling
        // ClearPool
        OracleConnection.ClearPool (connNew);

        // cleanup
        conn.Close();
        Console.WriteLine("Done!");
    }
}
```

## ClearInteractiveTokenCache

The static method clears the connection pool, Microsoft Entra ID, and OCI IAM access tokens from the ODP.NET cache.

### Declaration

```
// C#  
public void static ClearInteractiveTokenCache();
```

### Description

Invoking this method removes all the Microsoft Entra ID and OCI IAM access tokens from ODP.NET's cache so that they cannot be re-used when creating a new connection pool at the application level. Users will be prompted for login credentials upon the next connection request.

This method also clears the access token cache on the connection pool level, which means existing pools can not use the cached tokens.

Existing open connections do not use cached tokens and will continue to work. Only new connection requests have to acquire new cached tokens to connect.

## UnregisterCloudConfigNotification

This method unregisters an OracleConnection from receiving cloud provider change notifications.

### Declaration

```
// C#  
public static void UnregisterCloudConfigNotification(OracleConnection con);
```

### Remarks

This method unregisters connections that use connection URLs from receiving cloud provider change notifications. From a pooled connection, this method unregisters all connections within that pool. This method can be called from open or closed connections.

### Exceptions

None.

### Code Sample

```
// ODP.NET for Azure App Configuration code sample  
string connStr = "config-azure://myAppConfig?key=test/  
&SERVICE_BUS_HOST={serviceBusHost}&SERVICE_BUS_QUEUE={queueName}";  
OracleConnection conn = new OracleConnection(connStr);  
// Connection is opened and registered for change notifications  
conn.Open();  
  
// Unregister from change notifications  
OracleConnection.UnregisterCloudConfigNotifications(conn);
```

## OracleConnection Properties

OracleConnection properties are listed in [Table 6-50](#)

**Table 6-50 OracleConnection Properties**

| Property                                        | Description                                                                                                                                                                                                                         |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AccessToken</a>                     | Used to get or set OracleAccessToken on the connection                                                                                                                                                                              |
| <a href="#">ActionName</a>                      | Specifies the action name for the connection                                                                                                                                                                                        |
| <a href="#">AllowCertificateSelectionUI</a>     | Indicates whether to allow the user to select a specific TLS/SSL certificate via a graphical interface for their database connection when using a MCS wallet location<br><i>Not Available in ODP.NET, Unmanaged Driver</i>          |
| <a href="#">AutoCommit</a>                      | Specifies whether to commit each SQL statement implicitly or only until an explicit commit occurs                                                                                                                                   |
| <a href="#">AutoProxy</a>                       | Enables using a HTTPS proxy server for the ODP.NET connection                                                                                                                                                                       |
| <a href="#">BindByName</a>                      | Specifies the binding method in the collection<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                 |
| <a href="#">ChunkMigrationConnectionTimeout</a> | This setting pauses the connection request until the migration completes or fails to migrate in the specified time, then connect to the correct shard with the data requested.<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">ClientId</a>                        | Specifies the client identifier for the connection                                                                                                                                                                                  |
| <a href="#">ClientInfo</a>                      | Specifies the client information for the connection                                                                                                                                                                                 |
| <a href="#">ClientTimeZoneFileVersion</a>       | Returns the highest time zone file version in the TimeZoneFileLocation directory and embedded in ODP.NET                                                                                                                            |
| <a href="#">CommandTimeout</a>                  | Specifies the number of seconds the command is allowed to execute before terminating the execution with an exception<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                           |
| <a href="#">ConnectionIdPrefix</a>              | Identifies a particular application's connections by appending its string to the connection identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                         |
| <a href="#">ConnectionString</a>                | Specifies connection information or URL used to connect to an Oracle database                                                                                                                                                       |

Table 6-50 (Cont.) OracleConnection Properties

| Property                                    | Description                                                                                                                                                                                                                       |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ConnectionTimeout</a>           | Indicates the maximum amount of time that the Open method can take to obtain a pooled connection before the request is terminated                                                                                                 |
| <a href="#">ConnectionType</a>              | Determines whether a particular connection object is associated with a TimesTen database connection, an Oracle database connection, or no physical connection<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| Container                                   | Inherited from System.ComponentModel.Component                                                                                                                                                                                    |
| <a href="#">Credential</a>                  | Used to get or set an OracleCredential object on the connection                                                                                                                                                                   |
| <a href="#">Database</a>                    | <i>Not Supported</i>                                                                                                                                                                                                              |
| <a href="#">DatabaseCharset</a>             | Specifies the CHAR database character set on the connection and is used to optimize connection establishment<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                 |
| <a href="#">DatabaseNCharset</a>            | Specifies the NCHAR database character set on the connection and is used to optimize connection establishment<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                |
| <a href="#">DatabaseDomainName</a>          | Specifies the name of the database domain to which the connection is set                                                                                                                                                          |
| <a href="#">DatabaseEditionName</a>         | Sets or gets the edition name for the OracleConnection object                                                                                                                                                                     |
| <a href="#">DatabaseMaxIdentifierLength</a> | Specifies the maximum identifier length the connection supports                                                                                                                                                                   |
| <a href="#">DatabaseName</a>                | Specifies the name of the database to which the connection is set                                                                                                                                                                 |
| <a href="#">DatabaseTimeZoneFileVersion</a> | Returns the database's time zone file version                                                                                                                                                                                     |
| <a href="#">DataSource</a>                  | Specifies the Oracle Net Services Name, Connect Descriptor, or an easy connect naming that identifies the database to which to connect                                                                                            |
| <a href="#">DRCPConnectionClass</a>         | Specifies a logical name that identifies the DRCP connection pool that the ODP.NET connection will use                                                                                                                            |
| <a href="#">DRCPPurity</a>                  | Specifies whether an application can reuse a pooled session (Pooled) or must use a new session (New)                                                                                                                              |
| <a href="#">FetchSize</a>                   | Specifies the total memory size, in bytes, that the provider allocates to cache data fetched in one database round-trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                      |
| <a href="#">HostName</a>                    | Specifies the name of the host to which the connection is set                                                                                                                                                                     |

Table 6-50 (Cont.) OracleConnection Properties

| Property                               | Description                                                                                                                                        |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">HttpsProxy</a>             | Specifies the HTTPS proxy server                                                                                                                   |
| <a href="#">HttpsProxyPort</a>         | Specifies the HTTPS proxy server port number                                                                                                       |
| <a href="#">InstanceName</a>           | Specifies the name of the instance to which the connection is set                                                                                  |
| <a href="#">IsInTransaction</a>        | Specifies if the current application is in a transaction                                                                                           |
| <a href="#">IsNNEChecksummed</a>       | Indicates if the connection uses Oracle Database Native Network Encryption (NNE) checksumming<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">IsNNEEncrypted</a>         | Indicates if the connection uses Oracle Database Native Network Encryption (NNE).<br><i>Not Available in ODP.NET, Unmanaged Driver</i>             |
| <a href="#">IsTLSEncrypted</a>         | Indicates if the connection uses TCPS, SSL, or TLS<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                            |
| <a href="#">KeepAlive</a>              | Specifies whether to keep an idle connection alive.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                           |
| <a href="#">KeepAliveInterval</a>      | Specifies the time interval after an unacknowledged probe before a new probe is sent.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>         |
| <a href="#">KeepAliveTime</a>          | Specifies the idle time before a keepalive probe is sent.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                     |
| <a href="#">MaxStatementCacheSize</a>  | Specifies the maximum number of statements that can be cached when self-tuning is enabled<br><i>Not Available in ODP.NET, Unmanaged Driver</i>     |
| <a href="#">ModuleName</a>             | Specifies the module name for the connection                                                                                                       |
| <a href="#">NamesDirectoryPath</a>     | Specifies the naming method order used for client name resolution lookups                                                                          |
| <a href="#">OciCompartment</a>         | Gets or sets the Oracle Cloud Identifier (OCID) of the target database's compartment                                                               |
| <a href="#">OciDatabase</a>            | Gets or sets the target database's Oracle Cloud Identifier (OCID)                                                                                  |
| <a href="#">OciIamUrl</a>              | Gets or sets the URL end point for getting the database token                                                                                      |
| <a href="#">OciTenacy</a>              | Gets or sets the Oracle Cloud Identifier (OCID) of the IAM user's cloud tenancy to retrieve the database token                                     |
| <a href="#">PasswordAuthentication</a> | Sets the connection PASSWORD_AUTH parameter value                                                                                                  |
| <a href="#">PDBName</a>                | Used to set and get the name of the pluggable database to which the session is connected to                                                        |

Table 6-50 (Cont.) OracleConnection Properties

| Property                                           | Description                                                                                                                                                                    |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Pipelining</a>                         | Enables asynchronous execution on the database server side<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                |
| <a href="#">PoolName</a>                           | Specifies the name that uniquely identifies the pool in .NET metrics or performance counters.<br><i>Not available in ODP.NET, Unmanaged Driver and ODP.NET, Managed Driver</i> |
| <a href="#">ProviderName</a>                       | Specifies the ODP.NET provider type and version<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                           |
| <a href="#">ProviderNuGetVersion</a>               | Specifies the ODP.NET NuGet version number<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                |
| <a href="#">ProviderVersion</a>                    | Specifies the ODP.NET assembly version                                                                                                                                         |
| <a href="#">RemoteConfigurationFiltering</a>       | Specifies whether local configuration file access, such as to wallet and tnsnames.ora files, is allowed from centralized configuration providers                               |
| <a href="#">Roles</a>                              | Retrieves the OracleRoleCollection object associated with the connection.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                 |
| <a href="#">RowsToFetchPerRoundTrip</a>            | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                    |
| <a href="#">SDU</a>                                | Specifies the session data unit size (SDU) for Oracle networking communication between client and server                                                                       |
| <a href="#">ServerVersion</a>                      | Specifies the version number of the Oracle database to which the OracleConnection has established a connection                                                                 |
| <a href="#">ServiceName</a>                        | Specifies the name of the service to which the connection is set                                                                                                               |
| <a href="#">ServiceRelocationConnectionTimeout</a> | Specifies the time to wait before retrying connecting to a service that becomes unavailable<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                               |
| <a href="#">SessionlessTransactionOptions</a>      | Indicates the sessionless transaction options<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                             |
| <a href="#">SessionlessTransactionId</a>           | Returns the sessionless transaction identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                            |
| Site                                               | Inherited from System.ComponentModel.Component                                                                                                                                 |
| <a href="#">SqlNetAllowedLogonVersionClient</a>    | Specifies the minimum authentication protocol that is to be used for a given OracleConnection object                                                                           |
| <a href="#">SqlNetAuthenticationServices</a>       | This property enables one or more authentication services, such as TCP/IP with SSL.                                                                                            |
| <a href="#">SqlNetEncryptionClient</a>             | Specifies the encryption client behavior<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                  |

Table 6-50 (Cont.) OracleConnection Properties

| Property                                               | Description                                                                                                                                                                                                                                             |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SqlNetEncryptionTypesClient</a>            | Specifies encryption algorithms that the client can use.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                           |
| <a href="#">SqlNetCryptoChecksumClient</a>             | Specifies the checksum client behavior.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                            |
| <a href="#">SqlNetCryptoChecksumTypesClient</a>        | Specifies the checksum algorithms the client can use.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                              |
| <a href="#">SqlNetWalletOverride</a>                   | Specifies whether the client overrides the strong authentication credential with the stored wallet password credential for the database connection                                                                                                      |
| <a href="#">SSLCertificateThumbprint</a>               | Specifies the TLS/SSL certificate thumbprint in the certificate store for the ODP.NET connection to use                                                                                                                                                 |
| <a href="#">SSLServerCertDN</a>                        | Sets the distinguished name (DN) string that will be used to validate the server certificate DN                                                                                                                                                         |
| <a href="#">SSLServerDNMatch</a>                       | Enables server certificate distinguished name (DN) validation                                                                                                                                                                                           |
| <a href="#">SSLVersion</a>                             | Enforces the connection to use a specific SSL/TLS version<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                          |
| <a href="#">State</a>                                  | Specifies the current state of the connection                                                                                                                                                                                                           |
| <a href="#">StatementCacheSize</a>                     | Specifies the current size of the statement cache associated with this connection                                                                                                                                                                       |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the <code>InvalidCastException</code> and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal<br><i>Not available in ODP.NET, Unmanaged Driver</i>                      |
| <a href="#">SwitchedConnection</a>                     | If the returned pooled connection changed its service name ( <code>ServiceName</code> ) or pluggable database ( <code>PDBName</code> ) in order to connect to the desired pluggable database, then this property will consider the connection switched. |
| <a href="#">TAFMode</a>                                | Configures Transparent Application Failover behavior on the connection<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                             |
| <a href="#">TLSExcludeVersion</a>                      | Indicates which SSL/TLS versions connections should not be enabled for.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                            |
| <a href="#">TLSVersion</a>                             | Enforces the connection to use a specific SSL/TLS version<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                          |
| <a href="#">TnsAdmin</a>                               | Specifies the directory location of <code>tnsnames.ora</code> or <code>sqlnet.ora</code> , or both<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                 |

Table 6-50 (Cont.) OracleConnection Properties

| Property                                            | Description                                                                                                                                                                                                                                                    |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">TokenAuthentication</a>                 | Sets the value for TOKEN_AUTH parameter for the connection<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                |
| <a href="#">TokenLocation</a>                       | Gets or sets the token location path for the connection where the signature token and private key files are located<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                       |
| <a href="#">UseClientInitiatedCQN</a>               | Specifies whether to use Client Initiated Continuous Query Notification (CICQN) or traditional Continuous Query Notification (CQN) that does not rely on a persistent connection<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                          |
| <a href="#">UseHourOffsetForUnsupportedTimezone</a> | Specifies whether the hour offset can be used for the session time zone, when the Oracle time zone region name that is associated with the .NET locale is not supported by the Oracle database being used<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">UseSNI</a>                              | Specifies whether to use Server Name Indication (SNI)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                     |
| <a href="#">WalletLocation</a>                      | Specifies the location of wallets. Wallets are certificates, keys, and trustpoints processed by SSL/TLS<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                   |
| <a href="#">WalletPassword</a>                      | Stores the password to decrypt the PKCS #12 wallet<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                        |

## AccessToken

This property is used to get or set OracleAccessToken on the connection.

### Declaration

```
// C#
public OracleAccessToken AccessToken { get; set; }
```

### Property Value

An `OracleAccessToken` object containing a database token and private key, or an access token, used for opening a connection.

### Exceptions

- An `InvalidOperationException` will be raised if
  - the connection is already open,
  - the value of the `TokenAuthentication` property is not compatible with the type of token being set. This is applicable for managed ODP.NET and ODP.NET Core only,
  - `TokenAuthentication` has been set by the application as disabled, or the `TokenLocation` property is set. This is applicable for managed ODP.NET and ODP.NET Core only.
  - the `Credential` property is set,
  - the user or proxy information in the connection string is not compatible with token authentication,
  - user id value is other than /,
  - password, proxy user id, and proxy password is set.
- `ArgumentNullException` if any argument is null.

### Description

If the token represents the same identity, then the same `OracleAccessToken` object should be set on the `OracleConnection`. The `OracleAccessToken` object, not the token, is used to identify the connection pool.

If an access token has expired, then `OracleConnection.OpenWithNewToken` must be called to open a new connection. Since the `OracleAccessToken` object cannot be modified, it is not possible to specify a refreshed access token on the `AccessToken` property. However, existing connections can still be dispensed, even after the access token has expired.

In unmanaged ODP.NET, if `CPVersion` is not set to any value, `AccessToken` property is set by the application, and `Open()` method is invoked, then the connection will set the value of `CPVersion` to 2.0. `CPVersion` cannot be set to 1.0 in this scenario. Doing so will result in an exception.

## ActionName

This property specifies the action name for the connection.

**Declaration**

```
// C#  
public string ActionName {set;}
```

**Property Value**

The string to be used as the action name.

**Remarks**

The default value is null.

Using the ActionName property allows the application to set the action name in the application context for a given OracleConnection object.

For unmanaged ODP.NET with CPVersion = 1.0, the ActionName property is reset to null upon the next server roundtrip following a Close or Dispose method call on the OracleConnection object. For all other ODP.NET provider types and CPVersion settings, ActionName property is reset to null when the Close or Dispose method is called on the OracleConnection object.

## AllowCertificateSelectionUI

This property indicates whether to allow the user to select a specific TLS/SSL certificate via a graphical interface for their database connection when using a MCS wallet location.

**Declaration**

```
// C#  
public Boolean AllowCertificateSelectionUI { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

The property default value is false.

This property generates a pop up window for the end user to select a TLS/SSL certificate only when all of the following conditions are met:

- AllowCertificateSelectionUI is set to true
- App is running on Windows operating system

- App has specified a Microsoft Certificate Store (MCS) wallet location
- The connection uses mutual TLS
- There is more than one private key containing certificates in the MY/CurrentUser MCS

If `AllowCertificateSelectionUI` is false and configuration-based certificate selection is not set (e.g. thumbprint is not set), then ODP.NET will choose the first certificate with a private key in the MCS.

If enabling this property, set its value to true prior to opening the ODP.NET connection.

ODP.NET will filter out trusted certificates (public key only) from the end user display to simplify their selection process.

After a certificate is selected in the user interface, it is cached via a key. The key value consists of the connection string, database server host, and port number. The cache can be cleared by calling the `ClearAllPools()` method.

To specify the certificate via a thumbprint instead of a graphical interface, use the `OracleConfiguration` or `OracleConnection.SSLCertificateThumbprint` property.

## AutoCommit

This property specifies whether to commit each SQL statement implicitly or only until an explicit commit occurs.

### Declaration

```
// C#  
public bool AutoCommit {get; set;}
```

### Property Value

Bool

### Exception

`System.ObjectDisposedException` – This property cannot be accessed after the `OracleConnection` object is already disposed.

### Remarks

By default, this property is set to true, which commits each SQL statement implicitly.

This property can be set before or after the connection opens.

If the `AutoCommit` property is toggled from false to true, the current transaction is committed.

When an explicit transaction is created, this property will be set to false. Once the explicit transaction is committed or rolled back, the property value reverts to the originally set `AutoCommit` value.

If a local transaction is already started implicitly, invoking `BeginTransaction()` will inherit the transaction that was implicitly started.

If the transaction is created explicitly using `BeginTransaction()`, the transaction can be operated on either through the `OracleConnection` methods or `OracleTransaction` methods. But once the transaction is over via a `Commit()` or a `Rollback()` invoked on either object, the `OracleTransaction` cannot be used henceforth.

If the `OracleConnection` object is closed while an implicit transaction is underway, the transaction is rolled back. After the `AutoCommit` property is set, that setting is honored for all subsequent `Open()` calls on that specific `OracleConnection` object until the `AutoCommit` value is modified.

## AutoProxy

This property enables using a HTTPS proxy server for the ODP.NET connection.

### Declaration

```
// C#  
public bool AutoProxy {get; set;}
```

### Property Type

`System.Boolean`

### Remarks

Default is null. When set to false or null, `OracleConnection` `HttpsProxy` and `HttpsProxyPort` properties are used for the HTTPS proxy server configuration.

If set to true, the default or system proxy server is used as the HTTPS proxy server. `HttpsProxy` and `HttpsProxyPort` are then ignored.

#### See Also

## BindByName

This property specifies whether the binding method used for the parameter collection is by name or by position on a particular `OracleConnection` object.

### Declaration

```
// C#  
public bool BindByName { get; set;}
```

### Property Type

`System.Boolean`

### Property Value

Returns `true` if the parameters are bound by name; returns `false` if the parameters are bound by position.

### Exceptions

`System.ObjectDisposedException` - This property cannot be accessed after the `OracleConnection` object is already disposed.

### Remarks

The default value is `false`.

`BindByName` is ignored under the following conditions:

- The value of the `XmlCommandType` property is `Insert`, `Update`, or `Delete`.
- The value of the `XmlCommandType` property is `Query`, but there are no parameters set on the `OracleCommand`.

If the `OracleCommand` `XmlCommandType` property is `OracleXmlCommandType.Query` and any parameters are set on the `OracleCommand`, then its `BindByName` property must be set to `true`. Otherwise, the following `OracleCommand` methods throw an `InvalidOperationException`.

- `ExecuteNonQuery`
- `ExecuteXmlReader`
- `ExecuteStream`
- `ExecuteToStream`

The `BindByName` property can be configured on `OracleCommand`, `OracleConnection`, and `OracleConfiguration` objects. By default, `OracleConnection` `BindByName` property value inherits `OracleConfiguration` `BindByName` property value at construction time; `OracleCommand` `BindByName` property value inherits `OracleConnection` `BindByName` property value at construction time. The value of `OracleCommand` `BindByName` will be used to determine the binding method during command execution.

## ChunkMigrationConnectionTimeout

In sharding, a connection request to a specific shard can occur while data is migrating from the original shard to a new one. This setting will pause the connection request until the migration completes or fails to migrate in the specified time, then connect to the correct shard with the data requested.

### Declaration

```
// C#  
public int ChunkMigrationConnectionTimeout {get;set;}
```

### Property Value

The maximum time, in seconds, for a pooled connection request to pause waiting for a chunk migration or split partitionset for a particular chunk.

### Remarks

If a specific shard connection request occurs while data is migrating to a new shard or being split and moved to a new shard through a split partitionset operation, then this setting pauses the connection request until the data migration completes or fails in the specified time. It then connects to the correct shard with the data requested.

Default is 120 seconds. This setting requires connection pooling to be enabled.

ODP.NET reads the chunk migration connection timeout setting only upon pool creation. A new timeout setting will not be used until a new pool is created.

This setting is in effect if

- write access is required and a chunk is read-only, or
- during a chunk migration or split partitionset, the chunk becomes unavailable to read.

If the connection requires only read-only access, then this setting will not be used unless the chunk becomes unavailable.

If the connection requires write access and the chunk does not become writable or available before the chunk migration connection timeout expires, then a new connection will be created. If the connection cannot be created, then an `OracleException` will occur.

During chunk migration or split partitionset, an ODP.NET connection request obeys only the chunk migration connection timeout. All other connection timeout values, such as `OracleConnection.ConnectionTimeout`, are ignored.

Oracle recommends setting the ODP.NET chunk migration connection timeout to a value greater than the chunk move server timeout. One way to set this server timeout is using the Global Data Services Control Utility (GDSCCTL) `move chunk` command's `timeout` option. This server-side timeout only applies to chunk migrations, not split partitionset.

The OracleConnection ChunkMigrationConnectionTimeout property inherits from the OracleConfiguration ChunkMigrationConnectionTimeout property. The OracleConnection property can be separately set to override the property set in the OracleConfiguration class.

## ClientId

This property specifies the client identifier for the connection.

### Declaration

```
// C#  
public string ClientId {set;}
```

### Property Value

The string to be used as the client identifier.

### Remarks

The default value is null.

Using the ClientId property allows the application to set the client identifier in the application context for a given OracleConnection object.

For unmanaged ODP.NET with CPVersion = 1.0, the ClientId property is reset to null upon the next server roundtrip following a Close or Dispose method call on the OracleConnection object. For all other ODP.NET provider types and CPVersion settings, ClientId property is reset to null when the Close or Dispose method is called on the OracleConnection object.

## ClientInfo

This property specifies the client information for the connection.

**Declaration**

```
// C#  
public string ClientInfo {set;}
```

**Property Value**

The string to be used as the client information.

**Remarks**

The default value is null.

Using the ClientInfo property allows the application to set the client information in the application context for a given OracleConnection object.

For unmanaged ODP.NET with CPVersion = 1.0, the ClientInfo property is reset to null upon the next server roundtrip following a Close or Dispose method call on the OracleConnection object. For all other ODP.NET provider types and CPVersion settings, ClientInfo property is reset to null when the Close or Dispose method is called on the OracleConnection object.

## ClientTimeZoneFileVersion

This property returns the highest time zone file version in the TimeZoneFileLocation directory and embedded in ODP.NET.

**Declaration**

```
// C#  
public string ClientTimeZoneFileVersion {get;}
```

**Property Type**

int

**Exception**

InvalidOperationException - The connection is not in an open state.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## CommandTimeout

This property specifies the minimum number of seconds that the command is allowed to execute before terminating with an exception on a particular `OracleConnection` object.

### Declaration

```
// C#  
public int CommandTimeout { get; set;}
```

### Property Type

`System.Int32`

### Exceptions

`InvalidArgument` - The specified value is less than 0 or greater than `System.Int32.MaxValue`.

`System.ObjectDisposedException` - This property cannot be accessed after the `OracleConnection` object is already disposed.

### Remarks

Default is 0 (seconds), which enforces no time limit.

When the specified timeout value expires before a command execution finishes, ODP.NET will begin the process of canceling the command. If cancellation is successful, then an exception is thrown with the message: ORA-01013: user requested cancel of current operation. Other possible exceptions thrown after a command timeout expiration occurs include ORA-00936 and ORA-00604. If the command is executed in time without any errors, then no exceptions are thrown.

ODP.NET does not guarantee a command will be cancelled at the exact moment the timeout value is reached. The timeout value is the minimum time to allow a command to complete before the cancellation process begins. It is possible for commands to complete after the timeout value expires.

In a situation where multiple `OracleCommand` objects use the same connection, the timeout expiration on one of the `OracleCommand` objects may terminate any of the executions on the single connection. To make the timeout expiration of a `OracleCommand` cancel only its own command execution, simply use one `OracleCommand` for each connection if that `OracleCommand` sets the `CommandTimeout` property to a value greater than 0.

The `CommandTimeout` property can be configured on `OracleCommand`, `OracleConnection`, and `OracleConfiguration` objects. By default, `OracleConnection` `CommandTimeout` property value inherits `OracleConfiguration` `CommandTimeout` property value at construction time; `OracleCommand` `CommandTimeout` property value inherits `OracleConnection` `CommandTimeout` property value at construction time. The value of `OracleCommand` `CommandTimeout` will be used during command execution.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- [OracleConnection Members](#)

## ConnectionIdPrefix

This property is used to identify a particular application's connections by appending its string to the connection identifier. The identifier and prefix can be used to uniquely identify the application connections for tracing and diagnosis purposes.

**Declaration**

```
// C#  
public string ConnectionIdPrefix { set; }
```

**Property Value**

System.String

**Remarks**

The property value is an 8-byte identifier limited to alphanumeric characters and underscore (\_).

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ConnectionString

This property specifies connection information or URL used to connect to an Oracle database.

**Declaration**

```
// C#  
public override string ConnectionString { get; set; }
```

**Property Value**

If the connection string is supplied through the constructor, this property is set to that string.

**Implements**

IDbConnection

## Exceptions

`ArgumentException` - An invalid syntax is specified for the connection string.

`InvalidOperationException` - `ConnectionString` is being set while the connection is open.

## Remarks

The default value is an empty string.

`ConnectionString` must be a connection string URL or a string of attribute name and value pairings, separated by a semi-colon, for example:

```
"User Id=scott;password=tiger;data source=oracle"
```

Connection string URLs are used with centralized configuration providers.

If the `ConnectionString` is not in a proper format, an exception is thrown. All spaces are ignored unless they are within double quotes.

When the `ConnectionString` property is set, the `OracleConnection` object immediately parses the string for errors. An `ArgumentException` is thrown if the `ConnectionString` contains invalid attributes or invalid values. Attribute values for User Id, Password, Proxy User Id, Proxy Password, and Data Source (if provided) are not validated until the `Open` method is called.

The connection must be closed to set the `ConnectionString` property. When the `ConnectionString` property is reset, all previously set values are reinitialized to their default values before the new values are applied.

Starting with ODP.NET 11.1, password and proxy password connection string attribute values are accepted as case-sensitive strings. Thus, they are passed to the database for authentication in the case provided in the connection string. Therefore, if the database is configured to support case-sensitive passwords, passwords must be passed in the correct case.

If a connection string attribute is set more than once, the last setting takes effect and no exceptions are thrown.

Boolean connection string attributes can be set to either `true`, `false`, `yes`, or `no`.

## Supported Connection String Attributes

[Table 6-51](#) lists the supported connection string attributes.

**Table 6-51 Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                            | Default Value |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Application Continuity      | Enables database requests to automatically replay transactional or non-transactional operations in a non-disruptive and rapid manner in the event of a severed database session, which results in a recoverable error. | true          |

**Table 6-51 (Cont.) Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Default Value |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Connection Lifetime         | <p>Minimum life time (in seconds) of the connection.</p> <p>This attribute specifies the lifetime of the connection in seconds. Before the <code>Connection</code> is placed back into the pool upon a <code>Close()</code> or <code>Dispose()</code> call, the lifetime of the connection is checked. If the lifetime of the connection exceeds this property value and the number of connections will not fall below <code>Min Pool Size</code>, then the connection is destroyed. If this property value is 0, then the connection lifetime is never checked.</p>                                                                                                                                                                                                                      | 0             |
| Connection Timeout          | <p>The time to wait (in seconds) for a new connection or an idle connection from the connection pool before a connection time out error can occur.</p> <p>This attribute specifies the minimum amount of time (in seconds) that the <code>Open()</code> method must take to obtain a pooled connection before it terminates the request. This value comes into effect only if no free connection is available from the connection pool and the <code>Max Pool Size</code> is reached. If a free connection is not available within the specified time, an exception is thrown. <code>Connection Timeout</code> does not limit the time required to open new connections.</p> <p>This attribute value takes effect for pooled connection requests and not for new connection requests.</p> | 15            |
| Data Source                 | Oracle Net Services Name, Connect Descriptor, or an easy connect naming that identifies the database to which to connect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | empty string  |
| DBA Privilege               | <p>Administrative privileges.</p> <p>This connection string attribute accepts <code>SYSASM</code>, <code>SYSBACKUP</code>, <code>SYSDBA</code>, <code>SYSDG</code>, <code>YSKM</code>, <code>SYSOPER</code>, and <code>SYSRAC</code> as the attribute value. It is case-insensitive.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | empty string  |
| Decr Pool Size              | <p>Number of connections that are closed when an excessive amount of established connections are unused.</p> <p>This connection string attribute controls the maximum number of unused connections that are closed when the pool regulator makes periodic checks. The regulator thread is spawned every 3 minutes and closes up to <code>Decr Pool Size</code> amount of pooled connections if they are not used. The pool regulator never takes the total number of connections below the <code>Min Pool Size</code> by closing pooled connections.</p>                                                                                                                                                                                                                                  | 1             |

**Table 6-51 (Cont.) Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Default Value     |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Enlist                      | Controls the enlistment behavior and capabilities of a connection in context of COM+ transactions or System.Transactions.<br><br>If this attribute is set to <code>true</code> , the connection is automatically enlisted in the thread's transaction context. If this attribute is <code>false</code> , no enlistments are made. If this attribute is set to <code>dynamic</code> , applications can dynamically enlist in distributed transactions. This attribute can be set to <code>true</code> , <code>false</code> , <code>yes</code> , <code>no</code> , or <code>dynamic</code> . | <code>true</code> |
| HA Events                   | Enables ODP.NET connection pool to proactively remove connections from the pool when an Oracle database service, service member, or node goes down.<br><br>This feature can be used with Global Data Services, including Oracle RAC, Data Guard, GoldenGate, and single instance deployments. " <code>pooling=true</code> " must also be set<br><br>This attribute can be set to <code>true</code> , <code>false</code> , <code>yes</code> , or <code>no</code> .                                                                                                                          | <code>true</code> |
| Load Balancing              | Enables ODP.NET connection pool to balance work requests across Oracle database instances based on the load balancing advisory and service goal.<br><br>This feature can be used with Global Data Services, including Oracle RAC, Active Data Guard, and GoldenGate. " <code>pooling=true</code> " must also be set.<br><br>This attribute can be set to <code>true</code> , <code>false</code> , <code>yes</code> , or <code>no</code> .                                                                                                                                                  | <code>true</code> |
| Incr Pool Size              | Number of new connections to be created when all connections in the pool are in use.<br><br>This connection string attribute determines the number of new connections that are established when a pooled connection is requested, but no unused connections are available and Max Pool Size is not reached. If new connections have been created for a pool, the regulator thread skips a cycle and does not have an opportunity to close any connections for 6 minutes. Note, however, that some connections can be still be closed during this time if their lifetime has been exceeded. | 5                 |
| Max Pool Size               | Maximum number of connections in a pool.<br><br>This attribute specifies the maximum number of connections allowed in the particular pool used by that OracleConnection. Simply changing this attribute in the connection string does not change the Max Pool Size restriction on a currently existing pool. Doing so simply creates a new pool with a different Max Pool Size restriction. This attribute must be set to a value greater than the Min Pool Size. This value is ignored unless Pooling is turned on.                                                                       | 100               |

**Table 6-51 (Cont.) Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Default Value |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Metadata Pooling            | Caches metadata information.<br>This attribute indicates whether or not metadata information for executed queries are cached for improved performance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | True          |
| Min Pool Size               | Minimum number of connections in a pool.<br>This attribute specifies the minimum number of connections to be maintained by the pool during its entire lifetime. Simply changing this attribute in the connection string does not change the Min Pool Size restriction on a currently existing pool. Doing so simply creates a new pool with a different Min Pool Size restriction. This value is ignored unless Pooling is turned on.                                                                                                                                                                                                                           | 1             |
| Password                    | Password for the user specified by User Id.<br>This attribute specifies an Oracle user's password. Password is case-sensitive by default for Oracle Database 11g release 1 (11.1) and later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | empty string  |
| Persist Security Info       | Retrieval of the password in the connection string.<br>If this attribute is set to false, the Password value setting is not returned when the application requests the ConnectionString after the connection is successfully opened by the Open() method. This attribute can be set to either true, false, yes, or no.                                                                                                                                                                                                                                                                                                                                          | false         |
| Pooling                     | Connection pooling.<br>This attribute specifies whether or not connection pooling is to be used. Pools are created using an attribute value matching algorithm. This means that connection strings which only differ in the number of spaces in the connection string use the same pool. If two connection strings are identical except that one sets an attribute to a default value while the other does not set that attribute, both requests obtain connections from the same pool. This attribute can be set to either true, false, yes, or no.                                                                                                            | true          |
| Proxy User Id               | User name of the proxy user.<br>This connection string attribute specifies the middle-tier user, or the proxy user, who establishes a connection on behalf of a client user specified by the User Id attribute. ODP.NET attempts to establish a proxy connection if either the Proxy User Id or the Proxy Password attribute is set to a non-empty string.<br>For the proxy user to connect to an Oracle database using operating system authentication, the Proxy User Id must be set to "/". The Proxy Password is ignored in this case. The User Id cannot be set to "/" when establishing proxy connections. The case of this attribute value is preserved. | empty string  |

**Table 6-51 (Cont.) Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Default Value |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Proxy Password              | <p>Password of the proxy user.</p> <p>This connection string attribute specifies the password of the middle-tier user or the proxy user. This user establishes a connection on behalf of a client user specified by the User Id attribute. ODP.NET attempts to establish a proxy connection if either the Proxy User Id or the Proxy Password attribute is set to a non-empty string.</p> <p>The case of this attribute value is preserved if it is surrounded by double quotes.</p> | empty string  |
| Statement Cache Purge       | <p>Statement cache purged when the connection goes back to the pool.</p> <p>If statement caching is enabled, setting this attribute to <code>true</code> purges the Statement Cache when the connection goes back to the pool.</p>                                                                                                                                                                                                                                                   | false         |
| Statement Cache Size        | <p>Statement cache enabled and cache size set size, that is, the maximum number of statements that can be cached.</p> <p>A value greater than zero enables statement caching and sets the cache size to itself. This value should not be greater than the value of the <code>OPEN_CURSORS</code> parameter set in the <code>init.ora</code> database configuration file.</p>                                                                                                         | 0             |
| Self Tuning                 | <p>Enables or disables self-tuning for the connection.</p> <p>If self-tuning is enabled, then the <code>StatementCacheSize</code> settings in the registry, configuration files, and connection string are ignored.</p> <p>If self-tuning is disabled, then a <code>StatementCacheSize</code> value of 0 is used unless <code>StatementCachSize</code> is specified in the registry, configuration file, or connection string.</p>                                                   | true          |
| Tns_Admin                   | <p>Directory where ODP.NET can find its <code>sqlnet.ora</code> and <code>tnsnames.ora</code> configuration files.</p> <p><i>Not available in ODP.NET, Unmanaged Driver</i></p>                                                                                                                                                                                                                                                                                                      | empty string  |
| Token_Auth                  | <p>This attribute specifies the access token authentication type. Possible values are:</p> <p>AZURE_INTERACTIVE,<br/>AZURE_SERVICE_PRINCIPAL,<br/>AZURE_MANAGED_IDENTITY,<br/>AZURE_DEVICE_CODE,<br/>AZURE_DEFAULT,<br/>OCITOKEN,<br/>OAUTH, or<br/>DISABLED.</p> <p>Only supported for managed ODP.NET and ODP.NET Core.</p>                                                                                                                                                        | DISABLED      |

**Table 6-51 (Cont.) Supported Connection String Attributes**

| Connection String Attribute | Description                                                                                                                                                                                                                                                                                                                      | Default Value                                 |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Token_Location              | This attribute is the file-based token location. The value can be a directory where a file named "token" is or it can be the file's full path specification.<br>Only supported for managed ODP.NET and ODP.NET Core.                                                                                                             | Varies depending on token authentication type |
| User Id                     | Oracle user name.<br><br>This attribute specifies the Oracle user name. The case of this attribute value is preserved if it is surrounded by double quotes. For the user to connect to an Oracle database using operating system authentication, set the User Id to "/". Any Password attribute setting is ignored in this case. | empty string                                  |
| Validate Connection         | Validation of connections coming from the pool.<br><br>Validation causes a round-trip to the database for each connection. Therefore, it should only be used when necessary.                                                                                                                                                     | false                                         |
| Wallet_Location             | ODP.NET wallet directory<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                    | empty string                                  |
| Wallet_Password             | Stores PKCS #12 wallet password<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                             | empty string                                  |

## ConnectionTimeout

This property indicates the minimum amount of time that the Open method can take to obtain a pooled connection before the request is terminated.

**Declaration**

```
// C#
public override int ConnectionTimeout {get;}
```

**Property Value**

The minimum time allowed for a pooled connection request, in seconds.

**Implements**

IDbConnection

**Remarks**

This property indicates the connection timeout that has been set using the `ConnectionString` attribute `Connection Timeout`.

This property is read-only.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ConnectionType

This property enables an ODP.NET application to determine whether a particular connection object is associated with an Oracle database connection, a TimesTen database connection, or no physical connection at all.

**Declaration**

```
// C#  
public OracleConnectionType ConnectionType {get;}
```

**Property Value**

The `OracleConnectionType` that this connection object is associated with.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [OracleConnectionType Enumeration](#)

## Credential

This property is used to get or set an `OracleCredential` object on the connection.

**Declaration**

```
// C#  
public OracleCredential Credential { get; set; }
```

**Property Value**

An `OracleCredential` object to be used for opening connection.

**Exceptions**

An `InvalidOperationException` will be raised in following scenarios:

- If connection is already open.
- If connection string has already been set on this connection and it contains any of user id, password, DBA Privilege, proxy user id or proxy password.
- The `AccessToken` property is set.
- The `TokenLocation` properties is set. This is aplicable for managed ODP.NET and ODP.NET Core only.
- `TokenAuthentication` is set to something other than disabled. This is applicable for managed ODP.NET and ODP.NET Core only.

**Remarks**

To obtain the `OracleCredential` object through the property getter, "persist security info" must be set to true in the connection string.

If "Persist security info" is set to false in the Connection String, then the `OracleCredential` object is not returned through the property getter after the password has been validated.

**① See Also**

## Database

This property is not supported.

**Declaration**

```
// C#  
public override string Database {get;}
```

**Property Value**

A string.

**Implements**

`IDbConnection.Database`

**Remarks**

This property is not supported. It always returns an empty string.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## DatabaseCharset

This property specifies the CHAR database character set on the connection and is used to optimize connection establishment.

**Declaration**

```
// C#  
public OracleDatabaseCharset DatabaseCharset {get; set;}
```

**Remarks**

The default value is `OracleDatabaseCharset.AL32UTF8`.

When the application provides the actual CHAR database character set to connect with, the connection can be established in an optimized way with fewer roundtrips. If the property contains a non-matching character set value, connection establishment follows a traditional, less optimized process.

When retrieving the database character set value, the connection must be open. If it is not open, an exception occurs.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [OracleDatabaseCharset Enumeration](#)

## DatabaseNCharset

This property specifies the NCHAR database character set on the connection and is used to optimize connection establishment.

**Declaration**

```
// C#  
public OracleDatabaseNCharset DatabaseNCharset {get; set;}
```

**Remarks**

The default value is `OracleDatabaseNCharset.AL16UTF16`.

When the application provides the actual NCHAR database character set to connect with, the connection can be established in an optimized way with fewer roundtrips. If the property contains a non-matching character set value, connection establishment follows a traditional, less optimized process.

When retrieving the database character set value, the connection must be open. If it is not open, an exception occurs.

#### ① See Also

- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [OracleDatabaseNCharset Enumeration](#)

## DatabaseDomainName

This property specifies the name of the database domain that this connection is connected to.

### Declaration

```
// C#  
public string DatabaseDomainName {get;}
```

### Property Value

The database domain that this connection is connected to.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## DatabaseEditionName

DatabaseEditionName property sets or gets the edition name for the OracleConnection object.

### Declaration

```
// C#  
public string DatabaseEditionName{get;set;}
```

### Property Value

A string to be used as the edition name for the OracleConnection object.

### Exceptions

- `InvalidOperationException()` - if the connection is already open.

- `InvalidOperationException()` - If `CPVersion` is set to 1.0 when the connection is opened. `DatabaseEditionName` property is supported only with `CPVersion` of 2.0 or higher.

### Remarks

Property must be set before opening a connection or after closing a connection.

The edition name for the connection to use can be set in one of three places: `DatabaseEditionName` in the application code, `Edition` in the .NET configuration file, or `Edition` in the Windows Registry. The .NET configuration value overrides the Registry value and the `DatabaseEditionName` property value overrides the .NET configuration value.

`DatabaseEditionName` property value is case sensitive.

Only supported for .NET Framework 4 and higher.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## DatabaseMaxIdentifierLength

This property specifies the maximum identifier length the connection supports.

### Declaration

```
// C#  
public int DatabaseMaxIdentifierLength {get;}
```

### Remarks

The connection must be open when using this property. If the connection is closed, an exception occurs.

The Oracle Database maximum identifier length varies depending on the version. Older Oracle databases supported a 30 byte maximum and newer databases support a 128 byte maximum.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [OracleDatabaseNCharset Enumeration](#)

## DatabaseName

This property specifies the name of the database that this connection is connected to.

**Declaration**

```
// C#  
public string DatabaseName {get;}
```

**Property Value**

The database that this connection is connected to.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## DatabaseTimeZoneFileVersion

This property returns the database's time zone file version.

**Declaration**

```
// C#  
public string DatabaseTimeZoneFileVersion {get;}
```

**Property Type**

int

**Remarks**

An alternative method to check the Oracle database's time zone file version is to run the following query:

```
SELECT * FROM V$TIMEZONE_FILE ;
```

**Exception**

InvalidOperationException - The connection is not in an open state.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## DataSource

This property specifies the Oracle Net Services Name, Connect Descriptor, or an easy connect naming that identifies the database to which to connect

**Declaration**

```
// C#  
public override string DataSource {get;}
```

**Property Value**

Oracle Net Services Name, Connect Descriptor, or an easy connect naming that identifies the database to which to connect.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## DRCPConnectionClass

This property specifies a logical name that identifies the DRCP connection pool that the ODP.NET connection will use.

**Declaration**

```
// C#  
public string DRCPConnectionClass {get; set;}
```

**Property Value**

The string to be used that uniquely identifies the DRCP server side connection pool for the ODP.NET application to use.

**Exceptions**

- `InvalidOperationException()` - if `CPVersion=1.0` and the `DRCPConnectionClass` is set to a non-null / non-empty string. Applies to unmanaged ODP.NET only.
- `InvalidOperationException()` - if the `DRCPConnectionClass` is set to a non-null / non-empty string after opening a connection.
- `InvalidOperationException()` - if DRCP is not enabled and the `DRCPConnectionClass` is set to a non-null / non-empty string.

**Remarks**

A different client-side connection pool will be created for each unique `DRCPConnectionClass` property value. Each of these pools will use the same DRCP.

The default value is null. The character limit is 1024 minus the number of characters in the user id.

If this property is used, it must be set prior to opening the connection.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## DRCP Purity

Session purity specifies whether an application can reuse a pooled session (Pooled) or must use a new session (New).

**Declaration**

```
// C#  
public OracleDRCP Purity DRCP Purity {get; set;}
```

**Property Value**

OracleDRCP Purity Enumeration values.

**Exceptions**

- `InvalidOperationException()` - if `CPVersion=1.0` and the `DRCP Purity` is set to a non-null / non-empty string. Applies to unmanaged ODP.NET only.
- `InvalidOperationException()` - if the `DRCP Purity` is set to a non-null / non-empty string after opening a connection.
- `InvalidOperationException()` - if DRCP is not enabled and the `DRCP Purity` is set to a non-null / non-empty string.

**Remarks**

The default value is Pooled.

If set to New, then ODP.NET will dispense a new DRCP connection, rather than try to find an existing connection from the DRCP. In general, this property is used by applications that want a connection without any preexisting session state set.

If set to Pooled, then ODP.NET will first attempt to use a preexisting connection, that already exists in the DRCP pool.

Using this property will not cause a new DRCP to be created, just a new connection from an existing DRCP.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [OracleDRCP Purity Enumeration](#)

## FetchSize

This property specifies the total memory size, in bytes, that the provider allocates to cache data fetched in one database round-trip, used by `OracleDataReader`'s internal cache to store result set data.

### Declaration

```
// C#  
public long FetchSize { get; set;}
```

### Property Type

`System.Int64` (long)

### Exceptions

`InvalidArgument` - The specified value is less than 0 or greater than `System.Int64.MaxValue`.

`System.ObjectDisposedException` - This property cannot be accessed after the `OracleConnection` object is already disposed.

### Remarks

The default value is 131072.

The `FetchSize` property can be configured on `OracleDataReader`, `OracleCommand`, `OracleConnection`, and `OracleConfiguration` objects. By default, `OracleConnection` `FetchSize` property value inherits `OracleConfiguration` `FetchSize` property value at construction time; `OracleCommand` `FetchSize` property value inherits `OracleConnection` `FetchSize` property value at construction time; `OracleDataReader` `FetchSize` property value inherits `OracleCommand` `FetchSize` property value at a command execution. The value of `OracleDataReader` `FetchSize` determines the amount of data the `OracleDataReader` fetches into its internal cache for each database round-trip.

If the `OracleCommand.XmlCommandType` property is set to any value other than `None`, this property is ignored.

The `OracleCommand` `RowSize` and `OracleCommand` `FetchSize` properties handle UDT and XMLType data differently than other scalar data types. Because only a reference to the UDT and XMLType data is stored in the ODP.NET's internal cache, the `OracleCommand` `RowSize` property accounts for only the memory needed for the reference (which is very small) and not the actual size of the UDT and XMLType data. Thus, applications can inadvertently fetch a large number of UDT or XMLType instances from the database in a single database round-trip. This is because the actual size of UDT and XMLType data do not count against the `FetchSize`, and it would require numerous UDT and XMLType references to fill up the default cache size of 131072 bytes. Therefore, when fetching UDT or XMLType data, the `FetchSize` property must be appropriately configured to control the number of UDT and XMLType instances that are to be fetched, rather than the amount of the actual UDT and XMLType data to be fetched.

**Note**

For LOB and LONG data types, only the sizes specified in the `OracleCommand InitialLOBFetchSize` and `OracleCommand InitialLONGFetchSize` properties are accounted for by the `RowSize` property in addition to the metadata and reference information that is maintained by the cache for each LOB in the select list.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## HostName

This property specifies the name of the host that this connection is connected to.

**Declaration**

```
// C#  
public string HostName {get;}
```

**Property Value**

The host that this connection is connected to.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## HttpsProxy

This property specifies the HTTPS proxy server.

**Declaration**

```
// C#  
public string HttpsProxy {get; set;}
```

**Property Type**

System.String

**Remarks**

The value must be set to a valid host name or IP address of a HTTPS proxy server. This property has no default value. An invalid host name or IP address throws an exception.

This property overrides all other HTTPS\_PROXY settings, including the full connect descriptor and Easy Connect Plus configuration.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## HttpsProxyPort

This property specifies the HTTPS proxy server port number.

#### Declaration

```
// C#  
public static int HttpsProxyPort {get; set;}
```

#### Remarks

The default value is 80. The value must be between 0 and 65535.

An invalid specified port throws an exception.

This property overrides the HTTPS\_PROXY\_PORT setting, including the full connect descriptor and Easy Connect Plus configuration.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## InstanceName

This property specifies the name of the instance that this connection is connected to.

#### Declaration

```
// C#  
public string InstanceName {get;}
```

#### Property Value

The instance that this connection is connected to.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## IsInTransaction

This property specifies if the current application is in a transaction.

**Declaration**

```
// C#  
public bool IsInTransaction {get;}
```

**Property Value**

Boolean

**Remarks**

This property will be true if the connection is in a local implicit or explicit transaction, sessionless transaction, or a distributed transaction.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## IsNNEChecksummed

This property indicates if the connection uses Oracle Database Native Network Encryption (NNE) checksumming.

**Declaration**

```
// C#  
public bool IsNNEChecksummed { get; }
```

**Property Type**

System.Boolean

**Exceptions**

InvalidOperationException - This exception is thrown when the connection is not open.

**Remarks**

This property is true if the connection uses NNE checksumming; Otherwise, it is false.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## IsNNEncrypted

This property indicates if the connection uses Oracle Database Native Network Encryption (NNE).

**Declaration**

```
// C#  
public bool IsNNEncrypted { get; }
```

**Property Type**

System.Boolean

**Exceptions**

InvalidOperationException - This exception is thrown when the connection is not open.

**Remarks**

This property is true if the connection uses NNE; Otherwise, it is false.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## IsTLSEncrypted

This property indicates if the connection uses TCPS, SSL, or TLS.

**Declaration**

```
// C#  
public bool IsTLSEncrypted { get; }
```

**Property Type**

System.Boolean

**Exceptions**

InvalidOperationException - This exception is thrown when the connection is not open.

**Remarks**

This property is true if the connection uses TCPS, SSL, or TLS; Otherwise, it is false.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## KeepAlive

This property specifies whether to keep an idle connection alive.

**Declaration**

```
// C#  
public Boolean KeepAlive { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

Turn KeepAlive on to prevent an idle TCP connection from being killed, such as a by a firewall. KeepAlive will keep the connection alive by periodically sending a probe packet with no data in it and the ACK flag turned on.

This setting is used in conjunction with KeepAliveInterval and KeepAliveTime.

The KeepAlive default is false.

Starting in ODP.NET Core 19.10, KeepAlive is supported on non-Windows operating systems, such as Oracle Linux. For these non-Windows operating systems, .NET Core 3 or higher is required.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## KeepAliveInterval

This property specifies the time interval after an unacknowledged probe before a new probe is sent.

**Declaration**

```
// C#  
public int KeepAliveInterval { get; set; }
```

**Property Type**

System.Int32

**Remarks**

In seconds. The interval default is 6 seconds between unacknowledged probes.

When keepalive probes are sent, they are normally acknowledged by the remote TCP. If the connection remains idle, but TCP does see the probe acknowledgements, then TCP will send the probes at a rate of once every KeepAliveTime duration.

When these probes are not acknowledged, the probes are then sent at intervals set by KeepAliveInterval. Probes will continue to be sent at the KeepAliveInterval until the server acknowledges the probe, independent connection activity occurs, or 10 consecutive unacknowledged probes have been sent.

After a probe is acknowledged, future probes will be sent again at the KeepAliveTime interval.

If 10 probes are sent without acknowledgement, the connection is deemed EOF/Reset.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## KeepAliveTime

This property specifies the idle time before a keepalive probe is sent.

**Declaration**

```
// C#  
public int KeepAliveTime { get; set; }
```

**Property Type**

System.Int32

**Remarks**

In seconds. The default is 60 seconds.

KeepAliveTime specifies the idle time to wait until sending a probe to verify the connection remains active and to keep that connection active. If the remote TCP sends back an acknowledgement of receiving the probe, then no further probe is sent until another KeepAliveTime idle period has elapsed.

Whenever independent connection activity occurs, KeepAliveTime is reset. When that activity ends, the KeepAliveTime starts its countdown to sending a probe.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## MaxStatementCacheSize

This property specifies the maximum number of statements that can be cached on a particular OracleConnection object when self-tuning is enabled.

**Declaration**

```
// C#  
public int MaxStatementCacheSize { get; set;}
```

**Property Type**

System.Int32

**Exceptions**

InvalidArgument - The specified value is less than 0 or greater than System.Int32.MaxValue .

System.ObjectDisposedException - This property cannot be accessed after the OracleConnection object is already disposed.

**Remarks**

The default value is 100.

The MaxStatementCacheSize property can be configured on OracleConnection and OracleConfiguration objects. By default, OracleConnection MaxStatementCacheSize property value inherits OracleConfiguration MaxStatementCacheSize property value at construction time. The value of OracleConnection MaxStatementCacheSize will be used during the connection.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [Self-Tuning Statement Caching](#)

## ModuleName

This property specifies the module name for the connection.

**Declaration**

```
// C#  
public string ModuleName {set;}
```

**Property Value**

The string to be used as the module name.

**Remarks**

The default value is null.

Using the ModuleName property allows the application to set the module name in the application context for a given OracleConnection object.

For unmanaged ODP.NET with CPVersion = 1.0, the ModuleName property is reset to null upon the next server roundtrip following a Close or Dispose method call on the OracleConnection object. For all other ODP.NET provider types and CPVersion settings, ModuleName property is reset to null when the Close or Dispose method is called on the OracleConnection object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

- *Oracle Database Security Guide*

## NamesDirectoryPath

This property specifies the naming method order used for client name resolution lookups.

**Declaration**

```
// C#  
public string NamesDirectoryPath { get; set; }
```

**Property Type**

System.String

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OciCompartment

This property gets or sets the Oracle Cloud Identifier (OCID) of the target database's compartment.

### Declaration

```
// C#  
public string OciCompartment { get; set; }
```

### Property Type

System.String

### Remarks

This property is optional by default. This property is mandatory if the `OciDatabase` property is set.

If `OciCompartment` is not set, then ODP.NET requests access to all the cloud tenancy's databases identified in the `OciTenancy` property.

There is no default value for this property.

The value of this property will be part of pool manager identification so different value for this property will result in different connection pools.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OciDatabase

This property gets or sets the target database's Oracle Cloud Identifier (OCID).

### Declaration

```
// C#  
public string OciDatabase { get; set; }
```

### Property Type

System.String

### Remarks

This property is optional.

If it is not set, then ODP.NET requests access to all the cloud compartment's databases identified in the `OciCompartment` property. If `OciCompartment` property is also not set, then ODP.NET requests access to all the tenancy's databases specified in the `OciTenancy` property.

There is no default value for this property.

The value of this property will be part of pool manager identification so different value for this property will result in different connection pools.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OciIamUrl

This property gets or sets the URL end point for getting the database token.

#### Declaration

```
// C#  
public string OciIamUrl { get; set; }
```

#### Property Type

System.String

#### Remarks

This is a mandatory property for IAM alternate password use. If not set in that usage scenario, ODP.NET raises an error.

The property value is part of the connection pool manager identification. Different property values result in different connection pools.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OciTenacy

This property gets or sets the Oracle Cloud Identifier (OCID) of the IAM user's cloud tenancy to retrieve the database token.

#### Declaration

```
// C#  
public string OciTenacy { get; set; }
```

#### Property Type

System.String

### Remarks

This is a mandatory property for IAM alternate password use. If not set in that usage scenario, ODP.NET raises an error.

The property value is part of the connection pool manager identification. Different property values result in different connection pools.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## PasswordAuthentication

This property sets the connection PASSWORD\_AUTH parameter value.

### Declaration

```
// C#  
public OraclePasswordAuth PasswordAuthentication { get; set; }
```

### Property Type

An OraclePasswordAuth enumeration

### Remarks

The possible parameter values are OciToken, AzureToken, and PasswordVerifier. The default value is PasswordVerifier, which indicates the typical database username and password can be used for authentication. AzureToken is only available with ODP.NET Core and managed ODP.NET.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## PDBName

This property is used to set and get the name of the pluggable database to which the session is connected to.

### Declaration

```
// C#  
public string PDBName { get; set; }
```

### Property Value

PDBName returns a string specifying the pluggable database name for the connection.

### Exceptions

- `InvalidOperationException()` - if the connection is already open.
- `InvalidOperationException()` - if the `CPVersion` is set to 1.0 and the `PDBName` property is set. Applicable only to ODP.NET, Unmanaged Driver.
- `InvalidOperationException()` - If `PDBName` value is retrieved when `CPVersion` is set to 1.0. Applicable only to ODP.NET, Unmanaged Driver.

### Remarks

Pluggable databases are available in Oracle Database 12c and higher. The `ServiceName` and `PDBName` properties can be used to connect to the specified Service that is running on a particular PDB.

Property must be set before opening the connection so that a connection with requested pluggable database name is returned.

If the `PDBName` property is set before connection is opened, then the connection's pluggable database name will be the same as `PDBName` when `OracleConnection.Open()` is successfully executed.

If only the `PDBName` property is set, then the default service of the pluggable database is used as the `ServiceName` for this connection.

In unmanaged ODP.NET, if the `PDBName` property is set *and* if the .NET configuration setting, `CPVersion`, is *not* set, then the `CPVersion` attribute will be automatically set to 2.0.

`PDBName` property's value is case insensitive.

The `PDBName` property can be used to retrieve the session's pluggable database name after the connection has been opened. If it is used to get the pluggable database name before the connection is opened, then it just returns the pluggable database name provided by the application, if any.

Only supported for .NET Framework 4 and higher.

## Pipelining

This property enables asynchronous execution on the database server side on a particular `OracleConnection` object.

**Declaration**

```
// C#  
public bool Pipelining { get; set;}
```

**Property Type**

System.Boolean

**Exceptions**

System.ObjectDisposedException - This property cannot be accessed after the OracleConnection object is already disposed.

**Remarks**

The default value is false.

To enable pipelining, that is, database server asynchronous execution; set this property to true, and enable asynchronous ODP.NET, that is, client side asynchronous execution as well. Pipelining can only be enabled if async ODP.NET is enabled.

The Pipelining property can be configured on OracleConnection and OracleConfiguration objects. By default, OracleConnection Pipelining property value inherits OracleConfiguration Pipelining property value at construction time. The value of OracleConnection Pipelining will be used during the connection.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [Asynchronous Programming and Pipelining](#)

## PoolName

This property specifies the name that uniquely identifies the pool in .NET metrics or performance counters.

**Declaration**

```
// C#  
public string PoolName { get; }
```

**Property Type**

System.String

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ProviderName

This property specifies the ODP.NET provider type and version.

**Declaration**

```
// C#  
public static string ProviderName { get; }
```

**Property Type**

System.String

**Property Values**

Managed ODP.NET returns a string consisting of "ODPM.NET : x.x.x.0.0".

ODP.NET Core returns a string consisting of "ODPC.NET : x.x.x.0.0 : y,y".

"x.x.x" is the NuGet package version, such as 23.5.0, of the provider. "y.y" is the target .NET Standard or .NET runtime version, such as 2.1, of the provider.

**Remarks**

The property is read-only.

The string is returned regardless of the connection state.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ProviderNuGetVersion

This property specifies the ODP.NET NuGet version number.

**Declaration**

```
// C#  
public static string ProviderNuGetVersion { get; }
```

**Property Type**

System.String

### Property Values

This property returns a string with the ODP.NET NuGet package version number in the format of x.x.x[-suffix] where each x is a digit in the version. The suffix is optional. A suffix could be -dev, for example, to represent a developer release..

### Remarks

The property is read-only.

The string is returned regardless of the connection state.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ProviderVersion

This property specifies the ODP.NET assembly version.

### Declaration

```
// C#  
public static string ProviderVersion { get; }
```

### Property Type

System.String

### Property Values

The first ODP.NET Core 19c release has a ProviderVersion of 2.0.19.1. Managed and managed ODP.NET have version 4.122.19.1.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)

## RemoteConfigurationFiltering

This property specifies whether local configuration file access, such as to wallet and tnsnames.ora files, is allowed from centralized configuration providers.

### Declaration

```
// C#  
public bool RemoteConfigurationFiltering { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

By default, RemoteConfigurationFiltering is set to true. However, the property is ignored unless the connection string is populated with an URL.

When true, local file access is disallowed from centralized configuration providers to wallet, token, tnsnames.ora, and sqlnet.ora files. When false, local file access is allowed.

This property is intended for cloud deployments in which local file access is generally eschewed. Nonetheless, it can be used for on-premises deployments to limit local ODP.NET file access. The fundamental requirement is that an URL must be furnished for each connection string property.

For the centralized configuration providers, RemoteConfigurationFiltering affects the following connection attributes:

- tns\_admin
- token\_location
- wallet\_location

token\_location and wallet\_location values can be URLs of cloud key vault secrets that store Base64 formatted strings of token data and wallet data, respectively. In a development environment, token\_location and wallet\_location values can be also the Base64 formatted strings of token data and wallet data. These values are not considered local file access and can be used when RemoteConfigurationFiltering is true.

**See Also**

- [Centralized Configuration Providers for Deployments](#)
- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## Roles

This property retrieves the OracleRoleCollection object associated with the connection.

**Declaration**

```
// C#  
public OracleRoleCollection Roles{get;}
```

**Property Value**

An OracleRoleCollection object containing the role list for the connection.

**Exceptions**

ObjectDisposedException - The object is already disposed.

### Remarks

The `OracleRoleCollection` object specifies roles to be set on newly created or pool-dispensed connections.

If no `OracleRoleCollection` instance is associated with the connection object, ODP.NET creates a new instance and returns it to the application.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## RowsToFetchPerRoundTrip

This property specifies the total number of rows to retrieve per database round trip.

### Declaration

```
// C#  
public Int64 RowsToFetchPerRoundTrip { get; set; }
```

### Property Type

`System.Int64`

### Remarks

This property has no default value. If it is not set, ODP.NET ignores this property.

The row data fetched in a single round trip applies to scalar types only, such as `NUMBER` and `VARCHAR2` columns. If reference data types, such as LOBs, UDTs, and `XMLType`, exist in the result set, they are retrieved in separate round trips. These reference types can have their own fetch tuning parameters as reference type data sizes can vary in size from row to row, sometimes significantly.

`RowsToFetchPerRoundTrip` can be set before or after the `OracleCommand` executes on `OracleConnection`, `OracleCommand`, `OracleDataReader`, or `OracleRefCursor`. The value can also be changed after initial data fetches so that more or fewer rows are fetched on subsequent round trips. For `OracleConfiguration`, this property can only be set before the first connection opens.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)

## SDU

This property specifies the session data unit size (SDU) for Oracle networking communication between client and server.

### Declaration

```
// C#  
public int SDU { set; }
```

### Remarks

Before sending data across the network, ODP.NET or Oracle database buffers and encapsulates data into the SDU. They send the data stored in this buffer when the buffer is full, flushed, or when database server tries to read data. When large amounts of data are being transmitted or when the message size is consistent, adjusting the size of the SDU buffers can improve performance, network utilization, or memory consumption.

The default value is 65536 bytes, equivalent to 64 KB.

ODP.NET and Oracle database can each set its own SDU size. The actual SDU size used is negotiated at connect time. The smaller of the two values is chosen. Oracle AI Database 26ai uses a 64 KB SDU size. Earlier database releases set their default SDU size to 8 KB.

The OracleConfiguration SDU size can only be set before the first connection is established globally in the the .NET domain.

The OracleConnection SDU size can only be set before the connection is established. Moreover, the OracleConnection SDU size for a connection pool can only be set one time. All follow on set attempts are ignored for that pool.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ServerVersion

This property specifies the version number of the Oracle database to which the OracleConnection has established a connection.

### Declaration

```
// C#  
public override string ServerVersion {get;}
```

### Property Value

The version of the Oracle database.

### Exceptions

InvalidOperationException - The connection is closed.

**Remarks**

The default is an empty string.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ServiceName

This property is used to set and get the database service name to which the session will be connected to when connecting to a pluggable database.

**Declaration**

```
// C#  
public string ServiceName{ get; set;}
```

**Property Value**

ServiceName returns a string specifying the service name of the connection.

**Exceptions**

InvalidOperationException() - the connection is already open.

InvalidOperationException() - if the CPVersion is set to 1.0 and the ServiceName property is set. Applicable only to ODP.NET, Unmanaged Driver.

**Remarks**

Pluggable databases are available in Oracle Database 12c and higher. The ServiceName and PDBName properties can be used to connect to the specified Service that is running on a particular PDB.

ServiceName must be set before opening the connection so that the correct service is used for the connection.

PDBName property must be set when the ServiceName property is set. Otherwise, an exception is thrown when the connection is opened.

If the ServiceName property is specified before connection is opened, then the connection's service will be the same as the specified ServiceName when the connection is opened.

If the service name is not changed before the connection is next opened, then the connection will continue using the ServiceName value that had been previously set.

In unmanaged ODP.NET, if the ServiceName property is set *and* if the CPVersion attribute is *not* set, then the CPVersion attribute will be automatically set to 2.0.

ServiceName property's value is case insensitive.

The `ServiceName` property can also be used to retrieve the session service name after opening the connection. If retrieved before opening the connection, then `ServiceName` returns the service name provided by the application, if any.

Only supported for .NET Framework 4 and higher.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## ServiceRelocationConnectionTimeout

This property specifies the time, in seconds, for the particular `OracleConnection` to wait before retrying connecting to a service that becomes unavailable.

### Declaration

```
// C#
public string ServiceRelocationConnectionTimeout { get; set;}
```

### Property Type

`System.String`

### Exceptions

`System.ObjectDisposedException` - This property cannot be accessed after the `OracleConnection` object is already disposed.

`FormatException` - The provided string cannot be converted to a `System.Int32`.

`OverflowException` - The provided string represents a number that is less than `System.Int32.MinValue` or greater than `System.Int32.MaxValue`.

### Remarks

Default value is 90 (seconds).

Whenever a database service becomes unavailable, such as due to a service being relocated, an application can encounter numerous connectivity errors during this time. To avoid unnecessary connection attempts to an unavailable service which will result in an error, the driver will block any connection attempts until the service is up or until this property's specified time limit expires from the time when the service DOWN event was received, whichever comes first.

`ServiceRelocationConnectionTimeout` itself can be set based upon the value of `drain_timeout`. For example, if ODP.NET administrators desire the service relocation connection timeout to be `drain_timeout` plus 50 seconds, then they would set `ServiceRelocationConnectionTimeout` in the following manner:

```
//C#
OracleConnection conn = new OracleConnection();
conn.ServiceRelocationConnectionTimeout = "drain_timeout + 50";
```

The `ServiceRelocationConnectionTimeout` property can be configured on `OracleConnection` and `OracleConfiguration` objects. By default, `OracleConnection` `ServiceRelocationConnectionTimeout` property value inherits `OracleConfiguration` `ServiceRelocationConnectionTimeout` property value at construction time. The value of `OracleConnection` `ServiceRelocationConnectionTimeout` will be used during the connection.

#### ① See Also

- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [DrainTimeout](#)
- [ServiceRelocationConnectionTimeout](#)

## SessionlessTransactionId

This property returns the sessionless transaction identifier.

#### Declaration

```
// C#  
public byte[] SessionlessTransactionId { get; }
```

#### Property Value

The byte array which represents the global transaction identifier of the sessionless transaction identifier.

#### Remarks

If the session not associated with a sessionless transaction, it returns null.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SessionlessTransactionOptions

This property indicates the sessionless transaction options.

#### Declaration

```
// C#  
public OracleSessionTransactionOptions SessionlessTransactionOptions { get; set; }
```

**Property Value**

The `OracleSessionTransactionOption` indicates the options to operate on a sessionless transaction.

**Remarks**

Default value is null.

This property auto-initializes a sessionless transaction if its properties are not set.

The `SessionTransactionOptions` property is only read and used when `BeginSessionlessTransaction()` or `ResumeSessionlessTransaction` is invoked. Any change in `SessionlessTransactionOptions` property values afterwards will not be reflected in the sessionless transaction.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SqlNetAllowedLogonVersionClient

This property is used to specify the minimum authentication protocol that is to be used for a given `OracleConnection` object.

**Declaration**

```
// C#  
public OracleAllowedLogonVersionClient SqlNetAllowedLogonVersionClient { set; }
```

**Property Type**

`OracleAllowedLogonVersionClient`

**Property Value**

An `OracleAllowedLogonVersionClient` enumeration value.

**Example**

```
// C#  
OracleConfiguration.SqlNetAllowedLogonVersionClient =  
OracleAllowedLogonVersionClient.Version12a;
```

**Remarks**

The default is `OracleAllowedLongVersionClient.12`.

### ① See Also

- Oracle Database Net Services Reference to better understand the minimum authentication protocol that is to be used when authenticating against the Oracle database for a given OracleConnection object
- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- [OracleAllowedLogonVersionClient Enumeration](#)

## SqlNetAuthenticationServices

This property enables one or more authentication services, such as TCP/IP with SSL.

### Declaration

```
// C#  
public string SqlNetAuthenticationServices { get; set; }
```

### Property Type

System.String

Valid values are: All, Kerberos5, NTS, TCPS, or NONE.

### ① Note

ODP.NET Core does not currently support the Kerberos5 value.

### Example

```
//C#  
con.SqlNetAuthenticationServices = "(nts, tcps)";
```

### ① See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SqlNetCryptoChecksumClient

This property specifies the checksum client behavior.

### Declaration

```
// C#  
public string SqlNetCryptoChecksumClient {get; set;}
```

**Return Value**

System.String

**Remarks**

Default value is null. Null setting means other configuration methods determine the client's data integrity behavior.

Possible string values:

- accepted - enable the security service if required or requested by the database.
- rejected - disable the security service, even if required by the database.
- requested - enable the security service if the database allows it.
- required - enable the security service and disallow the connection if the database is not enabled for the security service.

All other string values are incorrect and should not be used.

**Example**

```
conn.SqlNetCryptoChecksumClient = "REQUESTED";
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SqlNetCryptoChecksumTypesClient

This property specifies the checksum algorithms the client can use.

**Declaration**

```
// C#  
public string SqlNetEncryptionTypesClient {get; set;}
```

**Return Value**

System.String

**Remarks**

Default value is null. Null setting means other configuration methods determine the client's data integrity algorithms.

Possible string values:

- SHA1
- SHA256
- SHA384
- SHA512

All other string values are incorrect and should not be used.

### Example

```
// Allow ODP.NET app to use SHA256 and SHA512 checksum algorithms
conn.SqlNetEncryptionClient = "(SHA256, SHA512)";
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SqlNetEncryptionClient

This property specifies the encryption client behavior.

### Declaration

```
// C#
public string SqlNetEncryptionClient {get; set;}
```

### Return Value

System.String

### Remarks

Default value is null. Null setting means other configuration methods determine the client's encryption behavior.

Possible string values:

- `accepted` - enable the security service if required or requested by the database.
- `rejected` - disable the security service, even if required by the database.
- `requested` - enable the security service if the database allows it.
- `required` - enable the security service and disallow the connection if the database is not enabled for the security service.

All other string values are incorrect and should not be used.

### Example

```
conn.SqlNetEncryptionClient = "REQUESTED";
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SqlNetEncryptionTypesClient

This property specifies encryption algorithms that the client can use.

### Declaration

```
// C#  
public string SqlNetEncryptionTypesClient {get; set;}
```

### Return Value

System.String

### Remarks

Default value is null. Null setting means other configuration methods determine the client's encryption algorithms.

Possible string values:

- AES128
- AES192
- AES256
- 3DES112
- 3DES168

All other string values are incorrect and should not be used.

Using 3DES 112-bit (3DES112) or 3DES 168-bit (3DES168) requires ODP.NET SQLNET.Allow\_Weak\_Crypto/SqlNetAllowWeakCrypto to be set to true.

### Example

```
// Allow ODP.NET app to use AES128 and AES192 encryption algorithms  
conn.SqlNetEncryptionTypesClient = "(AES128, AES192)";
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- OracleConfiguration [SqlNetAllowWeakCrypto](#)

## SqlNetWalletOverride

This property specifies whether the client overrides the strong authentication credential with the stored wallet password credential for the database connection.

### Declaration

```
// C#  
public bool SqlNetWalletOverride { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

Default is false. By setting this value to true, ODP.NET uses the stored wallet password credential to connect.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SSLCertificateThumbprint

This property specifies the TLS/SSL certificate thumbprint in the certificate store for the ODP.NET connection to use.

**Declaration**

```
// C#  
public string SSLCertificateThumbprint { get; set; }
```

**Remarks**

When there are multiple certificates possible for ODP.NET to use from the certificate store, specifying the thumbprint tells ODP.NET which certificate to connect the user with. This avoids the user from performing certificate selection manually, such as via a graphical interface. Users can select a certificate manually using the `OracleConnection.AllowCertificateSelectionUI` property.

ODP.NET supports certificates through thumbprint only. It supports the SHA1 and SHA2 algorithms.

ODP.NET expects thumbprints in the format of `<Algorithm>:<Hash>`. For example,

- SHA1:1B:11:01:5E:D1:7C:20:B2:62:39:3E:04:7B:83:47:DE:70:2E:4E:44
- SHA256:CD:C6:8B:0D:36:FE:20:0E:7F:86:5F:94:0B:4D:EC:EE:1B:C0:D1:09

Or

- SHA1:1B11015ED17C20B262393E047B8347DE702E4E44
- SHA256:CDC68B0D36FE200E7F865F940B4DECEE1BC0D109

**Code Sample**

```
OracleConnection myCon = new OracleConnection();  
myCon.SSLCertificateThumbprint =  
"SHA1:1B:11:01:5E:D1:7C:20:B2:62:39:3E:04:7B:83:47:DE:70:2E:4E:44";
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SSLServerCertDN

This property sets the distinguished name (DN) string that will be used to validate the server certificate DN.

**Declaration**

```
// C#  
public string SSLServerCertDN {get; set;}
```

**Property Type**

System.String

**Remarks**

This property overrides the SSL\_SERVER\_CERT\_DN parameter, including the full connect descriptor and Easy Connect Plus configuration.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SSLServerDNMatch

This property enables server certificate distinguished name (DN) validation.

**Declaration**

```
// C#  
public bool SSLServerDNMatch {get; set;}
```

**Property Type**

System.Boolean

**Remarks**

This property enables server certificate validation through DN matching. By default, this property is null to allow other configuration parameters to enforce DN matching.

Set to true to enforce a match. To enforce DN matching, the SSLServerCertDN property value must match the DN from the server certificate for the connection to succeed. Otherwise, the connection fails.

Set to false to not enforce a match.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SSLVersion

This property enforces the connection to use a specific SSL/TLS version.

### Declaration

```
// C#  
public string SSLVersion {get; set;}
```

### Property Type

System.String

### Description

Supported values are: undetermined |1.2|TLSv1.2|1.3|TLSv1.3. To specify more than one SSL/TLS version, enclose the version numbers between parentheses and separate the values with a comma. For example, (1.2,1.3).

Starting with ODP.NET 23.9, you can specify a minimum TLS version by appending the plus (+) sign after the version, such as 1.2+ or TLSv1.2+. This value indicates to use TLS 1.2 or higher, whichever highest version the database server supports.

In some cases, apps may want to set a minimum TLS version, but not support one or more higher versions. To identify excluded versions, set the `TLSExcludeVersion` property on `OracleConfiguration`, `OracleConnection`, or equivalent.

The default value is an undetermined version. An undetermined version means ODP.NET is allowed to use any TLS version, this property is allowed to specify. An exception will be thrown for invalid value.

This property overrides the `SSL_VERSION` parameter, including the full connect descriptor and Easy Connect Plus configuration.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## State

This property specifies the current state of the connection.

**Declaration**

```
// C#  
public override ConnectionState State {get;}
```

**Property Value**

The ConnectionState of the connection.

**Implements**

IDbConnection

**Remarks**

ODP.NET supports ConnectionState.Closed and ConnectionState.Open for this property. The default value is ConnectionState.Closed.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## StatementCacheSize

This property specifies the current size of the statement cache associated with this connection.

**Declaration**

```
// C#  
public int StatementCacheSize{get;}
```

**Property Value**

An integer value indicating the size of the statement cache.

**Remarks**

If self tuning is not enabled, then the default value of this property depends upon the statement cache size specified in the connection string, application configuration file, or the registry. If none of these values are specified, then a default value of 0 is used.

If self tuning is enabled, then the property value is adjusted automatically. Any values specified in the connection string, application configuration file, or the registry are ignored.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## SuppressGetDecimalInvalidCastException

This property specifies whether to suppress the `InvalidCastException` and return a rounded-off 28 or 29 precision Oracle `NUMBER` value that can be represented as a .NET `Decimal`.

**Declaration**

```
// C#  
public bool SuppressGetDecimalInvalidCastException { get; set; }
```

**Property Type**

`System.Boolean`

**Remarks**

Oracle `NUMBER` has a maximum of 38 precision. .NET `Decimal` has a maximum of 28 or 29 precision. When the `OracleDataReader.GetDecimal()`, `GetValue()`, or `OracleDataAdapter.Fill()` method is called for an Oracle `NUMBER` value that cannot be represented as a .NET `Decimal`, then ODP.NET throws an `InvalidCastException` because not all the precision can be preserved when converting the number to a .NET `Decimal`.

This behavior occurs when `SuppressGetDecimalInvalidCastException` is set to `false`, which is the default value.

When `SuppressGetDecimalInvalidCastException` is set to `true`, the resulting .NET `Decimal` is rounded off to 28 or 29 precision, allowing as much of the value to be represented without throwing an exception. If the resulting rounded number is larger than can be stored in a .NET `Decimal`, an exception will be thrown, such as the number  $1 \times 10^{32}$ .

The `SuppressGetDecimalInvalidCastException` property can also be configured on `OracleConfiguration`, `OracleDataReader`, and `OracleDataAdapter` objects. The `OracleConnection.SuppressGetDecimalInvalidCastException` property value inherits `OracleConfiguration.SuppressGetDecimalInvalidCastException` property value at construction time.

By using `OracleConnection.SuppressGetDecimalInvalidCastException`, this ODP.NET setting becomes enabled for all the connection's command executions. It can be overridden at the `OracleDataReader` or `OracleDataAdapter` level, which each has its own `SuppressGetDecimalInvalidCastException` property.

### ① See Also

- OracleConfiguration [SuppressGetDecimalInvalidCastException](#)
- OracleDataReader [SuppressGetDecimalInvalidCastException](#)
- OracleDataAdapter [SuppressGetDecimalInvalidCastException](#)
- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

- [OracleConnection Members](#)

## SwitchedConnection

This property applies to pluggable database connections. Upon an `OracleConnection.Open()`, if the connection returned from the pool had to change its service name (`ServiceName`) or pluggable database (`PDBName`) in order to connect to the desired pluggable database, then the connection is considered switched. Thus, `SwitchedConnection` will then return `TRUE`. In all other cases, it will return `FALSE`.

### Declaration

```
// C#  
public bool SwitchedConnection { get; }
```

### Remarks

Applications should use this property carefully when using `DRCPConnectionString` values that are common across PDBs/Services. If the same `DRCPConnectionString` values are used across PDBs/Services, but their semantics are different, then this property value can help determine if the requested connection is returned or not.

For example, in a scenario where the same `DRCPConnectionString` that is used across PDBs/Services has a different semantic, the application should first check to see if the session has been switched or not. If it has switched between PDBs/Services, then the application should consider that the connection with a matching `DRCPConnectionString` was not dispensed.

Only supported for .NET Framework 4 and higher.

## TAFMode

This property configures Transparent Application Failover behavior on the connection.

### Declaration

```
// C#  
public OracleTAFMode TAFMode
```

### Remarks

Applications set this property on the connection to configure TAF behavior. The set value is only considered for the first pooled connection, which is then cached for the pool. Subsequent connections ignore the set value and instead use the cached value.

To use a new value, applications must call `ClearPool()` or `ClearAllPools()` to remove the cached `OracleTAFMode` value from the pool. The reset pool can then use the newly provided value.

## TLSExcludeVersion

This property indicates which SSL/TLS versions connections should not be enabled for.

### Declaration

```
// C#  
public string TLSExcludeVersion { get; set; }
```

### Property Type

System.String

### Description

The `TLSVersion` or `SSLVersion` properties sets the supported connection SSL/TLS versions. `TLSExcludeVersion` sets the versions that the app connections cannot use.

Typically, `TLSExcludeVersion` is used when the TLS/SSL version has a minimum value set, such as `TLSv1.2+`, and the app wants to prevent connections from using a version above the minimum value, such as `TLS 1.3`.

Supported exclusion values are: `1.2|TLSv1.2|1.3|TLSv1.3`. To specify more than one SSL/TLS version to exclude, enclose the version numbers between parentheses and separate the values with a comma. For example, `(1.2,1.3)`.

This property has no default value.

An exception will be thrown for invalid value.

This property overrides the `TLS_EXCLUDE_VERSION` parameter, including the full connect descriptor and Easy Connect Plus configuration.

- [OracleConnection Members](#)

## TLSVersion

This property enforces the connection to use a specific SSL/TLS version.

**Declaration**

```
// C#  
public static string TLSVersion { get; set; }
```

**Property Type**

System.String

**Description**

Supported values are: undetermined |1.2|TLSv1.2|1.3|TLSv1.3. To specify more than one SSL/TLS version, enclose the version numbers between parentheses and separate the values with a comma. For example, (1.2,1.3).

Starting with ODP.NET 23.9, you can specify a minimum TLS version by appending the plus (+) sign after the version, such as 1.2+ or TLSv1.2+. This value indicates to use TLS 1.2 or higher, whichever highest version the database server supports.

In some cases, apps may want to set a minimum TLS version, but not support one or more higher versions. To identify excluded versions, set the TLSExcludeVersion property on OracleConfiguration, OracleConnection, or equivalent.

The default value is an undetermined version. An undetermined version means ODP.NET is allowed to use any TLS version, this property is allowed to specify. An exception will be thrown for invalid value.

This property overrides the SSL\_VERSION parameter, including the full connect descriptor and Easy Connect Plus configuration.

## TnsAdmin

This property specifies the directory location of tnsnames.ora or sqlnet.ora, or both.

**Declaration**

```
// C#  
public static string TnsAdmin { get; set; }
```

**Property Type**

System.String

**Remarks**

The backslash (\) is a special character in .NET that represents the beginning of an escape sequence. To specify a directory location, use any one of the following formats in .NET so that backslashes are correctly represented in a directory location:

```
// C#  
OracleConnection con = new OracleConnection();  
con.TnsAdmin = "D:\\oracle\\client\\admin";  
con.TnsAdmin = @"D:\oracle\client\admin";  
con.TnsAdmin = "D:/oracle/client/admin";
```

## TokenAuthentication

This property sets the value for TOKEN\_AUTH parameter for the connection.

**Declaration**

```
// C#  
public OracleTokenAuth TokenAuthentication { get; set; }
```

**Remarks**

The value of this property will be part of connection pool manager identification so different values for this property will result in different connection pools.

**Table 6-52 OracleTokenAuth Members**

| OciApiKey            | Token authentication using OCI_API_KEY authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                                       |
| OciInstancePrincipal | Token authentication using OCI_INSTANCE_PRINCIPAL authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                            |
| OciResourcePrincipal | Token authentication using OCI_RESOURCE_PRINCIPAL authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                            |
| OciDelegationToken   | Token authentication using OCI_DELEGATION_TOKEN authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                              |
| OciInteractive       | Token authentication using OCI_INTERACTIVE authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                                   |
| OciDefault           | Token authentication using the most appropriate method depending on the application environment. ODP.NET first attempts to retrieve the token using the OCI API key. If that fails, then ODP.NET checks whether it is in a Cloud Shell environment to attempt to get the token using delegation token authentication flow. Lastly, it attempts to use the instance principal authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| OciToken             | Token authentication is enabled for Oracle Identity and Access Management.                                                                                                                                                                                                                                                                                                                                                                             |
| OAuth                | Token authentication enabled for Microsoft Entra ID.                                                                                                                                                                                                                                                                                                                                                                                                   |

**Exceptions**

An `InvalidOperationException` will be raised if

- the connection is already open,
- the value of the `AccessToken` property is not compatible with the type of token authentication being set,
- `TokenAuthentication` is set to disabled and the `AccessToken` or `TokenLocation` properties are set,
- `TokenAuthentication` is set to a value other than disabled, and the `Credential` property is set,
- the user or proxy information in the connection string is not compatible with token authentication,
- if user id value is other than /,
- password, proxy user id, and proxy password is set,

- TokenConfiguration is specified, and TokenAuthentication is set to OciToken, OAuth, or Disabled.

## TokenLocation

This property gets or sets the token location path for the connection where the access token, or database token and private key files, are present for ODP.NET token authentication. The file names do not need to be specified.

*Not Available in ODP.NET, Unmanaged Driver*

### Declaration

```
// C#  
public string TokenLocation { get; set; }
```

### Property Value

A directory location.

### Remarks

The value of this property will be part of connection pool manager identification so different values for this property will result in different connection pools.

### Expections

An `InvalidOperationException` will be raised if

- the connection is already open,
- the `AccessToken` or `Credential` properties are set,
- `TokenAuthentication` has been set to disabled by the application,
- the user or proxy information in the connection string is not compatible with token authentication,
- user id value is other than /, or
- password, proxy user id, and proxy password is set.

### Description

This property is mandatory for OAuth file-based access tokens, but optional for database tokens.

In the access token case, this property can be the directory where the file token is, or the full-path specification of the token file.

For OCI IAM PoP tokens, a file's full-path specification can be specified if it does not have the standard name, token. A file name does not need to be specified when it uses this standard, fixed name. Bearer token default token location is an empty string.

## UseClientInitiatedCQN

This property specifies, on a particular `OracleConnection` object, whether to use Client Initiated Continuous Query Notification (CICQN) or traditional Continuous Query Notification (CQN) that does not rely on a persistent connection.

### Declaration

```
// C#  
public bool UseClientInitiatedCQN { get; set; }
```

### Property Type

`System.Boolean`

### Exceptions

`System.ObjectDisposedException` - This property cannot be accessed after the `OracleConnection` object is already disposed.

### Remarks

The default value is false.

When set to true, ODP.NET creates and uses a separate connection to receive server-initiated database change notifications. This is known as CICQN. This single connection aggregates all notifications for the pool, but the connection does not count toward the Min Pool Size nor the Max Pool Size limits. For managed ODP.NET, if there are five connection pools using CICQN, then ODP.NET will then have five additional connections, one per pool.

When set to false, then ODP.NET will use traditional CQN to receive the database change notifications. The client creates a listening end point (i.e., IP address and port) that does not rely on a database connection to continuously exist.

CICQN is commonly used in cloud scenarios or if firewalls between the database and client do not allow access to the client port. Otherwise, traditional CQN is used.

ODP.NET CICQN requires Oracle Database 21c or higher.

`UseClientInitiatedCQN` must be set to its intended value prior to opening a database connection.

The `UseClientInitiatedCQN` property can be configured on `OracleConnection` and `OracleConfiguration` objects. By default, `OracleConnection UseClientInitiatedCQN` property value inherits `OracleConfiguration UseClientInitiatedCQN` property value at

construction time. The value of `OracleConnection.UseClientInitiatedCQN` will be used during the connection.

## UseHourOffsetForUnsupportedTimezone

This property specifies whether the hour offset can be used for the session time zone, when the Oracle time zone region name that is associated with the .NET locale is not supported by the Oracle Database being used.

### Declaration

```
// C#  
public bool UseHourOffsetForUnsupportedTimezone { get; set; }
```

### Property Type

`System.Boolean`

### Exceptions

`InvalidOperationException` – This exception will be thrown if this property is set when the Connection is in an Open state.

### Remarks

ODP.NET is built to support the latest available time zones the Oracle database client supports. However, older Oracle database server versions may not have the latest time zone files that support all the same time zones the client supports. Thus, the client could request a connection time zone the Oracle database does not support. In these situations, the connection request returns an "ORA-01882: timezone region not found" error.

When the `UseHourOffsetForUnsupportedTimezone` property is set to true, then ODP.NET will initialize the connection/session time zone using a "hour offset" instead of a time zone region name only if the Oracle Database cannot support the Oracle time zone associated with the .NET locale. ODP.NET can then successfully connect and avoid the ORA-01882 error. This also means if the Oracle Database does support the Oracle time zone associated with the .NET locale, then the connection/session will be initialized with an Oracle time zone region name, regardless of the `UseHourOffsetForUnsupportedTimezone` property setting.

By default, the `UseHourOffsetForUnsupportedTimezone` property is set to false.

Oracle does not recommend using the hour offset since datetimes with time zone values will *not* be daylight savings time sensitive. Even when the hour offset is enabled, ODP.NET first attempts to use the Oracle time zone region name associated with the .NET locale. Only when the ORA-01882 error is encountered will ODP.NET use the hour offset as the session time zone during a second connection attempt. Thus, there can be two connection requests if the first connection attempt fails with the ORA-01882 error.

The `UseHourOffsetForUnsupportedTimezone` property value specified for the first successfully created connection is used for all subsequent connections in that pool. When pooling is not used, the property's value will be specific for the particular `OracleConnection.Open()` invocation.

Oracle recommends resolving ORA-01882 errors by upgrading the Oracle database with the latest time zone/DST files. Oracle also recommends using the time zone region name for the session time zone so that datetime conversions with time zone values are daylight savings time sensitive.

If the Oracle Database time zone / DST files cannot be upgraded, the application should then set the `UseHourOffsetForUnsupportedTimezone` property to `true`.

### Sample Code

```
using System;
using Oracle.ManagedDataAccess.Client;

class Test
{
    static void Main(string[] args)
    {
        string constr = "user id=hr;password=<password>;data source=oracle;"

        OracleConnection con = new OracleConnection(constr);

        // Have the connection created with the 'hour offset' being used as the session time
        // zone
        // if the Oracle Database does not support the Oracle Time Zone associated with the
        // .NET application's locale
        con.UseHourOffsetForUnsupportedTimezone = true;

        // Establish a connection to Oracle
        con.Open();
        con.Dispose();
    }
}
```

## UseSNI

This property specifies whether to use Server Name Indication (SNI).

### Declaration

```
// C#
bool? UseSNI { get; set;}
```

### Property Type

`System.Boolean`

### Remarks

Default is false. False disables using SNI.

When UseSNI is set to true, the following configuration rules must be obeyed. Any deviation will disable SNI automatically.

- Only the following CONNECT\_DATA names can be used.
  - ServiceName
  - Server
  - InstanceName
  - ColocationTag
- The CONNECT\_DATA name values can only contain alphanumeric, underscore, hyphen, or period characters.
- No more than two consecutive period characters
- No hyphen character before or after a period
- No hyphen at the beginning or end of the CONNECT\_DATA name values above
- No period at the beginning or end of the CONNECT\_DATA name values above

## WalletLocation

This property specifies the location of wallets. Wallets are certificates, keys, and trustpoints processed by SSL/TLS.

### Declaration

```
// C#  
public static string WalletLocation { get; set; }
```

### Property Type

System.String

### Remarks

Microsoft Certificate Store (MCS) and file system wallets are supported.
