The backslash (\) is a special character in .NET that represents the beginning of an escape sequence. To specify a directory location, use any one of the following formats in .NET so that backslashes are correctly represented in a directory location:

```
// C#
OracleConnection con = new OracleConnection();
con.WalletLocation = "D:\\oracle\\client\\wallets";
con.WalletLocation = @"D:\oracle\client\wallets";
con.WalletLocation = "D:/oracle/client/wallets";
```

This property can accept file path or URL values that contain the wallet file.

It supports single sign-on files (.sso file extension) and PKCS #12 files (.p12 file extension). Since wallet location is a directory location, not file location, ODP.NET chooses the file to use based on the criteria:

- When the wallet password is not supplied:
  - Reads the .sso file, if present
  - Reads the .p12 file, if present
- When the wallet password is supplied:
  - Reads the .p12 file, if present

## WalletPassword

This property stores the password to decrypt the PKCS #12 wallet.

### Declaration

```
// C#
public OracleOpaqueString WalletPassword {get; set;}
```

### Property Value

The password to decrypt the encrypted PKCS #12 wallet.

### Remarks

Wallet passwords support the same functionality as traditional ODP.NET passwords.

Since PKCS #12 files are encrypted, apps must provide the wallet password as an `OracleOpaqueString`. When the wallet password is provided via the `OracleConfiguration.WalletPassword` or `OracleConnection.WalletPassword` class property, ODP.NET loads the associated PKCS #12 file as designated by the wallet location. Alternately, if no password is provided, ODP.NET loads the associated SSO file.

Changing the `WalletPassword` for an existing connection pool does not create a new pool. Only setting the property or unsetting it creates a new pool.

**Note**

The `OracleConfiguration.WalletPassword` is associated with the `OracleConfiguration.WalletLocation` and the `OracleConnection.WalletPassword` is associated with the `OracleConnection.WalletLocation`. For example, if `OracleConfiguration.WalletPassword` is set, and `OracleConnection.WalletLocation` is set, then the wallet password from `OracleConfiguration` will not be used when opening the wallet specified on the `OracleConnection`.

## OracleConnection Public Methods

`OracleConnection` public methods are listed in [Table 6-53](#).

**Table 6-53 OracleConnection Public Methods**

| Public Method                               | Description                                                                                                                             |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">BeginRequest</a>                | Starts an explicit request boundary when using Application Continuity<br><i>Not available in ODP.NET, Unmanaged Driver</i>              |
| <a href="#">BeginSessionlessTransaction</a> | Starts a new sessionless transaction and returns its global transaction identifier<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">BeginTransaction</a>            | Begins a local transaction (Overloaded)                                                                                                 |
| <a href="#">ChangeDatabase</a>              | <i>Not Supported</i>                                                                                                                    |
| <a href="#">Clone</a>                       | Creates a copy of an <code>OracleConnection</code> object                                                                               |
| <a href="#">Close</a>                       | Closes the database connection                                                                                                          |
| <a href="#">CreateCommand</a>               | Creates and returns an <code>OracleCommand</code> object associated with the <code>OracleConnection</code> object                       |
| <code>CreateObjRef</code>                   | Inherited from <code>System.MarshalByRefObject</code>                                                                                   |
| <a href="#">Commit()</a>                    | Commits the database transaction                                                                                                        |
| <a href="#">DisableReplay</a>               | Disables replay on the connection in Application Continuity<br><i>Not available in ODP.NET, Unmanaged Driver</i>                        |
| <code>Dispose</code>                        | Inherited from <code>System.ComponentModel.Component</code>                                                                             |
| <a href="#">EndRequest</a>                  | Indicates an ending explicit request boundary when using Application Continuity<br><i>Not available in ODP.NET, Unmanaged Driver</i>    |

Table 6-53 (Cont.) OracleConnection Public Methods

| Public Method                                | Description                                                                                                                                                  |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">EnlistDistributedTransaction</a> | Enables applications to explicitly enlist in a specified distributed transaction<br><i>Not supported in ODP.NET Core</i>                                     |
| <a href="#">EnlistTransaction</a>            | Enables applications to enlist in a specified distributed transaction                                                                                        |
| Equals                                       | Inherited from System.Object (Overloaded)                                                                                                                    |
| <a href="#">FlushCache</a>                   | Flushes all updates and deletes made through REF objects retrieved using this connection<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| GetHashCode                                  | Inherited from System.Object                                                                                                                                 |
| GetLifetimeService                           | Inherited from System.MarshalByRefObject                                                                                                                     |
| <a href="#">GetSchema</a>                    | Returns schema information for the data source of the OracleConnection                                                                                       |
| <a href="#">GetSessionInfo</a>               | Returns or refreshes the property values of the OracleGlobalization object that represents the globalization settings of the session (Overloaded)            |
| GetType                                      | Inherited from System.Object                                                                                                                                 |
| InitializeLifetimeService                    | Inherited from System.MarshalByRefObject                                                                                                                     |
| <a href="#">Open</a>                         | Opens a database connection with the property settings specified by the ConnectionString                                                                     |
| <a href="#">OpenAsync</a>                    | Returns a Task-based asynchronous version of OracleConnection.Open (Overloaded)                                                                              |
| <a href="#">OpenWithNewClientSecret</a>      | Opens a new connection using a new Microsoft Entra ID client secret<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                     |
| <a href="#">OpenWithNewPassword</a>          | Opens a new connection with the new password (Overloaded)                                                                                                    |
| <a href="#">OpenWithNewPasswordAsync</a>     | A Task-based asynchronous version of OracleConnection.OpenWithNewPassword(), which opens a new connection with the new password. (Overloaded)                |
| <a href="#">OpenWithNewToken</a>             | This method can be used to open a new connection by providing the refreshed/updated access token directly to ODP.NET (Overloaded)                            |
| <a href="#">PurgeStatementCache</a>          | Flushes the Statement Cache by closing all open cursors on the database, when statement caching is enabled                                                   |
| <a href="#">ResumeSessionlessTransaction</a> | Resumes a sessionless transaction using the provided unique transaction identifier<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                      |
| <a href="#">Rollback</a>                     | Rolls back the local transaction                                                                                                                             |
| <a href="#">Save(String)</a>                 | Creates a savepoint in the database                                                                                                                          |
| <a href="#">SetSessionInfo</a>               | Alters the session's globalization settings with the property values provided by the OracleGlobalization object                                              |

**Table 6-53 (Cont.) OracleConnection Public Methods**

| Public Method                                                        | Description                                                                                                                                                                                 |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SetShardingKey(OracleShardingKey, OracleShardingKey)</a> | Enables applications to set the sharding key and super sharding key before requesting a connection                                                                                          |
| <a href="#">SuspendSessionlessTransaction</a>                        | Suspends the active sessionless transaction immediately from the session.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                              |
| ToString                                                             | Inherited from System.Object                                                                                                                                                                |
| <a href="#">UseAzureTokenAuthentication</a>                          | Associates the Microsoft Entra ID token authentication settings with the OracleConnection object for use upon the next connection open<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">UseOciTokenAuthentication</a>                            | Associates the OCI IAM token authentication settings with the OracleConnection object for use upon the next connection open.<br><i>Not available in ODP.NET, Unmanaged Driver</i>           |

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## BeginRequest

This method starts an explicit request boundary when using Application Continuity.

**Declaration**

```
// C#
public void BeginRequest();
```

**Remarks**

When called after another BeginRequest, but before an EndRequest, this call is a no-op and does not throw any exception. Therefore, applications are allowed to call BeginRequest after a connection pool checkout, which implicitly calls BeginRequest.

**See Also**

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## BeginSessionlessTransaction

This method starts a new sessionless transaction and returns its global transaction identifier.

### Declaration

```
// C#  
public byte[] BeginSessionlessTransaction();
```

### Return Value

A unique transaction identifier of the sessionless transaction.

### Exceptions

**InvalidOperationException** - The connection is already associated with a transaction or is currently in a transaction.

**OracleException** - The database does not support sessionless transactions (ORA-26207).

### Remarks

The unique transaction identifier is used to resume the transaction using the `OracleConnection.ResumeSessionlessTransaction()` method.

The sessionless transaction isolation level is based on the session's current isolation level. `OracleConnection` can operate on a sessionless transaction through its `Commit()`, `Rollback()`, `SuspendSessionlessTransaction()`, and `ResumeSessionlessTransaction()` methods.

Auto-commit is disabled when this method is invoked successfully.

If the `OracleConnection.SessionlessTransactionOptions` is set, then `BeginSessionlessTransaction()` operates the sessionless transaction based upon the `OracleConnection.SessionlessTransactionOptions` specified settings.

If the `OracleConnection.SessionlessTransactionOptions` is not set, then `BeginSessionlessTransaction()` operates the sessionless transaction using the following default behavior:

- Sessionless transaction timeout is 60 seconds.
- The connection is associated with the `OracleConnection.BeginSessionlessTransaction()` sessionless transaction. The transaction starts upon the first `OracleCommand` SQL execution.
- The sessionless transaction will not be suspended implicitly after SQL execution.

- [OracleConnection Class](#)
- [OracleConnection Members](#)

## BeginTransaction

`BeginTransaction` methods begin local transactions.

**Overload List**

- [BeginTransaction\(\)](#)  
This method begins a local transaction.
- [BeginTransaction\(IsolationLevel\)](#)  
This method begins a local transaction with the specified isolation level.

## BeginTransaction()

This method begins a local transaction.

**Declaration**

```
// C#  
public OracleTransaction BeginTransaction();
```

**Return Value**

An `OracleTransaction` object representing the new transaction.

**Implements**

`IDbConnection`

**Exceptions**

`InvalidOperationException` - A transaction has already been started.

**Remarks**

The transaction is created with its isolation level set to its default value of `IsolationLevel.ReadCommitted`. All further operations related to the transaction must be performed on the returned `OracleTransaction` object.

If a local transaction is already started implicitly, invoking `BeginTransaction()` will inherit that transaction.

If the transaction is created explicitly using `BeginTransaction()`, the transaction can be operated on either through the `OracleConnection` methods or `OracleTransaction` methods. But once the transaction is over via a `Commit()` or a `Rollback()` invoked on either object, the `OracleTransaction` cannot be used henceforth.

The `BeginTransaction(IsolationLevel)` method overrides the `OracleConnection` `IsolationLevel` property. Once that transaction commits or rolls back, the connection's `IsolationLevel` returns to its previous value.

Auto-commit is disabled when this method is invoked successfully.

## BeginTransaction(IsolationLevel)

This method begins a local transaction with the specified isolation level.

### Declaration

```
// C#  
public OracleTransaction BeginTransaction(IsolationLevel isolationLevel);
```

### Parameters

- *isolationLevel*  
The isolation level for the new transaction.

### Return Value

An `OracleTransaction` object representing the new transaction.

### Implements

`IDbConnection`

### Exceptions

`InvalidOperationException` - A transaction has already been started.

`ArgumentException` - The `isolationLevel` specified is invalid.

### Remarks

The following isolation levels are supported: `IsolationLevel.ReadCommitted` and `IsolationLevel.Serializable`.

Although the `BeginTransaction` method supports the `IsolationLevel.Serializable` isolation level, serializable transactions are not supported when using `System.Transactions` and `TransactionScope`.

Requesting other isolation levels causes an exception.

If a local transaction is already started implicitly, invoking `BeginTransaction()` will inherit that transaction.

If the transaction is created explicitly using `BeginTransaction()`, the transaction can be operated on either through the `OracleConnection` methods or `OracleTransaction` methods. But once the transaction is over via a `Commit()` or a `Rollback()` invoked on either object, the `OracleTransaction` cannot be used henceforth.

The `BeginTransaction(IsolationLevel)` method overrides the `OracleConnection` `IsolationLevel` property. Once that transaction commits or rolls back, the connection's `IsolationLevel` returns to its previous value.

Auto-commit is disabled when this method is invoked successfully.

### Example

```
// C#  
  
using System;  
using System.Data;
```

```
using Oracle.DataAccess.Client;

class BeginTransactionSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Create an OracleCommand object using the connection object
        OracleCommand cmd = con.CreateCommand();

        // Start a transaction
        OracleTransaction txn = con.BeginTransaction(IsolationLevel.ReadCommitted);

        // Update EMP table
        cmd.CommandText = "update emp set sal = sal + 100";
        cmd.ExecuteNonQuery();

        // Rollback transaction
        txn.Rollback();
        Console.WriteLine("Transaction rolledback");

        // Clean up
        txn.Dispose();
        cmd.Dispose();
        con.Dispose();
    }
}
```

## ChangeDatabase

This method is not supported.

### Declaration

```
// C#
public override void ChangeDatabase(string databaseName);
```

### Parameters

- *databaseName*  
The name of the database that replaces the current database name.

### Implements

IDbConnection.ChangeDatabase

### Exceptions

NotSupportedException - Method not supported.

### Remarks

This method is not supported and throws a NotSupportedException if invoked.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)

## Clone

This method creates a copy of an OracleConnection object.

### Declaration

```
// C#  
public object Clone();
```

### Return Value

An OracleConnection object.

### Implements

ICloneable

### Remarks

The cloned object has the same property values as that of the object being cloned.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class CloneSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        // Need a proper casting for the return value when cloned  
        OracleConnection clonedCon = (OracleConnection)con.Clone();  
  
        // Cloned connection is always closed, regardless of its source,  
        // But the connection string should be identical
```

```
        clonedCon.Open();
        if (clonedCon.ConnectionString.Equals(con.ConnectionString))
            Console.WriteLine("The connection strings are the same.");
        else
            Console.WriteLine("The connection strings are different.");

        // Close and Dispose OracleConnection object
        clonedCon.Dispose();
    }
}
```

## Close

This method closes the connection to the database.

### Declaration

```
// C#
public override void Close();
```

### Implements

IDbConnection

### Remarks

Performs the following:

- Rolls back any pending local or active sessionless transactions that are not yet committed. The connection will no longer associate with any sessionless transaction or local transaction. Distributed transactions will rely on the distributed transaction coordinator on whether roll back is necessary.
- Places the connection in the pool if connection pooling is enabled. Even if connection pooling is enabled, the connection can be closed if it exceeds the connection lifetime specified in the connection string. If connection pooling is disabled, the connection is closed.
- Closes the connection to the database.

The connection can be reopened using `Open()`.

## CreateCommand

This method creates and returns an `OracleCommand` object associated with the `OracleConnection` object.

**Declaration**

```
// C#  
public OracleCommand CreateCommand();
```

**Return Value**

The `OracleCommand` object.

**Implements**

`IDbConnection`

**Example**

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class CreateCommandSample  
{  
    static void Main()  
    {  
        // Connect  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        // Execute a SQL SELECT  
        OracleCommand cmd = con.CreateCommand();  
        cmd.CommandText = "select * from emp";  
        OracleDataReader reader = cmd.ExecuteReader();  
  
        // Print all employee numbers  
        while (reader.Read())  
            Console.WriteLine(reader.GetInt32(0));  
  
        // Clean up  
        reader.Dispose();  
        cmd.Dispose();  
        con.Dispose();  
    }  
}
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## Commit()

This method commits the database transaction.

**Declaration**

```
// C#  
public void Commit();
```

**Exception**

`InvalidOperationException` – If the connection is closed or if the connection is enlisted in `System.Transactions`.

`System.ObjectDisposedException` – This property cannot be accessed after the `OracleConnection` object is already disposed.

**Remarks**

This method allows the user to commit an implicit or explicit local transaction or active sessionless transaction using an `OracleConnection` object. Once committed, the transaction ends. For local transactions, it has the same behavior as the `OracleTransaction Commit` method. However, there are instances when this method is necessary to invoke without the `OracleTransaction` object available, such as an implicit transaction using "SELECT ... FOR UPDATE" or an implicit transaction executing an INSERT/UPDATE/DELETE statement with auto-commit disabled.

This method should not encounter any exceptions when the connection is within an explicit local transaction, implicit local transaction, or not associated with a transaction. This method cannot be executed on a connection enlisted in `System.Transactions` (local or distributed).

When an explicit transaction begins, auto-commit is disabled regardless of the `AutoCommit` property value. Once the `Commit` method is invoked, `AutoCommit` reverts back to true if it was earlier enabled. Transaction isolation level will also reset to its earlier value on the `OracleConnection` object upon the commit.

## DisableReplay

This method disables replay on the connection in Application Continuity.

### Declaration

```
// C#  
public void DisableReplay();
```

### Remarks

By default, ODP.NET replays following a recoverable error. If any application uses a design unsuitable for replay, then this method can be called to disable replay on a per request basis. It can be added to the callback or to the main code. For example, if an application module uses the UTL\_SMTP package to send emails, the developer may not want those emails to be sent again upon replay.

Disabling replay does not alter the connection state by re-executing any method, SQL or PL/SQL. When it is disabled, both recording and replay are disabled until that request ends and an explicit BeginRequest is called.

There is no method to re-enable replay once disabled. It is invalid to reestablish the database session with time gaps in a replayed request. This principle ensures replay runs only if a complete call has been recorded.

#### ① See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## EndRequest

This method indicates an ending explicit request boundary when using Application Continuity.

### Declaration

```
// C#  
public void EndRequest();
```

### Remarks

Using this method demarcates the end of the request boundary and disables replay. A subsequent BeginRequest call will re-establish a request boundary. Existing state on the connection is not affected by this call.

Calling EndRequest multiple times without BeginRequest in between is allowed.

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## EnlistDistributedTransaction

This method enables applications to explicitly enlist in a specific distributed transaction after a connection has been opened.

### Declaration

```
// C#  
public void EnlistDistributedTransaction(ITransaction transaction);
```

### Parameters

- *transaction*  
An ITransaction interface.

### Exceptions

InvalidOperationException - The connection is part of a local transaction or the connection is closed.

### Remarks

EnlistDistributedTransaction enables objects to enlist in a specific transaction that is passed to the method. The ITransaction interface can be obtained by applying an (ITransaction) cast to the ContextUtil.Transaction property within the component that started the distributed transaction.

The connection must be open before calling this method or an InvalidOperationException is thrown.

If a connection is part of a local transaction that was started implicitly or explicitly while attempting to enlist in a distributed transaction, the local transaction is rolled back and an exception is thrown.

By default, distributed transactions roll back, unless the method-level AutoComplete declaration is set.

Invoking the commit on the ITransaction raises an exception.

Invoking the rollback on the ITransaction method and calling ContextUtil.SetComplete on the same distributed transaction raises an exception.

### Example

#### Application:

```
// C#  
  
/* This is the class that will utilize the Enterprise Services  
   component. This module needs to be built as an executable.  
  
   The Enterprise Services Component DLL must be built first  
   before building this module.  
   In addition, the DLL needs to be referenced appropriately  
   when building this application.  
*/  
  
using System;  
using System.EnterpriseServices;
```

```

using DistribTxnSample;

class DistribTxnSample_App
{
    static void Main()
    {
        DistribTxnSample_Comp comp = new DistribTxnSample_Comp();
        comp.DoWork();
    }
}

```

**Component:**

```

// C#

/* This module needs to be
   1) built as a component DLL/Library
   2) built with a strong name

   This library must be built first before the application is built.
*/

using System;
using System.Data;
using Oracle.DataAccess.Client;
using System.EnterpriseServices;

namespace DistribTxnSample
{
    [Transaction(TransactionOption.RequiresNew)]
    public class DistribTxnSample_Comp : ServicedComponent
    {
        public void DoWork()
        {
            string constr =
                "User Id=scott;Password=tiger;Data Source=oracle;enlist=false";
            OracleConnection con = new OracleConnection(constr);
            con.Open();

            // Enlist in a distributed transaction
            con.EnlistDistributedTransaction((ITransaction)ContextUtil.Transaction);

            // Update EMP table
            OracleCommand cmd = con.CreateCommand();
            cmd.CommandText = "UPDATE emp set sal = sal + .01";
            cmd.ExecuteNonQuery();

            // Commit
            ContextUtil.SetComplete();

            // Dispose OracleConnection object
            con.Dispose();
        }
    }
}

```

## EnlistTransaction

This method enlists the connection to the specified transaction.

### Declaration

```
// C#  
public override void EnlistTransaction(Transaction transaction)
```

### Parameters

- *transaction*  
A System.Transactions.Transaction object.

### Exceptions

InvalidOperationException - The connection is part of a local transaction or the connection is closed.

### Remarks

Invocation of this method immediately enlists the connection to a transaction that is specified by the provided transaction parameter.

If OracleConnection is still associated with a distributed transaction that has not completed from a previous EnlistTransaction method invocation, calling this method will cause an exception to be thrown.

In general, for transaction enlistments to succeed, the "enlist" connection string attribute must be set to "true" before invoking the Open method. Setting the "enlist" connection string attribute to "true" will implicitly enlist the connection when the Open method is called, if the connection is within a transaction context. The "enlist" attribute should be set to "false" or "dynamic" only if the connection will never enlist in a transaction.

- [OracleConnection Members](#)
- ["System.Transactions and Promotable Transactions"](#)
- ["EnlistDistributedTransaction"](#)

## FlushCache

This method flushes all updates and deletes made through REF objects retrieved using this connection.

**Declaration**

```
// c#  
public void FlushCache();
```

**Exceptions**

InvalidOperationException - The specified connection is not open.

**Remarks**

Before flushing objects, it is required that the application has explicitly started a transaction by executing the BeginTransaction method on the OracleConnection object. This is because if the object being flushed has not already been locked by the application, an exclusive lock is obtained implicitly for the object. The lock is only released when the transaction commits or rollbacks.

## GetSchema

GetSchema methods return schema information for the data source of the OracleConnection.

**Overload List**

- [GetSchema\(\)](#)  
This method returns schema information for the data source of the OracleConnection.
- [GetSchema \(string collectionName\)](#)  
This method returns schema information for the data source of the OracleConnection using the specified string for the collection name.

- [GetSchema \(string collectionName, string\[\] restrictions\)](#)

This method returns schema information for the data source of the `OracleConnection` using the specified string for the collection name and the specified string array for the restriction values.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## GetSchema()

This method returns schema information for the data source of the `OracleConnection`.

### Declaration

```
// C#  
public override DataTable GetSchema();
```

### Return Value

A `DataTable` object.

### Exceptions

`InvalidOperationException` – The connection is closed.

### Remarks

This method returns a `DataTable` object that contains a row for each metadata collection available from the database.

The method is equivalent to specifying the `String` value `"MetaDataCollections"` when using the `GetSchema(String)` method.

### Example

```
// C#  
  
using System;  
using System.Data;  
using System.Data.Common;  
using Oracle.DataAccess.Client;  
  
class GetSchemaSample  
{  
    static void Main(string[] args)  
    {  
        string constr = "User Id=scott; Password=tiger; Data Source=oracle;";  
        string ProviderName = "Oracle.DataAccess.Client";  
  
        DbProviderFactory factory = DbProviderFactories.GetFactory(ProviderName);
```

```
using (DbConnection conn = factory.CreateConnection())
{
    try
    {
        conn.ConnectionString = constr;
        conn.Open();

        //Get all the schema collections and write to an XML file.
        //The XML file name is Oracle.DataAccess.Client_Schema.xml
        DataTable dtSchema = conn.GetSchema();
        dtSchema.WriteXml(ProviderName + "_Schema.xml");
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.Message);
        Console.WriteLine(ex.StackTrace);
    }
}
}
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)

## GetSchema (string collectionName)

This method returns schema information for the data source of the OracleConnection using the specified string for the collection name.

### Declaration

```
// C#
public override DataTable GetSchema (string collectionName);
```

### Parameters

*collectionName*

Name of the collection for which metadata is required.

### Return Value

A DataTable object.

### Exceptions

ArgumentException – The requested collection is not defined.

InvalidOperationException – The connection is closed.

InvalidOperationException – The requested collection is not supported by current version of Oracle database.

InvalidOperationException – No population string is specified for requested collection.

## Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;

class GetSchemaSample
{
    static void Main(string[] args)
    {
        string constr = "User Id=scott; Password=tiger; Data Source=oracle;";
        string ProviderName = "Oracle.DataAccess.Client";

        DbProviderFactory factory = DbProviderFactories.GetFactory(ProviderName);

        using (DbConnection conn = factory.CreateConnection())
        {
            try
            {
                conn.ConnectionString = constr;
                conn.Open();

                //Get MetaDataCollections and write to an XML file.
                //This is equivalent to GetSchema()
                DataTable dtMetadata =
                    conn.GetSchema(DbMetaDataCollectionNames.MetaDataCollections);
                dtMetadata.WriteXml(ProviderName + "_MetaDataCollections.xml");

                //Get Restrictions and write to an XML file.
                DataTable dtRestrictions =
                    conn.GetSchema(DbMetaDataCollectionNames.Restrictions);
                dtRestrictions.WriteXml(ProviderName + "_Restrictions.xml");

                //Get DataSourceInformation and write to an XML file.
                DataTable dtDataSrcInfo =
                    conn.GetSchema(DbMetaDataCollectionNames.DataSourceInformation);
                dtDataSrcInfo.WriteXml(ProviderName + "_DataSourceInformation.xml");

                //data types and write to an XML file.
                DataTable dtDataTypes =
                    conn.GetSchema(DbMetaDataCollectionNames.DataTypes);
                dtDataTypes.WriteXml(ProviderName + "_DataTypes.xml");

                //Get ReservedWords and write to an XML file.
                DataTable dtReservedWords =
                    conn.GetSchema(DbMetaDataCollectionNames.ReservedWords);
                dtReservedWords.WriteXml(ProviderName + "_ReservedWords.xml");

                //Get all the tables and write to an XML file.
                DataTable dtTables = conn.GetSchema("Tables");
                dtTables.WriteXml(ProviderName + "_Tables.xml");

                //Get all the views and write to an XML file.
                DataTable dtViews = conn.GetSchema("Views");
                dtViews.WriteXml(ProviderName + "_Views.xml");

                //Get all the columns and write to an XML file.
                DataTable dtColumns = conn.GetSchema("Columns");
```

```
        dtColumns.WriteXml(ProviderName + "_Columns.xml");
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.Message);
        Console.WriteLine(ex.StackTrace);
    }
}
}
```

#### ① See Also

## GetSchema (string collectionName, string[] restrictions)

This method returns schema information for the data source of the `OracleConnection` using the specified string for the collection name and the specified string array for the restriction values.

### Declaration

```
// C#
public override DataTable GetSchema (string collectionName,
    string[] restrictions);
```

### Parameters

- *collectionName*  
The name of the collection of metadata being retrieved.
- *restrictions*  
An array of restrictions that apply to the metadata being retrieved.

### Return Value

A `DataTable` object.

### Exception

- `ArgumentException` – The requested collection is not defined.
- `InvalidOperationException` – One of the following conditions exist:
  - The connection is closed.
  - The requested collection is not supported by the current version of Oracle database.
  - More restrictions were provided than the requested collection supports.
  - No population string is specified for requested collection.

## Remarks

This method takes the name of a metadata collection and an array of String values that specify the restrictions for filtering the rows in the returned DataTable. This returns a DataTable that contains only rows from the specified metadata collection that match the specified restrictions.

For example, if the Columns collection has three restrictions (owner, tablename, and columnname), to retrieve all the columns for the EMP table regardless of schema, the GetSchema method must pass in at least these values: null, EMP.

If no restriction value is passed in, default values are used for that restriction, which is the same as passing in null. This differs from passing in an empty string for the parameter value. In this case, the empty string ("") is considered the value for the specified parameter.

*collectionName* is not case-sensitive, but restrictions (string values) are.

## Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;

class GetSchemaSample
{
    static void Main(string[] args)
    {
        string constr = "User Id=scott; Password=tiger; Data Source=oracle;";
        string ProviderName = "Oracle.DataAccess.Client";

        DbProviderFactory factory = DbProviderFactories.GetFactory(ProviderName);

        using (DbConnection conn = factory.CreateConnection())
        {
            try
            {
                conn.ConnectionString = constr;
                conn.Open();

                //Get Restrictions
                DataTable dtRestrictions =
                    conn.GetSchema(DbMetaDataCollectionNames.Restrictions);

                DataView dv = dtRestrictions.DefaultView;

                dv.RowFilter = "CollectionName = 'Columns'";
                dv.Sort = "RestrictionNumber";

                for (int i = 0; i < dv.Count; i++)
                    Console.WriteLine("{0} (default) {1}" ,
                                      dtRestrictions.Rows[i]["RestrictionName"],
                                      dtRestrictions.Rows[i]["RestrictionDefault"]);

                //Set restriction string array
                string[] restrictions = new string[3];

                //Get all columns from all tables owned by "SCOTT"
                restrictions[0] = "SCOTT";
                DataTable dtAllScottCols = conn.GetSchema("Columns", restrictions);
```

```

// clear collection
for (int i = 0; i < 3; i++)
    restrictions[i] = null;

//Get all columns from all tables named "EMP" owned by any
//owner/schema
restrictions[1] = "EMP";
DataTable dtAllEmpCols = conn.GetSchema("Columns", restrictions);

// clear collection
for (int i = 0; i < 3; i++)
    restrictions[i] = null;

//Get columns named "EMPNO" from tables named "EMP",
//owned by any owner/schema
restrictions[1] = "EMP";
restrictions[2] = "EMPNO";
DataTable dtAllScottEmpCols = conn.GetSchema("Columns", restrictions);

// clear collection
for (int i = 0; i < 3; i++)
    restrictions[i] = null;

//Get columns named "EMPNO" from all
//tables, owned by any owner/schema
restrictions[2] = "EMPNO";
DataTable dtAllEmpNoCols = conn.GetSchema("Columns", restrictions);
}
catch (Exception ex)
{
    Console.WriteLine(ex.Message);
    Console.WriteLine(ex.Source);
}
}
}
}

```

## GetSessionInfo

GetSessionInfo returns or refreshes an OracleGlobalization object that represents the globalization settings of the session.

#### Overload List:

- [GetSessionInfo\(\)](#)

This method returns a new instance of the OracleGlobalization object that represents the globalization settings of the session.

- [GetSessionInfo\(OracleGlobalization\)](#)

This method refreshes the provided `OracleGlobalization` object with the globalization settings of the session.

#### 📘 See Also

## GetSessionInfo()

This method returns a new instance of the `OracleGlobalization` object that represents the globalization settings of the session.

### Declaration

```
// C#  
public OracleGlobalization GetSessionInfo();
```

### Return Value

The newly created `OracleGlobalization` object.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class GetSessionInfoSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        // Get session info from connection object  
        OracleGlobalization info = con.GetSessionInfo();  
  
        // Update session info  
        info.DateFormat = "YYYY-MM-DD";  
        con.SetSessionInfo(info);  
  
        // Execute SQL SELECT  
        OracleCommand cmd = con.CreateCommand();  
        cmd.CommandText = "select TO_CHAR(hiredate) from emp";  
        Console.WriteLine("Hire Date ({0}): {1}",  
            info.DateFormat, cmd.ExecuteScalar());  
  
        // Clean up  
        cmd.Dispose();  
        con.Dispose();  
    }  
}
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## GetSessionInfo(OracleGlobalization)

This method refreshes the provided OracleGlobalization object with the globalization settings of the session.

**Declaration**

```
// C#  
public void GetSessionInfo(OracleGlobalization oraGlob);
```

**Parameters**

- *oraGlob*

The OracleGlobalization object to be updated.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## Open

This method opens a connection to an Oracle database.

**Declaration**

```
// C#  
public override void Open();
```

**Implements**

IDbConnection

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The connection is already opened or the connection string is null or empty.

OracleException – For token authentication, errors include "ORA-25707: The token is invalid.", "ORA-25708: The token has expired.", and "ORA-50109: Configuration for token-based authentication is invalid."

## Remarks

The connection is obtained from the pool if connection pooling is enabled. Otherwise, a new connection is established.

It is possible that the pool does not contain any unused connections when the `Open()` method is invoked. In this case, a new connection is established.

If no connections are available within the specified connection timeout value, when the Max Pool Size is reached, an `OracleException` is thrown.

For client-side validation of an access token:

- The access token must be 16KB bytes or less.
- There needs to be two periods, ".".
- It must be valid base 64.
- It must be valid JSON.
- There must be "sub" and "exp" claims.

The opened connection will have same `AutoCommit` property value as set by the application.

If the opened connection enlists in a distributed transaction, auto-commit will be disabled regardless of the `AutoCommit` value. Once that transaction completes, auto-commit functionality resets to the `AutoCommit` value.

The opened connection has the same `IsolationLevel` value as set by the application. If that connection enlists in a distributed transaction created using `TransactionScope`, then the application's `IsolationLevel` value is overridden. The connection object's `IsolationLevel` remains overridden once that transaction is over.

## OpenAsync

`OpenAsync` returns a Task-based asynchronous version of `OracleConnection.Open`.

### Overload List:

- [OpenAsync\(\)](#)

This method calls into the `OpenAsync` implementation with argument `cancellationToken` passed as `CancellationToken.None`.

- [OpenAsync\(CancellationToken cancellationToken\)](#)

This method returns a Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of opening connection.

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenAsync()

This method will call into the OpenAsync implementation with argument cancellationToken passed as CancellationTok

### Declaration

```
// C#  
public Task OpenAsync();
```

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of opening connection.

### Implements

DbConnection

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The connection is already opened or the connection string is null or empty.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenAsync(CancellationTok

This method returns a new Task-based asynchronous version of OracleConnection.Open.

### Declaration

```
// C#  
public override Task OpenAsync(CancellationTok
```

### Parameters

- `cancellationTok` - The input cancellation token which can be used by the application to cancel the task before connection timeout occurs.

## Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of opening connection.

## Implements

DbConnection

## Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The connection is already opened or the connection string is null or empty.

## Remarks

- After calling `OpenAsync`, `OracleConnection.State` will return `Connecting` until the returned Task is completed. Then, if the connection was successful, State will return `Open`. If the connection fails, State will return `Closed`.
- If the connection timeout time elapses without successfully connecting, the returned Task will be marked as faulted with an Exception.

## Example

```
using Oracle.ManagedDataAccess.Client;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main()
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";
            OracleConnection oc = new OracleConnection(connectionString);

            // Open a connection asynchronously
            Task task = oc.OpenAsync(CancellationToken.None);

            // Execute an operation while the connection is being opened asynchronously
            Console.WriteLine("Opening a connection asynchronously.");

            // wait for the connection to be opened
            await task;
            Console.WriteLine("Connection opened successfully");
            oc.Close();
        }
    }
}
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewClientSecret

This method opens a new connection using a new Microsoft Entra ID client secret.

**Declaration**

```
// C#  
public static void OpenWithNewClientSecret(this OracleConnection @this, SecureString  
clientSecret)
```

**Parameters**

*clientSecret* – new client secret SecureString object reference

**Exceptions**

- `ArgumentNullException` is raised if new client secret is passed in as null.
- `ArgumentException` is raised if new client secret length is 0 or if corresponding secure string is not set as readonly.
- `InvalidOperationException` - The connection is already opened or `TokenAuthentication` property is not set to `AzureServicePrincipal`.
- `OracleException` – For token authentication, errors include "ORA-50109: Configuration for token-based authentication is invalid"

**Description**

ODP.NET uses the new client secret value to open a new connection. If the new connection opens successfully, then this new client secret is cached with the connection pool. If the new connection fails to open successfully, then an exception is thrown and the new client secret is ignored.

**Remarks**

This method is recommended only for when the current Azure client secret expires or opening a connection with a different client secret.

ODP.NET does not check whether the new client secret is the same value or reference as the existing cached client secret in the connection pool.

This method should successfully open an entirely new connection and connection pool even if there is no existing connection pool associated.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewPassword

OpenWithNewPassword opens a new connection with the new password.

**Overload List:**

- [OpenWithNewPassword\(String\)](#)  
OpenWithNewPassword opens a new connection with the new password.
- [OpenWithNewPassword\(SecureString\)](#)  
OpenWithNewPassword opens a new connection with the new password. This method will also update the password in the OracleCredential instance that was passed using the OracleConnection constructor or through the OracleConnection Credential property.
- [OpenWithNewPassword\(OracleOpaqueString\)](#)  
OpenWithNewPassword opens connection with a new OracleOpaqueString password.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewPassword(String)

This method opens a new connection with the new password.

**Declaration**

```
// C#  
public void OpenWithNewPassword(string newPassword);
```

**Parameters**

- *newPassword*  
A string that contains the new password.

**Remarks**

This method uses the ConnectionString property settings to establish a new connection. The old password must be provided in the connection string as the Password attribute value.

This method can only be called on an OracleConnection in the *closed* state.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- ["Password Expiration"](#)

## OpenWithNewPassword(SecureString)

This method opens a new connection with the new password.

**Declaration**

```
// C#  
public void OpenWithNewPassword(SecureString newSecurePassword)
```

**Parameters**

- *newSecurePassword*

The SecureString object that contains the new password for a user id.

**Remarks**

Use this method to change the password for a user id. This method can only be used if an OracleCredential instance was passed using the OracleConnection constructor or through the OracleConnection Credential property.

This method will also update the password in the OracleCredential instance that was passed using the OracleConnection constructor or through the OracleConnection Credential property.

OracleCredential does not support double quotes around a SecureString password. Double quotes can be used within a password, however.

**Exceptions**

ArgumentNullException is raised if *newSecurePassword* is NULL or is not read only.

InvalidOperationException is raised if OracleCredential is not already set on the OracleConnection either through the OracleConnection constructor or through the Credential property of the OracleConnection.

InvalidOperationException is raised if the OracleConnection is already in the open state.

InvalidOperationException is raised if the connection string is NULL or of length 0.

InvalidOperationException is raised if the user id, proxy user id, password, proxy password, DBA privilege is set using the connection string.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- ["Password Expiration"](#)

## OpenWithNewPassword(OracleOpaqueString)

This method opens connection with a new `OracleOpaqueString` password.

### Declaration

```
// C#  
public void OpenWithNewPassword(OracleOpaqueString newOpaquePassword)
```

### Parameters

- *newOpaquePassword*  
The new password to open a connection with.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewPasswordAsync

`OpenWithNewPasswordAsync` is a Task-based asynchronous version of `OracleConnection.OpenWithNewPassword()`, which opens a new connection with the new password.

### Overload List:

- [OpenWithNewPasswordAsync\(String\)](#)  
Opens a new connection asynchronously with a new password.
- [OpenWithNewPasswordAsync\(string, CancellationToken\)](#)  
Opens a new connection asynchronously with a new password and token that can cancel the task.
- [OpenWithNewPasswordAsync\(SecureString\)](#)  
Opens a new connection asynchronously with a new `SecureString` password.
- [OpenWithNewPasswordAsync\(SecureString, CancellationToken\)](#)  
Opens a new connection asynchronously with a new `SecureString` password and token that can cancel the task.

- [OpenWithNewPasswordAsync\(OracleOpaqueString\)](#)  
Asynchronously opens connection with a new `OracleOpaqueString` password
- [OpenWithNewPasswordAsync\(OracleOpaqueString, CancellationToken\)](#)  
Asynchronously opens connection with a new `OracleOpaqueString` password and a `CancellationToken` to cancel thread.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewPasswordAsync(String)

This method opens a new connection asynchronously with a new password.

### Declaration

```
// C#  
public Task OpenWithNewPasswordAsync(string newPassword);
```

### Parameters

- *newPassword*  
A string that contains the new password.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of opening connection.

### Remarks

This method uses the `ConnectionString` property settings to establish a new connection. The old password must be provided in the connection string as the `Password` attribute value.

This method can only be called on an `OracleConnection` in the closed state.

### Example

```
namespace AsyncApp  
{  
    class AsyncDemo  
    {  
        static async Task Main()  
        {  
            //Specify old password in connection string  
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";  
            OracleConnection oc = new OracleConnection(connectionString);  
  
            String newPass = "newPass";  
  
            // Open a connection asynchronously with new password
```

```
Task task = oc.OpenWithNewPasswordAsync(newPass);

// Execute an operation while the connection is being opened asynchronously
Console.WriteLine("Opening a connection asynchronously.");

// wait for the connection to be opened
await task;
Console.WriteLine("Connection opened successfully, password changed to " +
newPass);
    oc.Close();
}
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)

## OpenWithNewPasswordAsync(string, CancellationToken)

This method opens a new connection asynchronously with a new password and token that can cancel the task.

### Declaration

```
// C#
public Task OpenWithNewPasswordAsync(string newPassword, CancellationToken
cancellation_token);
```

### Parameters

- *newPassword*  
A string that contains the new password.
- *cancellation\_token*  
The input cancellation token which can be used by the application to cancel the task before connection timeout occurs.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of opening connection.

### Remarks

This method uses the `ConnectionString` property settings to establish a new connection. The old password must be provided in the connection string as the `Password` attribute value.

This method can only be called on an `OracleConnection` in the closed state.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewPasswordAsync(SecureString)

This method opens a new connection asynchronously with a new SecureString password.

### Declaration

```
// C#  
public Task OpenWithNewPasswordAsync(SecureString newSecurePassword);
```

### Parameters

- *newSecurePassword*  
A SecureString object that contains the new password for a user id.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of opening connection.

### Exceptions

- `ArgumentNullException` - *newSecurePassword* is NULL or is not read only.
- `InvalidOperationException` - `OracleCredential` is not already set on the `OracleConnection` either through the `OracleConnection` constructor or through the `Credential` property of the `OracleConnection`.
- `InvalidOperationException` - the `OracleConnection` is already in the open state.
- `InvalidOperationException` - the connection string is NULL or of length 0.
- `InvalidOperationException` - the user id, proxy user id, password, proxy password, DBA privilege is set using the connection string.

### Remarks

Use this method to change the password for a user id. This method can only be used if an `OracleCredential` instance was passed using the `OracleConnection` constructor or through the `OracleConnection Credential` property.

This method will also update the password in the `OracleCredential` instance that was passed using the `OracleConnection` constructor or through the `OracleConnection Credential` property.

`OracleCredential` does not support double quotes around a `SecureString` password. However, double quotes can be used within a password.

## OpenWithNewPasswordAsync(SecureString, CancellationToken)

This method opens a new connection asynchronously with a new SecureString password and token that can cancel the task.

### Declaration

```
// C#  
public Task OpenWithNewPasswordAsync(SecureString newSecurePassword, CancellationToken  
    cancellationToken);
```

### Parameters

- *newSecurePassword*  
A SecureString object that contains the new password for a user id.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task before connection timeout occurs.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of opening connection.

### Exceptions

- *ArgumentNullException* - newSecurePassword is NULL or is not read only.
- *InvalidOperationException* - OracleCredential is not already set on the OracleConnection either through the OracleConnection constructor or through the Credential property of the OracleConnection.
- *InvalidOperationException* - the OracleConnection is already in the open state.
- *InvalidOperationException* - the connection string is NULL or of length 0.
- *InvalidOperationException* - the user id, proxy user id, password, proxy password, DBA privilege is set using the connection string.

### Remarks

Use this method to change the password for a user id. This method can only be used if an OracleCredential instance was passed using the OracleConnection constructor or through the OracleConnection Credential property.

This method will also update the password in the `OracleCredential` instance that was passed using the `OracleConnection` constructor or through the `OracleConnection.Credential` property.

`OracleCredential` does not support double quotes around a `SecureString` password. However, double quotes can be used within a password.

## OpenWithNewPasswordAsync(OracleOpaqueString)

This method asynchronously opens connection with a new `OracleOpaqueString` password.

### Declaration

```
// C#  
public void OpenWithNewPasswordAsync(OracleOpaqueString newOpaquePassword)
```

### Parameters

- *newOpaquePassword*  
The new password to open a connection with.

#### See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewPasswordAsync(OracleOpaqueString, CancellationToken)

This method asynchronously opens connection with a new `OracleOpaqueString` password.

### Declaration

```
// C#  
public void OpenWithNewPasswordAsync(OracleOpaqueString newOpaquePassword,  
CancellationToken token)
```

### Parameters

- *newOpaquePassword*  
The new password to open a connection with.

- *token*

Token to cancel thread.

#### ① See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewToken

OpenWithNewToken opens a new connection by providing the refreshed/updated access token directly to ODP.NET.

#### Overload List:

- [OpenWithNewToken\(char\[\]\)](#)

OpenWithNewToken(char[]) opens a new connection by providing the refreshed/updated access token directly to ODP.NET instead of through the token refresh call back.

- [OpenWithNewToken\(char\[\], char\[\]\)](#)

OpenWithNewToken(char[], char[]) opens a new connection by providing the refreshed/updated signature token and private key directly to ODP.NET instead of through the token refresh call back

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewToken(char[])

This method can be used to open a new connection by providing the refreshed/updated access token directly to ODP.NET instead of through the token refresh call back. It is recommended to be used only in cases the application is unable or fails to provide the refreshed/updated access token through the token refresh call back.

#### Declaration

```
// C#  
public void OpenWithNewToken(char[] token)
```

#### Exceptions

- `ArgumentNullException` is raised if token is passed in as null.

- `InvalidOperationException` - The connection is already opened, or there is not an `OracleAccessToken` object set on the connection.
- `OracleException` – For token authentication, errors include “ORA-25707: The token is invalid.”, and “ORA-25708: The token has expired.”

### Description

ODP.NET uses the provided access token to open a new database connection. If the new connection is opened successfully, then the underlying `OracleAccessToken` object is updated with the new access token. If the driver fails to open the new connection, then an exception is thrown and the access token is ignored.

The `char[]` passed for the access token will be cleared ODP.NET for security reasons. The application should not depend on the `char[]` once this method is called.

For client-side validation of an access token:

- The access token must be 16KB bytes or less.
- There needs to be two periods, ".".
- It must be valid base 64.
- It must be valid JSON.
- There must be "sub" and "exp" claims.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## OpenWithNewToken(char[], char[])

This method can be used by the application to open a new connection by providing the refreshed/updated signature token and private key directly to ODP.NET instead of through the token refresh call back. It is recommended to be used only in cases the application is unable or fails to provide the refreshed/updated token and private key through the token refresh call back.

### Declaration

```
// C#  
public void OpenWithNewToken(char[] dbToken, char[] privateKey)
```

### Exceptions

- `ArgumentNullException` is raised if any parameters are passed in as null.
- Exception if connection is already open.
- Exception if the 'sub' value of the new token does not match the 'sub' value of the current token.

### Description

The 'sub' value of the new token must be the same as the 'sub' value of the current token. ODP.NET will use the application provided signature token and private key to open a new connection to the database. If the new connection can be opened successfully, then the underlying `OracleAccessToken` object will be updated with these new token and private key. If ODP.NET fails to open the new connection, then an exception will be thrown to the application and the `OracleAccessToken` object will not be updated with the new token and private key.

The `char[]` passed by the application for DB token and private key will be cleared by ODP.NET. Applications should not depend on these `char[]` once this constructor is called.

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## PurgeStatementCache

This method flushes the statement cache by closing all open cursors on the database, when statement caching is enabled.

### Declaration

```
// C#  
public void PurgeStatementCache();
```

### Remarks

Flushing the statement cache repetitively results in decreased performance and may negate the performance benefit gained by enabling the statement cache.

Statement caching remains enabled after the call to `PurgeStatementCache`.

Invocation of this method purges the cached cursors that are associated with the `OracleConnection`. It does not purge all the cached cursors in the database.

### Example

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class PurgeStatementCacheSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle;" +  
            "Statement Cache Size=20";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        OracleCommand cmd = new OracleCommand("select * from emp", con);
```

```
cmd.CommandType = CommandType.Text;
OracleDataReader reader = cmd.ExecuteReader();

// Purge Statement Cache
con.PurgeStatementCache();

// Close and Dispose OracleConnection object
Console.WriteLine("Statement Cache Flushed");
con.Close();
con.Dispose();
}
}
```

#### See Also

## ResumeSessionlessTransaction

This method resumes a sessionless transaction using the provided unique transaction identifier.

### Declaration

```
// C#
public void ResumeSessionlessTransaction(byte[] txnID);
```

### Parameters

- `txnID`  
the sessionless transaction identifier.

### Exceptions

`InvalidOperationException` - The connection is already associated with a transaction or is currently in a transaction.

`ArgumentException` - The specified sessionless transaction identifier is invalid.

`OracleException` - The provided sessionless transaction identifier does not exist in the database (ORA-26218).

`OracleException` - The database does not support sessionless transactions (ORA-26207).

### Remarks

The transaction identifier can be obtained from the `BeginSessionlessTransaction()` method return value. `OracleConnection` can operate on a sessionless transaction through its `Commit()`, `Rollback()`, and `SuspendSessionlessTransaction()` methods.

Auto-commit is disabled when this method is invoked successfully.

If the `OracleConnection.SessionlessTransactionOptions` is set, then `ResumeSessionlessTransaction()` operates the sessionless transaction based upon the `OracleConnection.SessionlessTransactionOptions` specified settings.

If the `OracleConnection.SessionlessTransactionOptions` is not set, then `ResumeSessionlessTransaction()` operates the sessionless transaction using the following default behavior:

- Sessionless transaction timeout is 60 seconds.
- The connection is associated with the `OracleConnection.ResumeSessionlessTransaction()` sessionless transaction. The transaction only resumes upon the first `OracleCommand` SQL execution.
- The sessionless transaction will not be suspended implicitly after SQL execution.

#### See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## Rollback

Rollback rolls back the local transaction.

#### Overload List:

- [Rollback\(\)](#)  
This method rolls back the local transaction.
- [Rollback\(String\)](#)  
This method rolls back the local transaction to a specified savepoint.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## Rollback()

This method rolls back the local transaction.

#### Declaration

```
// C#  
public void Rollback();
```

### Exception

`InvalidOperationException` – If the connection is closed or if the connection is enlisted in `System.Transactions` (both local and distributed).

`System.ObjectDisposedException` – This property cannot be accessed after the `OracleConnection` object is already disposed.

### Remarks

This method allows the user to rollback a local transaction or sessionless transaction using an `OracleConnection` object. Once rolled back, the transaction ends. For local transactions, it has the same behavior as the `OracleTransaction.Rollback` method. However, there are instances when this method is necessary to invoke without the `OracleTransaction` object available, such as an implicit transaction using “SELECT ... FOR UPDATE” or an implicit transaction executing an INSERT/UPDATE/DELETE statement with auto-commit disabled.

This method should not encounter any exceptions when the connection is within an explicit local transaction, implicit local transaction, or not associated with a transaction. This method cannot be executed on a connection enlisted in `System.Transactions` (local or distributed).

When an explicit transaction begins, auto-commit is disabled regardless of the `AutoCommit` property value. Once the `Rollback` method is invoked, `AutoCommit` reverts back to true if it was earlier enabled. Transaction isolation level will also reset to its earlier value on the `OracleConnection` object upon the rollback.

#### ① See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## Rollback(String)

This method rolls back the local transaction to a specified savepoint.

### Declaration

```
// C#  
public void Rollback(string savepointName);
```

### Exception

`InvalidOperationException` – If the connection is closed or if the connection is enlisted in `System.Transactions` (both local and distributed).

`System.ObjectDisposedException` – This property cannot be accessed after the `OracleConnection` object is already disposed.

`Oracle.ManagedDataAccess.Client.OracleException` – When a savepoint passed in has not been previously established by a `Save(String savepoint)`, or is an invalid savepoint.

## Remarks

After a rollback to a savepoint, the current transaction remains active and can be used for further operations.

This method allows the application to rollback a local transaction to the specific savepoint. It has the same behavior as the `OracleTransaction.Rollback(string savepoint)` method. However, there are instances when this method is necessary to invoke without the `OracleTransaction` object available, such as an implicit transaction using "SELECT ... FOR UPDATE" or an implicit transaction executing an INSERT/UPDATE/DELETE statement with auto-commit disabled.

This method should not encounter any exceptions when the connection is within an explicit local transaction, implicit local transaction, or not associated with a transaction. This method cannot be executed on a connection enlisted in `System.Transactions`.

Since savepoints are created in the database in a case-insensitive manner, the savepoints name cases of the Rollback and Save method do not have to match.

### See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## Save(String)

This method creates a savepoint in the database.

### Declaration

```
// C#  
public void Save(string savePointName);
```

### Parameters

*savePointName* - The name of the savepoint being created in the current transaction.

### Exception

`InvalidOperationException` – The transaction has already been completed successfully, has been rolled back, the connection is closed, or if the connection is enlisted in `System.Transactions` (local or distributed).

`System.ObjectDisposedException` – This property cannot be accessed after the `OracleConnection` object is already disposed.

### Remarks

After creating a savepoint, the transaction does not enter a completed state. It can be rolled back to the specific savepoint instead of rolling back the entire transaction

This method allows the user to create a savepoint within a transaction. It has the same behavior as the `OracleTransaction.Save(string savepoint)` method. However, there are instances when this method is necessary to invoke without the `OracleTransaction` object

available, such as an implicit transaction using "SELECT ... FOR UPDATE" or an implicit transaction executing an INSERT/UPDATE/DELETE statement with auto-commit disabled.

This method should not encounter any exceptions when the connection is within an explicit local transaction, implicit local transaction, or not associated with a transaction. This method cannot be executed on a connection enlisted in System.Transactions.

If a previously used savepoint name is specified in the same transaction, the previous one is overwritten with the current savepoint.

Since savepoints are created in the database in a case-insensitive manner, the savepoint name cases of Rollback and Save methods do not have to match.

## SetSessionInfo

This method alters the session's globalization settings with all the property values specified in the provided OracleGlobalization object.

### Declaration

```
// C#  
public void SetSessionInfo(OracleGlobalization oraGlob);
```

### Parameters

- *oraGlob*

An OracleGlobalization object.

### Remarks

Calling this method is equivalent to calling an ALTER SESSION SQL on the session.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class SetSessionInfoSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        // Get session info from connection object  
        OracleGlobalization info = con.SetSessionInfo();  
    }  
}
```

```
// Execute SQL SELECT
OracleCommand cmd = con.CreateCommand();
cmd.CommandText = "select TO_CHAR(hiredate) from emp";
Console.WriteLine("Hire Date ({0}): {1}",
    info.DateFormat, cmd.ExecuteScalar());

// Update session info
info.DateFormat = "MM-DD-RR";
con.SetSessionInfo(info);

// Execute SQL SELECT again
Console.WriteLine("Hire Date ({0}): {1}",
    info.DateFormat, cmd.ExecuteScalar());

// Clean up
cmd.Dispose();
con.Dispose();
}
}
```

## SetShardingKey(OracleShardingKey, OracleShardingKey)

This instance method enables applications to set the sharding key and the super sharding key before requesting a connection.

### Declaration

```
// C#
public void SetShardingKey(OracleShardingKey shardKey, OracleShardingKey
superShardingKey);
```

### Exceptions

**InvalidArgumentException** – An invalid Oracle sharding key is supplied.

**InvalidOperationException** – The method is invoked when the connection is in an Open state.

### Remarks

This method sets the sharding key and the super sharding key that is to be used for returning the proper connection upon the Open method invocation.

This method can only be invoked when the connection is in a Closed state.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
```

```
class Sharding
{
    static void Main()
    {
        OracleConnection con = new OracleConnection("user id=hr;password=hr;Data
Source=orcl;");
        //Setting a shard key
        OracleShardingKey shardingKey = new OracleShardingKey(OracleDbType.Int32, 123);
        //Setting a second shard key value for a composite key
        shardingKey.SetShardingKey(OracleDbType.Varchar2, "gold");
        //Creating and setting the super shard key
        OracleShardingKey superShardingKey = new OracleShardingKey();
        superShardingKey.SetShardingKey(OracleDbType.Int32, 1000);

        //Setting super sharding key and sharding key on the connection
        con.SetShardingKey(shardingKey, superShardingKey);
        con.Open();

        //perform SQL query
    }
}
```

## SuspendSessionlessTransaction

This method suspends the active sessionless transaction immediately from the session.

### Declaration

```
// C#
public void SuspendSessionlessTransaction();
```

### Exceptions

OracleException - The active transaction is not a sessionless transaction (ORA-26202).

### Remarks

If the connection is associated with the active sessionless transaction, the transaction is suspended immediately and will not be associated with the session.

If the connection is not associated with a sessionless transaction, it is a no-op.

## UseAzureTokenAuthentication

This method associates the Microsoft Entra ID token authentication settings with the `OracleConnection` object for use upon the next connection open.

**Declaration**

```
// C#
public static void UseAzureTokenAuthentication(this OracleConnection @this,
AzureTokenAuthentication azureTokenAuthentication = null)
```

**Parameters**

*azureTokenAuthentication* – `AzureTokenAuthentication` object reference. Default value is `null`.

**Description**

This method accepts an `AzureTokenAuthentication` object reference, which ODP.NET uses for access token retrieval upon opening a connection. Once opened, the object becomes read-only and cannot be modified further.

If multiple connections use the same `AzureTokenAuthentication` object reference, connection string, and pool identifiers, then all those connections will be part of the same connection pool.

If the `AzureTokenAuthentication` object reference is omitted, ODP.NET only uses token parameters configured through `tnsnames.ora`, Easy Connect Plus, `sqlnet.ora`, SEPS wallet, and/or Azure .NET SDK environment variables. These parameters values then act as connection pool identifiers.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)

## UseOciTokenAuthentication

This method associates the OCI IAM token authentication settings with the `OracleConnection` object for use upon the next connection open.

**Declaration**

```
// C#
public static void UseOciTokenAuthentication(this OracleConnection @this,
OciTokenAuthentication ociTokenAuth);
```

## Remarks

The object hashcode passed in this method is part of the connection pool manager identification so that different objects result in different connection pools.

Once the ODP.NET OCI token authentication object opens a connection successfully, it becomes read only and can no longer be modified.

## Exceptions

- If the connection is already open
- TokenAuthentication property is set to any value other than `OciApiKey`, `OciInstancePrincipal`, `OciDelegationToken`, `OciInteractive`, or `OciDefault`.

## OracleConnection Events

OracleConnection events are listed in [Table 6-54](#).

**Table 6-54 OracleConnection Events**

| Event Name                     | Description                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ConnectionOpen</a> | This event is triggered upon the <code>OracleConnection.Open()</code> method                                                  |
| Disposed                       | Inherited from <code>System.ComponentModel.Component</code>                                                                   |
| <a href="#">Failover</a>       | An event that is triggered when an Oracle failover occurs<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">HAEvent</a>        | An event that is triggered when an HA event occurs                                                                            |
| <a href="#">InfoMessage</a>    | An event that is triggered for any message or warning sent by the database                                                    |
| <a href="#">StateChange</a>    | An event that is triggered when the connection state changes                                                                  |

### See Also

## ConnectionOpen

This event is triggered upon the `OracleConnection.Open()` method or a connection opening to undertake Application Continuity failover and replay.

### Declaration

```
// C#  
public event OracleConnectionOpenEventHandler ConnectionOpen;
```

### Event Data

The event handler receives a `OracleConnectionOpenEventArgs` object which exposes the following property containing information about the `ConnectionOpen` event.

- `Connection`  
`OracleConnection` object on which `Open()` is called.

### Exceptions

- `InvalidOperationException()` - if `CPVersion=1.0` and the `ConnectionOpen` event is used. Applies to unmanaged ODP.NET only.
- `InvalidOperationException()` - if the `ConnectionOpen` event is set after opening a connection.

### Remarks

This feature requires `CPVersion=2.0` to be used.

In order to configure the connection before it is dispensed, the application should register the callback to the `ConnectionOpen` event before `Open()` is called.

Only supported for .NET Framework 4.x and .NET (Core).

### Application Continuity Scenarios

For applications that set state only at the beginning of a request or for stateful applications that gain performance benefits from using connections with a preset state, they can register for a `ConnectionOpen` event and then check the reason for the event before taking appropriate action.

When registered, the event will be executed upon successful reconnection following a recoverable error. The triggering event reason will be available through `ConnectionOpenReason` property of `OracleConnectionOpenEventArgs` object provided with the event.

The application is responsible for ensuring the initialization actions are the same as that of the original connection before failover. If the event invocation fails, then replay is disabled on that connection.

### Example

```
// C#  
// NOTE: The sample below requires CPVersion=2.0 to be configured in the .NET  
configuration  
using System;  
using Oracle.ManagedDataAccess.Client;
```

```
class ConOpenEventSample
{
    public static void ConOpenCallback(OracleConnectionOpenEventArgs eventArgs)
    {
        OracleCommand cmd = new OracleCommand("ALTER SESSION SET
NLS_LANGUAGE='GERMAN'", eventArgs.Connection);
        cmd.ExecuteNonQuery();
        cmd.Dispose();
    }

    static void Main(string[] args)
    {
        // Establish a connection
        string constr = "user id=hr;password=hr;data source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.ConnectionOpen += ConOpenCallback;
        con.Open();
        con.Dispose();
    }
}
```

## Failover

This event is triggered when an Oracle failover occurs.

### Declaration

```
// C#
public event OracleFailoverEventHandler Failover;
```

### Event Data

The event handler receives an `OracleFailoverEventArgs` object which exposes the following properties containing information about the event.

- `FailoverType`  
Indicates the type of the failover.
- `FailoverEvent`  
Indicates the state of the failover.

## Remarks

The Failover event is raised when a connection to an Oracle instance is unexpectedly severed. The client should create an `OracleFailoverEventHandler` delegate to listen to this event.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnection Class](#)
- [OracleConnection Members](#)
- ["OracleFailoverEventArgs Properties"](#)
- ["OracleFailoverEventHandler Delegate"](#)

## HAEvent

This event is triggered when an HA event occurs.

### Declaration

```
// C#  
public static event OracleHAEventHandler HAEvent;
```

### Event Data

The event handler receives an `OracleHAEventArgs` object which exposes the following properties containing information about the event.

- **Source**  
Indicates the source of the event.
- **Status**  
Indicates the status of the event.
- **DatabaseName**  
Indicates the database name affected by this event.
- **DatabaseDomainName**  
Indicates the database domain name affected by this event.
- **HostName**  
Indicates the host name affected by this event.
- **InstanceName**  
Indicates the instance name affected by this event.
- **ServiceName**  
Indicates the service name affected by this event.
- **Time**  
Indicates the time of the event.

### Remarks

The HAEvent is static, which means that any HA Events that happen within the application domain can trigger this event. Note that in order to receive HA event notifications, OracleConnection objects that establish connections within the application domain must have "ha\_events=true" in the application. Otherwise, the application never receives any HA Events.

## InfoMessage

This event is triggered for any message or warning sent by the database.

### Declaration

```
// C#  
public event OracleInfoMessageEventHandler InfoMessage;
```

### Event Data

The event handler receives an OracleInfoMessageEventArgs object which exposes the following properties containing information about the event.

- Errors  
The collection of errors generated by the data source.
- Message  
The error text generated by the data source.
- Source  
The name of the object that generated the error.

### Remarks

In order to respond to warnings and messages from the database, the client should create an OracleInfoMessageEventHandler delegate to listen to this event.

## StateChange

This event is triggered when the connection state changes.

### Declaration

```
// C#  
public override event StateChangeEventHandler StateChange;
```

### Event Data

The event handler receives a `StateChangeEventArgs` object which exposes the following properties containing information about the event.

- `CurrentState`  
The new state of the connection.
- `OriginalState`  
The original state of the connection.

### Remarks

The `StateChange` event is raised after a connection changes state, whenever an explicit call is made to `Open`, `Close` or `Dispose`.

## OracleConnectionOpenEventArgs Class

The `OracleConnectionOpenEventArgs` class provides connection information for the `OracleConnection.Open()` method. When a connection is opened, the callback registered using `ConnectionOpen` is triggered along with the `OracleConnectionOpenEventArgs` object.

Class Inheritance

System.Object  
    System.EventArgs  
        Oracle.DataAccess.Client.OracleConnectionOpenEventArgs

Declaration

```
// C#  
public sealed class OracleConnectionOpenEventArgs
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Connection

This property specifies the OracleConnection on which connection open event has occurred.

**Declaration**

```
// C#  
public Connection{ get;}
```

**Property Value**

Returns a OracleConnection object on which Open( ) is called.

**Remarks**

Only supported for .NET Framework 4.x and .NET (Core).

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionOpenEventArgs Class](#)
- [OracleConnectionOpenEventArgs Members](#)

# ConnectionOpenReason

This property indicates the reason triggering the ConnectionOpen event.

## Declaration

```
// C#
public OracleConnectionOpenReason ConnectionOpenReason { get; }
```

## Property Value

Returns OracleConnectionOpenReason enumeration value indicating the ConnectionOpen event triggering reason.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionOpenEventArgs Class](#)
- [OracleConnectionOpenEventArgs Members](#)

# OracleConnectionOpenEventHandler Delegate

The OracleConnectionOpenEventHandler delegate represents the signature of the method that handles OracleConnection.ConnectionOpen event.

## Declaration

```
// C#
public delegate void OracleConnectionOpenEventHandler (OracleConnectionOpenEventArgs
eventArgs);
```

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Parameters

- *eventArgs*  
The OracleConnectionOpenEventArgs object that contains the connection data.

① See Also

- [ConnectionOpen](#)

# OracleConnectionStringBuilder Class

An OracleConnectionStringBuilder object allows applications to create or modify connection strings.

## Class Inheritance

System.Object

System.Data.Common.DbConnectionStringBuilder

Oracle.DataAccess.Client.OracleConnectionStringBuilder

## Declaration

```
// C#
public sealed class OracleConnectionStringBuilder : DbConnectionStringBuilder
```

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Remarks

The following rules must be followed for setting values with reserved characters:

1. Values containing characters enclosed within single quotes  
If the value contains characters that are enclosed within single quotation marks, then the entire value must be enclosed within double quotation marks.  
For example, password = "' scOTT'" where the value is 'scOTT'.
2. Values containing characters enclosed within double quotes

Values should be enclosed in double quotation marks to preserve the case and to avoid the upper casing of values.

If the value contains characters enclosed in double quotation marks, then it must be enclosed in single quotation marks.

For example, password = "scoTT" where the value is "scoTT".

### 3. Values containing characters enclosed in both single and double quotes

If the value contains characters enclosed in both single and double quotation marks, the quotation mark used to enclose the value must be doubled each time it occurs within the value.

For example, password = '"sco''TT"' where the value is "sco'TT".

### 4. Values containing spaces

All leading and trailing spaces are ignored, but the spaces between the value are recognized. If the value needs to have leading or trailing spaces then it must be enclosed in double quotation marks.

For example, User ID = Sco TT where the value is <Sco TT>.

For example, User ID = "Sco TT " where the value is <Sco TT>.

### 5. Keywords occurring multiple times in a connection string

If a specific keyword occurs multiple times in a connection string, the last occurrence listed is used in the value set.

For example, with "User ID = scott; password = tiger; User ID = david" connection string, User ID value is david.

To limit malicious access, the APIs of OracleConnectionStringBuilder, Add and Item, insert double quotes around connection string attributes that use special characters. Using special characters in strings can be a format string attack method. Adding double quotes for attributes will not affect database access in most cases. However, there are attributes that require exact string matching, such as passwords. OracleConnectionStringBuilder's addition of double quotes to a password with special characters may result in a generation of a connection string that fails to authenticate against the database.

## Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;
using System.Collections;

class ConnectionStringBuilderSample
{
    static void Main(string[] args)
    {
        bool bRet = false;

        // Create an instance of OracleConnectionStringBuilder
        OracleConnectionStringBuilder connStrBuilder =
            new OracleConnectionStringBuilder();

        // Add new key/value pairs to the connection string
        connStrBuilder.Add("User Id", "scott");
        connStrBuilder.Add("Password", "tiger");
```

```
connStrBuilder.Add("Data Source", "oracle");
connStrBuilder.Add("pooling", false);

// Modify the existing value
connStrBuilder["Data source"] = "inst1";

// Remove an entry from the connection string
bRet = connStrBuilder.Remove("pooling");

//ContainsKey indicates whether or not the specific key exist
//returns true even if the user has not specified it explicitly
Console.WriteLine("Enlist exist: " +
    connStrBuilder.ContainsKey("Enlist"));

//returns false
connStrBuilder.ContainsKey("Invalid");

// ShouldSerialize indicates whether or not a specific key
// exists in connection string inherited from DbConnectionStringBuilder.
// returns true if the key is explicitly added the user otherwise false;
// this will return false as this key doesn't exists.
connStrBuilder.ShouldSerialize("user");

// returns false because this key is not added by user explicitly.
connStrBuilder.ShouldSerialize("Enlist");

// IsFixedSize [read-only property]
Console.WriteLine("Connection String is fixed size only: "
    + connStrBuilder.IsFixedSize);
Console.WriteLine("Key/Value Pair Count: " + connStrBuilder.Count);

//adding a new key which is not supported by the provider
//is not allowed.
try
{
    //this will throw an exception.
    connStrBuilder.Add("NewKey", "newValue");
}
catch (Exception ex)
{
    Console.WriteLine(ex.Message);
}

Console.WriteLine("Key/Value Pair Count: " + connStrBuilder.Count);

//modifying a existing key is allowed.
connStrBuilder.Add("Enlist", false);
Console.WriteLine("Key/Value Pair Count: " + connStrBuilder.Count);

// Get all the keys and values supported by the provider.
ICollection keyCollection = connStrBuilder.Keys;
ICollection valueCollection = connStrBuilder.Values;

IEnumerator keys = keyCollection.GetEnumerator();
IEnumerator values = valueCollection.GetEnumerator();

while (keys.MoveNext())
{
    values.MoveNext();
    Console.WriteLine("Key: {0}    Value: {1} \n"
        , keys.Current , values.Current);
}
```

```
}  
}
```

## OracleConnectionStringBuilder Members

OracleConnectionStringBuilder members are listed in the following tables.

### OracleConnectionStringBuilder Constructors

OracleConnectionStringBuilder constructors are listed in [Table 6-57](#).

**Table 6-57 OracleConnectionStringBuilder Constructors**

| Constructor                                                | Description                                                                     |
|------------------------------------------------------------|---------------------------------------------------------------------------------|
| <a href="#">OracleConnectionStringBuilder Constructors</a> | Instantiates a new instance of OracleConnectionStringBuilder class (Overloaded) |

### OracleConnectionStringBuilder Public Properties

OracleConnectionStringBuilder instance properties are listed in [Table 6-58](#).

**Table 6-58 OracleConnectionStringBuilder Public Properties**

| Properties                         | Description                                                                                             |
|------------------------------------|---------------------------------------------------------------------------------------------------------|
| BrowsableConnectionString          | Inherited from System.Data.Common.DbConnectionStringBuilder                                             |

## OracleConnectionStringBuilder Constructors

OracleConnectionStringBuilder constructors instantiate new instances of the OracleConnectionStringBuilder class.

**Overload List:**

- [OracleConnectionStringBuilder\(\)](#)  
This constructor instantiates a new instance of OracleConnectionStringBuilder class.
- [OracleConnectionStringBuilder\(string\)](#)  
This constructor instantiates a new instance of the OracleConnectionStringBuilder class with the provided connection string.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

### OracleConnectionStringBuilder()

This constructor instantiates a new instance of the OracleConnectionStringBuilder class.

**Declaration**

```
// C#  
public OracleConnectionStringBuilder();
```

**Remarks**

The ConnectionString property is empty after the object is created.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

### OracleConnectionStringBuilder(string)

This constructor instantiates a new instance of the OracleConnectionStringBuilder class with the provided connection string.

**Declaration**

```
// C#
public OracleConnectionStringBuilder(string connectionString);
```

**Parameters**

- *connectionString*  
The connection information.

**Exceptions**

ArgumentNullException - The *connectionString* parameter is null.

ArgumentException - The *connectionString* parameter is invalid.

**Remarks**

The *ConnectionString* property of this instance is set to the supplied connection string.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## OracleConnectionStringBuilder Public Properties

OracleConnectionStringBuilder public properties are listed in [Table 6-60](#).

**Table 6-60 OracleConnectionStringBuilder Public Properties**

| Properties                         | Description                                                                                             |
|------------------------------------|---------------------------------------------------------------------------------------------------------|
| BrowsableConnectionString          | Inherited from System.Data.Common.DbConnectionStringBuilder                                             |
| <a href="#">ConnectionLifetime</a> | Specifies the value corresponding to the Connection Lifetime attribute in the ConnectionString property |
| ConnectionString                   | Inherited from System.Data.Common.DbConnectionStringBuilder                                             |
| <a href="#">ConnectionTimeout</a>  | Specifies the value corresponding to the Connection Timeout attribute in the ConnectionString property  |
| <a href="#">ContextConnection</a>  | Specifies the value corresponding to the Context Connection attribute in the ConnectionString property  |
| Count                              | Inherited from System.Data.Common.DbConnectionStringBuilder                                             |
| <a href="#">DataSource</a>         | Specifies the value corresponding to the Data Source attribute in the ConnectionString property         |

**Table 6-60 (Cont.) OracleConnectionStringBuilder Public Properties**

| Properties                          | Description                                                                                               |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <a href="#">DBAPrivilege</a>        | Specifies the value corresponding to the DBA Privilege attribute in the ConnectionString property         |
| <a href="#">DecrPoolSize</a>        | Specifies the value corresponding to the Decr Pool Size attribute in the ConnectionString property        |
| <a href="#">Enlist</a>              | Specifies the value corresponding to the Enlist attribute in the ConnectionString property                |
| <a href="#">HAEvents</a>            | Specifies the value corresponding to the HA Events attribute in the ConnectionString property             |
| <a href="#">IncrPoolSize</a>        | Specifies the value corresponding to the Incr Pool Size attribute in the ConnectionString property        |
| <a href="#">IsFixedSize</a>         | Indicates whether or not the Connection String Builder has a fixed size                                   |
| IsReadOnly                          | Inherited from System.Data.Common.DbConnectionStringBuilder                                               |
| <a href="#">Item</a>                | Specifies the value associated with the specified attribute                                               |
| <a href="#">Keys</a>                | Specifies a collection of attributes contained in the Connection String Builder                           |
| <a href="#">LoadBalancing</a>       | Specifies the value corresponding to the Load Balancing attribute in the ConnectionString property        |
| <a href="#">MaxPoolSize</a>         | Specifies the value corresponding to the Max Pool Size attribute in the ConnectionString property         |
| <a href="#">MetadataPooling</a>     | Specifies the value that corresponds to the Metadata Pooling attribute in the ConnectionString property   |
| <a href="#">MinPoolSize</a>         | Specifies the value corresponding to the Min Pool Size attribute in the ConnectionString property         |
| <a href="#">Password</a>            | Specifies the value corresponding to the Password attribute in the ConnectionString property              |
| <a href="#">PersistSecurityInfo</a> | Specifies the value corresponding to the Persist Security Info attribute in the ConnectionString property |
| <a href="#">Pooling</a>             | Specifies the value corresponding to the Pooling attribute in the ConnectionString property               |
| <a href="#">ProxyPassword</a>       | Specifies the value corresponding to the Proxy User Id attribute in the ConnectionString property         |
| <a href="#">ProxyUserId</a>         | Specifies the value corresponding to the Proxy User Id attribute in the ConnectionString property         |
| <a href="#">SelfTuning</a>          | Specifies the value corresponding to the Self Tuning attribute in the ConnectionString property           |
| <a href="#">StatementCachePurge</a> | Specifies the value corresponding to the Statement Cache Purge attribute in the ConnectionString property |
| <a href="#">StatementCacheSize</a>  | Specifies the value corresponding to the Statement Cache Size attribute in the ConnectionString property  |
| <a href="#">TnsAdmin</a>            | Specifies the directory where ODP.NET can find its sqlnet.ora and tnsnames.ora configuration files        |

**Table 6-60 (Cont.) OracleConnectionStringBuilder Public Properties**

| Properties                          | Description                                                                                                                                                                 |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">TokenAuthentication</a> | Specifies the value corresponding to the token_auth attribute in the ConnectionString property.<br>This property is supported by managed ODP.NET and ODP.NET Core only.     |
| <a href="#">TokenLocation</a>       | Specifies the value corresponding to the token_location attribute in the ConnectionString property.<br>This property is supported by managed ODP.NET and ODP.NET Core only. |
| <a href="#">UserID</a>              | Specifies the value corresponding to the User Id attribute in the ConnectionString property                                                                                 |
| <a href="#">ValidateConnection</a>  | Specifies the value corresponding to the Validate Connection attribute in the ConnectionString property                                                                     |
| <a href="#">Values</a>              | Specifies a collection of values contained in the Connection String Builder                                                                                                 |
| <a href="#">WalletLocation</a>      | Specifies the ODP.NET wallet directory                                                                                                                                      |
| <a href="#">WalletPassword</a>      | Stores the password to decrypt the PKCS #12 wallet<br><i>This property is supported by managed ODP.NET and ODP.NET Core only.</i>                                           |

**① See Also**

## ConnectionLifeTime

This property specifies the value corresponding to the Connection LifeTime attribute in the ConnectionString property.

**Declaration**

```
// C#  
public int ConnectionLifeTime{get; set;}
```

**Property Value**

An int that represents the value of the supplied attribute.

**Exceptions**

OracleException - The specified value is less than zero.

### Remarks

When an `OracleConnectionStringBuilder` instance is created, this property is set to the default value of the corresponding connection string attribute.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## ConnectionTimeout

This property specifies the value corresponding to the Connection Timeout attribute in the `ConnectionString` property.

### Declaration

```
// C#  
public int ConnectionTimeout{get; set;}
```

### Property Value

An `int` that represents the value of the supplied attribute.

### Exceptions

`OracleException` - The specified value is less than zero.

### Remarks

When an `OracleConnectionStringBuilder` instance is created, this property is set to the default value of the corresponding connection string attribute.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## ContextConnection

This property specifies the value corresponding to the Context Connection attribute in the `ConnectionString` property.

**Declaration**

```
// C#  
public bool ContextConnection {get; set;}
```

**Property Value**

A bool that represents the value of the supplied attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## DataSource

This property specifies the value corresponding to the Data Source attribute in the ConnectionString property.

**Declaration**

```
// C#  
public string DataSource{get; set;}
```

**Property Value**

A string that represents the value of the supplied attribute.

**Exceptions**

ArgumentNullException - The specified value is null.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## DBAPrivilege

This property specifies the value corresponding to the DBA Privilege attribute in the ConnectionString property.

**Declaration**

```
// C#  
public string DBAPrivilege{get; set;}
```

**Property Value**

A string that represents the value of the supplied attribute.

Possible values are SYSDBA, SYSASM, SYSOPER, SYSBACKUP, SYSDG, SYSKM, or SYSRAC.

**Exceptions**

ArgumentNullException - The specified value is null.

OracleException - The specified value is invalid.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## DecrPoolSize

This property specifies the value corresponding to the Decr Pool Size attribute in the ConnectionString property.

**Declaration**

```
// C#  
public int DecrPoolSize{get; set;}
```

**Property Value**

An int that represents the value of the supplied attribute.

**Exceptions**

OracleException - The specified value is less than 1.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Enlist

This property specifies the value corresponding to the Enlist attribute in the `ConnectionString` property.

### Declaration

```
// C#  
public string Enlist{get; set;};
```

### Property Value

A string that represents the value of the supplied attribute. Values are case-insensitive. Possible values are: `dynamic`, `true`, `false`, `yes`, and `no`.

### Exceptions

`ArgumentNullException` - The specified value is null.

`OracleException` - The supplied value is not one of following: `dynamic`, `true`, `false`, `yes`, or `no`.

### Remarks

When an `OracleConnectionStringBuilder` instance is created, this property is set to the default value of the corresponding connection string attribute.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## HAEvents

This property specifies the value corresponding to the HA Events attribute in the `ConnectionString` property.

### Declaration

```
// C#  
public bool HAEvents{get; set;}
```

### Property Value

A `bool` that represents the value of the supplied attribute.

**Remarks**

When an `OracleConnectionStringBuilder` instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## IncrPoolSize

This property specifies the value corresponding to the `Incr Pool Size` attribute in the `ConnectionString` property.

**Declaration**

```
// C#  
public int IncrPoolSize{get; set;}
```

**Property Value**

An `int` that represents the value of the supplied attribute.

**Exceptions**

`OracleException` - The specified value is less than 1.

**Remarks**

When an `OracleConnectionStringBuilder` instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## IsFixedSize

Indicates whether or not the `Connection String Builder` has a fixed size.

**Declaration**

```
// C#  
public override bool IsFixedSize{get;}
```

**Property Value**

Returns true if the Connection String Builder has a fixed size; otherwise, returns false.

**Remarks**

Attributes cannot be added or removed. They can only be modified for connection strings with a fixed size.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Item

This property specifies the value associated with the specified attribute.

**Declaration**

```
// C#  
public override object this[string keyword]{get; set;}
```

**Property Value**

An object value corresponding to the attribute.

**Exceptions**

ArgumentNullException - The specified attribute is null.

OracleException - The specified attribute is not supported or the specified value is invalid.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Keys

This property specifies a collection of attributes contained in the Connection String Builder.

**Declaration**

```
// C#  
public override ICollection Keys{get;}
```

**Property Value**

Returns an ICollection that represents the attributes in the Connection String Builder.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## LoadBalancing

This property specifies the value corresponding to the Load Balancing attribute in the ConnectionString property.

**Declaration**

```
// C#  
public bool LoadBalancing {get; set;}
```

**Property Value**

A bool that contains the value of the supplied attribute.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## MaxPoolSize

This property specifies the value corresponding to the Max Pool Size attribute in the ConnectionString property.

**Declaration**

```
// C#  
public int MaxPoolSize{get; set;}
```

**Property Value**

An int that represents the value of the supplied attribute.

### Exceptions

OracleException - The specified value is less than 1.

### Remarks

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## MetadataPooling

This property specifies the value that corresponds to the Metadata Pooling attribute in the ConnectionString property.

### Declaration

```
// C#  
public bool MetadataPooling{get; set;};
```

### Property Value

A bool containing the value of the supplied attribute.

### Remarks

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## MinPoolSize

This property specifies the value corresponding to the Min Pool Size attribute in the ConnectionString property.

### Declaration

```
// C#  
public int MinPoolSize{get; set;}
```

**Property Value**

An int that contains the value of the supplied attribute.

**Exceptions**

OracleException - The specified value is less than 0.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Password

This property specifies the value corresponding to the Password attribute in the ConnectionString property.

**Declaration**

```
// C#  
public string Password{get; set;}
```

**Property Value**

A string that contains the value of the supplied attribute.

**Exception**

ArgumentNullException - The specified value is null.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## PersistSecurityInfo

This property specifies the value corresponding to the Persist Security Info attribute in the ConnectionString property.

**Declaration**

```
// C#  
public bool PersistSecurityInfo{get; set;}
```

**Property Value**

A bool that represents the value of the supplied attribute.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property gets set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Pooling

This property specifies the value corresponding to the Pooling attribute in the ConnectionString property.

**Declaration**

```
// C#  
public bool Pooling {get; set;}
```

**Property Value**

A bool that represents the value of the supplied attribute.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## ProxyPassword

This property specifies the value corresponding to the Proxy Password attribute in the ConnectionString property.

**Declaration**

```
// C#  
public string ProxyPassword {get; set;}
```

**Property Value**

A string that represents the value of the supplied attribute.

**Exception**

ArgumentNullException - The specified value is null.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## ProxyUserId

This property specifies the value corresponding to the Proxy User Id attribute in the ConnectionString property.

**Declaration**

```
// C#  
public string ProxyUserId {get; set;}
```

**Property Value**

A string that represents the value of the supplied attribute.

**Exception**

ArgumentNullException - The specified value is null.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## SelfTuning

This property specifies the value corresponding to the Self Tuning attribute in the ConnectionString property.

**Declaration**

```
// C#  
public bool SelfTuning {get; set;}
```

**Property Value**

A bool that represents the value of the supplied attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## StatementCachePurge

This property specifies the value corresponding to the Statement Cache Purge attribute in the ConnectionString property.

**Declaration**

```
// C#  
public bool StatementCachePurge {get; set;}
```

**Property Value**

A bool that represents the value of the supplied attribute.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## StatementCacheSize

This property specifies the value corresponding to the Statement Cache Size attribute in the ConnectionString property.

**Declaration**

```
// C#  
public int StatementCacheSize{get; set;}
```

**Property Value**

An int that represents the value of the supplied attribute.

**Exceptions**

OracleException - The specified value is less than zero.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## TnsAdmin

This property specifies the directory where ODP.NET can find its sqlnet.ora and tnsnames.ora configuration files.

**Declaration**

```
// C#  
public string TnsAdmin{get; set;}
```

**Property Value**

A string that represents the value of the supplied attribute.

**Remarks**

The default value is an empty string.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## TokenAuthentication

This property specifies the value corresponding to the token\_auth attribute in the ConnectionString.

**Declaration**

```
// C#  
public OracleTokenAuth TokenAuthentication { get; set; }
```

**Property Value**

An OracleTokenAuth value.

**Exceptions**

None.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## TokenLocation

This property specifies the value corresponding to the token\_location attribute in the ConnectionString property.

**Declaration**

```
// C#  
public string TokenLocation { get; set; }
```

**Property Value**

A string that represents the value of the supplied attribute.

**Exceptions**

None.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## UserID

This property specifies the value corresponding to the User Id attribute in the ConnectionString property.

**Declaration**

```
// C#  
public string UserID{get; set;}
```

**Property Value**

A string that represents the value of the supplied attribute.

**Exception**

ArgumentNullException - The specified value is null.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## ValidateConnection

This property specifies the value corresponding to the Validate Connection attribute in the ConnectionString property.

**Declaration**

```
// C#  
public bool ValidateConnection{get; set;}
```

**Property Value**

A bool that represents the value of the supplied attribute.

**Remarks**

When an OracleConnectionStringBuilder instance is created, this property is set to the default value of the corresponding connection string attribute.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Values

This property specifies a collection of values contained in the Connection String Builder.

**Declaration**

```
// C#  
public override ICollection Values{get;}
```

**Property Value**

Returns an *ICollection* that represents the values in the Connection String Builder.

**Remarks**

The order of the values in the *ICollection* is unspecified, but is the same as the associated attributes in the *ICollection* returned by the *Keys* property.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## WalletLocation

This property specifies the ODP.NET wallet directory.

**Declaration**

```
// C#  
public string WalletLocation{get; set;}
```

**Property Value**

A string that represents the value of the supplied attribute.

**Remarks**

The default value is an empty string.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## WalletPassword

This property stores the password to decrypt the PKCS #12 wallet.

### Declaration

```
// C#  
public string WalletPassword {get; set;}
```

### Property Value

The connection string attribute used to decrypt the PKCS #12 wallet.

### Remarks

Wallet passwords support the same functionality as traditional ODP.NET passwords.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## OracleConnectionStringBuilder Public Methods

OracleConnectionStringBuilder public methods are listed in [Table 6-61](#).

**Table 6-61 OracleConnectionStringBuilder Public Methods**

| Methods                     | Description                                                                                    |
|-----------------------------|------------------------------------------------------------------------------------------------|
| Add                         | Inherited from System.Data.Common.DbConnectionStringBuilder                                    |
| <a href="#">Clear</a>       | Clears the connection string contents                                                          |
| <a href="#">ContainsKey</a> | Indicates whether or not a specific attribute in the connection string is supported by ODP.NET |
| EquivalentTo                | Inherited from System.Data.Common.DbConnectionStringBuilder                                    |
| <a href="#">Remove</a>      | Removes the entry corresponding to the specified attribute from the connection string          |

**Table 6-61 (Cont.) OracleConnectionStringBuilder Public Methods**

| Methods                     | Description                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------|
| ShouldSerialize             | Inherited from <code>System.Data.Common.DbConnectionStringBuilder</code>          |
| ToString                    | Inherited from <code>System.Data.Common.DbConnectionStringBuilder</code>          |
| <a href="#">TryGetValue</a> | Returns the value corresponding to the supplied attribute, as an output parameter |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Clear

This method clears the connection string contents.

**Declaration**

```
// C#  
public override void Clear();
```

**Remarks**

All key/value pairs are removed from the `OracleConnectionStringBuilder` object and the `ConnectionString` property is set to `Empty`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## ContainsKey

This method indicates whether or not a specific attribute in the connection string is supported by ODP.NET.

**Declaration**

```
// C#  
public override bool ContainsKey(string keyword);
```

**Parameters**

- *keyword*  
The attribute being verified.

**Return Value**

Returns true if the specified attribute exists; otherwise, returns false.

**Exceptions**

ArgumentNullException - The specified attribute is null.

**Remarks**

This method indicates if the attribute is part of the provider-supported attributes. It does not indicate if the user added the attribute to the connection string.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## Remove

This method removes the entry corresponding to the specified attribute from the connection string.

**Declaration**

```
// C#  
public override bool Remove(string keyword);
```

**Parameters**

- *keyword*  
The attribute that specifies the entry to be removed.

**Return Value**

Returns true if the attribute existed in the connection string and the corresponding entry was removed; otherwise, returns false.

**Exceptions**

ArgumentNullException - The specified attribute is null.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

## TryGetValue

This method returns the value corresponding to the supplied attribute, as an output parameter.

### Declaration

```
// C#  
public override bool TryGetValue(string keyword, out object value);
```

### Parameters

- *keyword*  
The attribute for which the value is being retrieved.
- *value*  
The value of the supplied attribute.  
Sets *value* to the default value if the attribute is not present in the connection string.

### Return Value

Returns `true` if the value that corresponds to the attribute has been successfully retrieved; otherwise, returns `false`. If the attribute is not present in the connection string, returns `false` and sets the *value* to null.

### Exceptions

`ArgumentNullException` - The specified attribute is null.

### Remarks

If the function returns `false`, sets *value* to null.

If the attribute is not present in the connection string, sets *value* to the default value.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleConnectionStringBuilder Class](#)
- [OracleConnectionStringBuilder Members](#)

# OracleCredential Class

OracleCredential class provides a secure way to provide password while opening connection with Oracle Database using the ODP.NET driver. Use this class to avoid providing passwords in clear text in the connection string while opening a connection with Oracle Database. One can pass user id, password and DBA Privilege specific attributes through OracleCredential constructors and thus these attributes do not need to be in the connection string.

Operating system authenticated and context connections are not supported through OracleCredential class. An ArgumentException will be thrown if "/" is passed for userId or proxyUserId arguments of OracleCredential constructor.

ODP.NET uses a modified connection pooling algorithm with OracleCredential, which is described in more detail in the section [Connection Pooling with OracleCredential](#).

## Class Inheritance

System.Object  
Oracle.DataAccess.Client.OracleCredential

## Declaration

```
// C#  
public sealed class OracleCredential
```

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#  
using System;  
using System.Data;  
using System.Security;  
using Oracle.DataAccess.Client;  
//using Oracle.ManagedDataAccess.Client;  
  
class OracleCredentialSample
```

```
{
    static void Main()
    {
        // Connect
        string constr = "Data Source=oracle";

        SecureString secPwd = new SecureString();
        secPwd.AppendChar('h');
        secPwd.AppendChar('r');

        // Make the password read-only.
        secPwd.MakeReadOnly();

        // Create OracleCredential with userid and secure password.
        OracleCredential oc = new OracleCredential("hr", secPwd);

        OracleConnection con = new OracleConnection(constr, oc);
        con.Open();

        // Execute a SQL SELECT

        OracleCommand cmd = con.CreateCommand();
        cmd.CommandText = "select * from employees";

        OracleDataReader reader = cmd.ExecuteReader();

        // Print all employee numbers
        while (reader.Read())
            Console.WriteLine(reader.GetInt32(0));

        // Clean up
        reader.Dispose();
        cmd.Dispose();
        con.Dispose();
    }
}
```

## OracleCredential Members

OracleCredential members are listed in the following tables.

### OracleCredential Constructors

OracleCredential constructors are listed in [Table 6-62](#).

**Table 6-62 OracleCredential Constructors**

| Constructor                                   | Description                                                        |
|-----------------------------------------------|--------------------------------------------------------------------|
| <a href="#">OracleCredential Constructors</a> | Instantiates a new instance of OracleCredential class (Overloaded) |

**OracleCredential Properties**

OracleCredential properties are listed in [Table 6-63](#).

**Table 6-63 OracleCredential Properties**

| Property                      | Description                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DBAPrivilege</a>  | Returns the DBA Privilege used to create the OracleCredential object. OracleDBAPrivilege.None is returned if it was not provided by the user. |
| <a href="#">Password</a>      | Returns the password of the OracleCredential object                                                                                           |
| <a href="#">ProxyPassword</a> | Returns the proxy user password of the OracleCredential object                                                                                |
| <a href="#">ProxyUserId</a>   | Returns the proxy user id of the OracleCredential object                                                                                      |
| <a href="#">UserId</a>        | Returns the user id of the OracleCredential object                                                                                            |

**OracleCredential Public Methods**

OracleCredential public methods are listed in [Table 6-70](#).

**Table 6-64 OracleCredential Public Methods**

| Public Method                    | Description                                                                                                              |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Equals(Object)                   | Inherited from System.Object                                                                                             |
| Equals(Object)                   | Inherited from System.Object                                                                                             |
| GetHashCode()                    | Inherited from System.Object                                                                                             |
| GetType()                        | Inherited from System.Object                                                                                             |
| <a href="#">SetPassword</a>      | Sets or updates the password on the OracleCredential instance<br><i>Not available in ODP.NET, Unmanaged Driver</i>       |
| <a href="#">SetProxyPassword</a> | Sets or updates the proxy password on the OracleCredential instance<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| ToString()                       | Inherited from System.Object                                                                                             |

## OracleCredential Constructors

OracleCredential constructors instantiate new instances of an OracleCredential class.

**Overload List:**

- [OracleCredential\(string, SecureString\)](#)

This constructor creates an `OracleCredential` object with the user id and the secured password.

- [OracleCredential\(string, SecureString, OracleDBAPrivilege\)](#)

This constructor creates an `OracleCredential` object with the user id, the secured password, and the DBA privilege request.

- [OracleCredential\(string, SecureString, string, SecureString\)](#)

This constructor creates an `OracleCredential` object with the user id and the secured password for the end user, as well as the user id and the secured password for the proxy user.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCredential Class](#)
- [OracleCredential Members](#)

## OracleCredential(string, SecureString)

This constructor creates an `OracleCredential` object with the user id and the secured password.

### Declaration

```
// C#  
public OracleCredential(string userId, SecureString password)
```

### Exceptions

- `ArgumentNullException` is raised if any parameters are passed as null.
- `ArgumentException` is raised if "/" is passed for `userId` argument.
- `ArgumentException` is raised if the `SecureString` containing the password is not read-only.
- `InvalidOperationException` is raised when `OracleCredential` object is used with any of user id, password, proxy user id, proxy password and/or dba privilegeconnection string attribute(s) present in the connection string.

### Remarks

With this constructor, `OracleDBAPrivilege.None` is used for the DBA privilege when requesting for a connection.

#### See Also

## OracleCredential(string, SecureString, OracleDBAPrivilege)

This constructor creates an `OracleCredential` object with the user id, the secured password, and the DBA privilege request.

### Declaration

```
// C#  
public OracleCredential(string userId, SecureString password, OracleDBAPrivilege  
dbaprivilege)
```

### Exceptions

- `ArgumentNullException` is raised if any parameters are passed as null.
- `ArgumentException` is raised if "/" is passed for `userId` argument.
- `ArgumentException` is raised if the `SecureString` containing the password is not read-only.
- `InvalidOperationException` is raised when `OracleCredential` object is used with any of user id, password, proxy user id, proxy password and/or dba privilegeconnection string attribute(s) present in the connection string.

### Remarks

With this constructor, the specified `dbaprivilege` is for the DBA privilege when requesting for a connection.

## OracleCredential(string, SecureString, string, SecureString)

This constructor creates an `OracleCredential` object with the user id and the secured password for the end user, as well as the user id and the secured password for the proxy user.

### Declaration

```
// C#  
public OracleCredential(string userId, SecureString password, string proxyUserId,  
SecureString proxyPassword)
```

### Exceptions

- `ArgumentNullException` is raised if any parameters are passed as null.
- `ArgumentException` is raised if "/" is passed for `userId` argument.
- `ArgumentException` is raised if the `SecureString` containing the password is not read-only.

- InvalidOperationException is raised when OracleCredential object is used with any of user id, password, proxy user id, proxy password and/or dba privilegeconnection string attribute(s) present in the connection string.

Remarks

With this constructor, OracleDBAPrivilege.None is for the DBA privilege when requesting for a connection.

OracleCredential Properties

OracleCredential properties are listed in [Table 6-65](#).

Table 6-65 OracleCredential Properties

| Property                      | Description                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DBAPrivilege</a>  | Returns the DBA Privilege used to create the OracleCredential object. OracleDBAPrivilege.None is returned if it was not provided by the user. |
| <a href="#">Password</a>      | Returns the password of the OracleCredential object.                                                                                          |
| <a href="#">ProxyPassword</a> | Returns the proxy user password of the OracleCredential object.                                                                               |
| <a href="#">ProxyUserId</a>   | Returns the proxy user id of the OracleCredential object.                                                                                     |
| <a href="#">UserId</a>        | Returns the user id of the OracleCredential object.                                                                                           |

DBAPrivilege

This property returns the DBA Privilege that is associated with the user.

Declaration

```
// C#
OracleDBAPrivilege DBAPrivilege { get; }
```

**Property Value**

The `OracleDBAPrivilege` enum value that is associated with the user.

**Remarks**

`OracleDBAPrivilege.None` is returned if it was not set by the user.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCredential Class](#)

- [OracleDBAPrivilege Enumeration](#)

## Password

This property returns the encrypted password of the user.

**Declaration**

```
// C#
SecureString Password { get; }
```

**Property Value**

The encrypted password of the user.

`OracleCredential` does not support double quotes around a `SecureString` password. Double quotes can be used within a password, however.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCredential Class](#)
- [OracleCredential Members](#)

## ProxyPassword

This property returns the encrypted password of the proxy user.

**Declaration**

```
// C#
SecureString ProxyUserPassword { get; }
```

**Property Value**

The encrypted password of the proxy user.

**Remarks**

OracleCredential does not support double quotes around a SecureString password. Double quotes can be used within a password, however.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

## ProxyUserId

This property returns the proxy user id.

**Declaration**

```
// C#  
string ProxyUserId { get; }
```

**Property Value**

The proxy user id.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleCredential Class](#)
- [OracleCredential Members](#)

## UserId

This property returns the user id.

**Declaration**

```
// C#  
string UserId { get; }
```

**Property Value**

The user id.

# SetPassword

This method sets or updates the password on the OracleCredential instance.

**Declaration**

```
// C#
public void SetPassword(OracleOpaqueString opaquePassword)
```

**Parameters**

- *opaquePassword*  
new user password

**Exceptions**

Throws ORA-50129 if user id is not set on the `OracleCredential`.

Throws `ArgumentNullException` if *opaquePassword* is null.

Throws `ArgumentException` if password has length of 0.

Throws ORA-50128 if *opaquePassword* is not read only.

**Remarks**

This method cannot update the database user's password.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCredential Class](#)
- [OracleCredential Members](#)

## SetProxyPassword

This method sets or updates the proxy password on the `OracleCredential` instance.

**Declaration**

```
// C#  
public void SetProxyPassword(OracleOpaqueString opaqueProxyPassword)
```

**Parameters**

- *opaqueProxyPassword*  
new proxy password

**Exceptions**

Throws ORA-50129 if user id is not set on the `OracleCredential`.

Throws `ArgumentNullException` if *opaqueProxyPassword* is null.

Throws `ArgumentException` if password has length of 0.

Throws ORA-50128 if *opaqueProxyPassword* is not read only.

**Remarks**

This method cannot update the proxy database user's password.

# OracleDataAdapter Class

An `OracleDataAdapter` object represents a data provider object that populates the `DataSet` and updates changes in the `DataSet` to the Oracle database.

### Class Inheritance

### Declaration

```
// C#
public sealed class OracleDataAdapter : DbDataAdapter, IDbDataAdapter
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example

The following example uses the `OracleDataAdapter` and the dataset to update the EMP table:

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleDataAdapterSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        string cmdstr = "SELECT empno, sal from emp";

        // Create the adapter with the selectCommand txt and the
        // connection string
        OracleDataAdapter adapter = new OracleDataAdapter(cmdstr, constr);

        // Create the builder for the adapter to automatically generate
        // the Command when needed
        OracleCommandBuilder builder = new OracleCommandBuilder(adapter);

        // Create and fill the DataSet using the EMP
        DataSet dataset = new DataSet();
        adapter.Fill(dataset, "EMP");

        // Get the EMP table from the dataset
        DataTable table = dataset.Tables["EMP"];

        // Indicate DataColumn EMPNO is unique
        // This is required by the OracleCommandBuilder to update the EMP table
        table.Columns["EMPNO"].Unique = true;

        // Get the first row from the EMP table
        DataRow row = table.Rows[0];

        // Update the salary
        double sal = double.Parse(row["SAL"].ToString());
        row["SAL"] = sal + .01;

        // Now update the EMP using the adapter
        // The OracleCommandBuilder will create the UpdateCommand for the
        // adapter to update the EMP table
        adapter.Update(dataset, "EMP");

        Console.WriteLine("Row updated successfully");
    }
}
```

## OracleDataAdapter Members

OracleDataAdapter members are listed in the following tables.

### OracleDataAdapter Constructors

OracleDataAdapter constructors are listed in [Table 6-67](#).

**Table 6-67 OracleDataAdapter Constructors**

| Constructor                                    | Description                                                         |
|------------------------------------------------|---------------------------------------------------------------------|
| <a href="#">OracleDataAdapter Constructors</a> | Instantiates a new instance of OracleDataAdapter class (Overloaded) |

### OracleDataAdapter Static Methods

The OracleDataAdapter static method is listed in [Table 6-68](#).

**Table 6-68 OracleDataAdapter Static Method**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

### OracleDataAdapter Properties

OracleDataAdapter properties are listed in [Table 6-69](#).

**Table 6-69 OracleDataAdapter Properties**

| Property                      | Description                                                                |
|-------------------------------|----------------------------------------------------------------------------|
| AcceptChangesDuringFill       | Inherited from System.Data.Common.DataAdapter                              |
| Container                     | Inherited from System.ComponentModel.Component                             |
| ContinueUpdateOnError         | Inherited from System.Data.Common.DataAdapter                              |
| <a href="#">DeleteCommand</a> | A SQL statement or stored procedure to delete rows from an Oracle database |

Table 6-69 (Cont.) OracleDataAdapter Properties

| Property                                               | Description                                                                                                                                                                                            |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">IdentityInsert</a>                         | Determines whether or not to insert identity column values in the DataSet into the database when the Update method is invoked.<br><i>Not Available in the ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">IdentityUpdate</a>                         | Determines whether or not to update identity column values in the DataSet into the database when the Update method is invoked.<br><i>Not Available in the ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">InsertCommand</a>                          | A SQL statement or stored procedure to insert new rows into an Oracle database                                                                                                                         |
| MissingMappingAction                                   | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| MissingSchemaAction                                    | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| <a href="#">Requery</a>                                | Determines whether or not the SelectCommand is reexecuted on the next call to Fill                                                                                                                     |
| <a href="#">ReturnProviderSpecificTypes</a>            | Determines if the Fill method returns ODP.NET-specific values or .NET common language specification values                                                                                             |
| <a href="#">SafeMapping</a>                            | Creates a mapping between column names in the result set to .NET types, to preserve the data<br><i>Not Available in the ODP.NET, Managed Driver and ODP.NET Core</i>                                   |
| <a href="#">SelectCommand</a>                          | A SQL statement or stored procedure that returns a single or multiple result set                                                                                                                       |
| Site                                                   | Inherited from System.ComponentModel.Component                                                                                                                                                         |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the InvalidCastException and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET decimal.                                      |
| TableMappings                                          | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| <a href="#">UpdateBatchSize</a>                        | Specifies a value that enables or disables batch processing support, and specifies the number of SQL statements that can be executed in a single round-trip to the database                            |
| <a href="#">UpdateCommand</a>                          | A SQL statement or stored procedure to update rows from the DataSet to an Oracle database                                                                                                              |

**OracleDataAdapter Public Methods**

OracleDataAdapter public methods are listed in [Table 6-70](#).

Table 6-70 OracleDataAdapter Public Methods

| Public Method | Description                                    |
|---------------|------------------------------------------------|
| CreateObjRef  | Inherited from System.MarshalByRefObject       |
| Dispose       | Inherited from System.ComponentModel.Component |
| Equals        | Inherited from System.Object (Overloaded)      |

**Table 6-70 (Cont.) OracleDataAdapter Public Methods**

| Public Method             | Description                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------|
| <a href="#">Fill</a>      | Adds or refreshes rows in the DataSet to match the data in the Oracle database (Overloaded) |
| FillSchema                | Inherited from System.Data.Common.DbDataAdapter                                             |
| GetFillParameters         | Inherited from System.Data.Common.DbDataAdapter                                             |
| GetHashCode               | Inherited from System.Object                                                                |
| GetLifetimeService        | Inherited from System.MarshalByRefObject                                                    |
| GetType                   | Inherited from System.Object                                                                |
| InitializeLifetimeService | Inherited from System.MarshalByRefObject                                                    |

**OracleDataAdapter Events**

OracleDataAdapter events are listed in [Table 6-71](#).

**Table 6-71 OracleDataAdapter Events**

| Event Name                  | Description                                                                |
|-----------------------------|----------------------------------------------------------------------------|
| Disposed                    | Inherited from System.ComponentModel.Component                             |
| FillError                   | Inherited from System.Data.Common.DbDataAdapter                            |
| <a href="#">RowUpdated</a>  | This event is raised when row(s) have been updated by the Update( ) method |
| <a href="#">RowUpdating</a> | This event is raised when row data are about to be updated to the database |

## OracleDataAdapter Constructors

OracleDataAdapter constructors create new instances of an OracleDataAdapter class.

**Overload List:**

- [OracleDataAdapter\(\)](#)  
This constructor creates an instance of an OracleDataAdapter class.
- [OracleDataAdapter\(OracleCommand\)](#)  
This constructor creates an instance of an OracleDataAdapter class with the provided OracleCommand as the SelectCommand.
- [OracleDataAdapter\(string, OracleConnection\)](#)  
This constructor creates an instance of an OracleDataAdapter class with the provided OracleConnection object and the command text for the SelectCommand.
- [OracleDataAdapter\(string, string\)](#)  
This constructor creates an instance of an OracleDataAdapter class with the provided connection string and the command text for the SelectCommand.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## OracleDataAdapter()

This constructor creates an instance of an `OracleDataAdapter` class with no arguments.

**Declaration**

```
// C#  
public OracleDataAdapter();
```

**Remarks**

Initial values are set for the following `OracleDataAdapter` properties as indicated:

- `MissingMappingAction = MissingMappingAction.Passthrough`
- `MissingSchemaAction = MissingSchemaAction.Add`

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## OracleDataAdapter(OracleCommand)

This constructor creates an instance of an `OracleDataAdapter` class with the provided `OracleCommand` as the `SelectCommand`.

**Declaration**

```
// C#  
public OracleDataAdapter(OracleCommand selectCommand);
```

**Parameters**

- *selectCommand*  
The `OracleCommand` that is to be set as the `SelectCommand` property.

**Remarks**

Initial values are set for the following `OracleDataAdapter` properties as indicated:

- `MissingMappingAction = MissingMappingAction.Passthrough`
- `MissingSchemaAction = MissingSchemaAction.Add`

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## OracleDataAdapter(string, OracleConnection)

This constructor creates an instance of an `OracleDataAdapter` class with the provided `OracleConnection` object and the command text for the `SelectCommand`.

**Declaration**

```
// C#
public OracleDataAdapter(string selectCommandText, OracleConnection
    selectConnection);
```

**Parameters**

- *selectCommandText*  
The string that is set as the `CommandText` of the `SelectCommand` property of the `OracleDataAdapter`.
- *selectConnection*  
The `OracleConnection` to connect to the Oracle database.

**Remarks**

The `OracleDataAdapter` opens and closes the connection, if it is not already open. If the connection is open, it must be explicitly closed.

Initial values are set for the following `OracleDataAdapter` properties as indicated:

- `MissingMappingAction` = `MissingMappingAction.Passthrough`
- `MissingSchemaAction` = `MissingSchemaAction.Add`

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## OracleDataAdapter(string, string)

This constructor creates an instance of an `OracleDataAdapter` class with the provided connection string and the command text for the `SelectCommand`.

### Declaration

```
// C#  
public OracleDataAdapter(string selectCommandText, string  
    selectConnectionString);
```

### Parameters

- *selectCommandText*  
The string that is set as the CommandText of the SelectCommand property of the OracleDataAdapter.
- *selectConnectionString*  
The connection string.

### Remarks

Initial values are set for the following OracleDataAdapter properties as indicated:

- MissingMappingAction = MissingMappingAction.Passthrough
- MissingSchemaAction = MissingSchemaAction.Add

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## OracleDataAdapter Static Methods

The OracleDataAdapter static method is listed in [Table 6-72](#).

**Table 6-72 OracleDataAdapter Static Method**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## OracleDataAdapter Properties

OracleDataAdapter properties are listed in [Table 6-73](#).

**Table 6-73 OracleDataAdapter Properties**

| Property                                               | Description                                                                                                                                                                                            |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AcceptChangesDuringFill                                | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| Container                                              | Inherited from System.ComponentModel.Component                                                                                                                                                         |
| ContinueUpdateOnError                                  | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| <a href="#">DeleteCommand</a>                          | A SQL statement or stored procedure to delete rows from an Oracle database                                                                                                                             |
| <a href="#">IdentityInsert</a>                         | Determines whether or not to insert identity column values in the DataSet into the database when the Update method is invoked.<br><i>Not Available in the ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">IdentityUpdate</a>                         | Determines whether or not to update identity column values in the DataSet into the database when the Update method is invoked.<br><i>Not Available in the ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">InsertCommand</a>                          | A SQL statement or stored procedure to insert new rows into an Oracle database                                                                                                                         |
| MissingMappingAction                                   | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| MissingSchemaAction                                    | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| <a href="#">Requery</a>                                | Determines whether or not the SelectCommand is reexecuted on the next call to Fill                                                                                                                     |
| <a href="#">ReturnProviderSpecificTypes</a>            | Determines if the Fill method returns ODP.NET-specific values or .NET common language specification values                                                                                             |
| <a href="#">SafeMapping</a>                            | Creates a mapping between column names in the result set to .NET types, to preserve the data<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                                       |
| <a href="#">SelectCommand</a>                          | A SQL statement or stored procedure that returns a single or multiple result set                                                                                                                       |
| Site                                                   | Inherited from System.ComponentModel.Component                                                                                                                                                         |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the InvalidCastException and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET decimal.                                      |
| TableMappings                                          | Inherited from System.Data.Common.DataAdapter                                                                                                                                                          |
| <a href="#">UpdateBatchSize</a>                        | Specifies a value that enables or disables batch processing support, and specifies the number of SQL statements that can be executed in a single round-trip to the database                            |
| <a href="#">UpdateCommand</a>                          | A SQL statement or stored procedure to update rows from the DataSet to an Oracle database                                                                                                              |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- [OracleDataAdapter Members](#)

## DeleteCommand

This property is a SQL statement or stored procedure to delete rows from an Oracle database.

**Declaration**

```
// C#  
public OracleCommand DeleteCommand {get; set;}
```

**Property Value**

An OracleCommand used during the Update call to delete rows from tables in the Oracle database, corresponding to the deleted rows in the DataSet.

**Remarks**

Default = null

If there is primary key information in the DataSet, the DeleteCommand can be automatically generated using the OracleCommandBuilder, if no command is provided for this.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## IdentityInsert

When inserting DataSet data into the database, this property indicates whether the database generates the inserted row's identity column value or DataSet supplies this value.

**Declaration**

```
// C#  
public bool IdentityInsert {get; set;}
```

**Property Value**

When set to true, ODP.NET inserts DataSet identity column values into the database. When set to false, the database determines the inserted identity column values.

### Remarks

This property applies only to identity columns of type GENERATED BY DEFAULT and GENERATED BY DEFAULT ON NULL. Identity column of type GENERATED ALWAYS will ignore this property and will always use database generated values.

When set to false, the server will generate an identity value for the row. That generated identity value returns back to the client to update the DataSet value.

When this property is set to true for the GENERATED BY DEFAULT case and the application attempts to insert a NULL value into the database's identity column, the NOT NULL constraint is violated and an error occurs. ODP.NET will then allow the database to generate the identity column value and return the generated value to the DataSet.

The default value for this property is false.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- [OracleIdentityType Enumeration](#)

## IdentityUpdate

When updating DataSet data into the database, this property indicates whether to replace the database's identity column values with values of the DataSet or leave the current values unchanged.

### Declaration

```
// C#  
public bool IdentityUpdate {get; set;}
```

### Property Value

When set to true, ODP.NET updates the database identity column values with the values of the DataSet. When set to false, the database identity columns are left unchanged.

### Remarks

This property applies only to identity columns of type GENERATED BY DEFAULT and GENERATED BY DEFAULT ON NULL. In the case of type GENERATED ALWAYS, this property will be ignored and the database will always retain its current identity values.

When set to false, the existing identity column value in the server is returned to the DataSet.

When this property is set to true for the GENERATED BY DEFAULT and GENERATED BY DEFAULT ON NULL cases and the application attempts to update the database's identity column with a NULL value, the NOT NULL constraint is violated and an error occurs. ODP.NET then does not update the identity column value and instead returns the existing identity column value of the database to the DataSet.

The default value for this property is false.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- [OracleIdentityType Enumeration](#)

## InsertCommand

This property is a SQL statement or stored procedure to insert new rows into an Oracle database.

### Declaration

```
// C#  
public OracleCommand InsertCommand {get; set;}
```

### Property Value

An `OracleCommand` used during the `Update` call to insert rows into a table, corresponding to the inserted rows in the `DataSet`.

### Remarks

Default = null

If there is primary key information in the `DataSet`, the `InsertCommand` can be automatically generated using the `OracleCommandBuilder`, if no command is provided for this property.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## Requery

This property determines whether or not the `SelectCommand` is reexecuted on the next call to `Fill`.

### Declaration

```
// C#  
public Boolean Requery {get; set;}
```

### Property Value

Returns `true` if the `SelectCommand` is reexecuted on the next call to `Fill`; otherwise, returns `false`.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- ["OracleDataAdapter Requery Property"](#)

## ReturnProviderSpecificTypes

This property determines if the Fill method returns ODP.NET-specific values or .NET common language specification compliant values.

### Declaration

```
// C#  
public Boolean ReturnProviderSpecificTypes {get; set;}
```

### Property Value

A value that indicates whether or not the Fill method returns ODP.NET-specific values.

Starting with ODP.NET 12.1.0.2, when set to true and LegacyEntireLOBFetch = 0 (default), BLOB and CLOB column values are represented in the DataTable as OracleBlob and OracleClob, respectively.

A value of false indicates that the Fill method returns .NET common language specification compliant values. The default is false.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## SafeMapping

This property creates a mapping between column names in the result set to .NET types that represent column values in the DataSet, to preserve the data.

### Declaration

```
// C#  
public Hashtable SafeMapping {get; set;}
```

### Property Value

A hash table.

**Remarks**

Default = null

The SafeMapping property is used, when necessary, to preserve data in the following types:

- DATE
- TimeStamp (refers to all TimeStamp objects)
- INTERVAL DAY TO SECOND
- NUMBER

**Example**

See the example in "[OracleDataAdapter Safe Type Mapping](#)".

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- "[OracleDataAdapter Safe Type Mapping](#)"

## SelectCommand

This property is a SQL statement or stored procedure that returns single or multiple result sets.

**Declaration**

```
// C#  
public OracleCommand SelectCommand {get; set;}
```

**Property Value**

An OracleCommand used during the Fill call to populate the selected rows to the DataSet.

**Remarks**

Default = null

If the SelectCommand does not return any rows, no tables are added to the dataset and no exception is raised.

If the SELECT statement selects from a VIEW, no key information is retrieved when a FillSchema() or a Fill() with MissingSchemaAction.AddWithKey is invoked.

Setting the SelectCommand property will also set the SuppressGetDecimalInvalidCastException property to the OracleCommand.Connection SuppressGetDecimalInvalidCastException property value, unless SuppressGetDecimalInvalidCastException property has been set explicitly.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- ["OracleDataAdapter Requery Property"](#)

## SuppressGetDecimalInvalidCastException

This property specifies whether to suppress the `InvalidCastException` and return a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET decimal.

**Declaration**

```
// C#  
public bool SuppressGetDecimalInvalidCastException { get; set; }
```

**Property Type**

System.Boolean

**Remarks**

Oracle NUMBER has a maximum of 38 precision. .NET Decimal has a maximum of 28 or 29 precision. When the `GetDecimal()` method is called for an Oracle NUMBER value that cannot be represented as a .NET Decimal, then ODP.NET throws an `InvalidCastException` because not all the precision can be preserved when converting the number to a .NET Decimal.

This behavior occurs when `SuppressGetDecimalInvalidCastException` is set to false. Its default value is false.

When `SuppressGetDecimalInvalidCastException` is set to true, then the resulting decimal will be rounded off to 28 or 29 precision so that it can fit as a .NET decimal without throwing an exception. If the resulting rounded number is larger than can be stored in a .NET Decimal, an exception will be thrown, such as the number  $1 \times 10^{32}$ .

The `SuppressGetDecimalInvalidCastException` property can also be configured on `OracleConfiguration`, `OracleConnection`, and `OracleDataReader` objects. The `OracleDataAdapter.SuppressGetDecimalInvalidCastException` property value inherits `OracleConnection`, `OracleCommand.Connection`, or `OracleConfiguration.SuppressGetDecimalInvalidCastException` property value at construction time.

By using `OracleDataAdapter.SuppressGetDecimalInvalidCastException`, this ODP.NET setting becomes enabled for the `OracleDataAdapter`'s lifetime.

**① See Also**

## UpdateBatchSize

This property specifies a value that enables or disables batch processing support, and specifies the number of SQL statements that can be executed in a single round-trip to the database.

**Declaration**

```
// C#  
public virtual int UpdateBatchSize {get; set;}
```

**Property Value**

An integer that returns the batch size.

**Exceptions**

`ArgumentOutOfRangeException` - The value is set to a number  $< 0$ .

**Remarks**

Update batches executed with large amounts of data may encounter an "PLS-00123: Program too large" error. To avoid this error, reduce the size of `UpdateBatchSize` to a smaller value.

For each row in the `DataSet` that has been modified, added, or deleted, one SQL statement will be executed on the database.

Values are as follows:

- Value = 0  
The data adapter executes all the SQL statements in a single database round-trip
- Value = 1 - Default value  
This value disables batch updating and SQL statements are executed one at a time.
- Value =  $n$  where  $n > 1$   
The data adapter updates  $n$  rows of data per database round-trip.

## UpdateCommand

This property is a SQL statement or stored procedure to update rows from the DataSet to an Oracle database.

**Declaration**

```
// C#  
public OracleCommand UpdateCommand {get; set;}
```

**Property Value**

An OracleCommand used during the Update call to update rows in the Oracle database, corresponding to the updated rows in the DataSet.

**Remarks**

Default = null

If there is primary key information in the DataSet, the UpdateCommand can be automatically generated using the OracleCommandBuilder, if no command is provided for this property.

## OracleDataAdapter Public Methods

OracleDataAdapter public methods are listed in [Table 6-74](#).

**Table 6-74 OracleDataAdapter Public Methods**

| Public Method | Description                                    |
|---------------|------------------------------------------------|
| CreateObjRef  | Inherited from System.MarshalByRefObject       |
| Dispose       | Inherited from System.ComponentModel.Component |
| Equals        | Inherited from System.Object (Overloaded)      |

Table 6-74 (Cont.) OracleDataAdapter Public Methods

| Public Method             | Description                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------|
| <a href="#">Fill</a>      | Adds or refreshes rows in the DataSet to match the data in the Oracle database (Overloaded) |
| FillSchema                | Inherited from System.Data.Common.DbDataAdapter                                             |
| GetFillParameters         | Inherited from System.Data.Common.DbDataAdapter                                             |
| GetHashCode               | Inherited from System.Object                                                                |
| GetLifetimeService        | Inherited from System.MarshalByRefObject                                                    |
| GetType                   | Inherited from System.Object                                                                |
| InitializeLifetimeService | Inherited from System.MarshalByRefObject                                                    |
| ToString                  | Inherited from System.Object                                                                |
| Update                    | Inherited from System.Data.Common.DbDataAdapter                                             |

## Fill

Fill populates or refreshes the specified DataTable or DataSet.

#### Overload List:

- [Fill\(DataTable, OracleRefCursor\)](#)  
This method adds or refreshes rows in the specified DataTable to match those in the provided OracleRefCursor object.
- [Fill\(DataSet, OracleRefCursor\)](#)  
This method adds or refreshes rows in the DataSet to match those in the provided OracleRefCursor object.
- [Fill\(DataSet, string, OracleRefCursor\)](#)  
This method adds or refreshes rows in the specified source table of the DataSet to match those in the provided OracleRefCursor object.
- [Fill\(DataSet, int, int, string, OracleRefCursor\)](#)  
This method adds or refreshes rows in a specified range in the DataSet to match rows in the provided OracleRefCursor object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## Fill(DataTable, OracleRefCursor)

This method adds or refreshes rows in the specified DataTable to match those in the provided OracleRefCursor object.

**Declaration**

```
// C#  
public int Fill(DataTable dataTable, OracleRefCursor refCursor);
```

**Parameters**

- *dataTable*  
The DataTable object being populated.
- *refCursor*  
The OracleRefCursor that rows are being retrieved from.

**Return Value**

The number of rows added to or refreshed in the DataTable.

**Exceptions**

ArgumentNullException - The *dataTable* or *refCursor* parameter is null.

InvalidOperationException - The OracleRefCursor is already being used to fetch data.

NotSupportedException - The SafeMapping type is not supported.

**Remarks**

No schema or key information is provided, even if the Fill method is called with MissingSchemaAction set to MissingSchemaAction.AddWithKey.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- ["OracleDataAdapter Requery Property"](#)

## Fill(DataSet, OracleRefCursor)

This method adds or refreshes rows in the DataSet to match those in the provided OracleRefCursor object.

### Declaration

```
// C#  
public int Fill(DataSet dataSet, OracleRefCursor refCursor);
```

### Parameters

- *dataSet*  
The DataSet object being populated.
- *refCursor*  
The OracleRefCursor that rows are being retrieved from.

### Return Value

Returns the number of rows added or refreshed in the DataSet.

### Exceptions

ArgumentNullException - The *dataSet* or *refCursor* parameter is null.

InvalidOperationException - The OracleRefCursor is already being used to fetch data.

InvalidOperationException - The OracleRefCursor is ready to fetch data.

NotSupportedException - The SafeMapping type is not supported.

### Remarks

If there is no DataTable to refresh, a new DataTable named Table is created and populated using the provided OracleRefCursor object.

No schema or key information is provided, even if the Fill method is called with MissingSchemaAction set to MissingSchemaAction.AddWithKey.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- ["OracleDataAdapter Requery Property"](#)

## Fill(DataSet, string, OracleRefCursor)

This method adds or refreshes rows in the specified source table of the DataSet to match those in the provided OracleRefCursor object.

**Declaration**

```
// C#  
public int Fill(DataSet dataSet, string srcTable, OracleRefCursor  
    refCursor);
```

**Parameters**

- *dataSet*  
The DataSet object being populated.
- *srcTable*  
The name of the source table used in the table mapping.
- *refCursor*  
The OracleRefCursor that rows are being retrieved from.

**Return Value**

Returns the number of rows added or refreshed into the DataSet.

**Exceptions**

ArgumentNullException - The *dataSet* or *refCursor* parameter is null.

InvalidOperationException - The OracleRefCursor is already being used to fetch data or the source table name is invalid.

NotSupportedException - The SafeMapping type is not supported.

**Remarks**

No schema or key information is provided, even if the Fill method is called with MissingSchemaAction set to MissingSchemaAction.AddWithKey.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)
- ["OracleDataAdapter Requery Property"](#)

## Fill(DataSet, int, int, string, OracleRefCursor)

This method adds or refreshes rows in a specified range in the DataSet to match rows in the provided OracleRefCursor object.

**Declaration**

```
// C#  
public int Fill(DataSet dataSet, int startRecord, int maxRecords,  
    string srcTable, OracleRefCursor refCursor);
```

### Parameters

- *dataSet*  
The DataSet object being populated.
- *startRecord*  
The record number to start with.
- *maxRecords*  
The maximum number of records to obtain.
- *srcTable*  
The name of the source table used in the table mapping.
- *refCursor*  
The OracleRefCursor that rows are being retrieved from.

### Return Value

This method returns the number of rows added or refreshed in the DataSet. This does not include rows affected by statements that do not return rows.

### Exceptions

ArgumentNullException - The *dataSet* or *refCursor* parameter is null.

InvalidOperationException - The OracleRefCursor is already being used to fetch data or the source table name is invalid.

NotSupportedException - The SafeMapping type is not supported.

### Remarks

No schema or key information is provided, even if the Fill method is called with MissingSchemaAction set to MissingSchemaAction.AddWithKey.

## OracleDataAdapter Events

OracleDataAdapter events are listed in [Table 6-75](#).

**Table 6-75 OracleDataAdapter Events**

| Event Name                  | Description                                                                 |
|-----------------------------|-----------------------------------------------------------------------------|
| Disposed                    | Inherited from System.ComponentModel.Component                              |
| FillError                   | Inherited from System.Data.Common.DbDataAdapter                             |
| <a href="#">RowUpdated</a>  | This event is raised when row(s) have been updated by the Update ( ) method |
| <a href="#">RowUpdating</a> | This event is raised when row data are about to be updated to the database  |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataAdapter Class](#)
- [OracleDataAdapter Members](#)

## RowUpdated

This event is raised when row(s) have been updated by the Update ( ) method.

**Declaration**

```
// C#  
public event OracleRowUpdatedEventHandler RowUpdated;
```

**Event Data**

The event handler receives an `OracleRowUpdatedEventArgs` object which exposes the following properties containing information about the event.

- **Command**  
The `OracleCommand` executed during the Update.
- **Errors** (inherited from `RowUpdatedEventArgs`)  
The exception, if any, is generated during the Update.
- **RecordsAffected** (inherited from `RowUpdatedEventArgs`)  
The number of rows modified, inserted, or deleted by the execution of the Command.
- **Row** (inherited from `RowUpdatedEventArgs`)  
The `DataRow` sent for Update.
- **StatementType** (inherited from `RowUpdatedEventArgs`)  
The type of SQL statement executed.
- **Status** (inherited from `RowUpdatedEventArgs`)  
The `UpdateStatus` of the Command.
- **TableMapping** (inherited from `RowUpdatedEventArgs`)  
The `DataTableMapping` used during the Update.

## Example

The following example shows how to use the RowUpdating and RowUpdated events.

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class RowUpdatedSample
{
    // Event handler for RowUpdating event
    protected static void OnRowUpdating(object sender,
                                        OracleRowUpdatingEventArgs e)
    {
        Console.WriteLine("Row updating....");
        Console.WriteLine("Event arguments:");
        Console.WriteLine("Command Text: " + e.Command.CommandText);
        Console.WriteLine("Command Type: " + e.StatementType);
        Console.WriteLine("Status: " + e.Status);
    }

    // Event handler for RowUpdated event
    protected static void OnRowUpdated(object sender,
                                       OracleRowUpdatedEventArgs e)
    {
        Console.WriteLine("Row updated....");
        Console.WriteLine("Event arguments:");
        Console.WriteLine("Command Text: " + e.Command.CommandText);
        Console.WriteLine("Command Type: " + e.StatementType);
        Console.WriteLine("Status: " + e.Status);
    }

    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        string cmdstr = "SELECT EMPNO, ENAME, SAL FROM EMP";

        // Create the adapter with the selectCommand txt and the
        // connection string
        OracleDataAdapter adapter = new OracleDataAdapter(cmdstr, constr);

        // Create the builder for the adapter to automatically generate
        // the Command when needed
        OracleCommandBuilder builder = new OracleCommandBuilder(adapter);

        // Create and fill the DataSet using the EMP
        DataSet dataset = new DataSet();
        adapter.Fill(dataset, "EMP");

        // Get the EMP table from the dataset
        DataTable table = dataset.Tables["EMP"];

        // Indicate DataColumn EMPNO is unique
        // This is required by the OracleCommandBuilder to update the EMP table
        table.Columns["EMPNO"].Unique = true;

        // Get the first row from the EMP table
        DataRow row = table.Rows[0];

        // Update the salary
```

```
double sal = double.Parse(row["SAL"].ToString());
row["SAL"] = sal + .01;

// Set the event handlers for the RowUpdated and the RowUpdating event
// the OnRowUpdating() method will be triggered before the update, and
// the OnRowUpdated() method will be triggered after the update
adapter.RowUpdating += new OracleRowUpdatingEventHandler(OnRowUpdating);
adapter.RowUpdated += new OracleRowUpdatedEventHandler(OnRowUpdated);

// Now update the EMP using the adapter
// The OracleCommandBuilder will create the UpdateCommand for the
// adapter to update the EMP table
// The OnRowUpdating() and the OnRowUpdated() methods will be triggered
adapter.Update(dataset, "EMP");
}
}
```

## RowUpdating

This event is raised when row data are about to be updated to the database.

### Declaration

```
// C#
public event OracleRowUpdatingEventHandler RowUpdating;
```

### Event Data

The event handler receives an `OracleRowUpdatingEventArgs` object which exposes the following properties containing information about the event.

- **Command**  
The `OracleCommand` executed during the Update.
- **Errors** (inherited from `RowUpdatingEventArgs`)  
The exception, if any, is generated during the Update.
- **Row** (inherited from `RowUpdatingEventArgs`)  
The `DataRow` sent for Update.
- **StatementType** (inherited from `RowUpdatingEventArgs`)  
The type of SQL statement executed.
- **Status** (inherited from `RowUpdatingEventArgs`)  
The `UpdateStatus` of the Command.
- **TableMapping** (inherited from `RowUpdatingEventArgs`)

The DataTableMapping used during the Update.

Example

The example for the RowUpdated event also shows how to use the RowUpdating event. See RowUpdated event "[Example](#)".

# OracleDatabase Class

An OracleDatabase object represents an Oracle Database instance.

Class Inheritance

System.Object

Oracle.DataAccess.Client.OracleDatabase

Declaration

```
// C#
public sealed class OracleDatabase : IDisposable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Example

```
// C#

using System;
```

```
using Oracle.DataAccess.Client;

namespace Startup
{
    class Test
    {
        static void Main()
        {
            OracleConnection con = null;
            OracleDatabase db = null;
            string constring = "dba privilege=sysdba;user id=scott;password=tiger;data
source=oracle";

            try
            {
                // Open a connection to see if the DB is up
                con = new OracleConnection(constring);
                con.Open();

                Console.WriteLine("The Oracle database is already up.");
            }
            catch (OracleException ex)
            {
                // If the database is down, start up the DB
                if (ex.Number == 1034)
                {
                    Console.WriteLine("The Oracle database is down.");

                    // Create an instance of an OracleDatabase object
                    db = new OracleDatabase(constring);

                    // Start up the database
                    db.Startup();

                    Console.WriteLine("The Oracle database is now up.");

                    // Executing Startup() is the same as the following:
                    // db.Startup(OracleDBStartupMode.NoRestriction, null, true);
                    // which is also the same as:
                    // db.Startup(OracleDBStartupMode.NoRestriction, null, false);
                    // db.ExecuteNonQuery("ALTER DATABASE MOUNT");
                    // db.ExecuteNonQuery("ALTER DATABASE OPEN");

                    // Dispose the OracleDatabase object
                    db.Dispose();
                }
                else
                {
                    Console.WriteLine("Error: " + ex.Message);
                }
            }
            finally
            {
                // Dispose the OracleConnetion object
                con.Dispose();
            }
        }
    }
}
```

## OracleDatabase Members

OracleDatabase members are listed in the following tables.

### OracleDatabase Constructors

The OracleDatabase constructor is listed in [Table 6-76](#).

**Table 6-76 OracleDatabase Constructors**

| Constructor                                 | Description                                         |
|---------------------------------------------|-----------------------------------------------------|
| <a href="#">OracleDatabase Constructors</a> | Instantiates a new instance of OracleDatabase class |

### OracleDatabase Properties

The OracleDatabase properties are listed in [Table 6-77](#).

**Table 6-77 OracleDatabase Properties**

| Property                      | Description                                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">ServerVersion</a> | Specifies the database version number of the Oracle Database instance to which the connection is made |

### OracleDatabase Public Methods

The OracleDatabase public methods are listed in [Table 6-78](#).

**Table 6-78 OracleDatabase Public Methods**

| Public Method                   | Description                                                     |
|---------------------------------|-----------------------------------------------------------------|
| <a href="#">Dispose</a>         | Releases any resources or memory allocated by the object.       |
| <a href="#">ExecuteNonQuery</a> | Executes the supplied non-SELECT statement against the database |
| <a href="#">Shutdown</a>        | Shuts down the database (Overloaded)                            |
| <a href="#">Startup</a>         | Starts up the database (Overloaded)                             |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDatabase Class](#)

## OracleDatabase Constructors

The OracleDatabase constructors instantiate a new instance of the OracleDatabase class.

### Overload List

- [OracleDatabase Constructor\(string\)](#)  
The OracleDatabase constructor instantiates a new instance of the OracleDatabase class using the supplied connection string.
- [OracleDatabase Constructor\(string, OracleCredential\)](#)  
The OracleDatabase constructor instantiates a new instance of the OracleDatabase class using the supplied connection string and OracleCredential object .

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)

## OracleDatabase Constructor(string)

The OracleDatabase constructor instantiates a new instance of the OracleDatabase class using the supplied connection string.

### Declaration

```
// C#  
public OracleDatabase(string connectionString);
```

### Parameters

- *connectionString*

The connection information used to connect to the Oracle Database instance.

### Remarks

The *connectionString* follows the same format used by the OracleConnection object. However, the OracleDatabase constructor accepts only the user\_id, password, data source, and dba\_privilege connection string attributes. All other attribute values are ignored. The supplied *connectionString* must contain the dba\_privilege connection string attribute that is set to SYSDBA, SYSASM, SYSOPER, or another valid administrator privilege.

The `OracleDatabase` object creates a connection upon construction and remains connected throughout its lifetime. The connection is destroyed when the `OracleDatabase` object is disposed. This connection is not pooled to be used by another `OracleDatabase` object.

#### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)

## OracleDatabase Constructor(string, OracleCredential)

The `OracleDatabase` constructor instantiates a new instance of the `OracleDatabase` class using the supplied connection string and `OracleCredential` object.

### Declaration

```
// C#  
public OracleDatabase(string connectionString, OracleCredential orclCredential)
```

### Parameters

- *connectionString*  
connection string that does not contain any of user id, password, DBA Privilege, proxy user id, nor proxy password.
- *orclCredential*  
`OracleCredential` object containing user credentials. If this parameter is passed as null then `OracleConnection`'s behavior will be same as `OracleConnection` with normal connection string.

### Exceptions

`InvalidOperationException` is raised when non-null `OracleCredential` object is used with a connection string containing any of user id, password, DBA Privilege, proxy user id, or proxy password.

#### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)

## OracleDatabase Properties

The `OracleDatabase` properties are listed in [Table 6-79](#).

**Table 6-79 OracleDatabase Properties**

| Property                      | Description                                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">ServerVersion</a> | Specifies the database version number of the Oracle Database instance to which the connection is made |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)

## ServerVersion

This property returns the database version number of the Oracle Database instance to which the connection is made.

**Declaration**

```
Public string ServerVersion {get;}
```

**Property value**

Returns the database version of the Oracle Database instance.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)

## OracleDatabase Public Methods

The OracleDatabase public methods are listed in [Table 6-80](#).

**Table 6-80 OracleDatabase Public Methods**

| Public Method                   | Description                                                     |
|---------------------------------|-----------------------------------------------------------------|
| <a href="#">Dispose</a>         | Releases any resources or memory allocated by the object.       |
| <a href="#">ExecuteNonQuery</a> | Executes the supplied non-SELECT statement against the database |

## Dispose

This method releases any resources or memory allocated by the object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)

## ExecuteNonQuery

This method executes the supplied non-SELECT statement against the database.

**Declaration**

```
// C#  
public void ExecuteNonQuery(string sql);
```

**Exceptions**

OracleException - The command execution has failed.

**Remarks**

This method is meant for execution of DDL statements such as ALTER DATABASE statements to OPEN and MOUNT the database, for example. This method should not be used to execute SQL SELECT statements. This method does not support any parameter binding.

## Shutdown

Shutdown methods shut down a database instance.

**Overload List**

- [Shutdown\(\)](#)  
This method shuts down the database.
- [Shutdown\(OracleDBShutdownMode, bool\)](#)  
This method shuts down the database using the specified mode.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)
- ["OracleDBShutdownMode Enumeration"](#)

## Shutdown()

This method shuts down the database.

**Declaration**

```
// C#  
public void Shutdown();
```

**Exceptions**

OracleException - The database shutdown request has failed.

**Remarks**

This method shuts down a database instance in the `OracleDBShutdownMode.Default` mode. New connections are refused, and the method waits for the existing connections to end.

**Note**

As the shutdown is effected using the `OracleDBShutdownMode.Default` mode, the shutdown request may remain pending if there are open connections other than the connection created by the `OracleDatabase` object.

After the connections have closed, the method closes the database, dismounts the database, and shuts down the instance using the `OracleDBShutdownMode.Final` mode.

This method does not throw exceptions for cases where the database has been already closed, dismounted, or shutdown appropriately. If other errors are encountered, then an exception is thrown.

Invoking this method against an Oracle Real Application Clusters (Oracle RAC) database shuts down only that database instance to which the `OracleDatabase` object is connected.

## Shutdown(OracleDBShutdownMode, bool)

This method shuts down the database instance using the specified mode.

**Declaration**

```
//C#  
public void Shutdown(OracleDBShutdownMode shutdownMode, bool bCloseDismountAndFinalize);
```

**Parameters**

- *shutdownMode*  
A `OracleDBShutdownMode` enumeration value.
- *bCloseDismountAndFinalize*  
A boolean signifying whether the database is to be closed, dismounted, and finalized.

**Exceptions**

`OracleException` - The database shutdown request has failed.

**Remarks**

This method shuts down a database instance in the specified mode. If the *bCloseDismountAndFinalize* parameter is true, then the method also closes the database, dismounts the database, and shuts down the instance using the `OracleDBShutdownMode.Final` mode.

If the *bCloseDismountAndFinalize* parameter is true, then this method does not throw exceptions for cases where the database has been already closed, dismounted, or shutdown appropriately. If other errors are encountered, then an exception is thrown.

If the *bCloseDismountAndFinalize* parameter is false, then the application needs to explicitly close and dismount the database. The application can then reinvoke the method using the `OracleDBShutdownMode.Final` mode to properly shut down the database. For example, if `db` is an instance of the `OracleDatabase` class, then the application invokes the following:

1. `db.Shutdown(OracleDBShutdownMode.Default, false);`
2. `db.ExecuteNonQuery("ALTER DATABASE CLOSE NORMAL");`
3. `db.ExecuteNonQuery("ALTER DATABASE DISMOUNT");`
4. `db.Shutdown(OracleDBShutdownMode.Final);`

#### Note

- The `OracleDBShutdownMode.Final` enumeration value should not be used as the *shutdownMode* for the initial method invocation. The `OracleDBShutdownMode.Final` mode should be used only if the database is already closed and dismounted. Otherwise, the method might wait indefinitely.
- If the specified *shutdownMode* is `OracleDBShutdownMode.Final`, then the value of the *bCloseDismountAndFinalize* input parameter is ignored, as the database should have been closed and dismounted already.

If the specified *shutdownMode* is `OracleDBShutdownMode.Abort`, then the value of the *bCloseDismountAndFinalize* input parameter is ignored, as the `Abort` mode requires the database to be closed, dismounted, and finalized.

Invoking this method against an Oracle Real Application Clusters (Oracle RAC) database shuts down only that database instance to which the `OracleDatabase` object is connected.

#### Example

```
using System;
using Oracle.DataAccess.Client;

namespace Shutdown
{
    class Test
    {
        static void Main()
        {
            OracleConnection con = null;
            OracleDatabase db = null;
            string constring = "user id=scott;password=tiger;data source=oracle;" +
                "pooling=false;dba privilege=sysdba";

            try
            {
                // Open a connection to see if the DB is up;
                con = new OracleConnection(constring);
                con.Open();

                Console.WriteLine("The Oracle database is currently up.");
            }
        }
    }
}
```

```

        // If open succeeds, we know that the database is up.
        // We have to dispose the connection so that we can
        // shutdown the database.
        con.Dispose();

        // Shutdown the database
        db = new OracleDatabase(constring);
        db.Shutdown();

        Console.WriteLine("The Oracle database is shut down.");

        // Executing Shutdown() above is the same as the following:
        // db.Shutdown(OracleDBShutdownMode.Default, false);
        // db.ExecuteNonQuery("ALTER DATABASE CLOSE NORMAL");
        // db.ExecuteNonQuery("ALTER DATABASE DISMOUNT");
        // db.Shutdown(OracleDBShutdownMode.Final);

        // Dispose the OracleDatabase object
        db.Dispose();
    }
    catch (OracleException ex)
    {
        Console.WriteLine("An error has occurred: {0}", ex.Message);
    }
}
}
}

```

## Startup

Startup methods enable a user with database administrator privileges to start a database instance.

### Overload List

- [Startup\(\)](#)  
This method starts a database instance using the server-side parameter file.
- [Startup\(OracleDBStartupMode, bool\)](#)  
This method starts up the database using the specified startup mode.  
*Not Available in ODP.NET, Unmanaged Driver*
- [Startup\(OracleDBStartupMode, string, bool\)](#)  
This method starts a database instance using the client-side parameter file.  
*Not Available in ODP.NET, Managed Driver and ODP.NET Core*

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)
- ["OracleDBStartupMode Enumeration"](#)

## Startup()

This method starts up the database.

### Declaration

```
// C#  
public void Startup();
```

### Exceptions

OracleException - The database startup request has failed.

### Remarks

This method starts a database instance in the `OracleDbStartupMode.Normal` mode using the server-side parameter file (spfile). After the database is successfully started, this method also executes the `ALTER DATABASE MOUNT` and `ALTER DATABASE OPEN` statements.

This method does not throw exceptions for cases where the database is already mounted, opened, or started appropriately. If other errors are encountered, then an exception is thrown.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDatabase Class](#)
- [OracleDatabase Members](#)
- ["OracleDBStartupMode Enumeration"](#)

## Startup(OracleDBStartupMode, bool)

This method starts up the database using the specified startup mode.

### Declaration

```
// C#  
public void Startup(OracleDbStartupMode startupMode, bool bMountAndOpen);
```

### Parameters

startupMode - An `OracleDBStartupMode` enumeration value.

`bMountAndOpen` - A true/false value signifying whether the database is to be mounted and opened.

### Exceptions

`OracleException` - The database startup request has failed.

### Remarks

This method starts a database instance in the specified mode. After the database is successfully started, and if `bMountAndOpen` input parameter is true, this method also executes the `ALTER DATABASE MOUNT` and `ALTER DATABASE OPEN` statements.

If `bMountAndOpen` is true, then this method does not throw an exception for cases where the database is already mounted, opened, or started appropriately. If other errors are encountered, then an exception is thrown.

If `bMountAndOpen` is false, then the database must be mounted and opened explicitly by the application. For example, if `db` is an instance of the `OracleDatabase` class, then the application invokes the following:

- `db.Startup(OracleDBStartupMode.NoRestriction, false);`
- `db.ExecuteNonQuery("ALTER DATABASE MOUNT");`
- `db.ExecuteNonQuery("ALTER DATABASE OPEN");`

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## Startup(OracleDBStartupMode, string, bool)

This method starts up the database using the specified startup mode.

### Declaration

```
// C#  
public void Startup(OracleDbStartupMode startupMode, string pfile, bool bMountAndOpen);
```

### Parameters

- *startupMode*  
An `OracleDBStartupMode` enumeration value.
- *pfile*  
The location and name of the client-side parameter file. For example, "c:\admin\init.ora".  
  
The name of the parameter file varies depending on the operating system. For example, it can be in mixed case or lowercase, or it can have a logical name or a variation of the name `init.ora`. The default location is usually `ORACLE_HOME/dbs` or `ORACLE_HOME/database`.
- *bMountAndOpen*

A true/false value signifying whether the database is to be mounted and opened.

### Exceptions

OracleException - The database startup request has failed.

### Remarks

This method starts a database instance in the specified mode using the specified client-side parameter file. After the database is successfully started, and if *bMountAndOpen* input parameter is true, this method also executes the ALTER DATABASE MOUNT and ALTER DATABASE OPEN statements.

If *bMountAndOpen* is true, then this method does not throw an exception for cases where the database is already mounted, opened, or started appropriately. If other errors are encountered, then an exception is thrown.

If *bMountAndOpen* is false, then the database must be mounted and opened explicitly by the application. For example, if *db* is an instance of the OracleDatabase class, then the application invokes the following:

1. `db.Startup(OracleDBStartupMode.NoRestriction, null, false);`
2. `db.ExecuteNonQuery("ALTER DATABASE MOUNT");`
3. `db.ExecuteNonQuery("ALTER DATABASE OPEN");`

## OracleDataReader Class

An OracleDataReader object represents a forward-only, read-only, in-memory result set.

Unlike the DataSet, the OracleDataReader object stays connected and fetches one row at a time.

The following section contain related information:

- ["Obtaining LONG and LONG RAW Data"](#).
- ["Obtaining Data from an OracleDataReader Object"](#).

### Class Inheritance

System.Object

System.MarshalByRefObject

System.Data.Common.DataReader

System.Data.Common.DbDataReader

Oracle.DataAccess.Client.OracleDataReader

Declaration

```
// C#
public sealed class OracleDataReader : DbDataReader, IEnumerable,
    IDataReader, IDisposable, IDataRecord
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

An OracleDataReader instance is constructed by a call to the ExecuteReader method of the OracleCommand object. The only properties that can be accessed after the DataReader is closed or has been disposed, are IsClosed and RecordsAffected.

To minimize the number of open database cursors, OracleDataReader objects should be explicitly disposed.

Example

The following OracleDataReader example retrieves the data from the EMP table:

```
/* Database Setup, if you have not done so yet.
connect scott/tiger@oracle
CREATE TABLE empInfo (
empno NUMBER(4) PRIMARY KEY,
empName VARCHAR2(20) NOT NULL,
hiredate DATE,
salary NUMBER(7,2),
jobDescription Clob,
byteCodes BLOB
);

Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(1,'KING','SOFTWARE ENGR', '5657');
Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(2,'SCOTT','MANAGER', '5960');
commit;

*/

// C#
```

```
using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleDataReaderSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        string cmdstr = "SELECT * FROM EMPINFO";
        OracleConnection connection = new OracleConnection(constr);
        OracleCommand cmd = new OracleCommand(cmdstr, con);

        OracleDataReader reader = cmd.ExecuteReader();

        // Declare the variables to retrieve the data in EmpInfo
        short empNo;
        string empName;
        DateTime hireDate;
        double salary;
        string jobDesc;
        byte[] byteCodes = new byte[10];

        // Read the next row until end of row
        while (reader.Read())
        {
            empNo = reader.GetInt16(0);
            Console.WriteLine("Employee number: " + empNo);
            empName = reader.GetString(1);
            Console.WriteLine("Employee name: " + empName);

            // The following columns can have NULL value, so it
            // is important to call IsDBNull before getting the column data
            if (!reader.IsDBNull(2))
            {
                hireDate = reader.GetDateTime(2);
                Console.WriteLine("Hire date: " + hireDate);
            }

            if (!reader.IsDBNull(3))
            {
                salary = reader.GetDouble(3);
                Console.WriteLine("Salary: " + salary);
            }

            if (!reader.IsDBNull(4))
            {
                jobDesc = reader.GetString(4);
                Console.WriteLine("Job Description: " + jobDesc);
            }

            if (!reader.IsDBNull(5))
            {
                long len = reader.GetBytes(5, 0, byteCodes, 0, 10);

                Console.Write("Byte codes: ");
                for (int i = 0; i < len; i++)
                    Console.Write(byteCodes[i].ToString("x"));
            }
        }
    }
}
```

```
        Console.WriteLine();  
    }  
  
    Console.WriteLine();  
}  
  
// Clean up  
reader.Dispose();  
con.Dispose();  
}  
}
```

## OracleDataReader Members

OracleDataReader members are listed in the following tables.

### OracleDataReader Static Methods

The OracleDataReader static method is listed in [Table 6-81](#).

**Table 6-81 OracleDataReader Static Method**

| Method                 | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

### OracleDataReader Properties

OracleDataReader properties are listed in [Table 6-82](#).

**Table 6-82 OracleDataReader Properties**

| Property                         | Description                                                       |
|----------------------------------|-------------------------------------------------------------------|
| <a href="#">Depth</a>            | Gets a value indicating the depth of nesting for the current row  |
| <a href="#">FetchSize</a>        | Specifies the size of OracleDataReader's internal cache           |
| <a href="#">FieldCount</a>       | Gets the number of columns in the result set                      |
| <a href="#">HasRows</a>          | Indicates whether the OracleDataReader has one or more rows       |
| <a href="#">HiddenFieldCount</a> | Gets the number of fields in the OracleDataReader that are hidden |
| <a href="#">IsClosed</a>         | Indicates whether or not the data reader is closed                |

**Table 6-82 (Cont.) OracleDataReader Properties**

| Property                                               | Description                                                                                                                                               |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Item</a>                                   | Gets the value of the column (Overloaded)                                                                                                                 |
| <a href="#">InitialLOBFetchSize</a>                    | Specifies the amount that the OracleDataReader initially fetches for LOB columns                                                                          |
| <a href="#">InitialLONGFetchSize</a>                   | Specifies the amount that the OracleDataReader initially fetches for LONG and LONG RAW columns                                                            |
| <a href="#">RecordsAffected</a>                        | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement                                                                   |
| <a href="#">RowSize</a>                                | Gets the amount of memory the internal cache of the OracleDataReader needs to store one row of data.                                                      |
| <a href="#">RowsToFetchPerRoundTrip</a>                | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                               |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the InvalidCastException and return a rounded-off 28 precision value if the Oracle NUMBER value has more than 28 precision. |
| <a href="#">UseEdmMapping</a>                          | Indicates whether or not the OracleDataReader utilizes the Entity Data Model mapping configuration when returning values                                  |
| <a href="#">VisibleFieldCount</a>                      | Gets the number of fields in the OracleDataReader that are not hidden                                                                                     |

**OracleDataReader Public Methods**

OracleDataReader public methods are listed in [Table 6-83](#).

**Table 6-83 OracleDataReader Public Methods**

| Public Method                        | Description                                                                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Close</a>                | Closes the OracleDataReader                                                                                                                 |
| CreateObjRef                         | Inherited from System.MarshalByRefObject                                                                                                    |
| <a href="#">Dispose</a>              | Releases any resources or memory allocated by the object                                                                                    |
| Equals                               | Inherited from System.Object (Overloaded)                                                                                                   |
| <a href="#">GetBoolean</a>           | Returns the bool value of the specified numeric column                                                                                      |
| <a href="#">GetByte</a>              | Returns the byte value of the specified column                                                                                              |
| <a href="#">GetByteArray(int)</a>    | Returns the byte array value of the specified numeric column<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">GetByteArray(string)</a> | Returns the byte array value of the specified numeric column<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">GetBytes</a>             | Populates the provided byte array with up to the maximum number of bytes, from the specified offset (in bytes) of the column                |
| <a href="#">GetChar</a>              | <i>Not Supported</i>                                                                                                                        |
| <a href="#">GetChars</a>             | Populates the provided character array with up to the maximum number of characters, from the specified offset (in characters) of the column |

Table 6-83 (Cont.) OracleDataReader Public Methods

| Public Method                          | Description                                                                                                                                                  |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GetData</a>                | <i>Not Supported</i>                                                                                                                                         |
| <a href="#">GetDataTypeName</a>        | Returns the ODP.NET type name of the specified column                                                                                                        |
| <a href="#">GetDateTime</a>            | Returns the DateTime value of the specified column                                                                                                           |
| <a href="#">GetDateTimeOffset</a>      | Returns the DateTimeOffset value of the specified column                                                                                                     |
| <a href="#">GetDecimal</a>             | Returns the decimal value of the specified NUMBER column                                                                                                     |
| <a href="#">GetDouble</a>              | Returns the double value of the specified NUMBER column or BINARY_DOUBLE column                                                                              |
| <a href="#">GetDoubleArray(int)</a>    | Returns the double[] value of the specified VECTOR column                                                                                                    |
| <a href="#">GetDoubleArray(string)</a> | Returns the double[] value of the specified VECTOR column                                                                                                    |
| <a href="#">GetEnumerator</a>          | Returns an IEnumerator that can be used to iterate through the collection                                                                                    |
| <a href="#">GetFieldType</a>           | Returns the Type of the specified column                                                                                                                     |
| <a href="#">GetFieldValueAsync</a>     | Returns a Task-based asynchronous version of <code>OracleDataReader.GetFieldValue()</code> , which returns the column value as a specified type (Overloaded) |
| <a href="#">GetFloat</a>               | Returns the float value of the specified NUMBER column or BINARY_FLOAT column                                                                                |
| <a href="#">GetFloatArray(int)</a>     | Returns the float[] value of the specified VECTOR column                                                                                                     |
| <a href="#">GetFloatArray(string)</a>  | Returns the float[] value of the specified VECTOR column                                                                                                     |
| <a href="#">GetGuid</a>                | Returns the Guid value of the specified binary data column                                                                                                   |
| <code>GetHashCode</code>               | Inherited from <code>System.Object</code>                                                                                                                    |
| <a href="#">GetInt16</a>               | Returns the Int16 value of the specified NUMBER column                                                                                                       |
| <a href="#">GetInt16Array(int)</a>     | Returns the short[] value of the specified VECTOR column                                                                                                     |
| <a href="#">GetInt16Array(string)</a>  | Returns the short[] value of the specified VECTOR column                                                                                                     |
| <a href="#">GetInt32</a>               | Returns the Int32 value of the specified NUMBER column                                                                                                       |
| <a href="#">GetInt64</a>               | Returns the Int64 value of the specified NUMBER column                                                                                                       |
| <code>GetLifetimeService</code>        | Inherited by <code>System.MarshalByRefObject</code>                                                                                                          |
| <a href="#">GetName</a>                | Returns the name of the specified column                                                                                                                     |
| <a href="#">GetNonZeroDoubleArray</a>  | Returns the non-zero-dimension values double[] of the specified sparse VECTOR column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>       |
| <a href="#">GetNonZeroFloatArray</a>   | Returns the non-zero-dimension values float[] of the specified sparse VECTOR column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>        |
| <a href="#">GetNonZeroIndexArray</a>   | Returns the non-zero-dimension indices long[] of the specified sparse VECTOR column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>        |
| <a href="#">GetNonZeroInt16Array</a>   | Returns the non-zero-dimension values short[] of the specified sparse VECTOR column. (Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>       |

Table 6-83 (Cont.) OracleDataReader Public Methods

| Public Method                                | Description                                                                                                                                                          |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GetOracleBFile</a>               | Returns an <code>OracleBFile</code> object of the specified BFILE column                                                                                             |
| <a href="#">GetOracleBinary</a>              | Returns an <code>OracleBinary</code> structure of the specified column                                                                                               |
| <a href="#">GetOracleBlob</a>                | Returns an <code>OracleBlob</code> object of the specified BLOB column                                                                                               |
| <a href="#">GetOracleBlobForUpdate</a>       | Returns an updatable <code>OracleBlob</code> object of the specified BLOB column<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                 |
| <a href="#">GetOracleBoolean(int)</a>        | Returns the <code>OracleBoolean</code> value of the column                                                                                                           |
| <a href="#">GetOracleClob</a>                | Returns an <code>OracleClob</code> object of the specified CLOB column                                                                                               |
| <a href="#">GetOracleClobForUpdate</a>       | Returns an updatable <code>OracleClob</code> object of the specified CLOB column<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                 |
| <a href="#">GetOracleDataReader</a>          | Returns the <code>OracleDataReader</code> object corresponding to the REF CURSOR type column in the select list<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">GetOracleDate</a>                | Returns an <code>OracleDate</code> structure of the specified DATE column                                                                                            |
| <a href="#">GetOracleDecimal</a>             | Returns an <code>OracleDecimal</code> structure of the specified NUMBER column                                                                                       |
| <a href="#">GetOracleIntervalDS</a>          | Returns an <code>OracleIntervalDS</code> structure of the specified INTERVAL DAY TO SECOND column                                                                    |
| <a href="#">GetOracleIntervalYM</a>          | Returns an <code>OracleIntervalYM</code> structure of the specified INTERVAL YEAR TO MONTH column                                                                    |
| <a href="#">GetOracleRef</a>                 | Returns an <code>OracleRef</code> object of the specified REF column                                                                                                 |
| <a href="#">GetOracleRefCursor</a>           | Returns the <code>OracleRefCursor</code> object corresponding to the REF CURSOR type column in the select list<br><i>Not Available in ODP.NET, Unmanaged Driver</i>  |
| <a href="#">GetOracleString</a>              | Returns an <code>OracleString</code> structure of the specified column                                                                                               |
| <a href="#">GetOracleTimeStamp</a>           | Returns an <code>OracleTimeStamp</code> structure of the Oracle TimeStamp column                                                                                     |
| <a href="#">GetOracleTimeStampLTZ</a>        | Returns an <code>OracleTimeStampLTZ</code> structure of the specified Oracle TimeStamp WITH LOCAL TIME ZONE column                                                   |
| <a href="#">GetOracleTimeStampTZ</a>         | Returns an <code>OracleTimeStampTZ</code> structure of the specified Oracle TimeStamp WITH TIME ZONE column                                                          |
| <a href="#">GetOracleXmlType</a>             | Returns an <code>OracleXmlType</code> object of the specified XMLType column                                                                                         |
| <a href="#">GetOracleValue</a>               | Returns the specified column value as a ODP.NET type                                                                                                                 |
| <a href="#">GetOracleValues</a>              | Gets all the column values as ODP.NET types                                                                                                                          |
| <a href="#">GetOracleVector</a>              | Returns <code>OracleVector</code> object of the specified VECTOR column. (Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">GetOrdinal</a>                   | Returns the 0-based ordinal (or index) of the specified column name                                                                                                  |
| <a href="#">GetProviderSpecificFieldType</a> | Returns the provider-specific type of the specified column                                                                                                           |

Table 6-83 (Cont.) OracleDataReader Public Methods

| Public Method                                  | Description                                                                                                                       |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GetProviderSpecificValue</a>       | Returns an object that represents the underlying provider-specific value of the specified ordinal                                 |
| <a href="#">GetProviderSpecificValues</a>      | Returns an array of objects that represent the underlying provider-specific values                                                |
| <a href="#">GetSchemaTable</a>                 | Returns a DataTable that describes the column metadata of the OracleDataReader                                                    |
| <a href="#">GetString</a>                      | Returns the string value of the specified column                                                                                  |
| <a href="#">GetTimeSpan</a>                    | Returns the TimeSpan value of the specified INTERVAL DAY TO SECOND column                                                         |
| GetType                                        | Inherited from System.Object class                                                                                                |
| <a href="#">GetValue</a>                       | Returns the column value as a .NET type                                                                                           |
| <a href="#">GetValues</a>                      | Gets all the column values as .NET types                                                                                          |
| <a href="#">GetVectorDimensions</a>            | Returns the number of dimensions of the specified VECTOR column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">GetVectorNumericFormat(int)</a>    | Returns the OracleDbType value of the VECTOR column numeric format                                                                |
| <a href="#">GetVectorNumericFormat(string)</a> | Returns the OracleDbType value of the VECTOR column numeric format                                                                |
| <a href="#">GetXmlReader</a>                   | Returns the value of an XMLType column as an instance of an .NET XmlTextReader                                                    |
| <a href="#">IsDBNull</a>                       | Indicates whether or not the column value is null                                                                                 |
| <a href="#">IsDBNullAsync</a>                  | Returns a Task-based asynchronous version of OracleDataReader.IsDBNull() (Overloaded)                                             |
| <a href="#">NextResult</a>                     | Advances the data reader to the next result set when reading the results                                                          |
| <a href="#">NextResultAsync</a>                | Returns a Task-based asynchronous version of OracleDataReader.NextResult() (Overloaded)                                           |
| <a href="#">Read</a>                           | Reads the next row in the result set                                                                                              |
| <a href="#">ReadAsync</a>                      | Returns a Task-based asynchronous version of OracleDataReader.Read() (Overloaded)                                                 |
| ToString                                       | Inherited from System.Object                                                                                                      |

## OracleDataReader Properties

OracleDataReader properties are listed in [Table 6-85](#).

**Table 6-85 OracleDataReader Properties**

| Property                                               | Description                                                                                                                                                            |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Depth</a>                                  | Gets a value indicating the depth of nesting for the current row                                                                                                       |
| <a href="#">FetchSize</a>                              | Specifies the size of OracleDataReader's internal cache                                                                                                                |
| <a href="#">FieldCount</a>                             | Gets the number of columns in the result set                                                                                                                           |
| <a href="#">HasRows</a>                                | Indicates whether the OracleDataReader has one or more rows                                                                                                            |
| <a href="#">HiddenFieldCount</a>                       | Gets the number of fields in the OracleDataReader that are hidden                                                                                                      |
| <a href="#">IsClosed</a>                               | Indicates whether or not the data reader is closed                                                                                                                     |
| <a href="#">Item</a>                                   | Gets the value of the column (Overloaded)                                                                                                                              |
| <a href="#">InitialLOBFetchSize</a>                    | Specifies the amount that the OracleDataReader initially fetches for LOB columns                                                                                       |
| <a href="#">InitialLONGFetchSize</a>                   | Specifies the amount that the OracleDataReader initially fetches for LONG and LONG RAW columns                                                                         |
| <a href="#">RecordsAffected</a>                        | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement                                                                                |
| <a href="#">RowSize</a>                                | Gets the amount of memory the internal cache of the OracleDataReader needs to store one row of data                                                                    |
| <a href="#">RowsToFetchPerRoundTrip</a>                | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                            |
| <a href="#">SuppressGetDecimalInvalidCastException</a> | Specifies whether to suppress the <code>InvalidCastException</code> and return a rounded-off 28 precision value if the Oracle NUMBER value has more than 28 precision. |
| <a href="#">UseEdmMapping</a>                          | Indicates whether or not the OracleDataReader utilizes the Entity Data Model mapping configuration when returning values                                               |

**Table 6-85 (Cont.) OracleDataReader Properties**

| Property                          | Description                                                           |
|-----------------------------------|-----------------------------------------------------------------------|
| <a href="#">VisibleFieldCount</a> | Gets the number of fields in the OracleDataReader that are not hidden |

## Depth

This property gets a value indicating the depth of nesting for the current row.

**Declaration**

```
// C#  
public override int Depth {get;}
```

**Property Value**

The depth of nesting for the current row.

**Implements**

IDataReader

**Exceptions**

InvalidOperationException - The reader is closed.

**Remarks**

Default = 0

This property always returns zero because Oracle does not support nesting.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## FetchSize

This property specifies the size of OracleDataReader's internal cache.

## Declaration

```
// C#  
public long FetchSize {get; set;}
```

## Property Value

A long that specifies the amount of memory (in bytes) that the `OracleDataReader` uses for its internal cache.

## Exceptions

`ArgumentException` - The `FetchSize` value specified is invalid.

## Remarks

Default = The `OracleCommand`'s `FetchSize` property value.

The `FetchSize` property is inherited by the `OracleDataReader` that is created by a command execution returning a result set. The `FetchSize` property on the `OracleDataReader` object determines the amount of data fetched into its internal cache for each database round-trip.

The `RowSize` and `FetchSize` properties handle UDT and `XMLType` data differently than other scalar data types. Because only a reference to the UDT and `XMLType` data is stored in the ODP.NET's internal cache, the `RowSize` property accounts for only the memory needed for the reference (which is very small) and not the actual size of the UDT and `XMLType` data. Thus, applications can inadvertently fetch a large number of UDT or `XMLType` instances from the database in a single database round-trip. This is because the actual size of UDT and `XMLType` data does not count against the `FetchSize`, and it would require numerous UDT and `XMLType` references to fill up the default cache size of 131072 bytes. Therefore, when fetching UDT or `XMLType` data, the `FetchSize` property must be appropriately configured to control the number of UDT and `XMLType` instances that are to be fetched, rather than the amount of the actual UDT and `XMLType` data to be fetched.

NOTE: For LOB and LONG data types, only the sizes specified in the `InitialLOBFetchSize` and `InitialLONGFetchSize` properties are accounted for by the `RowSize` property in addition to the metadata and reference information that is maintained by the cache for each LOB in the select list.

- `OracleCommand` ["RowSize"](#)

## FieldCount

This property returns the number of columns in the result set.

**Declaration**

```
// C#  
public override int FieldCount {get;}
```

**Property Value**

The number of columns in the result set if one exists, otherwise 0.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The reader is closed.

**Remarks**

Default = 0

This property has a value of 0 for queries that do not return result sets.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## HasRows

This property indicates whether the OracleDataReader has one or more rows.

**Declaration**

```
// C#  
public override bool HasRows {get;}
```

**Return Value**

bool

**Remarks**

HasRows indicates whether or not the OracleDataReader has any rows.

The value of HasRows does not change based on the row position. For example, even if the application has read all the rows from the result set and the next Read method invocation will return false, the HasRows property still returns true since the result set was not empty to begin with.

Rows are fetched to determine the emptiness of the OracleDataReader when HasRows property is accessed for the first time after the creation of the OracleDataReader object.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;

class HasRowsSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleCommand cmd = new OracleCommand(
            "select * from emp where empno = 9999", con);

        OracleDataReader reader = cmd.ExecuteReader();

        if (!reader.HasRows)
            Console.WriteLine("The result set is empty.");
        else
            Console.WriteLine("The result set is not empty.");

        con.Dispose();
    }
}
```

## HiddenFieldCount

This property gets the number of fields in the OracleDataReader that are hidden.

### Declaration

```
// C#
public int HiddenFieldcount { get; }
```

### Property Value

The number of fields in the OracleDataReader that are hidden.

### Exceptions

InvalidOperationException - The reader is closed.

**Remarks**

OracleDataReader.FieldCount and OracleDataReader.VisibleFieldCount return the visible field count.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)
- ["VisibleFieldCount"](#)
- ["FieldCount "](#)

## IsClosed

This property indicates whether or not the data reader is closed.

**Declaration**

```
// C#  
public override bool IsClosed {get;}
```

**Property Value**

If the OracleDataReader is in a closed state, returns true; otherwise, returns false.

**Implements**

IDataReader

**Remarks**

Default = true

IsClosed and RecordsAffected are the only two properties that are accessible after the OracleDataReader is closed.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## Item

This property gets the value of the column in .NET data type.

**Overload List:**

- [Item \[index\]](#)  
This property gets the .NET Value of the column specified by the column index.
- [Item \[string\]](#)  
This property gets the .NET Value of the column specified by the column name.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## Item [index]

This property gets the .NET Value of the column specified by the column index.

**Declaration**

```
// C#  
public override object this[int index] {get;}
```

**Parameters**

- *index*  
The zero-based index of the column.

**Property Value**

The .NET value of the specified column.

**Implements**

IDataRecord

**Remarks**

Default = Not Applicable

In C#, this property is the indexer for this class.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## Item [string]

This property gets the .NET Value of the column specified by the column name.

### Declaration

```
// C#  
public override object this[string columnName] {get;}
```

### Parameters

- *columnName*  
The name of the column.

### Property Value

The .NET Value of the specified column.

### Implements

IDataRecord

### Remarks

Default = Not Applicable

A case-sensitive search is made to locate the specified column by its name. If this fails, then a case-insensitive search is made.

In C#, this property is the indexer for this class.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## InitialLOBFetchSize

This property specifies the amount that the OracleDataReader initially fetches for LOB columns.

### Declaration

```
// C#  
public int InitialLOBFetchSize {get;}
```

### Property Value

The size of the chunk to retrieve.

### Exceptions

InvalidOperationException - The reader is closed.

### Remarks

The maximum value supported for `InitialLOBFetchSize` is 2 GB.

Default is the `OracleCommand.InitialLOBFetchSize`, from which this value is inherited.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)
- ["InitialLOBFetchSize"](#) for further information on `OracleCommand.InitialLOBFetchSize`
- ["Obtaining LOB Data"](#)

## InitialLONGFetchSize

This property specifies the amount that the `OracleDataReader` initially fetches for LONG and LONG RAW columns.

### Declaration

```
// C#  
public long InitialLONGFetchSize {get;}
```

### Property Value

The size of the chunk to retrieve. The default is 0.

### Exceptions

`InvalidOperationException` - The reader is closed.

### Remarks

The maximum value supported for `InitialLONGFetchSize` is 32767. If this property is set to a higher value, the provider resets it to 32767.

Default is `OracleCommand.InitialLONGFetchSize`, from which this value is inherited.

This property is read-only for the `OracleDataReader`.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)
- ["InitialLONGFetchSize"](#) for further information on `OracleCommand.InitialLONGFetchSize`
- ["Obtaining LONG and LONG RAW Data"](#)

## RecordsAffected

This property gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

### Declaration

```
// C#  
public int RecordsAffected {get;}
```

### Property Value

The number of rows affected by execution of the SQL statement.

### Implements

`IDataReader`

### Remarks

Default = 0

The value of -1 is returned for SELECT statements.

`IsClosed` and `RecordsAffected` are the only two properties that are accessible after the `OracleDataReader` is closed.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## RowSize

This property gets the amount of memory the internal cache of the `OracleDataReader` needs to store one row of data.

**Declaration**

```
// C#  
public long RowSize {get;}
```

**Property Value**

A long that indicates the amount of memory (in bytes) that an `OracleDataReader` needs to store one row of data for the executed query.

**Remarks**

The `RowSize` property is set to a nonzero value when the `OracleDataReader` object is created. This property can be used at design time or dynamically during runtime, to set the `FetchSize` property, based on the number of rows. For example, to enable the `OracleDataReader` object to fetch *N* rows for each database round-trip, the `OracleDataReader` `FetchSize` property can be set dynamically to `RowSize * N`. Note that for the `FetchSize` property to take effect appropriately, it must be set before the first invocation of `OracleDataReader.Read()` for the particular result set.

ODP.NET now supports values up to 32K for `VARCHAR2`, `NVARCHAR2` or `RAW` type columns in its calculation of `RowSize` value

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)
- ["FetchSize"](#)

## RowsToFetchPerRoundTrip

This property specifies the total number of rows to retrieve per database round trip.

**Declaration**

```
// C#  
public Int64 RowsToFetchPerRoundTrip { get; set; }
```

**Property Type**

`System.Int64`

**Remarks**

This property has no default value. If it is not set, then ODP.NET ignores this property.

The row data fetched in a single round trip applies to scalar types only, such as `NUMBER` and `VARCHAR2` columns. If reference data types, such as LOBs, UDTs, and `XMLType`, exist in the result set, they are retrieved in separate round trips. These reference types can have their own fetch tuning parameters as reference type data sizes can vary in size from row to row, sometimes significantly.

RowsToFetchPerRoundTrip can be set before or after the OracleCommand executes on OracleConnection, OracleCommand, OracleDataReader, or OracleRefCursor. The value can also be changed after initial data fetches so that more or fewer rows are fetched on subsequent round trips. For OracleConfiguration, this property can only be set before the first connection opens.

## SuppressGetDecimalInvalidCastException

This property specifies whether to suppress the InvalidCastException and return a rounded-off 28 precision value if the Oracle NUMBER value has more than 28 precision.

### Declaration

```
// C#  
public bool SuppressGetDecimalInvalidCastException { get; set; }
```

### Property Type

System.Boolean

### Remarks

Oracle NUMBER has a maximum of 38 precision. .NET Decimal has a maximum of 28 or 29 precision. When the GetDecimal() method is called for an Oracle NUMBER value that cannot be represented as a .NET Decimal, then ODP.NET throws an InvalidCastException because not all the precision can be preserved when converting the number to a .NET Decimal.

This behavior occurs when SuppressGetDecimalInvalidCastException is set to false. Its default value is false.

When SuppressGetDecimalInvalidCastException is set to true, then the resulting decimal will be rounded off to 28 or 29 precision so that it can fit as a .NET decimal without throwing an exception. If the resulting rounded number is larger than can be stored in a .NET Decimal, an exception will be thrown, such as the number  $1 \times 10^{32}$ .

The SuppressGetDecimalInvalidCastException property can also be configured on OracleConfiguration, OracleConnection, and OracleDataAdapter objects. The OracleDataReader SuppressGetDecimalInvalidCastException property value inherits OracleConnection SuppressGetDecimalInvalidCastException property value at construction time.

By using OracleDataReader.SuppressGetDecimalInvalidCastException, this ODP.NET setting becomes enabled for reader's lifetime.

## UseEdmMapping

This read-only property indicates whether or not the OracleDataReader utilizes the Entity Data Model mapping configuration when returning values.

**Declaration**

```
// C#  
public bool UseEdmMapping {get;}
```

**Property Value**

A boolean that indicates whether the OracleDataReader uses the Entity Data Model mapping configuration for returning values.

**Remarks**

Default is false.

The value is inherited from the OracleCommand object.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

- [OracleCommand Class](#)

## VisibleFieldCount

This property gets the number of fields in the OracleDataReader that are not hidden.

**Declaration**

```
// C#  
public override int VisibleFieldcount { get; }
```

**Property Value**

The number of fields that are not hidden.

## Exceptions

InvalidOperationException - The reader is closed.

## Remarks

If an application sets the AddRowid property on an OracleCommand object to true, then the application can access the RowId but it is not a visible field. If RowId is added in the select statement list, then it is a visible field. OracleDataReader.VisibleFieldCount and OracleDataReader.FieldCount always have the same value.

## Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;

class VisibleFieldCountSample
{
    static void Main(string[] args)
    {
        string constr = "User Id=scott; Password=tiger; Data Source=oracle;";
        DbProviderFactory factory =
            DbProviderFactories.GetFactory("Oracle.DataAccess.Client");

        using (DbConnection conn = factory.CreateConnection())
        {
            conn.ConnectionString = constr;
            try
            {
                conn.Open();
                OracleCommand cmd = (OracleCommand)factory.CreateCommand();
                cmd.Connection = (OracleConnection)conn;

                //to gain access to ROWIDs of the table
                cmd.AddRowid = true;
                cmd.CommandText = "select empno, ename from emp;";

                OracleDataReader reader = cmd.ExecuteReader();

                int visFC = reader.VisibleFieldCount; //Results in 2
                int hidFC = reader.HiddenFieldCount; // Results in 1

                Console.WriteLine("Visible field count: " + visFC);
                Console.WriteLine("Hidden field count: " + hidFC);

                reader.Dispose();
                cmd.Dispose();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.Message);
                Console.WriteLine(ex.StackTrace);
            }
        }
    }
}
```

## OracleDataReader Public Methods

OracleDataReader public methods are listed in [Table 6-86](#).

**Table 6-86 OracleDataReader Public Methods**

| Public Method                          | Description                                                                                                                                 |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Close</a>                  | Closes the OracleDataReader                                                                                                                 |
| CreateObjRef                           | Inherited from System.MarshalByRefObject                                                                                                    |
| <a href="#">Dispose</a>                | Releases any resources or memory allocated by the object                                                                                    |
| Equals                                 | Inherited from System.Object (Overloaded)                                                                                                   |
| <a href="#">GetBoolean</a>             | Returns the bool value of the specified numeric column                                                                                      |
| <a href="#">GetByte</a>                | Returns the byte value of the specified column                                                                                              |
| <a href="#">GetByteArray(int)</a>      | Returns the byte array value of the specified numeric column<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">GetByteArray(string)</a>   | Returns the byte array value of the specified numeric column<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">GetBytes</a>               | Populates the provided byte array with up to the maximum number of bytes, from the specified offset (in bytes) of the column                |
| <a href="#">GetChar</a>                | <i>Not Supported</i>                                                                                                                        |
| <a href="#">GetChars</a>               | Populates the provided character array with up to the maximum number of characters, from the specified offset (in characters) of the column |
| <a href="#">GetData</a>                | <i>Not Supported</i>                                                                                                                        |
| <a href="#">GetDataTypeName</a>        | Returns the ODP.NET type name of the specified column                                                                                       |
| <a href="#">GetDateTime</a>            | Returns the DateTime value of the specified column                                                                                          |
| <a href="#">GetDateTimeOffset</a>      | Returns the DateTimeOffset value of the specified column                                                                                    |
| <a href="#">GetDecimal</a>             | Returns the decimal value of the specified NUMBER column                                                                                    |
| <a href="#">GetDouble</a>              | Returns the double value of the specified NUMBER column or BINARY_DOUBLE column                                                             |
| <a href="#">GetDoubleArray(int)</a>    | Returns the double[] value of the specified VECTOR column                                                                                   |
| <a href="#">GetDoubleArray(string)</a> | Returns the double[] value of the specified VECTOR column                                                                                   |

Table 6-86 (Cont.) OracleDataReader Public Methods

| Public Method                          | Description                                                                                                                                                                      |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GetEnumerator</a>          | Returns an <code>IEnumerator</code> that can be used to iterate through the collection                                                                                           |
| <a href="#">GetFieldType</a>           | Returns the Type of the specified column                                                                                                                                         |
| <a href="#">GetFieldValueAsync</a>     | Returns a Task-based asynchronous version of <code>OracleDataReader.GetFieldValue()</code> , which returns the column value as a specified type (Overloaded)                     |
| <a href="#">GetFloat</a>               | Returns the <code>float</code> value of the specified <code>NUMBER</code> column or <code>BINARY_FLOAT</code> column                                                             |
| <a href="#">GetFloatArray(int)</a>     | Returns the <code>float[]</code> value of the specified <code>VECTOR</code> column                                                                                               |
| <a href="#">GetFloatArray(string)</a>  | Returns the <code>float[]</code> value of the specified <code>VECTOR</code> column                                                                                               |
| <a href="#">GetGuid</a>                | Returns the <code>Guid</code> value of the specified binary data column                                                                                                          |
| <code>GetHashCode</code>               | Inherited from <code>System.Object</code>                                                                                                                                        |
| <a href="#">GetInt16</a>               | Returns the <code>Int16</code> value of the specified <code>NUMBER</code> column                                                                                                 |
| <a href="#">GetInt16Array(int)</a>     | Returns the <code>short[]</code> value of the specified <code>VECTOR</code> column                                                                                               |
| <a href="#">GetInt16Array(string)</a>  | Returns the <code>short[]</code> value of the specified <code>VECTOR</code> column                                                                                               |
| <a href="#">GetInt32</a>               | Returns the <code>Int32</code> value of the specified <code>NUMBER</code> column                                                                                                 |
| <a href="#">GetInt64</a>               | Returns the <code>Int64</code> value of the specified <code>NUMBER</code> column                                                                                                 |
| <code>GetLifetimeService</code>        | Inherited by <code>System.MarshalByRefObject</code>                                                                                                                              |
| <a href="#">GetName</a>                | Returns the name of the specified column                                                                                                                                         |
| <a href="#">GetNonZeroDoubleArray</a>  | Returns the non-zero-dimension values <code>double[]</code> of the specified sparse <code>VECTOR</code> column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">GetNonZeroFloatArray</a>   | Returns the non-zero-dimension values <code>float[]</code> of the specified sparse <code>VECTOR</code> column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>  |
| <a href="#">GetNonZeroIndexArray</a>   | Returns the non-zero-dimension indices <code>long[]</code> of the specified sparse <code>VECTOR</code> column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>  |
| <a href="#">GetNonZeroInt16Array</a>   | Returns the non-zero-dimension values <code>short[]</code> of the specified sparse <code>VECTOR</code> column. (Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">GetOracleBFile</a>         | Returns an <code>OracleBFile</code> object of the specified <code>BFILE</code> column                                                                                            |
| <a href="#">GetOracleBinary</a>        | Returns an <code>OracleBinary</code> structure of the specified column                                                                                                           |
| <a href="#">GetOracleBlob</a>          | Returns an <code>OracleBlob</code> object of the specified <code>BLOB</code> column                                                                                              |
| <a href="#">GetOracleBlobForUpdate</a> | Returns an updatable <code>OracleBlob</code> object of the specified <code>BLOB</code> column<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                |
| <a href="#">GetOracleBoolean(int)</a>  | Returns the <code>OracleBoolean</code> value of the column                                                                                                                       |
| <a href="#">GetOracleClob</a>          | Returns an <code>OracleClob</code> object of the specified <code>CLOB</code> column                                                                                              |

Table 6-86 (Cont.) OracleDataReader Public Methods

| Public Method                                | Description                                                                                                                                                          |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GetOracleClobForUpdate</a>       | Returns an updatable <code>OracleClob</code> object of the specified CLOB column<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                 |
| <a href="#">GetOracleDataReader</a>          | Returns the <code>OracleDataReader</code> object corresponding to the REF CURSOR type column in the select list<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">GetOracleDate</a>                | Returns an <code>OracleDate</code> structure of the specified DATE column                                                                                            |
| <a href="#">GetOracleDecimal</a>             | Returns an <code>OracleDecimal</code> structure of the specified NUMBER column                                                                                       |
| <a href="#">GetOracleIntervalDS</a>          | Returns an <code>OracleIntervalDS</code> structure of the specified INTERVAL DAY TO SECOND column                                                                    |
| <a href="#">GetOracleIntervalYM</a>          | Returns an <code>OracleIntervalYM</code> structure of the specified INTERVAL YEAR TO MONTH column                                                                    |
| <a href="#">GetOracleRef</a>                 | Returns an <code>OracleRef</code> object of the specified REF column                                                                                                 |
| <a href="#">GetOracleRefCursor</a>           | Returns the <code>OracleRefCursor</code> object corresponding to the REF CURSOR type column in the select list<br><i>Not Available in ODP.NET, Unmanaged Driver</i>  |
| <a href="#">GetOracleString</a>              | Returns an <code>OracleString</code> structure of the specified column                                                                                               |
| <a href="#">GetOracleTimeStamp</a>           | Returns an <code>OracleTimeStamp</code> structure of the Oracle TimeStamp column                                                                                     |
| <a href="#">GetOracleTimeStampLTZ</a>        | Returns an <code>OracleTimeStampLTZ</code> structure of the specified Oracle TimeStamp WITH LOCAL TIME ZONE column                                                   |
| <a href="#">GetOracleTimeStampTZ</a>         | Returns an <code>OracleTimeStampTZ</code> structure of the specified Oracle TimeStamp WITH TIME ZONE column                                                          |
| <a href="#">GetOracleXmlType</a>             | Returns an <code>OracleXmlType</code> object of the specified XMLType column                                                                                         |
| <a href="#">GetOracleValue</a>               | Returns the specified column value as a ODP.NET type                                                                                                                 |
| <a href="#">GetOracleValues</a>              | Gets all the column values as ODP.NET types                                                                                                                          |
| <a href="#">GetOracleVector</a>              | Returns <code>OracleVector</code> object of the specified VECTOR column. (Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                           |
| <a href="#">GetOrdinal</a>                   | Returns the 0-based ordinal (or index) of the specified column name                                                                                                  |
| <a href="#">GetProviderSpecificFieldType</a> | Returns the provider-specific type of the specified column                                                                                                           |
| <a href="#">GetProviderSpecificValue</a>     | Returns an object that represents the underlying provider-specific value of the specified ordinal                                                                    |
| <a href="#">GetProviderSpecificValues</a>    | Returns an array of objects that represent the underlying provider-specific values                                                                                   |
| <a href="#">GetSchemaTable</a>               | Returns a <code>DataTable</code> that describes the column metadata of the <code>OracleDataReader</code>                                                             |
| <a href="#">GetString</a>                    | Returns the string value of the specified column                                                                                                                     |
| <a href="#">GetTimeSpan</a>                  | Returns the <code>TimeSpan</code> value of the specified INTERVAL DAY TO SECOND column                                                                               |

Table 6-86 (Cont.) OracleDataReader Public Methods

| Public Method                                  | Description                                                                                                                       |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| GetType                                        | Inherited from System.Object class                                                                                                |
| <a href="#">GetValue</a>                       | Returns the column value as a .NET type                                                                                           |
| <a href="#">GetValues</a>                      | Gets all the column values as .NET types                                                                                          |
| <a href="#">GetVectorDimensions</a>            | Returns the number of dimensions of the specified VECTOR column.(Overloaded)<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |
| <a href="#">GetVectorNumericFormat(int)</a>    | Returns the OracleDbType value of the VECTOR column numeric format                                                                |
| <a href="#">GetVectorNumericFormat(string)</a> | Returns the OracleDbType value of the VECTOR column numeric format                                                                |
| <a href="#">GetXmlReader</a>                   | Returns the value of an XMLType column as an instance of an .NET XmlTextReader                                                    |
| <a href="#">IsDBNull</a>                       | Indicates whether or not the column value is null                                                                                 |
| <a href="#">IsDBNullAsync</a>                  | Returns a Task-based asynchronous version of OracleDataReader.IsDBNull() (Overloaded)                                             |
| <a href="#">NextResult</a>                     | Advances the data reader to the next result set when reading the results                                                          |
| <a href="#">NextResultAsync</a>                | Returns a Task-based asynchronous version of OracleDataReader.NextResult() (Overloaded)                                           |
| <a href="#">Read</a>                           | Reads the next row in the result set                                                                                              |
| <a href="#">ReadAsync</a>                      | Returns a Task-based asynchronous version of OracleDataReader.Read() (Overloaded)                                                 |
| ToString                                       | Inherited from System.Object                                                                                                      |

**See Also**

## Close

This method closes the OracleDataReader.

**Declaration**

```
// C#
public override void Close();
```

**Implements**

IDataReader

**Remarks**

The Close method frees all resources associated with the OracleDataReader.

**Example**

The code example for the OracleDataReader class includes the Close method. See OracleDataReader Overview "[Example](#)".

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## Dispose

This method releases any resources or memory allocated by the object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

**Remarks**

The Dispose method also closes the OracleDataReader.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetBoolean

This method returns the bool value of the specified numeric column.

**Declaration**

```
// C#  
public override bool GetBoolean(int index);
```

**Parameters**

- *index*

The zero-based column index.

### Return Value

The bool value of the column.

### Implements

IDataRecord

### Exceptions

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type.

### Remarks

- This method can be called on the BOOLEAN column, any numeric database type column (NUMBER, BINARY\_DOUBLE, BINARY\_FLOAT, and FLOAT), or any scalar character based column (CHAR, NCHAR, VARCHAR2, NVARCHAR2).
- For numeric columns, FALSE is returned if column value is 0; TRUE otherwise.
- For scalar character based column (CHAR, NCHAR, VARCHAR2, NVARCHAR2), GetBoolean can be called on Valid String literals.

Valid String literals to represent TRUE and FALSE (case insensitive) are as follows:

- For TRUE, valid string literals are (case insensitive) - true, yes, on, 1, t, y
- For FALSE, valid string literals are (case insensitive) - false, no, off, 0, f, n

If the string literals are anything other than those listed above, then an InvalidCastException will be returned when trying to read the value.

- IsDBNull should be called to check for NULL values before calling this method.

## GetByte

This method returns the byte value of the specified column.

### Declaration

```
// C#  
public override byte GetByte(int index);
```

### Parameters

- *index*

The zero-based column index.

**Return Value**

The value of the column as a byte.

**Implements**

IDataRecord

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

**Remarks**

`IsDBNull` should be called to check for `NULL` values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetByteArray(int)

This method returns the byte array value of the specified `VECTOR` column.

**Declaration**

```
// C#  
public override byte[] GetByteArray(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The byte array value of the column. A sparse vector type column will return the array value as a dense vector.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

While this accessor can retrieve data from columns of any numeric format, it is the only accessor for retrieving `byte[]` for `BINARY` format columns.

`IsDBNull` should be called to check for `NULL` values before calling this method.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetByteArray(string)

This method returns the byte array value of the specified `VECTOR` column.

### Declaration

```
// C#  
public override byte[] GetByteArray(string name);
```

### Parameters

- *name*  
The specified column name

### Return Value

The byte array value of the column. A sparse vector type column will return the array value as a dense vector.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

While this accessor can retrieve data from columns of any numeric format, it is the only accessor for retrieving `byte[]` for `BINARY` format columns.

`IsDBNull` should be called to check for `NULL` values before calling this method.

- [OracleDataReader Members](#)

## GetBytes

This method populates the provided byte array with up to the maximum number of bytes, from the specified offset (in bytes) of the column.

### Declaration

```
// C#  
public override long GetBytes(int index, long fieldOffset, byte[] buffer,  
    int bufferOffset, int length);
```

### Parameters

- *index*  
The zero-based column index.
- *fieldOffset*  
The offset within the column from which reading begins (in bytes).
- *buffer*  
The byte array that the data is read into.
- *bufferOffset*  
The offset within the buffer to begin reading data into (in bytes).
- *length*  
The maximum number of bytes to read (in bytes).

### Return Value

The number of bytes read.

### Implements

IDataRecord

### Exceptions

**InvalidOperationException** - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

**IndexOutOfRangeException** - The column index is invalid.

**InvalidCastException** - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

This method returns the number of bytes read into the buffer. This may be less than the actual length of the field if the method has been called previously for the same column.

If a null reference is passed for buffer, the length of the field in bytes is returned.

`IsDBNull` should be called to check for NULL values before calling this method.

## GetChar

This method is not supported.

### Declaration

```
// C#  
public override long GetChar(int index);
```

### Parameters

- *index*  
The zero based column index.

### Implements

`IDataRecord`

### Exceptions

`NotSupportedException` - This property is not supported.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetChars

This method populates the provided character array with up to the maximum number of characters, from the specified offset (in characters) of the column.

## Declaration

```
// C#  
public override long GetChars(int index, long fieldOffset, char[] buffer,  
    int bufferOffset, int length);
```

## Parameters

- *index*  
The zero based column index.
- *fieldOffset*  
The index within the column from which to begin reading (in characters).
- *buffer*  
The character array that the data is read into.
- *bufferOffset*  
The index within the buffer to begin reading data into (in characters).
- *length*  
The maximum number of characters to read (in characters).

## Return Value

The number of characters read.

## Implements

IDataRecord

## Exceptions

*InvalidOperationException* - The connection is closed, the reader is closed, *Read()* has not been called, or all rows have been read.

*IndexOutOfRangeException* - The column index is invalid.

*InvalidCastException* - The accessor method is invalid for this column type or the column value is NULL.

## Remarks

This method returns the number of characters read into the buffer. This may be less than the actual length of the field, if the method has been called previously for the same column.

If a null reference is passed for *buffer*, the length of the field in characters is returned.

*IsDBNull* should be called to check for NULL values before calling this method.

## GetDataTypeName

This method returns the ODP.NET type name of the specified column.

### Declaration

```
// C#  
public override string GetDataTypeName(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The name of the ODP.NET type of the column.

### Implements

IDataRecord

### Exceptions

InvalidOperationException - The reader is closed.  
IndexOutOfRangeException - The column index is invalid.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetDateTime

This method returns the DateTime value of the specified column.

**Declaration**

```
// C#  
public override DateTime GetDateTime(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The DateTime value of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetDateTimeOffset

This method returns the `DateTimeOffset` value of a `TIMESTAMP WITH TIME ZONE` column. `DateTimeOffset` represents a point in time. It is generally expressed as a date and time relative to Coordinated Universal Time (UTC).

### Declaration

```
// C#  
public override DateTimeOffset GetDateTimeOffset(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The `DateTimeOffset` value of the column.

### Implements

`IDataRecord`

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

- This method can be called only on a `TIMESTAMP WITH TIME ZONE` column.
- `IsDBNull` should be called to check for `NULL` values before calling this method.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetDecimal

This method returns the decimal value of the specified `NUMBER` column.

### Declaration

```
// C#  
public override decimal GetDecimal(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The decimal value of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetDouble

This method returns the double value of the specified NUMBER column or BINARY\_DOUBLE column.

**Declaration**

```
// C#  
public override double GetDouble(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The double value of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

GetDouble now supports retrieval of data from BINARY\_DOUBLE columns.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetDoubleArray(int)

This method returns the double[] value of the specified VECTOR column.

**Declaration**

```
// C#  
public double[] GetDoubleArray(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The double[] value of the column. A sparse vector type column will return the array value as a dense vector.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method. This method cannot be called on BINARY format vector columns.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetDoubleArray(string)

This method returns the double[] value of the specified VECTOR column.

**Declaration**

```
// C#  
public double[] GetDoubleArray(string name);
```

**Parameters**

- *name*  
The specified column name.

**Return Value**

The double[] value of the column. A sparse vector type column will return the array value as a dense vector.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - Unable to find specified column in result set.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method. This method cannot be called on BINARY format vector columns.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetEnumerator

This method returns an `IEnumerator` that can be used to iterate through the collection (record set).

### Declaration

```
// C#  
public override IEnumerator GetEnumerator();
```

### Return Value

An `IEnumerator` that can be used to iterate through the collection (record set).

### Exceptions

`InvalidOperationException` - The reader is closed.

## GetFieldType

This method returns the type of the specified column.

### Declaration

```
// C#  
public override Type GetFieldType(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The type of the default .NET type of the column.

### Implements

`IDataRecord`

### Exceptions

`InvalidOperationException` - The reader is closed, or the specified column is a UDT but no registered custom type mapping exists for the UDT.

`IndexOutOfRangeException` - The column index is invalid.

### Remarks

GetFieldType returns a type that corresponds to the value that the application obtains after invoking the GetValue accessor or Item property on the OracleDataReader. For example, if the column is a string, this method returns a .NET Type object for a .NET string.

If the attribute is a UDT, this method may return either of the following:

- A .NET Type of the custom type if a custom type mapping exists for the Oracle object or collection.
- A .NET Type of string if the column is an Oracle REF.

For VECTOR columns, this method returns a numeric array or byte array type based on the VECTOR numeric format. BINARY vectors can only return a .NET byte[]. If the VECTOR numeric format is '\*', then this method returns type of Array. For sparse VECTOR columns, this method returns type of string.

- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetFieldValueAsync

GetFieldValueAsync returns a Task-based asynchronous version of OracleDataReader.GetFieldValue(), which returns the column value as a specified type.

### Overload List:

- This method returns a Task-based asynchronous version of OracleDataReader.GetFieldValue()
- This method returns a Task-based asynchronous version of OracleDataReader.GetFieldValue()

## GetFieldValueAsync(int, CancellationToken)

### Declaration

```
// C#  
public override Task<T> GetFieldValueAsync<T>(int ordinal, CancellationToken  
cancellation_token);
```

### Type Parameters

T - The type of the value to be returned.

### Parameters

ordinal - The zero-based column index.

`cancellationToken` - The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<T>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

`DbDataReader`

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` – The value returned by the database cannot be cast to `T`.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetFieldValueAsync(int)

### Declaration

```
// C#  
public Task<T> GetFieldValueAsync<T>(int ordinal);
```

### Type Parameters

`T` - The type of the value to be returned.

### Parameters

`ordinal` - The zero-based column index.

### Return Value

`Task<T>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

`DbDataReader`

### Remarks

This will call into the `GetFieldValueAsync` implementation with argument `cancellationToken` passed as `CancellationToken.None`.

## Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` – The value returned by the database cannot be cast to T.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)

## GetFloat

This method returns the float value of the specified NUMBER column or BINARY\_FLOAT column.

### Declaration

```
// C#  
public override float GetFloat(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The float value of the column.

### Implements

`IDataRecord`

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

`IsDBNull` should be called to check for NULL values before calling this method.

`GetFloat` now supports retrieval of data from BINARY\_FLOAT columns.

**① See Also**

## GetFloatArray(int)

This method returns the float[] value of the specified VECTOR column.

**Declaration**

```
// C#  
public float[] GetFloatArray(int index);
```

**Parameters**

- *index*

The zero-based column index.

**Return Value**

The float[] value of the column. A sparse vector type column will return the array value as a dense vector.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method. This method cannot be called on BINARY format vector columns.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetFloatArray(string)

This method returns the float[] value of the specified VECTOR column.

**Declaration**

```
// C#  
public float[] GetFloatArray(string name);
```

**Parameters**

- *name*

The specified column name.

**Return Value**

The float[] value of the column. A sparse vector type column will return the array value as a dense vector.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - Unable to find specified column in result set.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method. This method cannot be called on BINARY format vector columns.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetGuid

This method returns the Guid value of the specified binary data column. A GUID is a Globally Unique Identifier.

**Declaration**

```
// C#  
public override Guid GetGuid(int index);
```

**Parameters**

- *index*

The zero-based column index.

**Return Value**

The Guid value of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

System.ArgumentException - Byte array for GUID must be exactly 16 bytes long.

**Remarks**

- This method can be called on columns that contain binary data, such as RAW and BLOB.
- An exception will be thrown if the binary data of the column is not 16 bytes in length.
- IsDBNull should be called to check for NULL values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetInt16

This method returns the Int16 value of the specified NUMBER column.

**Note**

short is equivalent to Int16.

**Declaration**

```
// C#  
public override short GetInt16(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The Int16 value of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetInt16Array(int)

This method returns the short[] value of the specified VECTOR column.

**Declaration**

```
// C#  
public short[] GetInt16Array(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The short[] value of the column. A sparse vector type column will return the array value as a dense vector.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method. This method cannot be called on BINARY format vector columns.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataReader Class](#)

## GetInt16Array(string)

This method returns the short[] value of the specified VECTOR column.

**Declaration**

```
// C#  
public short[] GetInt16Array(string name);
```

**Parameters**

- *name*  
The specified column name.

**Return Value**

The short[] value of the column. A sparse vector type column will return the array value as a dense vector.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - Unable to find specified column in result set.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method. This method cannot be called on BINARY format vector columns.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

## GetInt32

This method returns the Int32 value of the specified NUMBER column.

### Note

`int` is equivalent to `Int32`.

### Declaration

```
// C#  
public override int GetInt32(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The Int32 value of the column.

### Implements

IDataRecord

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

`IsDBNull` should be called to check for `NULL` values before calling this method.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## GetInt64

This method returns the Int64 value of the specified NUMBER column.

**Note**

long is equivalent to Int64.

**Declaration**

```
// C#  
public override long GetInt64(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The Int64 value of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetName

This method returns the name of the specified column.

**Declaration**

```
// C#  
public override string GetName(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The name of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The reader is closed.  
IndexOutOfRangeException - The column index is invalid.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetNonZeroDoubleArray

This method returns the non-zero-dimension values `double[]` of the specified sparse VECTOR column.

**Overload List:**

- [GetNonZeroDoubleArray\(int\)](#)  
This method returns the non-zero-dimension values `double[]` of the specified sparse VECTOR column.
- [GetNonZeroDoubleArray\(string\)](#)  
This method returns the non-zero-dimension values `double[]` of the specified sparse VECTOR column.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetNonZeroDoubleArray(int)

This method returns the non-zero-dimension values `double[]` of the specified sparse `VECTOR` column.

### Declaration

```
// C#  
public double[] GetNonZeroDoubleArray(int index);
```

### Parameters

*index*

A zero-based column index.

### Return Value

The non-zero-dimension values `double[]` of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type, the `VECTOR` column is a dense vector type column, a `BINARY` format vector column, or the column value is `NULL`.

### Remarks

`IsDBNull` should be called to check for `NULL` values before calling this method.

Only call this method on a sparse `VECTOR` column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`. This method cannot be called on `BINARY` format vector columns.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)

## GetNonZeroDoubleArray(string)

This method returns the non-zero-dimension values `double[]` of the specified sparse `VECTOR` column.

### Declaration

```
// C#  
public double[] GetNonZeroDoubleArray(string name);
```

**Parameters**

*name*

The specified column name.

**Return Value**

The non-zero-dimension values `double[]` of the column.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - Unable to find specified column in result set.

`InvalidCastException` - The accessor method is invalid for this column type, the `VECTOR` column is a dense vector type column, a `BINARY` format vector column, or the column value is `NULL`.

**Remarks**

`IsDBNull` should be called to check for `NULL` values before calling this method.

Only call this method on a sparse `VECTOR` column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`. This method cannot be called on `BINARY` format vector columns.

## GetNonZeroFloatArray(int)

This method returns the non-zero-dimension values `float[]` of the specified sparse VECTOR column.

**Declaration**

```
// C#  
public float[] GetNonZeroFloatArray(int index);
```

**Parameters**

*index*

A zero-based column index.

**Return Value**

The non-zero-dimension values `float[]` of the column.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type, the VECTOR column is a dense vector type column, a BINARY format vector column, or the column value is NULL.

**Remarks**

`IsDBNull` should be called to check for NULL values before calling this method.

Only call this method on a sparse VECTOR column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`. This method cannot be called on BINARY format vector columns.

## GetNonZeroFloatArray(string)

This method returns the non-zero-dimension values `float[]` of the specified sparse VECTOR column.

### Declaration

```
// C#  
public float[] GetNonZeroFloatArray(string name);
```

### Parameters

*name*

The specified column name.

### Return Value

The non-zero-dimension values `float[]` of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - Unable to find specified column in result set.

`InvalidCastException` - The accessor method is invalid for this column type, the VECTOR column is a dense vector type column, a BINARY format vector column, or the column value is NULL.

### Remarks

`IsDBNull` should be called to check for NULL values before calling this method.

Only call this method on a sparse VECTOR column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`. This method cannot be called on BINARY format vector columns.

## GetNonZeroIndexArray(int)

This method returns the non-zero-dimension indices `long[]` of the specified sparse VECTOR column.

### Declaration

```
// C#  
public long[] GetNonZeroIndexArray(int index);
```

### Parameters

*index*

A zero-based column index.

### Return Value

The non-zero-dimension indices `long[]` of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type, the VECTOR column is a dense vector type column, or the column value is NULL.

### Remarks

`IsDBNull` should be called to check for NULL values before calling this method.

Only call this method on a sparse VECTOR column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## GetNonZeroIndexArray(string)

This method returns the non-zero-dimension indices `long[]` of the specified sparse VECTOR column.

### Declaration

```
// C#  
public long[] GetNonZeroIndexArray(string name);
```

### Parameters

*name*

The specified column name.

### Return Value

The 1-based non-zero-dimension indices `long[]` of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - Unable to find specified column in result set.

`InvalidCastException` - The accessor method is invalid for this column type, the VECTOR column is a dense vector type column, or the column value is `NULL`.

### Remarks

`IsDBNull` should be called to check for `NULL` values before calling this method.

Only call this method on a sparse VECTOR column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`.

## GetNonZeroInt16Array(int)

This method returns the non-zero-dimension values `short[]` of the specified sparse VECTOR column.

### Declaration

```
// C#  
public short[] GetNonZeroInt16Array(int index);
```

### Parameters

*index*

A zero-based column index.

### Return Value

The non-zero-dimension values `short[]` of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type, the VECTOR column is a dense vector type column, a BINARY format vector column, or the column value is NULL.

### Remarks

`IsDBNull` should be called to check for NULL values before calling this method.

Only call this method on a sparse VECTOR column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`. This method cannot be called on BINARY format vector columns.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)

## GetNonZeroInt16Array(string)

This method returns the non-zero-dimension values `short[]` of the specified sparse VECTOR column.

### Declaration

```
// C#  
public short[] GetNonZeroInt16Array(string name);
```

### Parameters

*name*

The specified column name.

### Return Value

The non-zero-dimension values `short[]` of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - Unable to find specified column in result set.

`InvalidCastException` - The accessor method is invalid for this column type, the VECTOR column is a dense vector type column, a BINARY format vector column, or the column value is NULL.

### Remarks

`IsDBNull` should be called to check for NULL values before calling this method.

Only call this method on a sparse VECTOR column where `SchemaTable["VectorType"]` is `OracleVectorType.Sparse`. This method cannot be called on BINARY format vector columns.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## GetOracleBFile

This method returns an `OracleBFile` object of the specified BFILE column.

### Declaration

```
// C#  
public OracleBFile GetOracleBFile(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The `OracleBFile` value of the column.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

**Remarks**

`IsDBNull` should be called to check for `NULL` values before calling this method.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleBinary

This method returns an `OracleBinary` structure of the specified column.

**Declaration**

```
// C#  
public OracleBinary GetOracleBinary(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The `OracleBinary` value of the column.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

IsDBNull should be called to check for NULL values before calling this method.

GetOracleBinary is used on the following Oracle types:

- BFILE
- BLOB
- LONG RAW
- RAW

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleBlob

This method returns an OracleBlob object of the specified BLOB column.

### Declaration

```
// C#  
public OracleBlob GetOracleBlob(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The OracleBlob value of the column.

### Exceptions

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

IsDBNull should be called to check for NULL values before calling this method.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleBlobForUpdate

GetOracleBlobForUpdate returns an updatable OracleBlob object of the specified BLOB column.

**Overload List:**

- [GetOracleBlobForUpdate\(int\)](#)  
This method returns an updatable OracleBlob object of the specified BLOB column.
- [GetOracleBlobForUpdate\(int, int\)](#)  
This method returns an updatable OracleBlob object of the specified BLOB column using a WAIT clause.

## GetOracleBlobForUpdate(int)

This method returns an updatable OracleBlob object of the specified BLOB column.

**Declaration**

```
// C#  
public OracleBlob GetOracleBlobForUpdate(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

An updatable OracleBlob object.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

When the OracleCommand's ExecuteReader() method is invoked, all the data fetched by the OracleDataReader is from a particular snapshot. Therefore, calling an accessor method on the same column always returns the same value. However, the GetOracleBlobForUpdate()

method incurs a database round-trip to obtain a reference to the current BLOB data while also locking the row using the FOR UPDATE clause. This means that the `OracleBlob` obtained from `GetOracleBlob()` can have a different value than the `OracleBlob` obtained from `GetOracleBlobForUpdate()` since it is not obtained from the original snapshot.

The returned `OracleBlob` object can be used to safely update the BLOB because the BLOB column has been locked after a call to this method.

Invoking this method internally executes a `SELECT . . FOR UPDATE` statement without a `WAIT` clause. Therefore, the statement can wait indefinitely until a lock is acquired for that row.

`IsDBNull` should be called to check for NULL values before calling this method.

### Example

The following example gets the `OracleBlob` object for update from the reader, updates the `OracleBlob` object, and then commits the transaction.

```
/* Database Setup, if you have not done so yet.
connect scott/tiger@oracle
CREATE TABLE empInfo (
empno NUMBER(4) PRIMARY KEY,
empName VARCHAR2(20) NOT NULL,
hiredate DATE,
salary NUMBER(7,2),
jobDescription Clob,
byteCodes BLOB
);

Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(1,'KING','SOFTWARE ENGR', '5657');
Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(2,'SCOTT','MANAGER', '5960');
commit;

*/
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class GetOracleBlobForUpdateSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Get the ByteCodes for empno = 1
        string cmdstr = "SELECT BYTECODES, EMPNO FROM EMPINFO where EMPNO = 1";
        OracleCommand cmd = new OracleCommand(cmdstr, con);

        // Since we are going to update the OracleBlob object, we will
        //have to create a transaction
        OracleTransaction txn = con.BeginTransaction();

        // Get the reader
        OracleDataReader reader = cmd.ExecuteReader();
```

```
// Declare the variables to retrieve the data in EmpInfo
OracleBlob byteCodesBlob;

// Read the first row
reader.Read();
if (!reader.IsDBNull(0))
{
    byteCodesBlob = reader.GetOracleBlobForUpdate(0);

    // Close the reader
    reader.Close();

    // Update the ByteCodes object
    byte[] addedBytes = new byte[2] {0, 0};
    byteCodesBlob.Append(addedBytes, 0, addedBytes.Length);

    // Now commit the transaction
    txn.Commit();
    Console.WriteLine("Blob Column successfully updated");
}
else
    reader.Dispose();

// Close the connection
con.Dispose();
}
```

## GetOracleBlobForUpdate(int, int)

This method returns an updatable `OracleBlob` object of the specified BLOB column using a `WAIT` clause.

### Declaration

```
// C#
public OracleBlob GetOracleBlobForUpdate(int index, int wait);
```

### Parameters

- *index*  
The zero-based column index.
- *wait*  
The number of seconds the method waits to acquire a lock.

### Return Value

An updatable `OracleBlob` object.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

When the `OracleCommand`'s `ExecuteReader()` method is invoked, all the data fetched by the `OracleDataReader` is from a particular snapshot. Therefore, calling an accessor method on the same column always returns the same value. However, the `GetOracleBlobForUpdate()` method incurs a database round-trip to obtain a reference to the current BLOB data while also locking the row using the `FOR UPDATE` clause. This means that the `OracleBlob` obtained from `GetOracleBlob()` can have a different value than the `OracleBlob` obtained from `GetOracleBlobForUpdate()` since it is not obtained from the original snapshot.

`IsDBNull` should be called to check for `NULL` values before calling this method.

The returned `OracleBlob` object can be used to safely update the BLOB because the BLOB column has been locked after a call to this method.

Invoking this method internally executes a `SELECT . .FOR UPDATE` statement which locks the row.

Different `WAIT` clauses are appended to the statement, depending on the `wait` value. If the `wait` value is:

- 0  
"NOWAIT" is appended at the end of a `SELECT . .FOR UPDATE` statement. The statement executes immediately whether the lock is acquired or not. If the lock is not acquired, an exception is thrown.
- n  
"WAIT n" is appended at the end of a `SELECT . .FOR UPDATE` statement. The statement executes as soon as the lock is acquired. However, if the lock cannot be acquired by *n* seconds, this method call throws an exception.  
  
The `WAIT n` feature is only available for Oracle9i or later. For any version lower than Oracle9i, *n* is implicitly treated as -1 and nothing is appended at the end of a `SELECT . .FOR UPDATE` statement.
- -1  
Nothing is appended at the end of the `SELECT . .FOR UPDATE`. The statement execution waits indefinitely until a lock can be acquired.

### Example

The `GetOracleBlobForUpdate` methods are comparable. See ["Example"](#) for a code example demonstrating usage.

## GetOracleBoolean(int)

This method will return an `OracleBoolean` value of the specified column.

### Declaration

```
// C#  
public OracleBoolean GetOracleBoolean(int index);
```

### Parameter

`index` - The zero-based column index.

### Return Value

The `OracleBoolean` value of the column

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type.

### Remarks

- This method can be called on the `BOOLEAN` column, any numeric database type column (`NUMBER`, `BINARY_DOUBLE`, `BINARY_FLOAT`, and `FLOAT`), or any scalar character based column (`CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`)
- For numeric columns, `FALSE` is returned if column value is 0; `TRUE` otherwise.
- For scalar character based column (`CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`), `GetBoolean` can be called on Valid String literals.

Valid String literals to represent `TRUE` and `FALSE` (case insensitive) are as follows:

- For `TRUE`, valid string literals are (case insensitive) - `true`, `yes`, `on`, `1`, `t`, `y`
- For `FALSE`, valid string literals are (case insensitive) - `false`, `no`, `off`, `0`, `f`, `n`

If the string literals are anything other than those listed above, then an `InvalidCastException` will be returned when trying to read the value.

- `IsDBNull` should be called to check for `NULL` values before calling this method.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleClob

This method returns an OracleClob object of the specified CLOB column.

### Declaration

```
// C#  
public OracleClob GetOracleClob(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The OracleClob value of the column.

### Exceptions

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

IsDBNull should be called to check for NULL values before calling this method.

## GetOracleClobForUpdate

GetOracleClobForUpdate returns an updatable OracleClob object of the specified CLOB column.

**Overload List:**

- [GetOracleClobForUpdate\(int\)](#)  
This method returns an updatable `OracleClob` object of the specified CLOB column.
- [GetOracleClobForUpdate\(int, int\)](#)  
This method returns an updatable `OracleClob` object of the specified CLOB column using a `WAIT` clause.

## GetOracleClobForUpdate(int)

This method returns an updatable `OracleClob` object of the specified CLOB column.

**Declaration**

```
// C#  
public OracleClob GetOracleClobForUpdate(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

An updatable `OracleClob`.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

**Remarks**

When the `OracleCommand`'s `ExecuteReader()` method is invoked, all the data fetched by the `OracleDataReader` is from a particular snapshot. Therefore, calling an accessor method on the same column always returns the same value. However, the `GetOracleClobForUpdate()` method incurs a database round-trip to obtain a reference to the current CLOB data while also locking the row using the `FOR UPDATE` clause. This means that the `OracleClob` obtained from `GetOracleClob()` can have a different value than the `OracleClob` obtained from `GetOracleClobForUpdate()` since it is not obtained from the original snapshot.

The returned `OracleClob` object can be used to safely update the CLOB because the CLOB column is locked after a call to this method.

Invoking this method internally executes a `SELECT . . FOR UPDATE` statement without a `WAIT` clause. Therefore, the statement can wait indefinitely until a lock is acquired for that row.

`IsDBNull` should be called to check for `NULL` values before calling this method.

## Example

The following example gets the OracleClob object for update from the reader, updates the OracleClob object, and then commits the transaction.

```
/* Database Setup, if you have not done so yet.
connect scott/tiger@oracle
CREATE TABLE empInfo (
empno NUMBER(4) PRIMARY KEY,
empName VARCHAR2(20) NOT NULL,
hiredate DATE,
salary NUMBER(7,2),
jobDescription Clob,
byteCodes BLOB
);

Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(1,'KING','SOFTWARE ENGR', '5657');
Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(2,'SCOTT','MANAGER', '5960');
commit;

*/
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class GetOracleClobForUpdateSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Get the job description for empno = 1
        string cmdStr = "SELECT JOBDESCRIPTION, EMPNO FROM EMPINFO where EMPNO = 1";
        OracleCommand cmd = new OracleCommand(cmdStr, con);

        // Since we are going to update the OracleClob object, we will
        // have to create a transaction
        OracleTransaction txn = con.BeginTransaction();

        // Get the reader
        OracleDataReader reader = cmd.ExecuteReader();

        // Declare the variables to retrieve the data in EmpInfo
        OracleClob jobDescClob;

        // Read the first row
        reader.Read();

        if (!reader.IsDBNull(0))
        {
            jobDescClob = reader.GetOracleClobForUpdate(0);

            // Close the reader
            reader.Close();
        }
    }
}
```

```
// Update the job description Clob object
char[] jobDesc = "-SALES".ToCharArray();
jobDescClob.Append(jobDesc, 0, jobDesc.Length);

// Now commit the transaction
txn.Commit();
Console.WriteLine("Clob Column successfully updated");
}
else
    reader.Close();

// Close the connection
con.Close();
}
}
```

## GetOracleClobForUpdate(int, int)

This method returns an updatable `OracleClob` object of the specified CLOB column using a WAIT clause.

### Declaration

```
// C#
public OracleClob GetOracleClobForUpdate(int index, int wait);
```

### Parameters

- *index*  
The zero-based column index.
- *wait*  
The number of seconds the method waits to acquire a lock.

### Return Value

An updatable `OracleClob`.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is NULL.

## Remarks

When the `OracleCommand`'s `ExecuteReader()` method is invoked, all the data fetched by the `OracleDataReader` is from a particular snapshot. Therefore, calling an accessor method on the same column always returns the same value. However, the `GetOracleClobForUpdate()` method incurs a database round-trip to obtain a reference to the current CLOB data while also locking the row using the `FOR UPDATE` clause. This means that the `OracleClob` obtained from `GetOracleClob()` can have a different value than the `OracleClob` obtained from `GetOracleClobForUpdate()` since it is not obtained from the original snapshot.

Invoking this method internally executes a `SELECT . . FOR UPDATE` statement which locks the row.

The returned `OracleClob` object can be used to safely update the CLOB because the CLOB column is locked after a call to this method.

Different `WAIT` clauses are appended to the statement, depending on the *wait* value. If the *wait* value is:

- 0  
"NOWAIT" is appended at the end of a `SELECT . . FOR UPDATE` statement. The statement executes immediately whether the lock is acquired or not. If the lock is not acquired, an exception is thrown.
- *n*  
"WAIT *n*" is appended at the end of a `SELECT . . FOR UPDATE` statement. The statement executes as soon as the lock is acquired. However, if the lock cannot be acquired by *n* seconds, this method call throws an exception.  
  
The `WAIT n` feature is only available for Oracle9i or later. For any version lower than Oracle9i, *n* is implicitly treated as -1 and nothing is appended at the end of a `SELECT . . FOR UPDATE` statement.
- -1  
Nothing is appended at the end of the `SELECT . . FOR UPDATE`. The statement execution waits indefinitely until a lock can be acquired.

`IsDBNull` should be called to check for NULL values before calling this method.

## Example

The `GetOracleClobForUpdate` methods are comparable. See "[Example](#)" for a code example demonstrating usage.

## GetOracleDataReader

This method returns the `OracleDataReader` object corresponding to the `REF CURSOR` type column in the select list.

### Declaration

```
// C#  
public OracleDataReader GetOracleDataReader(int index);
```

### Parameters

- `index`  
The zero-based column index.

### Return Value

The `OracleDataReader` object of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

The application can read data from the returned `OracleDataReader` object.

The returned `OracleDataReader` object inherits the `FetchSize`, `InitialLOBFetchSize`, `InitialLONGFetchSize`, and `UseEdmMapping` property values from `OracleDataReader`.

### Sample

```
CREATE OR REPLACE FUNCTION refcurfunc1 RETURN SYS_REFCURSOR  
AS  
    VAR_REF SYS_REFCURSOR;  
BEGIN  
    OPEN VAR_REF FOR  
        SELECT *  
        FROM EMP;  
    RETURN VAR_REF;  
END;
```

```
using (OracleConnection con = new OracleConnection("user id = scott; password =  
<PASSWORD>; data source = oracle"))  
{  
    con.Open();  
  
    OracleCommand cmd = con.CreateCommand();  
    cmd.CommandText = "select refcurfunc1() from dual";  
    OracleDataReader reader = cmd.ExecuteReader();
```

```
while (reader.Read())
{
    OracleDataReader refCurReader = reader.GetOracleDataReader();
    while (refCurReader.Read())
    {
        Console.WriteLine("RefCursor Data: " + refCurReader.GetString(0));
    }
    refCurReader.Close();
    refCurReader.Dispose();
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## GetOracleDate

This method returns an OracleDate structure of the specified DATE column.

### Declaration

```
// C#
public OracleDate GetOracleDate(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The OracleDate value of the column.

### Exceptions

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

IsDBNull should be called to check for NULL values before calling this method.

**① See Also**

## GetOracleDecimal

This method returns an `OracleDecimal` structure of the specified `NUMBER` column.

**Declaration**

```
// C#  
public OracleDecimal GetOracleDecimal(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The `OracleDecimal` value of the column.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

**Remarks**

`IsDBNull` should be called to check for `NULL` values before calling this method.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleIntervalDS

This method returns an `OracleIntervalDS` structure of the specified `INTERVAL DAY TO SECOND` column.

**Declaration**

```
// C#  
public OracleIntervalDS GetOracleIntervalDS(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The `OracleIntervalDS` value of the column.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

**Remarks**

`IsDBNull` should be called to check for `NULL` values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleIntervalYM

This method returns an `OracleIntervalYM` structure of the specified `INTERVAL YEAR TO MONTH` column.

**Declaration**

```
// C#  
public OracleIntervalYM GetOracleIntervalYM(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The `OracleIntervalYM` value of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

`IsDBNull` should be called to check for `NULL` values before calling this method.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleRef

This method returns an `OracleRef` object of the specified REF column.

### Declaration

```
// C#  
public OracleRef GetOracleRef(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The `OracleRef` object of the specified column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, the `Read` method has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleRefCursor

This method returns the `OracleRefCursor` object corresponding to the `REF CURSOR` type column in the select list.

### Declaration

```
// C#  
public OracleRefCursor GetOracleRefCursor(int index);
```

### Parameters

- `index`  
The zero-based column index.

### Return Value

The `OracleRefCursor` object of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

The application can get the `OracleDataReader` object from the returned `OracleRefCursor` object to read data.

The returned `OracleRefCursor` object inherits the `FetchSize`, `InitialLOBFetchSize`, `InitialLONGFetchSize`, and `UseEdmMapping` property values from `OracleDataReader`.

To minimize the number of open server cursors, `OracleRefCursor` objects should be explicitly disposed.

### Sample

```
CREATE OR REPLACE FUNCTION refcurfunc1 RETURN SYS_REFCURSOR  
AS  
    VAR_REF SYS_REFCURSOR;  
BEGIN  
    OPEN VAR_REF FOR  
        SELECT *
```

```
        FROM EMP;  
        RETURN VAR_REF;  
    END;
```

```
using (OracleConnection con = new OracleConnection("user id = scott; password =  
<PASSWORD>; data source = oracle"))  
{  
    con.Open();  
  
    OracleCommand cmd = con.CreateCommand();  
    cmd.CommandText = "select refcurfunc1() from dual";  
    OracleDataReader reader = cmd.ExecuteReader();  
  
    while (reader.Read())  
    {  
        OracleRefCursor refCur = reader.GetOracleRefCursor(0);  
        OracleDataReader refCurReader = refCur.GetDataReader();  
        while (refCurReader.Read())  
        {  
            Console.WriteLine("RefCursor Data: " + refCurReader.GetString(0));  
        }  
        refCurReader.Close();  
        refCurReader.Dispose();  
        refCur.Dispose();  
    }  
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleString

This method returns an `OracleString` structure of the specified column.

### Declaration

```
// C#  
public OracleString GetOracleString(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The `OracleString` value of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

If the column is an Oracle REF column, the string returned is a hexadecimal value that represents the REF in the database.

For `VECTOR` columns, the string returned is a JSON string that represents the `VECTOR` in the database. A sparse vector type column will return a JSON string in sparse format.

For ODP.NET managed and core, a JSON formatted string is returned for the cursor result set from Oracle REF `CURSOR` columns.

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleTimeStamp

This method returns an `OracleTimeStamp` structure of the Oracle `TimeStamp` column.

### Declaration

```
// C#  
public OracleTimeStamp GetOracleTimeStamp(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The `OracleTimeStamp` value of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

**Remarks**

GetOracleTimeStamp is used with the Oracle Type TimeStamp.

IsDBNull should be called to check for NULL values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleTimeStampLTZ

This method returns an OracleTimeStampLTZ structure of the specified Oracle TimeStamp WITH LOCAL TIME ZONE column.

**Declaration**

```
// C#  
public OracleTimeStampLTZ GetOracleTimeStampLTZ(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The OracleTimeStampLTZ value of the column.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

GetOracleTimeStampLTZ is used with the Oracle Type TimeStamp with Local Time Zone columns.

IsDBNull should be called to check for NULL values before calling this method.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleTimeStampTZ

This method returns an `OracleTimeStampTZ` structure of the specified Oracle TimeStamp WITH TIME ZONE column.

### Declaration

```
// C#  
public OracleTimeStampTZ GetOracleTimeStampTZ(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The `OracleTimeStampTZ` value of the column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

Used with the Oracle Type TimeStamp with Local Time Zone columns

`IsDBNull` should be called to check for NULL values before calling this method.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleXmlType

This method returns an `OracleXmlType` object of the specified XMLType column.

**Declaration**

```
// C#  
public OracleXmlType GetOracleXmlType(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The OracleXmlType value of the column.

**Exceptions**

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleValue

This method returns the specified column value as an ODP.NET type.

**Declaration**

```
// C#  
public object GetOracleValue(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The value of the column as an ODP.NET type.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

### Remarks

If the column is an Oracle object or Oracle collection column and a custom type mapping exists, then a custom type is returned.

If the column is an Oracle REF column, then an `OracleRef` is returned.

For `VECTOR` columns, an `OracleVector` is returned. When retrieving from a sparse `VECTOR` column, you can cast the `OracleVector` to an `OracleSparseVector` object to utilize sparse vectors APIs.

For ODP.NET managed and core, a JSON formatted string is returned for the cursor result set from Oracle REF CURSOR columns.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetOracleValues

This method gets all the column values as ODP.NET types.

### Declaration

```
// C#  
public int GetOracleValues(object[] values);
```

### Parameters

- *values*  
An array of objects to hold the ODP.NET types as the column values.

### Return Value

The number of ODP.NET types in the *values* array.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

### Remarks

This method provides a way to retrieve all column values rather than retrieving each column value individually.

The number of column values retrieved is the minimum of the length of the *values* array and the number of columns in the result set.

## GetOracleVector

This method returns `OracleVector` object of the specified VECTOR column.

**Overload List:**

- [GetOracleVector\(int\)](#)  
This method returns `OracleVector` object of the specified VECTOR column.
- [GetOracleVector\(string\)](#)  
This method returns `OracleVector` object of the specified VECTOR column.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## GetOracleVector(int)

This method returns an `OracleVector` object of the specified VECTOR column.

**Declaration**

```
// C#  
public OracleVector GetOracleVector(int index);
```

**Parameters**

*index*

A zero-based column index.

**Return Value**

The `OracleVector` value of the column.

**Exceptions**

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type.

### Remarks

If the column value is NULL, then it returns `OracleVector.Null`.

When retrieving from a sparse VECTOR column, you can cast the `OracleVector` to an `OracleSparseVector` object to utilize sparse vectors APIs.

## GetOracleVector(string)

This method returns an `OracleVector` object of the specified VECTOR column.

### Declaration

```
// C#  
public OracleVector GetOracleVector (string name);
```

### Parameters

*name*

The specified column name.

### Return Value

The `OracleVector` value of the column.

### Exceptions

InvalidOperationException - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

IndexOutOfRangeException - Unable to find specified column in result set.

InvalidCastException - The accessor method is invalid for this column type, or the column value is NULL.

### Remarks

If the column value is NULL, then it returns `OracleVector.Null`.

When retrieving from a sparse VECTOR column, you can cast the `OracleVector` to an `OracleSparseVector` object to utilize sparse vectors APIs.

## GetOrdinal

This method returns the 0-based ordinal (or index) of the specified column name.

**Declaration**

```
// C#  
public override int GetOrdinal(string name);
```

**Parameters**

- *name*  
The specified column name.

**Return Value**

The index of the column.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The reader is closed.

IndexOutOfRangeException - The column index is invalid.

**Remarks**

A case-sensitive search is made to locate the specified column by its name. If this fails, then a case-insensitive search is made.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## GetProviderSpecificFieldType

This method returns the provider-specific type of the specified column.

### Declaration

```
// C#public override Type GetProviderSpecificFieldType(int index);
```

### Parameters

- *index*  
A zero-based column index.

### Return Value

The provider-specific type of the specified column. This is a member of the `Oracle.DataAccess.Types` namespace.

### Exceptions

`IndexOutOfRangeException` - The column index is invalid.

`InvalidOperationException` - The reader is closed, or the specified column is a UDT but no registered custom type mapping exists for the UDT.

### Remarks

`GetProviderSpecificFieldType` returns a type that corresponds to the value the application obtains after invoking the `GetProviderSpecificValue` accessor on the `OracleDataReader`. For example, if the column is a string, this method returns a .NET Type object for an `OracleString`.

If the attribute is a UDT, this method may return any of the following:

- A .NET Type of the custom type, if the column is an Oracle object or Oracle collection column and a custom type mapping exists.
- A .NET Type of `OracleRef` if the column is an Oracle REF.

For VECTOR columns, .NET Type object of an `OracleVector` is returned. Sparse vectors behave the same as dense vectors.

## GetProviderSpecificValue

This method returns an object that represents the underlying provider-specific value of the specified ordinal.

### Declaration

```
// C#  
public override object GetProviderSpecificValue (int index);
```

### Parameters

*index*

A zero-based column index.

### Return Value

An Object that is a representation of the underlying provider-specific field type.

### Exceptions

IndexOutOfRangeException - The column index is invalid.

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called or all rows have been read.

### Remarks

If the column is an Oracle object or collection column, and a custom type mapping exists, a custom type is returned.

If the column is an Oracle REF column, an OracleRef is returned.

For VECTOR columns, an OracleVector is returned. When retrieving from a sparse VECTOR column, you can cast the OracleVector to an OracleSparseVector object to utilize sparse vectors APIs.

## GetProviderSpecificValues

This method returns an array of objects that represent the underlying provider-specific values.

### Declaration

```
// C#  
public override int GetProviderSpecificValues(object [ ] values);
```

### Parameters

- *values*  
An array of objects.

### Return Value

The number of Object instances in the array.

### Exceptions

InvalidOperationException - The reader is closed.

GetSchemaTable

This method returns a DataTable that describes the column metadata of the OracleDataReader.

Declaration

```
// C#
public override DataTable GetSchemaTable();
```

Return Value

A DataTable that contains the metadata of the result set.

Implements

IDataReader

Exceptions

InvalidOperationException - The connection is closed or the reader is closed.

Remarks

The OracleDataReader.GetSchemaTable method returns the SchemaTable.

OracleDataReader SchemaTable

The OracleDataReader SchemaTable is a DataTable that describes the column metadata of the OracleDataReader.

The value of ColumnSize can show value up to 32K depending on the definition of VARCHAR2, NVARCHAR2, or RAW type columns in the table definition.

The columns of the SchemaTable are in the order shown.

Table 6-87 OracleDataReader SchemaTable

| Name          | Name Type     | Description                        |
|---------------|---------------|------------------------------------|
| ColumnName    | System.String | The name of the column.            |
| ColumnOrdinal | System.Int32  | The 0-based ordinal of the column. |

**Table 6-87 (Cont.) OracleDataReader SchemaTable**

| Name             | Name Type      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| IsReadOnly            | System.Boolean     | true if the column is read-only; otherwise false.                                                                                                                                                                                                                                                                                                                                                                  |
| IsLong                | System.Boolean     | true if the column is a LONG, LONG RAW, BLOB, CLOB, or BFILE; otherwise false.                                                                                                                                                                                                                                                                                                                                     |
| UdtTypeName           | System.String      | The type name of the UDT.                                                                                                                                                                                                                                                                                                                                                                                          |
| IsAutoIncrement       | System.Boolean     | true if the column assigns values to new rows in fixed increments; otherwise false.<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                                                                                                                                                                                                                                                            |
| IsIdentity            | System.Boolean     | true if the column is an identity column; otherwise false.                                                                                                                                                                                                                                                                                                                                                         |
| IdentityType          | OracleIdentityType | An OracleIdentityType enumeration value that specifies how the identity column values are generated; otherwise DbNull.Value, if the column is not an identity column.<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                                                                                                                                                                          |
| DomainSchema          | System.String      | The database schema name that contains the domain.<br><i>Requires Oracle AI Database 26ai or higher.</i>                                                                                                                                                                                                                                                                                                           |
| DomainName            | System.String      | The domain name<br><i>Requires Oracle AI Database 26ai or higher.</i>                                                                                                                                                                                                                                                                                                                                              |
| Annotations           | System.String      | All column annotations returned as a JSON string<br><i>Requires Oracle AI Database 26ai or higher.</i>                                                                                                                                                                                                                                                                                                             |
| VectorDimensions      | System.Int32       | The dimensions of the vector data type. Returns 0 if the dimension is '*', that is the Vector is of any dimension.                                                                                                                                                                                                                                                                                                 |
| VectorType            | OracleVectorType   | The vector data type. The possible values are OracleVectorType.Dense for dense vectors; OracleVectorType.Sparse for sparse vectors; and null for all other data types.<br><i>Not Available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                        |
| IsFloatingPointNumber | System.Boolean     | Specifies whether column values are floating-point numbers or not. true for floating-point number types, such as NUMBER, NUMBER(*), REAL, DOUBLE PRECISION, FLOAT(p), BINARY_DOUBLE, and BINARY_FLOAT. false for fixed-point number types, such as NUMBER(p, [s]), NUMBER(*, s), and DECIMAL, and for any other Oracle data types, such as VARCHAR2 and DATE.<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |

### Example

This example creates and uses the SchemaTable from the reader.

```
/* Database Setup, if you have not done so yet.
connect scott/tiger@oracle
CREATE TABLE empInfo (
empno NUMBER(4) PRIMARY KEY,
empName VARCHAR2(20) NOT NULL,
hiredate DATE,
salary NUMBER(7,2),
jobDescription Clob,
byteCodes BLOB
);

Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(1,'KING','SOFTWARE ENGR', '5657');
Insert into empInfo(EMPNO,EMPNAME,JOBDESCRIPTION,byteCodes) values
(2,'SCOTT','MANAGER', '5960');
commit;

*/
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class GetSchemaTableSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        string cmdstr = "SELECT EMPNO,EMPNAME FROM EMPINFO where EMPNO = 1";
        OracleCommand cmd = new OracleCommand(cmdstr, con);

        //get the reader
        OracleDataReader reader = cmd.ExecuteReader();

        //get the schema table
        DataTable schemaTable = reader.GetSchemaTable();

        //retrieve the first column info.
        DataRow row = schemaTable.Rows[0];

        //print out the column info
        Console.WriteLine("Column name: " + row["COLUMNNAME"]);
        Console.WriteLine("Precision: " + row["NUMERICPRECISION"]);
        Console.WriteLine("Scale: " + row["NUMERICSCALE"]);
        reader.Close();

        // Close the connection
        con.Close();
    }
}
```

## GetString

This method returns the string value of the specified column.

### Declaration

```
// C#  
public override string GetString(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The string value of the column.

### Implements

IDataRecord

### Exceptions

*InvalidOperationException* - The connection is closed, the reader is closed, *Read()* has not been called, or all rows have been read.

*IndexOutOfRangeException* - The column index is invalid.

*InvalidCastException* - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

*GetString()* can be called on all character-based column data types. Starting with managed ODP.NET and ODP.NET Core version 19.10, but not available in unmanaged ODP.NET, *GetString()* can be called on all non-binary data types, returning a string representation of the following additional types with the NLS format session setting honored:

- NUMBER
- DATE
- TIMESTAMP
- TIMESTAMP LTZ
- TIMESTAMP TZ
- INTERVAL YEAR TO MONTH

- INTERVAL DAY TO SECOND
- BINARY\_DOUBLE
- BINARY\_FLOAT
- FLOAT

Call the `IsDBNull` method to check for null values before calling this method.

If the column is an Oracle REF column, the string returned is a hexadecimal string that represents the REF in the database.

For VECTOR columns, the string returned is a JSON string that represents the VECTOR in the database. A sparse vector type column will return a JSON string in sparse format.

For ODP.NET managed and core, a JSON formatted string is returned for the cursor result set from Oracle REF CURSOR columns.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetTimeSpan

This method returns the `TimeSpan` value of the specified INTERVAL DAY TO SECOND column.

### Declaration

```
// C#  
public TimeSpan GetTimeSpan(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The `TimeSpan` value of the column.

### Implements

`IDataRecord`

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is NULL.

## Remarks

IsDBNull should be called to check for NULL values before calling this method.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetValue

This method returns the column value as a .NET type.

### Declaration

```
// C#  
public override object GetValue(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

The value of the column as a .NET type.

### Implements

IDataRecord

### Exceptions

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, all rows have been read, or no valid custom type mapping has been specified for the Oracle Object or Oracle Collection column.

IndexOutOfRangeException - The column index is invalid.

### Remarks

If the column is an Oracle Object or an Oracle Collection column, the .NET custom type corresponding to the custom type mapping is returned.

If the column is an Oracle REF column, a hexadecimal value is returned as a .NET string that represents the REF in the database.

If the UDT is NULL, DBNull.Value is returned.

For dense VECTOR columns, this method returns a numeric array or byte array type based on the VECTOR numeric format. BINARY vectors can only return a .NET byte[]. A sparse vector type column will return a .NET string in sparse format. A binary sparse vector returns a JSON-formatted binary sparse vector .NET string.

For ODP.NET managed and core, a JSON formatted string is returned for the cursor result set from Oracle REF CURSOR columns.

## GetValues

This method gets all the column values as .NET types.

### Declaration

```
// C#  
public override int GetValues(object[ ] values);
```

### Parameters

- *values*  
An array of objects to hold the .NET types as the column values.

### Return Value

The number of objects in the *values* array.

### Implements

IDataRecord

### Exceptions

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

### Remarks

This method provides a way to retrieve all column values rather than retrieving each column value individually.

The number of column values retrieved is the minimum of the length of the values array and the number of columns in the result set.

## GetVectorDimensions

This method returns the number of dimensions of the specified VECTOR column.

### Overload List:

- [GetVectorDimensions\(int\)](#)

This method returns the number of dimensions of the specified VECTOR column.

- [GetVectorDimensions\(string\)](#)

This method returns the number of dimensions of the specified VECTOR column.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetVectorDimensions(int)

This method returns the number of dimensions of the specified VECTOR column.

### Declaration

```
// C#  
public long[] GetVectorDimensions(int index);
```

### Parameters

*index*

A zero-based column index.

### Return Value

The number of dimensions of the VECTOR column.

### Exceptions

**InvalidOperationException** - The connection is closed, the reader is closed, `Read()` has not been called or all rows have been read.

**IndexOutOfRangeException** - The column index is invalid.

**InvalidCastException** - The accessor method is invalid for this column type or the column value is NULL.

### Remarks

`IsDBNull` should be called to check for NULL values before calling this method.

This method also works on VECTOR columns with flex (\*) dimensions, and returns the number of dimensions of the vector value in the current row.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetVectorDimensions(string)

This method returns the number of dimensions of the specified VECTOR column.

**Declaration**

```
// C#  
public long[] GetVectorDimensions(string name);
```

**Parameters**

*name*

The specified column name.

**Return Value**

The number of dimensions of the VECTOR column.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called or all rows have been read.

IndexOutOfRangeException - Unable to find specified column in result set.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

This method also works on VECTOR columns with flex (\*) dimensions, and returns the number of dimensions of the vector value in the current row.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetVectorNumericFormat(int)

This method returns the OracleDbType value of the VECTOR column numeric format.

**Declaration**

```
// C#  
public OracleDbType GetVectorNumericFormat(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

The numeric format of the VECTOR column.

**Exceptions**

InvalidOperationException - The connection is closed, the reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

InvalidCastException - The accessor method is invalid for this column type or the column value is NULL.

**Remarks**

IsDBNull should be called to check for NULL values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetVectorNumericFormat(string)

This method returns the OracleDbType value of the VECTOR column numeric format.

**Declaration**

```
// C#  
public OracleDbType GetVectorNumericFormat(string name);
```

**Parameters**

- *name*  
The specified column name.

**Return Value**

The numeric format of the VECTOR column.

### Exceptions

`InvalidOperationException` - The connection is closed, the reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - Unable to find specified column in result set.

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

`IsDBNull` should be called to check for `NULL` values before calling this method.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## GetXmlReader

This method returns the contents of an `XMLType` column as an instance of an .NET `XmlTextReader` object.

### Declaration

```
// C#  
public XmlReader GetXmlReader(int index);
```

### Parameters

- *index*  
The zero-based column index.

### Return Value

A .NET `XmlTextReader`.

### Exceptions

`InvalidCastException` - The accessor method is invalid for this column type or the column value is `NULL`.

### Remarks

`IsDBNull` should be called to check for `NULL` values before calling this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## IsDBNull

This method indicates whether or not the column value is NULL.

**Declaration**

```
// C#  
public override bool IsDBNull(int index);
```

**Parameters**

- *index*  
The zero-based column index.

**Return Value**

Returns true if the column is a NULL value; otherwise, returns false.

**Implements**

IDataRecord

**Exceptions**

InvalidOperationException - The reader is closed, Read() has not been called, or all rows have been read.

IndexOutOfRangeException - The column index is invalid.

**Remarks**

This method should be called to check for NULL values before calling the other accessor methods.

**Example**

The code example for the OracleDataReader class includes the IsDBNull method. See ["Example"](#).

**See Also**

- [OracleDataReader Members](#)

## IsDBNullAsync

### Overload List:

IsDBNullAsync returns a Task-based asynchronous version of `OracleDataReader.IsDBNull()`.

- [IsDBNullAsync\(int\)](#)

IsDBNullAsyncAsync returns a Task-based asynchronous version of `OracleDataReader.IsDBNullAsync()`.

- [IsDBNullAsync\(int, CancellationToken\)](#)

IsDBNullAsyncAsync returns a Task-based asynchronous version of `OracleDataReader.IsDBNullAsync()`.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## IsDBNullAsync(int)

This method returns a Task-based asynchronous version of `OracleDataReader.IsDBNull(int32)`.

### Declaration

```
// C#  
public Task<bool> IsDBNullAsync(int index);
```

### Parameter

*index* - The zero-based column index

### Return Value

`Task<bool>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution

### Implements

`DbDataReader`

### Exceptions

`InvalidOperationException` - The reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

### Remarks

This will call into the `NextResultAsync` implementation with argument `cancellationToken` passed as `CancellationToken.None`.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## IsDBNullAsync(int, CancellationToken)

This method returns a Task-based asynchronous version of `OracleDataReader.IsDBNull(int32)`.

**Declaration**

```
// C#  
public override Task<bool> IsDBNullAsync(int index, CancellationToken cancellationToken);
```

**Parameter**

- *index* - The zero-based column index
- *cancellationToken* - The input cancellation token which can be used by the application to cancel the task before command timeout occurs

**Return Value**

`Task<bool>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution

**Implements**

`DbDataReader`

**Exceptions**

`InvalidOperationException` - The reader is closed, `Read()` has not been called, or all rows have been read.

`IndexOutOfRangeException` - The column index is invalid.

**Example**

```
using Oracle.ManagedDataAccess.Client;  
using System;  
using System.Data;  
using System.Threading;  
  
namespace AsyncApp  
{  
    class AsyncDemo  
    {  
        static async Task Main()  
        {  
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";  
            OracleConnection oc = new OracleConnection(connectionString);  
            await oc.OpenAsync(CancellationToken.None);  
        }  
    }  
}
```

```
OracleCommand cmd = oc.CreateCommand();
cmd.CommandText = "select * from demo_table";

OracleDataReader reader;

reader = await cmd.ExecuteReaderAsync();
while (await reader.ReadAsync(CancellationToken.None))
{
    if(!(await reader.IsDBNullAsync(0)))
        Console.WriteLine(reader.GetValue(0));
}
}
```

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## NextResult

This method advances the data reader to the next result set.

### Declaration

```
// C#
public override bool NextResult();
```

### Return Value

Returns true if another result set exists; otherwise, returns false.

### Implements

IDataReader

### Exceptions

InvalidOperationException - The connection is closed or the reader is closed.

### Remarks

NextResult is used when reading results from stored procedure execution that return more than one result set.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## NextResultAsync

### Overload List:

NextResultAsync returns a Task-based asynchronous version of `OracleDataReader.NextResult()`.

- [NextResultAsync\(\)](#)

NextResultAsync returns a Task-based asynchronous version of `OracleDataReader.NextResult()`.

- [NextResultAsync\(CancellationTokens\)](#)

NextResultAsync returns a Task-based asynchronous version of `OracleDataReader.NextResult()`.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## NextResultAsync()

This method returns a Task-based asynchronous version of `OracleDataReader.NextResult()`.

### Declaration

```
// C#  
public Task<bool> NextResultAsync();
```

### Return Value

Task<bool> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution

### Implements

DbDataReader

### Exceptions

InvalidOperationException - The connection is closed, or the reader is closed.

### Remarks

This will call into the NextResultAsync implementation with argument cancellationTokens passed as CancellationTokens.None.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## NextResultAsync(CancellationToken)

This method returns a Task-based asynchronous version of `OracleDataReader.NextResult()`.

**Declaration**

```
// C#  
public Task<bool> NextResultAsync(CancellationToken cancellationToken);
```

**Parameter**

*cancellationToken* - The input cancellation token which can be used by the application to cancel the task before command timeout occurs.

**Return Value**

Task<bool> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution

**Implements**

DbDataReader

**Exceptions**

InvalidOperationException - The connection is closed, or the reader is closed.

**Example**

```
using Oracle.ManagedDataAccess.Client;  
using System;  
using System.Data;  
using System.Threading;  
using System.Threading.Tasks;  
  
namespace AsyncApp  
{  
    class AsyncDemo  
    {  
        static async Task Main()  
        {  
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";  
            OracleConnection oc = new OracleConnection(connectionString);  
            await oc.OpenAsync(CancellationToken.None);  
  
            OracleCommand cmd = oc.CreateCommand();  
            cmd.CommandText = "BEGIN OPEN :1 FOR SELECT * FROM EMPLOYEES; OPEN :2 FOR SELECT *  
FROM DEPARTMENTS; END; ";  
  
            OracleParameter p1 = cmd.Parameters.Add("1", OracleDbType.RefCursor);
```

```
p1.Direction = ParameterDirection.Output;

OracleParameter p2 = cmd.Parameters.Add("2", OracleDbType.RefCursor);
p2.Direction = ParameterDirection.Output;

OracleDataReader reader = await cmd.ExecuteReaderAsync();

await reader.ReadAsync(CancellationToken.None);
Console.WriteLine(reader.GetValue(0));

Task task = reader.NextResultAsync(CancellationToken.None);
Console.WriteLine("Hello World");
await task;

await reader.ReadAsync(CancellationToken.None);
Console.WriteLine(reader.GetValue(0));
oc.Close();
    }
}
}
```

- [OracleDataReader Members](#)

## Read

This method reads the next row in the result set.

### Declaration

```
// C#
public override bool Read();
```

### Return Value

Returns true if another row exists; otherwise, returns false.

### Implements

IDataReader

### Exceptions

InvalidOperationException - The connection is closed or the reader is closed.

### Remarks

The initial position of the data reader is before the first row. Therefore, the Read method must be called to fetch the first row. The row that was just read is considered the *current row*. If the OracleDataReader has no more rows to read, it returns false.

### Example

The code example for the OracleDataReader class includes the Read method. See "[Example](#)".

- [OracleDataReader Members](#)

## ReadAsync

**Overload List:**

ReadAsync returns a Task-based asynchronous version of `OracleDataReader.Read()`.

- [ReadAsync\(\)](#)

ReadAsync returns a Task-based asynchronous version of `OracleDataReader.Read()`.

- [ReadAsync\(CancellationToken\)](#)

ReadAsync returns a Task-based asynchronous version of `OracleDataReader.Read()` with an input `CancellationToken`.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleCommand Class](#)
- [OracleCommand Members](#)

## ReadAsync()

This method returns a Task-based asynchronous version of `OracleDataReader.Read()`.

**Declaration**

```
// C#  
public Task<bool> ReadAsync();
```

**Return Value**

`Task<bool>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution

**Implements**

`DbDataReader`

**Exceptions**

`InvalidOperationException` - The connection is closed, or the reader is closed.

## Remarks

This will call into the ReadAsync implementation with argument cancellationToken passed as CancellationToken.None.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataReader Class](#)
- [OracleDataReader Members](#)

## ReadAsync(CancellationToken)

This method returns a Task-based asynchronous version of `OracleDataReader.Read()`.

### Declaration

```
// C#  
public override Task<bool> ReadAsync(CancellationToken cancellationToken)
```

### Parameters

`cancellationToken` - The input cancellation token which can be used by the application to cancel the task before command timeout occurs.

### Return Value

`Task<bool>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution

### Implements

`DbDataReader`

### Exceptions

`InvalidOperationException` - The connection is closed, or the reader is closed.

### Example

```
using Oracle.ManagedDataAccess.Client;  
using System;  
using System.Threading;  
  
namespace AsyncApp  
{  
    class AsyncDemo  
    {  
        static async Task Main()  
        {  
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";  
            OracleConnection oc = new OracleConnection(connectionString);  
            await oc.OpenAsync(CancellationToken.None);  
  
            OracleCommand cmd = oc.CreateCommand();
```

```
cmd.CommandText = "select * from demo_table";

OracleDataReader reader;
reader = await cmd.ExecuteReaderAsync();
while (await reader.ReadAsync(CancellationToken.None))
{
    Console.WriteLine(reader.GetValue(0));
}
}
```

# OracleDataSource Class

An OracleDataSource object represents an Oracle database from which to open connections to or execute commands directly against.

OracleDataSource has no public constructor. To create an instance, use OracleClientFactory.CreateDataSource(string connectionString) or an OracleDataSourceBuilder.

**Class Inheritance**

System.Object

System.Data.Common.DbDataSource

Oracle.ManagedDataAccess.Client.OracleDataSource

**Declaration**

```
// C#
public class OracleDataSource : DbDataSource
```

**Requirements**

| Provider       | ODP.NET Core                            |
|----------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         |
| .NET Framework | -                                       |
| .NET (Core)    | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

**① See Also**

- [OracleDataSource Members](#)
- [OracleDataSource Public Methods](#)
- [OracleDataSource Properties](#)
- [OracleDataSource Public Events](#)

## OracleDataSource Members

OracleDataSource members are listed in the following tables.

### OracleDataSource Public Methods

OracleDataSource methods are listed in [Table 6-88](#).

**Table 6-88 OracleDataSource Public Methods**

| Method                              | Description                                                                                                   |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <a href="#">ClearPool</a>           | Clears the OracleDataSource associated pool.                                                                  |
| <a href="#">CreateCommand</a>       | Returns an OracleCommand ready to execute against the OracleDataSource                                        |
| <a href="#">CreateConnection</a>    | Returns a new, closed database connection represented by the OracleDataSource                                 |
| Dispose                             | void Dispose() disposes the OracleDataSource and clears the pool associated with it.                          |
| DisposeAsync                        | ValueTask DisposeAsync() asynchronously disposes the OracleDataSource and clears the pool associated with it. |
| <a href="#">OpenConnection</a>      | Returns a new, open database connection represented by the OracleDataSource                                   |
| <a href="#">OpenConnectionAsync</a> | Asynchronously returns a new, open database connection represented by the OracleDataSource                    |

### OracleDataSource Properties

OracleDataSource properties are listed in [Table 6-89](#).

**Table 6-89 OracleDataSource Properties**

| Property                                    | Description                                                |
|---------------------------------------------|------------------------------------------------------------|
| <a href="#">ConnectionString</a>            | The connection string associated with the OracleDataSource |
| <a href="#">DatabaseCharset</a>             | Returns the database character set                         |
| <a href="#">DatabaseMaxIdentifierLength</a> | Returns the database maximum identifier length             |
| <a href="#">DatabaseNCharset</a>            | Returns the database national character set                |
| <a href="#">Password</a>                    | Updates the OracleDataSource password                      |

**Table 6-89 (Cont.) OracleDataSource Properties**

| Property                      | Description                                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">ProxyPassword</a> | Updates the OracleDataSource proxy password                                                           |
| <a href="#">RetryCount</a>    | Specifies the number of times a TNS ADDRESS list is traversed before the connection attempt times out |
| <a href="#">RetryDelay</a>    | Specifies the delay in seconds between subsequent retries for a connection                            |

### OracleDataSource Public Events

OracleDataSource public events are listed in [Table 6-90](#).

**Table 6-90 OracleDataSource Public Events**

| Public Events  | Description                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConnectionOpen | OracleConnectionOpenEventHandler<br>ConnectionOpen is triggered upon the OracleDataSource.OpenConnection() method or a connection opening to undertake Application Continuity failover and replay.<br>See also OracleConnection ConnectionOpen event. |
| InfoMessage    | OracleInfoMessageEventHandler<br>InfoMessage is triggered for any message or warning sent by the database.<br>See also OracleConnection InfoMessage event.                                                                                            |
| HAEvent        | OracleHAEventHandler<br>HAEvent is triggered when an HA event occurs.<br>See also OracleConnection HAEvent event.                                                                                                                                     |
| Failover       | OracleFailoverEventHandler<br>Failover is triggered when an Oracle database failover occurs.<br>See also OracleConnection Failover event.                                                                                                             |
| StateChange    | StateChangeEventHandler<br>StateChange is triggered when the connection state changes.<br>See also OracleConnection StateChange event.                                                                                                                |

## OracleDataSource Public Methods

OracleDataSource public methods are listed in [Table 6-91](#).

**Table 6-91 OracleDataSource Public Methods**

| Property                  | Description                                  |
|---------------------------|----------------------------------------------|
| <a href="#">ClearPool</a> | Clears the OracleDataSource associated pool. |

**Table 6-91 (Cont.) OracleDataSource Public Methods**

| Property                            | Description                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CreateCommand</a>       | Returns an <code>OracleCommand</code> ready to execute against the <code>OracleDataSource</code>                                        |
| <a href="#">CreateConnection</a>    | Returns a new, closed database connection represented by the <code>OracleDataSource</code>                                              |
| Dispose                             | <code>void Dispose()</code> disposes the <code>OracleDataSource</code> and clears the pool associated with it.                          |
| DisposeAsync                        | <code>ValueTask DisposeAsync()</code> asynchronously disposes the <code>OracleDataSource</code> and clears the pool associated with it. |
| <a href="#">OpenConnection</a>      | Returns a new, open database connection represented by the <code>OracleDataSource</code>                                                |
| <a href="#">OpenConnectionAsync</a> | Asynchronously returns a new, open database connection represented by the <code>OracleDataSource</code>                                 |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## ClearPool

This method clears the `OracleDataSource` associated pool.

**Declaration**

```
// C#  
public void ClearPool()
```

**Remarks**

This method does nothing if pooling is disabled. `OracleConnection.ClearAllPools` does not clear pools associated with an `OracleDataSource`.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## CreateCommand

This method returns `OracleCommand` ready to execute against the `OracleDataSource`.

**Declaration**

```
// C#  
public DbCommand CreateCommand(string command)
```

**Parameters**

- *command*

The SQL command to execute

**Return Value**

An `OracleCommand` object ready to execute the command against the `OracleDataSource`.

**Remarks**

The command returned by this method does not have an explicit `OracleConnection` associated with it. Setting the connection on the `OracleCommand` object returned by this method will throw an exception.

Since the command is not associated with a connection, it cannot participate in transactions. Setting the transaction property on the `OracleCommand` object returned by this method throws an exception.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## CreateConnection

This method returns a new, closed database connection represented by the `OracleDataSource`.

**Declaration**

```
// C#  
public DbConnection CreateConnection()
```

**Return Value**

A closed `OracleConnection` that is represented by the `OracleDataSource`.

**Remarks**

It is the caller's responsibility to dispose connections obtained through this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## OpenConnection

This method returns a new, open database connection represented by the `OracleDataSource`.

**Declaration**

```
// C#  
public OracleConnection OpenConnection()
```

**Return Value**

An open `OracleConnection` that is represented by the `OracleDataSource`.

**Remarks**

It is the caller's responsibility to dispose connections obtained through this method.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## OpenConnectionAsync

This method asynchronously returns a new, open database connection represented by the `OracleDataSource`.

**Declaration**

```
// C#  
public ValueTask<OracleConnection> OpenConnectionAsync(CancellationToken  
    cancellationToken)
```

**Parameters**

- `cancellationToken`  
A token to cancel the asynchronous operation

**Return Value**

An open `OracleConnection` that is represented by the `OracleDataSource`.

## Remarks

It is the caller's responsibility to dispose connections obtained through this method.

## OracleDataSource Properties

OracleDataSource properties are listed in [Table 6-92](#).

**Table 6-92 OracleDataSource Properties**

| Property                                    | Description                                                                                           |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">ConnectionString</a>            | Returns the connection string associated with the OracleDataSource                                    |
| <a href="#">DatabaseCharset</a>             | Returns the database character set                                                                    |
| <a href="#">DatabaseMaxIdentifierLength</a> | Returns the database maximum identifier length                                                        |
| <a href="#">DatabaseNCharset</a>            | Returns the database national character set                                                           |
| <a href="#">Password</a>                    | Updates the OracleDataSource password                                                                 |
| <a href="#">ProxyPassword</a>               | Updates the OracleDataSource proxy password                                                           |
| <a href="#">RetryCount</a>                  | Specifies the number of times a TNS ADDRESS list is traversed before the connection attempt times out |
| <a href="#">RetryDelay</a>                  | Specifies the delay in seconds between subsequent retries for a connection                            |

### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

## ConnectionString

This property returns the connection string associated with the OracleDataSource.

### Declaration

```
// C#  
public string ConnectionString { get; }
```

**Remarks**

This property returns the connection string without the password when Persist Security Info is set to false.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)
- OracleConnection property [ConnectionString](#)

## DatabaseCharset

This property returns the database character set.

**Declaration**

```
// C#  
public OracleDatabaseCharset DatabaseCharset { get; }
```

**Remarks**

This property can only be accessed after an OracleConnection from this OracleDataSource has been opened. Otherwise, it throws an ORA-50001 error.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## DatabaseMaxIdentifierLength

This property returns the database maximum identifier length.

**Declaration**

```
// C#  
public int DatabaseMaxIdentifierLength { get; }
```

**Remarks**

This property can only be accessed after an OracleConnection from this OracleDataSource has been opened. Otherwise, it throws an ORA-50001 error.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## DatabaseNCharset

This property returns the database national character set.

### Declaration

```
// C#  
public OracleDatabaseNCharset DatabaseNCharset { get; }
```

### Remarks

This property can only be accessed after an `OracleConnection` from this `OracleDataSource` has been opened. Otherwise, it throws an ORA-50001 error.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## Password

This property updates the `OracleDataSource` password.

### Declaration

```
// C#  
public OracleOpaqueString Password { set; }
```

### Exceptions

`ArgumentNullException` - The specified value is null.

Throws "ORA-50029: Password is invalid" if provided password is empty (length of 0).

Throws "ORA-50095: Password should be read-only" if provided `OracleOpaqueString` is not read-only.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## ProxyPassword

This property updates the OracleDataSource proxy password.

### Declaration

```
// C#  
public OracleOpaqueString ProxyPassword { set; }
```

### Exceptions

ArgumentNullException - The specified value is null.

Throws "ORA-50029: ProxyPassword is invalid" if provided password is empty (length of 0).

Throws "ORA-50095: ProxyPassword should be read-only" if provided OracleOpaqueString is not read-only.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

## RetryCount

This property specifies the number of times a TNS ADDRESS list is traversed before the connection attempt times out.

### Declaration

```
// C#  
public int? RetryCount {get; set;}
```

### Exceptions

ArgumentException is thrown when set to a negative value.

### Remarks

By default, this property is set to null.

Null setting means other configuration methods determine the client retry count.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSource Class](#)
- [OracleDataSource Members](#)

RetryDelay

This property specifies the delay in seconds between subsequent retries for a connection.

Declaration

```
// C#
public int? RetryDelay {get; set;}
```

Exceptions

ArgumentException is thrown when set to a negative value.

Remarks

By default, this property is set to null.

Null setting means other configuration methods determine the client retry count.

OracleDataSource Public Events

OracleDataSource public events are listed in [Table 6-93](#).

Table 6-93 OracleDataSource Public Events

| Public Events  | Description                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConnectionOpen | OracleConnectionOpenEventHandler ConnectionOpen is triggered upon the OracleDataSource.OpenConnection() method or a connection opening to undertake Application Continuity failover and replay.<br>See also OracleConnection ConnectionOpen event. |
| InfoMessage    | OracleInfoMessageEventHandler InfoMessage is triggered for any message or warning sent by the database.<br>See also OracleConnection InfoMessage event.                                                                                            |

Table 6-93 (Cont.) OracleDataSource Public Events

| Public Events | Description                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| HAEvent       | OracleHAEventHandler HAEvent is triggered when an HA event occurs.<br>See also OracleConnection HAEvent event.                         |
| Failover      | OracleFailoverEventHandler Failover is triggered when an Oracle database failover occurs.<br>See also OracleConnection Failover event. |
| StateChange   | StateChangeEventHandler StateChange is triggered when the connection state changes.<br>See also OracleConnection StateChange event.    |

# OracleDataSourceBuilder Class

The OracleDataSourceBuilder class creates and configures an OracleDataSource.  
During the build, connection configuration is not verified.

**Class Inheritance**

System.Object  
  
Oracle.ManagedDataAccess.Client.OracleDataSource

**Declaration**

```
// C#  
public class DbDataSourceBuilder
```

**Requirements**

| Provider       | ODP.NET Core                            |
|----------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         |
| .NET Framework | -                                       |
| .NET (Core)    | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OracleDataSourceBuilder Members

OracleDataSourceBuilder members are listed in the following tables.

### OracleDataSourceBuilder Constructors

OracleDataSourceBuilder constructors are listed in [Table 6-94](#).

**Table 6-94 OracleDataSourceBuilder Constructors**

| Constructor                                         | Description                                                                                           |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">OracleDataSourceBuilder Constructor</a> | Instantiates a new instance of the OracleDataSourceBuilder class with the provided connection string. |

### OracleDataSourceBuilder Public Methods

OracleDataSourceBuilder methods are listed in [Table 6-95](#).

**Table 6-95 OracleDataSourceBuilder Public Methods**

| Method                           | Description                                                |
|----------------------------------|------------------------------------------------------------|
| <a href="#">Build</a>            | Returns a new OracleDataSource instance.                   |
| <a href="#">UsePassword</a>      | Sets the OracleDataSource password (Overloaded)            |
| <a href="#">UseProxyPassword</a> | Sets the OracleDataSource proxy user password (Overloaded) |

### OracleDataSourceBuilder Properties

OracleDataSourceBuilder properties are listed in [Table 6-96](#).

**Table 6-96 OracleDataSourceBuilder Properties**

| Property                         | Description                                       |
|----------------------------------|---------------------------------------------------|
| <a href="#">ConnectionString</a> | Specifies the OracleDataSource connection string. |

## OracleDataSourceBuilder Constructor

`OracleDataSourceBuilder(connectionString)` instantiates a new instance of the `OracleDataSourceBuilder` class with the provided connection string.

### Declaration

```
public OracleDataSourceBuilder(string connectionString)
```

### Parameters

- `connectionString`  
The connection information used to connect to the Oracle database.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## OracleDataSourceBuilder Public Methods

`OracleDataSourceBuilder` public methods are listed in [Table 6-97](#).

**Table 6-97 OracleDataSourceBuilder Public Methods**

| Method                           | Description                                                             |
|----------------------------------|-------------------------------------------------------------------------|
| <a href="#">Build</a>            | Returns a new <code>OracleDataSource</code> instance.                   |
| <a href="#">UsePassword</a>      | Sets the <code>OracleDataSource</code> password (Overloaded)            |
| <a href="#">UseProxyPassword</a> | Sets the <code>OracleDataSource</code> proxy user password (Overloaded) |

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## Build

This method returns a new `OracleDataSource` instance.

### Declaration

```
// C#  
public OracleDataSource Build()
```

### Return Value

Return Value is a new `OracleDataSource` with the configuration specified by the builder.

#### Note

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## UsePassword

The `UsePassword` public method sets the `OracleDataSource` password.

### Overload List:

- [UsePassword\(password\)](#)  
This method sets the `OracleDataSource` password.
- [UsePassword\(opaquePassword\)](#)  
This method sets the `OracleDataSource` password.

#### Note

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## UsePassword(password)

This method sets the `OracleDataSource` password.

### Declaration

```
// C#  
public OracleDataSourceBuilder UsePassword(string password)
```

**Parameters**

- password  
The database user password.

**Return Value**

The OracleDataSourceBuilder itself allowing additional OracleDataSourceBuilder methods to be chained.

**Remarks**

If a null value is the input parameter, connections will then use the connection string password.

If the password has zero length, ODP.NET throws ArgumentException of ORA-50029.

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## UsePassword(opaquePassword)

This method sets the OracleDataSource password.

**Declaration**

```
// C#  
public OracleDataSourceBuilder UsePassword(OracleOpaqueString opaquePassword)
```

**Parameters**

- opaquePassword  
The database user password.

**Return Value**

The OracleDataSourceBuilder itself allowing additional OracleDataSourceBuilder methods to be chained.

**Remarks**

If a null value is the input parameter, connections will then use the connection string password.

If the password has zero length, ODP.NET throws ArgumentException of ORA-50029.

If opaquePassword is not read only, ODP.NET throws an ORA-50095 error.

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## UseProxyPassword

The UseProxyPassword public method sets the OracleDataSource proxy user password.

**Overload List:**

- [UseProxyPassword\(proxyPassword\)](#)  
This method sets the OracleDataSource proxy user password.
- [UseProxyPassword\(opaquePassword\)](#)  
This method sets the OracleDataSource proxy user password.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## UseProxyPassword(proxyPassword)

This method sets the OracleDataSource proxy user password.

**Declaration**

```
// C#  
public OracleDataSourceBuilder UseProxyPassword(string proxyPassword)
```

**Parameters**

- proxyPassword  
The database proxy user password.

**Return Value**

The OracleDataSourceBuilder itself allowing additional OracleDataSourceBuilder methods to be chained.

**Remarks**

If a null value is the input parameter, connections will then use the connection string password.  
If the password has zero length, ODP.NET throws ArgumentException of ORA-50029.

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## UseProxyPassword(opaquePassword)

This method sets the OracleDataSource proxy user password.

**Declaration**

```
// C#  
public OracleDataSourceBuilder UseProxyPassword(OracleOpaqueString opaquePassword)
```

**Parameters**

- opaquePassword  
The database proxy user password.

**Return Value**

The OracleDataSourceBuilder itself allowing additional OracleDataSourceBuilder methods to be chained.

**Remarks**

If a null value is the input parameter, connections will then use the connection string password.

If the password has zero length, ODP.NET throws ArgumentException of ORA-50029.

If opaquePassword is not read only, ODP.NET throws an ORA-50095 error.

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

## OracleDataSourceBuilder Properties

OracleDataSourceBuilder properties are listed in [Table 6-98](#).

**Table 6-98 OracleDataSourceBuilder Properties**

| Property                         | Description                                       |
|----------------------------------|---------------------------------------------------|
| <a href="#">ConnectionString</a> | Specifies the OracleDataSource connection string. |

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

ConnectionString

This property specifies the OracleDataSource connection string.

Declaration

```
// C#
public string ConnectionString { get; }
```

Property Value

The connection string required to establish a connection to the Oracle database.

① Note

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceBuilder Class](#)
- [OracleDataSourceBuilder Members](#)

Methods, Properties, and Events in Common with OracleConnection or OracleDataSource

OracleDataSourcebuilder allows ODP.NET connections to be configured with many of the same properties and events that are part of OracleConnection or OracleDataSource. The table below shows the OracleDataSourceBuilder setter methods and properties with the counterpart OracleConnection or OracleDataSource properties.

① Note

These OracleDataSourceBuilder methods and properties do not have getters.

| OracleDataSourceBuilder Methods                                              | Corresponding OracleConnection or OracleDataSource Property |
|------------------------------------------------------------------------------|-------------------------------------------------------------|
| public OracleDataSourceBuilder UseAccessToken(OracleAccessToken accessToken) | AccessToken                                                 |

| OracleDataSourceBuilder Methods                                                                           | Corresponding OracleConnection or OracleDataSource Property |
|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| public OracleDataSourceBuilder UseActionName(string actionName)                                           | ActionName                                                  |
| public OracleDataSourceBuilder AllowCertificateSelectionUI(bool allowCertificateSelection)                | AllowCertificateSelectionUI                                 |
| public OracleDataSourceBuilder UseAutoCommit(bool useAutoCommit)                                          | AutoCommit                                                  |
| public OracleDataSourceBuilder UseAutoProxy(bool useAutoProxy)                                            | AutoProxy                                                   |
| public OracleDataSourceBuilder UseBindByName(bool useBindByName)                                          | BindByName                                                  |
| public OracleDataSourceBuilder UseChunkMigrationConnectionTimeout(string chunkMigrationConnectionTimeout) | ChunkMigrationConnectionTimeout                             |
| public OracleDataSourceBuilder UseClientId(string clientId)                                               | ClientId                                                    |
| public OracleDataSourceBuilder UseClientInfo(string clientInfo)                                           | ClientInfo                                                  |
| public OracleDataSourceBuilder UseCommandTimeout(int commandTimeout)                                      | CommandTimeout                                              |
| public OracleDataSourceBuilder UseConnectionIdPrefix(string connectionIdPrefix)                           | ConnectionIdPrefix                                          |
| public OracleDataSourceBuilder UseDatabaseCharset(OracleDatabaseCharset charset)                          | DatabaseCharset                                             |
| public OracleDataSourceBuilder UseDatabaseEditionName(string databaseEditionName)                         | DatabaseEditionName                                         |
| public OracleDataSourceBuilder UseDatabaseNCharset(OracleDatabaseNCharset nCharset)                       | DatabaseNCharset                                            |
| public OracleDataSourceBuilder UseDRCPConnectionClass(string drcpConnectionClass)                         | DRCPConnectionClass                                         |
| public OracleDataSourceBuilder UseDRCPpurity(OracleConnection.OracleDRCPpurity drcpPurity)                | DRCPpurity                                                  |
| public OracleDataSourceBuilder UseFetchSize(long fetchSize)                                               | FetchSize                                                   |
| public OracleDataSourceBuilder UseHttpsProxy(string httpsProxy)                                           | HttpsProxy                                                  |
| public OracleDataSourceBuilder UseHttpsProxyPort(int httpsProxyPort)                                      | HttpsProxyPort                                              |
| public OracleDataSourceBuilder UseKeepAlive(bool useKeepAlive)                                            | KeepAlive                                                   |

| OracleDataSourceBuilder Methods                                                                                    | Corresponding OracleConnection or OracleDataSource Property |
|--------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| <code>public OracleDataSourceBuilder UseKeepAliveInterval(int keepAliveInterval)</code>                            | KeepAliveInterval                                           |
| <code>public OracleDataSourceBuilder UseKeepAliveTime(int keepAliveTime)</code>                                    | KeepAliveTime                                               |
| <code>public OracleDataSourceBuilder UseMaxStatementCacheSize(int maxStatementCacheSize)</code>                    | MaxStatementCacheSize                                       |
| <code>public OracleDataSourceBuilder UseModuleName(string moduleName)</code>                                       | ModuleName                                                  |
| <code>public OracleDataSourceBuilder UseNamesDirectoryPath(string namesDirectoryPath)</code>                       | <a href="#">NamesDirectoryPath</a>                          |
| <code>public OracleDataSourceBuilder UseOciCompartment(string ociCompartment)</code>                               | OciCompartment                                              |
| <code>public OracleDataSourceBuilder UseOciDatabase(string ociDatabase)</code>                                     | OciDatabase                                                 |
| <code>public OracleDataSourceBuilder UseOciIamUrl(string ociIamUrl)</code>                                         | OciIamUrl                                                   |
| <code>public OracleDataSourceBuilder UseOciTenancy(string ociTenancy)</code>                                       | OciTenancy                                                  |
| <code>public OracleDataSourceBuilder UsePasswordAuthentication(OraclePasswordAuth passwordAuth)</code>             | PasswordAuthentication                                      |
| <code>public OracleDataSourceBuilder UsePdbName(string pdbName)</code>                                             | PDBName                                                     |
| <code>public OracleDataSourceBuilder UsePipelining(bool usePipelining)</code>                                      | Pipelining                                                  |
| <code>public OracleDataSourceBuilder UsePoolName(string poolName)</code>                                           | PoolName                                                    |
| <code>public OracleDataSourceBuilder UseRemoteConfigurationFiltering(bool useRemoteConfigFiltering)</code>         | RemoteConfigurationFiltering                                |
| <code>public OracleDataSourceBuilder UseRetryCount(int RetryCount)</code>                                          | <a href="#">RetryCount</a>                                  |

## OracleDataSourceCollection Class

An OracleDataSourceCollection supports adding and deleting network service name (i.e. TNS) entries for ODP.NET's use to connect to an Oracle database.

Class Inheritance

System.Object  
  
Oracle.ManagedDataAccess.Client.OracleDataSourceCollection

Declaration

```
// C#  
public sealed class OracleDataSourceCollection
```

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Example

```
using System;  
using Oracle.ManagedDataAccess.Client;  
  
namespace NetCoreApplication  
{  
    class DataSourceExample  
    {  
        static void Main(string[] args)  
        {  
            // Example to configure Data Sources for the ODP.NET Core provider.  
  
            // Add data source through Add method on OracleDataSourceCollection  
            OracleConfiguration.OracleDataSources.Add("orcl1",  
                "(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=host1)(PORT=1234))  
                (CONNECT_DATA=(SERVICE_NAME=oracle)(SERVER=dedicated)))");  
  
            // Add data source through indexer method on OracleDataSourceCollection  
            OracleConfiguration.OracleDataSources["orcl2"] =  
                "(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=host1)(PORT=1234))  
                (CONNECT_DATA=(SERVICE_NAME=oracle)(SERVER=dedicated)))";  
  
            // Get number of data sources configured  
            int numDataSources = OracleConfiguration.OracleDataSources.Count;  
  
            // Get OracleDataSourceCollection object  
            OracleDataSourceCollection dsColl = OracleConfiguration.OracleDataSources;  
  
            // Add server through Add method on OracleDataSourceCollection  
            dsColl.Add("orcl3", "(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=host3)(PORT=1234))  
            (CONNECT_DATA=(SERVICE_NAME=oracle)(SERVER=dedicated)))");  
        }  
    }  
}
```

```

// Add server through indexer method on OracleDataSourceCollection
dsColl["orcl4"] = "(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=host4)(PORT=1234))
(CONNECT_DATA=(SERVICE_NAME=oracle)(SERVER=dedicated)))";

// Remove a data source
OracleConfiguration.OracleDataSources.Remove("db2");

// Get number of data sources configured
numDataSources = OracleConfiguration.OracleDataSources.Count;

// Get value corresponding to a data source.
string dsVal = OracleConfiguration.OracleDataSources["db1"];

OracleConnection orclCon = null;

try
{
    // Open a test connection
    orclCon = new OracleConnection("user id=scott; password=tiger; data
source=orcl3");

    orclCon.Open();
    orclCon.Close();
}
catch (OracleException ex)
{
    Console.WriteLine(ex);
}
finally
{
    // Close the connection
    if (null != orclCon)
        orclCon.Close();
}
}
}
}

```

## OracleDataSourceCollection Members

OracleDataSourceCollection members are listed in the following tables.

### OracleDataSourceCollection Methods

OracleDataSourceCollection methods are listed in [Table 6-99](#).

**Table 6-99 OracleDataSourceCollection Methods**

| Method                 | Description                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>    | Adds unique network service name (TNS) entries in the OracleDataSourceCollection using net service names and complete connect descriptors |
| <a href="#">Remove</a> | Removes network service name entries from an OracleDataSourceCollection                                                                   |

**OracleDataSourceCollection Properties**

OracleDataSourceCollection properties are listed in [Table 6-100](#).

**Table 6-100 OracleDataSourceCollection Properties**

| Property              | Description                                                                            |
|-----------------------|----------------------------------------------------------------------------------------|
| <a href="#">Count</a> | Returns the number of OracleDataSourceCollection elements                              |
| <a href="#">This</a>  | Returns or sets the network service name entry with the specified network service name |

## OracleDataSourceCollection Methods

OracleDataSourceCollection methods are listed in [Table 6-101](#).

**Table 6-101 OracleDataSourceCollection Methods**

| Method                 | Description                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>    | Adds unique network service name (TNS) entries in the OracleDataSourceCollection using net service names and complete connect descriptors |
| <a href="#">Remove</a> | Removes network service name entries from an OracleDataSourceCollection                                                                   |

## Add

This method adds unique network service name (TNS) entries in the OracleDataSourceCollection using net service names and complete connect descriptors.

**Declaration**

```
// C#  
public void Add(string tnsName, string tnsDescriptor)
```

**Parameters**

- tnsName
  - Type: System.String
  - Network service name used as the ODP.NET connection string Data Source name.
- tnsDescriptor
  - Type: System.String
  - The complete connect descriptor information for this specific net service name.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceCollection Class](#)
- [OracleDataSourceCollection Members](#)

## Remove

This method removes network service name entries from an OracleDataSourceCollection.

**Declaration**

```
// C#  
public void Remove(string tnsName)
```

**Parameter**

tnsName

- Type: System.String
- Unique network service name to be removed from the collection.

**See Also**

Count

This is a read-only property that returns the number of OracleDataSourceCollection elements

Declaration

```
// C#
public int Count { get; }
```

Property Value

Type: System.Int32

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceCollection Class](#)
- [OracleDataSourceCollection Members](#)

This

This property returns or sets the network service name entry with the specified network service name.

Declaration

```
// C#
public string this[string tnsName] { get; set; }
```

Parameters

- tnsName
  - Type: System.String

- Unique network service name to be added or updated
- Value
  - Type: `System.String`
  - Connect descriptor to be added or updated.

# OracleDataSourceCommand Class

OracleDataSourceCommand opens a connection on behalf of an OracleDataSource object, executes a command, closes the connection.

This class has no public constructor. Class instances are obtained by calling `OracleDataSource.CreateCommand()`.

All OracleDataSourceCommand public methods function identically to OracleCommand public methods. The only difference is OracleDataSourceCommand internally opens a connection when an execution method (e.g., `ExecuteNonQuery()`) is called, then closes the connection after the execution completes. Data types that defer data retrieval, such as CLOBs, BLOBs, and REF Cursors, will not work unless the app uses `ExecuteReader()`. This method keeps the connection open until the reader is closed.

The user does not interact with any connections when working with OracleDataSourceCommand.

A few OracleDataSourceCommand public methods have exceptions to this behavior. Those exceptions are noted in each public method's remarks.

## Class Inheritance

System.Object  
System.Data.Common.DbCommand  
Oracle.ManagedDataAccess.Client.OracleCommand  
Oracle.ManagedDataAccess.Client.OracleDataSourceCommand

## Declaration

```
// C#  
public class OracleDataSourceCommand : OracleCommand
```

## Requirements

| Provider  | ODP.NET Core                    |
|-----------|---------------------------------|
| Assembly  | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET Core                            |
|----------------|-----------------------------------------|
| .NET Framework | -                                       |
| .NET (Core)    | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OracleDataSourceCommand Members

OracleDataSourceCommand members are listed in the following tables.

### OracleDataSourceCommand Public Methods

OracleDataSourceCommand methods are listed in [Table 6-103](#).

**Table 6-103 OracleDataSourceCommand Public Methods**

| Method                             | Description                                              |
|------------------------------------|----------------------------------------------------------|
| <a href="#">ExecuteReader</a>      | Returns an OracleDataReader. (Overloaded)                |
| <a href="#">ExecuteReaderAsync</a> | Returns an OracleDataReader asynchronously. (Overloaded) |

### OracleDataSourceCommand Properties

OracleDataSourceCommand properties are listed in [Table 6-104](#).

**Table 6-104 OracleDataSourceCommand Properties**

| Property    | Description                                                   |
|-------------|---------------------------------------------------------------|
| Connection  | OracleConnection Connection throws a NotSupportedException.   |
| Transaction | OracleTransaction Transaction throws a NotSupportedException. |

## OracleDataSource Public Methods

OracleDataSourceCommand public methods are listed in [Table 6-105](#).

**Table 6-105 OracleDataSourceCommand Public Methods**

| Method                             | Description                                                           |
|------------------------------------|-----------------------------------------------------------------------|
| <a href="#">ExecuteReader</a>      | Returns an <code>OracleDataReader</code> . (Overloaded)               |
| <a href="#">ExecuteReaderAsync</a> | Returns an <code>OracleDataReader</code> asynchronously. (Overloaded) |

**See Also**

## ExecuteReader

`OracleDataReader ExecuteReader` returns an `OracleDataReader`.

**Overload List:**

- `ExecuteReader()`

Since `OracleDataReader` relies on an open connection to fetch data, ODP.NET does not close the connection after `ExecuteReader()` returns.

ODP.NET sets the `CommandBehavior` to `CommandBehavior.CloseConnection`. As a result, the connection is closed once the reader is closed.

- `ExecuteReader(commandBehavior)`

`commandBehavior` argument is ignored. The `CommandBehavior.CloseConnection` value is used.

Since `OracleDataReader` relies on an open connection to fetch data, ODP.NET does not close the connection after `ExecuteReader()` returns.

ODP.NET sets the `CommandBehavior` to `CommandBehavior.CloseConnection`. As a result, the connection is closed once the reader is closed.

**Note**

- [OracleDataSourceCommand Members](#)

## ExecuteReaderAsync

ExecuteReaderAsync returns an `OracleDataReader` asynchronously.

### Overload List:

- [ExecuteReaderAsync\(cancellationToken\)](#)

This method returns an `OracleDataReader` asynchronously.

- [ExecuteReaderAsync\(commandBehavior, cancellationToken\)](#)

This method returns an `OracleDataReader` asynchronously with `CommandBehavior.CloseConnection`.

### Note

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceCommand Class](#)
- [OracleDataSourceCommand Members](#)

## ExecuteReaderAsync(cancellationToken)

This method returns an `OracleDataReader` asynchronously.

### Declaration

```
// C#  
public Task<OracleDataReader> ExecuteReaderAsync(CancellationToken cancellationToken)
```

### Parameters

- `cancellationToken`  
Token to cancel async call.

### Remarks

Since `OracleDataReader` relies on an open connection to fetch data, ODP.NET does not close the connection after `ExecuteReader()` returns.

ODP.NET sets the `CommandBehavior` to `CommandBehavior.CloseConnection`. As a result, the connection is closed once the reader is closed.

### Note

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceCommand Class](#)
- [OracleDataSourceCommand Members](#)

## ExecuteReaderAsync(commandBehavior, cancellationToken)

This method returns an `OracleDataReader` asynchronously.

### Declaration

```
// C#  
public Task<OracleDataReader> ExecuteReaderAsync(CommandBehavior commandBehavior,  
CancellationToken cancellationToken)
```

### Parameters

- `commandBehavior`  
This argument is ignored. The `CommandBehavior.CloseConnection` value is used.
- `cancellationToken`  
Token to cancel async call.

### Remarks

Since `OracleDataReader` relies on an open connection to fetch data, ODP.NET does not close the connection after `ExecuteReader()` returns.

ODP.NET sets the `CommandBehavior` to `CommandBehavior.CloseConnection`. As a result, the connection is closed once the reader is closed.

# OracleDataSourceEnumerator Class

An OracleDataSourceEnumerator object allows applications to generically obtain a collection of data sources to connect to.

### Class Inheritance

### Declaration

```
// C#
public sealed class OracleDataSourceEnumerator : DbDataSourceEnumerator
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example

```
// C#

using System;
using System.Data;
using System.Data.Common;
using Oracle.DataAccess.Client;

class DataSourceEnumSample
{
```

```
static void Main()
{
    string ProviderName = "Oracle.DataAccess.Client";

    DbProviderFactory factory = DbProviderFactories.GetFactory(ProviderName);

    if (factory.CanCreateDataSourceEnumerator)
    {
        DbDataSourceEnumerator dsenum = factory.CreateDataSourceEnumerator();
        DataTable dt = dsenum.GetDataSources();

        // Print the first column/row entry in the DataTable
        Console.WriteLine(dt.Columns[0] + " : " + dt.Rows[0][0]);
        Console.WriteLine(dt.Columns[1] + " : " + dt.Rows[0][1]);
        Console.WriteLine(dt.Columns[2] + " : " + dt.Rows[0][2]);
        Console.WriteLine(dt.Columns[3] + " : " + dt.Rows[0][3]);
        Console.WriteLine(dt.Columns[4] + " : " + dt.Rows[0][4]);
    }
    else
        Console.WriteLine("Data source enumeration is not supported by provider");
}
```

- [OracleDataSourceEnumerator Class](#)
- [OracleDataSourceEnumerator Members](#)

## OracleDataSourceEnumerator Public Methods

The OracleDataSourceEnumerator static method is listed in [Table 6-109](#).

**Table 6-109 OracleDataSourceEnumerator Method**

| Method                         | Description                                                                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------|
| <a href="#">GetDataSources</a> | Returns a DataTable object with information on all the TNS alias entries in the tnsnames.ora file |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceEnumerator Class](#)
- [OracleDataSourceEnumerator Members](#)

## GetDataSources

This method returns a `DataTable` object with information on all the .NET configuration file ODP.NET data sources, TNS alias entries in the `tnsnames.ora` file, and entries retrieved from the LDAP servers configured in `ldap.ora` if LDAP naming is enabled.

**Declaration**

```
// C#  
public override DataTable GetDataSources();
```

**Return Value**

A `DataTable` object.

**Remarks**

This method returns a `DataTable` object for each ODP.NET data source in the .NET configuration file, TNS alias entry that exists in the `tnsnames.ora` file, and each entry retrieved from the LDAP servers. If there are no ODP.NET data sources in the .NET configuration file, a `tnsnames.ora` file is not found, nor LDAP Naming is configured, then the returned `DataTable` object will be empty.

This method in ODP.NET, Managed Driver can fetch all the data source aliases from an LDAP server, such as Oracle Internet Directory or Microsoft Active Directory. This method in ODP.NET, Unmanaged Driver does not support retrieving data source aliases from an LDAP server.

When Oracle Internet Directory (OID) is used for the TNS naming repository, there is a limit of 1000 TNS entries retrieved.

The following columns are returned for each row, but only the `InstanceName` column is populated.

- `InstanceName` (type: `System.String`)
- `ServerName` (type: `System.String`)
- `ServiceName` (type: `System.String`)
- `Protocol` (type: `System.String`)
- `Port` (type: `System.String`)

If the TNS and/or LDAP information changes for existing pooled connections, then calling `GetDataSources` will not return these changes unless the pools have been cleared.

# OracleDBMSAssert Class

An OracleDBMSAssert class is an ODP.NET class whose methods are for validating and sanitizing input values, such as database identifiers and string literals. This class's methods can be used to prevent SQL injection.

## Class Inheritance

System.Object  
  
Oracle.ManagedDataAccess.Client.OracleDBMSAssert

## Declaration

```
// C#  
public static class OracleDBMSAssert
```

## Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe.

# OracleDBMSAssert Methods

OracleDBMSAssert methods are listed in [Table 6-110](#).

**Table 6-110 OracleDBMSAssert Methods**

| Method                              | Description                                                                |
|-------------------------------------|----------------------------------------------------------------------------|
| <a href="#">EnquoteIdentifier</a>   | Validates the identifier and returns the result. (Overloaded)              |
| <a href="#">EnquoteLiteral</a>      | Validates the literal and returns the result. (Overloaded)                 |
| <a href="#">EnquoteNCharLiteral</a> | Validates the literal, prefixes an N, and returns the result. (Overloaded) |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDBMSAssert Class](#)

## EnquoteIdentifier

This method validates the identifier and returns the result.

**Overload List:**

- [EnquoteIdentifier\(identifier, maxIdentifierLength, charset, bAlwaysQuote, bCapitalize\)](#)  
This method validates the identifier, adds double quotes if missing, and returns the result.
- [EnquoteIdentifier\(identifier, bAlwaysQuote, bCapitalize\)](#)  
This method adds double quotes to the identifier if missing and returns the result.

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteIdentifier(identifier, maxIdentifierLength, charset, bAlwaysQuote, bCapitalize)

This method validates the identifier, adds double quotes if missing, and returns the result.

**Declaration**

```
// C#
public static string EnquoteIdentifier(string identifier, int maxIdentifierLength,
    OracleDatabaseCharset charset, bool bAlwaysQuote = true, bool bCapitalize =
    true);
```

**Parameters**

- `identifier`  
The input identifier.

- `maxIdentifierLength`  
The maximum allowed identifier length in bytes.
- `charset`  
The database character set.
- `bAlwaysQuote`  
If true, then the returned identifier is always quoted. If false, then quotes will only be added for a simple identifier that is not already quoted if the case needs to be preserved.
- `bCapitalize`  
If true, a simple identifier will be uppercased except when it is already double quoted. If false, it is case-sensitive, and case will be preserved with double quotes, if it contains a lowercase letter.

### Return Value

The identifier is returned with double quotes, except for a simple identifier that is not already quoted in either of the following cases:

- `bAlwaysQuote` is false and `bCapitalize` is true.
- `bAlwaysQuote` is false, `bCapitalize` is false, and the identifier is uppercase.

### Exceptions

`ArgumentNullException` - Value cannot be null. (Parameter 'identifier')

`ArgumentException` - Value does not fall within the expected range. (Parameter 'maxIdentifierLength')

`OracleException` - Invalid identifier or literal.

### Remarks

This method's purpose is to prevent SQL injection.

Simple SQL names are supported as identifiers. In other words, qualified SQL names are not supported. For example, `SCHEMA.TABLE` would be a qualified SQL name.

A simple identifier that is not already quoted will only get quoted if `bAlwaysQuote` is true, or `bCapitalize` is false and it contains a lowercase letter. It will be uppercased if `bCapitalize` is true.

A quoted identifier is returned as is, but the identifier being quoted cannot contain double quotes or the null character.

Other identifiers can contain any characters, except double quotes and the null character. The identifier will be enclosed in double quotes.

Empty identifiers are not allowed.

Leading and trailing white space is not ignored nor trimmed when quoted.

Reserved words will always be quoted.

`maxIdentifierLength` and `charset` are used for identifier validation. An identifier length must be a minimum of one byte and maximum of `maxIdentifierLength` bytes, when represented in the database character set. The double quotes in a quoted identifier are not counted for the identifier length.

ODP.NET uses charset to verify the specified database character set that can represent the identifier. Sometimes alternative representations of quotes can be used to introduce SQL injection. An OracleException will be thrown if the quotes cannot be correctly represented in the database character set.

This table shows EnquoteIdentifier method output for various input values and settings.

| Input        | Output<br>bCapitalize=true<br>bAlwaysQuote=false | Output bCapitalize=false<br>bAlwaysQuote=false | Notes                                                                                                                                              |
|--------------|--------------------------------------------------|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLE123\$   | TABLE123\$                                       | TABLE123\$                                     | No quotes nor uppercasing needed.                                                                                                                  |
| table123\$   | TABLE123\$                                       | "table123\$"                                   | For bCapitalize=true, uppercasing is needed, but not quotes.<br>For bCapitalize=false, the identifier needs to be treated as lowercase and quoted. |
| "table123\$" | "table123\$"                                     | "table123\$"                                   | Already quoted and remains quoted.                                                                                                                 |
| table123?    | "table123?"                                      | "table123?"                                    | ? is not allowed in simple identifiers. No uppercasing. Quotes required.                                                                           |
| select       | "SELECT"                                         | "select"                                       | Reserved words are quoted. For bCapitalize=true, uppercasing is also needed.                                                                       |
| table123\$   | "table123\$"                                     | "table123\$"                                   | Leading and trailing white space is not ignored nor trimmed. Quotes are required. It will not be uppercased because it is not a simple identifier. |

This ODP.NET code sample shows how to use `OracleDBMSAssert.EnquoteIdentifier` to protect the query from SQL injection compromise.

### Example

```
// C#
using System;
using System.Data;
using Oracle.ManagedDataAccess.Client;

class EnquoteIdentifierSample
{
    static void Main()
    {
        string constr = "User Id=HR;Password=<PASSWORD>;Data Source=<DATA SOURCE>";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        string tableName "employees";
        string cmdText = "SELECT count(*) FROM " +
            OracleDBMSAssert.EnquoteIdentifier(tableName, 128, OracleDatabaseCharset.AL32UTF8,
            false);
        // Resulting Command Text: "SELECT count(*) FROM EMPLOYEES"

        OracleCommand cmd = new OracleCommand(cmdText);
        object count = cmd.ExecuteScalar();
        Console.WriteLine("There are " + count + " rows in the table.");

        cmd.Dispose();
        con.Dispose();
    }
}
```

#### Note

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteIdentifier(identifier, bAlwaysQuote, bCapitalize)

This method adds double quotes to the identifier if missing and returns the result.

### Declaration

```
// C#
public static string EnquoteIdentifier(string identifier, bool bAlwaysQuote = true, bool
    bCapitalize = true);
```

### Parameters

- `identifier`

The input identifier.

- **bAlwaysQuote**  
If true, then the returned identifier is always quoted. If false, then quotes will only be added for a simple identifier that is not already quoted if the case needs to be preserved.
- **bCapitalize**  
If true, a simple identifier will be uppercased except when it is already double quoted. If false, it is case-sensitive, and case will be preserved with double quotes, if it contains a lowercase letter.

### Return Value

The identifier is returned with double quotes, except for a simple identifier that is not already quoted in either of the following cases:

- **bAlwaysQuote** is false and **bCapitalize** is true.
- **bAlwaysQuote** is false, **bCapitalize** is false, and the identifier is uppercase.

### Exceptions

`ArgumentNullException` - Value cannot be null. (Parameter 'identifier')

`OracleException` - Invalid identifier or literal.

### Remarks

This method's purpose is to prevent SQL injection.

Simple SQL names are supported as identifiers. In other words, qualified SQL names are not supported. For example, `SCHEMA.TABLE` would be a qualified SQL name.

A simple identifier that is not already quoted will only get quoted if **bAlwaysQuote** is true, or **bCapitalize** is false and it contains a lowercase letter. It will be uppercased if **bCapitalize** is true.

A quoted identifier is returned as is, but the identifier being quoted cannot contain double quotes or the null character.

Other identifiers can contain any characters, except double quotes and the null character. The identifier will be enclosed in double quotes.

Empty identifiers are not allowed.

Leading and trailing white space is not ignored nor trimmed when quoted.

Reserved words will always be quoted.

If validation of the identifier length and representation in the database character set is needed, then use the other `EnquoteIdentifier` overload.

#### Note

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteLiteral

This method validates the literal and return the result.

### Overload List:

- [EnquoteLiteral\(literal, charset\)](#)

This method validates the literal, adds single quotes if required, and return the result.

- [EnquoteLiteral\(literal\)](#)

This method adds single quotes if required, and return the result.

### Note

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteLiteral(literal, charset)

This method validates the literal, adds single quotes if required, and return the result.

### Declaration

```
// C#  
public static string EnquoteLiteral(string literal, OracleDatabaseCharset charset);
```

### Parameters

- `literal`  
The input string literal.
- `charset`  
The database character set.

### Return Value

The literal is returned enclosed with single quotes.

### Exceptions

`ArgumentNullException` - Value cannot be null. (Parameter 'identifier')

`OracleException` - Invalid identifier or literal.

### Remarks

This method's purpose is to prevent SQL injection.

Any single quote in the literal is replaced with two single quotes for the purposes of escaping, or overloading. For example, the input string, `scott's`, becomes `'scott's'` in the return value.

Empty literals are allowed with ODP.NET adding quotes with this method.

Leading and trailing white space is not ignored nor trimmed when quoted.

ODP.NET uses charset to verify the specified database character set that can represent the literal. Sometimes alternative representations of quotes can be used to introduce SQL injection. An OracleException will be thrown if the quotes cannot be correctly represented in the database character set.

This table shows EnquoteLiteral method output for various input values.

| Input        | Output          | Notes                                                                                           |
|--------------|-----------------|-------------------------------------------------------------------------------------------------|
| scott        | 'scott'         | Add surrounding single quotes.                                                                  |
| scott's name | 'scott''s name' | Add surrounding single quotes.<br>The existing single quote is replaced with two single quotes. |
| scott        | ' scott '       | Add surrounding single quotes.<br>Leading and trailing white space is not ignored nor trimmed.  |

### Example

This ODP.NET code sample shows how to use OracleDBMSAssert.EnquoteLiteral to protect the query from SQL injection compromise.

```
// C#
using System;
using System.Data;
using Oracle.ManagedDataAccess.Client;

class EnquoteLiteralSample
{
    static void Main()
    {
        string constr = "User Id=HR;Password=<PASSWORD>;Data Source=<DATA SOURCE>";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        string empName "Walsh";
        string cmdText = "SELECT FIRST_NAME FROM EMPLOYEES WHERE LAST_NAME = " +
        OracleDBMSAssert.EnquoteLiteral(empName, OracleDatabaseCharset.AL32UTF8);
        // Resulting Command Text: "SELECT FIRST_NAME FROM EMPLOYEES WHERE LAST_NAME =
        'Walsh'"

        OracleCommand cmd = new OracleCommand(cmdText);
        DataReader reader = cmd.ExecuteReader();
        if(reader.Read())
        {
            Console.WriteLine("The first name for " + empName + " is " + reader.GetString(0));
        }

        reader.Dispose();
        cmd.Dispose();
        con.Dispose();
    }
}
```

```
}
```

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteLiteral(literal)

This method adds single quotes if required, and return the result.

**Declaration**

```
// C#  
public static string EnquoteLiteral(string literal);
```

**Parameters**

- `literal`  
The input literal.

**Return Value**

The literal is returned with single quotes.

**Exceptions**

ArgumentNullException - Value cannot be null. (Parameter 'identifier')

OracleException - Invalid identifier or literal.

**Remarks**

This method's purpose is to prevent SQL injection.

Any single quote in the literal is replaced with two single quotes for the purposes of escaping, or overloading. For example, the input string, `scott's`, becomes `'scott''s'` in the return value.

Empty literals are allowed.

Leading and trailing white space is not ignored nor trimmed when quoted.

If validation using the database character set is required, then use the other `EnquoteLiteral` overload.

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteNCharLiteral

EnquoteNCharLiteral validates the literal, prefixes an N, and returns the result.

**Overload List:**

- [EnquoteNCharLiteral\(literal, ncharset\)](#)

This method validates the literal, adds single quotes if required, prefixes an N, and returns the result.

- [EnquoteNCharLiteral\(literal\)](#)

This method adds single quotes if required, prefixes an N, and returns the result.

**Note**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteNCharLiteral(literal, ncharset)

This method validates the literal, adds single quotes if required, prefixes an N, and returns the result.

**Declaration**

```
// C#
public static string EnquoteNCharLiteral(string literal, OracleDatabaseNCharset
ncharset);
```

**Parameters**

- `literal`  
The input literal.
- `ncharset`  
The database national character set.

**Return Value**

The literal is returned with single quotes prefixed with an N.

### Exceptions

ArgumentNullException - Value cannot be null. (Parameter 'identifier')

OracleException - Invalid identifier or literal.

### Remarks

This method's purpose is to prevent SQL injection.

Any single quote in the literal is replaced with two single quotes for the purposes of escaping, or overloading. For example, the input string, scott's, becomes N'scott's' in the return value.

The literal is returned with single quotes prefixed with an N. Any single quote in the literal is replaced with two single quotes. This is called escaping or overloading.

Empty literals are allowed.

Leading and trailing white space is not ignored nor trimmed when quoted.

ODP.NET uses ncharset to verify the specified database national character set that can represent the literal. Sometimes alternative representations of quotes can be used to introduce SQL injection. An OracleException will be thrown if the quotes cannot be correctly represented in the database national character set.

#### Note

- [OracleDBMSAssert Class](#)
- [OracleDBMSAssert Methods](#)

## EnquoteNCharLiteral(literal)

This method adds single quotes if required, prefixes an N, and returns the result.

### Declaration

```
// C#  
public static string EnquoteNCharLiteral(string literal);
```

### Parameters

- literal  
The input literal.

### Return Value

The literal is returned with single quotes prefixed with an N.

### Exceptions

ArgumentNullException - Value cannot be null. (Parameter 'identifier')

OracleException - Invalid identifier or literal.

Remarks

This method's purpose is to prevent SQL injection.

Any single quote in the literal is replaced with two single quotes for the purposes of escaping, or overloading. For example, the input string, scott's, becomes N'scott''s' in the return value.

Empty literals are allowed.

Leading and trailing white space is not ignored nor trimmed when quoted.

If validation using the database character set is required, then use the other EnquoteLiteral overload.

OracleError Class

The OracleError class represents an error reported by Oracle.

Class Inheritance

System.Object

Oracle.DataAccess.Client.OracleError

Declaration

```
// C#
public sealed class OracleError
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver                      | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|------------------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                          | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                       | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |

| .NET (Core)    | -                                              | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Remarks

The `OracleError` class represents a warning or an error reported by Oracle.

If there are multiple errors, ODP.NET only returns the first error message on the stack.

## Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleErrorsSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Create an OracleCommand object using the connection object
        OracleCommand cmd = con.CreateCommand();

        try
        {
            cmd.CommandText = "insert into notable values (99, 'MyText')";
            cmd.ExecuteNonQuery();
        }
        catch (OracleException ex)
        {
            Console.WriteLine("Record is not inserted into the database table.");

            foreach (OracleError error in ex.Errors)
            {
                Console.WriteLine("Error Message: " + error.Message);
                Console.WriteLine("Error Source: " + error.Source);
            }
        }
    }
}
```

## OracleError Members

OracleError members are listed in the following tables.

### OracleError Static Methods

The OracleError static method is listed in [Table 6-111](#).

**Table 6-111 OracleError Static Method**

| Method              | Description                                            |
|---------------------|--------------------------------------------------------|
| <code>Equals</code> | Inherited from <code>System.Object</code> (Overloaded) |

### OracleError Properties

OracleError properties are listed in [Table 6-112](#).

**Table 6-112 OracleError Properties**

| Property                       | Description                                                                      |
|--------------------------------|----------------------------------------------------------------------------------|
| <a href="#">ArrayBindIndex</a> | Specifies the row number of errors that occurred during the Array Bind execution |
| <a href="#">DataSource</a>     | Specifies the Oracle service name (TNS name) that identifies the Oracle database |
| <a href="#">Message</a>        | Specifies the message describing the error                                       |
| <a href="#">Number</a>         | Specifies the Oracle error number                                                |
| <a href="#">Procedure</a>      | Specifies the stored procedure that causes the error                             |
| <a href="#">Source</a>         | Specifies the name of the data provider that generates the error                 |

### OracleError Methods

OracleError methods are listed in [Table 6-113](#).

**Table 6-113 OracleError Methods**

| Method                   | Description                                            |
|--------------------------|--------------------------------------------------------|
| <code>Equals</code>      | Inherited from <code>System.Object</code> (Overloaded) |
| <code>GetHashCode</code> | Inherited from <code>System.Object</code>              |
| <code>GetType</code>     | Inherited from <code>System.Object</code>              |
| <a href="#">ToString</a> | Returns a string representation of the OracleError     |

## ArrayBindIndex

This property specifies the row number of errors that occurred during the Array Bind execution.

**Declaration**

```
// C#  
public int ArrayBindIndex {get;}
```

**Property Value**

An int value that specifies the row number for errors that occurred during the Array Bind execution.

**Remarks**

Default = 0.

This property is used for Array Bind operations only.

ArrayBindIndex represents the zero-based row number at which the error occurred during an Array Bind operation. For example, if an array bind execution causes two errors on the 2nd and 4th operations, two OracleError objects appear in the OracleErrorCollection with the ArrayBindIndex property values 2 and 4 respectively.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleError Class](#)
- [OracleError Members](#)
- ["Array Binding"](#)

## DataSource

This property specifies the Oracle service name (TNS name) that identifies the Oracle database.

**Declaration**

```
// C#  
public string DataSource {get;}
```

**Property Value**

A string.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleError Class](#)
- [OracleError Members](#)

## Message

This property specifies the message describing the error.

### Declaration

```
// C#  
public string Message {get;}
```

### Property Value

A string.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleError Class](#)
- [OracleError Members](#)

## Number

This property specifies the Oracle error number.

### Declaration

```
// C#  
public int Number {get;}
```

### Property Value

An int.

### Remarks

#### ① Note

ODP.NET error numbers have changed in version 23 to better align with standard Oracle error number ranges.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleError Class](#)
- [OracleError Members](#)

## Procedure

This property specifies the stored procedure that causes the error.

### Declaration

```
// C#  
public string Procedure {get;}
```

### Property Value

The stored procedure name.

### Remarks

Represents the stored procedure which creates this OracleError object.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleError Class](#)
- [OracleError Members](#)

## Source

This property specifies the name of the data provider that generates the error.

### Declaration

```
// C#  
public string Source {get;}
```

### Property Value

A string.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleError Class](#)
- [OracleError Members](#)

## OracleError Methods

OracleError methods are listed in [Table 6-116](#).

**Table 6-116 OracleError Methods**

| Method                   | Description                                        |
|--------------------------|----------------------------------------------------|
| Equals                   | Inherited from System.Object (Overloaded)          |
| GetHashCode              | Inherited from System.Object                       |
| GetType                  | Inherited from System.Object                       |
| <a href="#">ToString</a> | Returns a string representation of the OracleError |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleError Class](#)
- [OracleError Members](#)

## ToString

Overrides Object

This method returns a string representation of the OracleError.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

Returns a string with the format Ora- error number: Class.Method name error message stack trace information.

**Example**

ORA-24333: zero iteration count

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleError Class](#)
- [OracleError Members](#)

## OracleErrorCollection Class

An OracleErrorCollection class represents a collection of all errors that are thrown by the Oracle Data Provider for .NET.

Class Inheritance

System.Object  
    System.ArrayList  
        Oracle.DataAccess.Client.OracleErrorCollection

Declaration

```
// C#  
public sealed class OracleErrorCollection : ArrayList
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

A simple ArrayList that holds a list of OracleErrors.  
If there are multiple errors, ODP.NET only returns the first error message on the stack.

Example

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class OracleErrorCollectionSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        // Create an OracleCommand object using the connection object  
        OracleCommand cmd = con.CreateCommand();  
  
        try  
        {
```

```
cmd.CommandText = "insert into notable values (99, 'MyText')";
cmd.ExecuteNonQuery();
}
catch (OracleException ex)
{
    Console.WriteLine("Record is not inserted into the database table.");

    foreach (OracleError error in ex.Errors)
    {
        Console.WriteLine("Error Message: " + error.Message);
        Console.WriteLine("Error Source: " + error.Source);
    }
}
}
```

## OracleException Class

The OracleException class represents an exception that is thrown when the Oracle Data Provider for .NET encounters an error. Each OracleException object contains at least one OracleError object in the Error property that describes the error or warning.

Class Inheritance

System.Object  
    System.Exception  
        System.SystemException  
            System.Runtime.InteropServices.ExternalException  
                System.Data.Common.DbException  
                    Oracle.DataAccess.Client.OracleException

Declaration

```
// C#  
public sealed class OracleException : SystemException
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

If there are multiple errors, ODP.NET only returns the first error message on the stack.

Example

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class OracleExceptionSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        // Create an OracleCommand object using the connection object
```

```
OracleCommand cmd = con.CreateCommand();

try
{
    cmd.CommandText = "insert into notable values (99, 'MyText')";
    cmd.ExecuteNonQuery();
}
catch (OracleException ex)
{
    Console.WriteLine("Record is not inserted into the database table.");
    Console.WriteLine("Exception Message: " + ex.Message);
    Console.WriteLine("Exception Source: " + ex.Source);
}
}
```

## OracleException Members

OracleException members are listed in the following tables.

### OracleException Static Methods

The OracleException static method is listed in [Table 6-123](#).

**Table 6-123 OracleException Static Method**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

### OracleException Properties

OracleException properties are listed in [Table 6-124](#).

**Table 6-124 OracleException Properties**

| Property                   | Description                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">DataSource</a> | Specifies the TNS name that contains the information for connecting to an Oracle instance |

**Table 6-124 (Cont.) OracleException Properties**

| Property                                 | Description                                                                                                                                       |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Errors</a>                   | Specifies a collection of one or more <code>OracleError</code> objects that contain information about exceptions generated by the Oracle database |
| <code>HelpLink</code>                    | Inherited from <code>System.Exception</code>                                                                                                      |
| <code>InnerException</code>              | Inherited from <code>System.Exception</code>                                                                                                      |
| <a href="#">IsRecoverable</a>            | Specifies whether the current operation producing this exception can succeed if retried                                                           |
| <a href="#">Message</a>                  | Specifies the error messages that occur in the exception                                                                                          |
| <a href="#">Number</a>                   | Specifies the Oracle error number                                                                                                                 |
| <a href="#">OracleLogicalTransaction</a> | Returns an <code>OracleLogicalTransaction</code> object for a recoverable error when using Transaction Guard                                      |
| <a href="#">Procedure</a>                | Specifies the stored procedure that cause the exception                                                                                           |
| <a href="#">Source</a>                   | Specifies the name of the data provider that generates the error                                                                                  |
| <code>StackTrace</code>                  | Inherited from <code>System.Exception</code>                                                                                                      |
| <code>TargetSite</code>                  | Inherited from <code>System.Exception</code>                                                                                                      |

**OracleException Methods**

OracleException methods are listed in [Table 6-125](#).

**Table 6-125 OracleException Methods**

| Method                        | Description                                                            |
|-------------------------------|------------------------------------------------------------------------|
| <code>Equals</code>           | Inherited from <code>System.Object</code> (Overloaded)                 |
| <code>GetBaseException</code> | Inherited from <code>System.Exception</code>                           |
| <code>GetHashCode</code>      | Inherited from <code>System.Object</code>                              |
| <a href="#">GetObjectData</a> | Sets the serializable info object with information about the exception |
| <code>GetType</code>          | Inherited from <code>System.Object</code>                              |
| <a href="#">ToString</a>      | Returns the fully qualified name of this exception                     |

**See Also**

## OracleException Properties

OracleException properties are listed in [Table 6-127](#).

**Table 6-127 OracleException Properties**

| Property                                 | Description                                                                                                                          |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DataSource</a>               | Specifies the TNS name that contains the information for connecting to an Oracle instance                                            |
| <a href="#">Errors</a>                   | Specifies a collection of one or more OracleError objects that contain information about exceptions generated by the Oracle database |
| HelpLink                                 | Inherited from System.Exception                                                                                                      |
| InnerException                           | Inherited from System.Exception                                                                                                      |
| <a href="#">IsRecoverable</a>            | Specifies whether the current operation producing this exception can succeed if retried                                              |
| <a href="#">Message</a>                  | Specifies the error messages that occur in the exception                                                                             |
| <a href="#">Number</a>                   | Specifies the Oracle error number                                                                                                    |
| <a href="#">OracleLogicalTransaction</a> | Returns an OracleLogicalTransaction object for a recoverable error when using Transaction Guard                                      |
| <a href="#">Procedure</a>                | Specifies the stored procedure that cause the exception                                                                              |
| <a href="#">Source</a>                   | Specifies the name of the data provider that generates the error                                                                     |
| StackTrace                               | Inherited from System.Exception                                                                                                      |
| TargetSite                               | Inherited from System.Exception                                                                                                      |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)

## DataSource

This property specifies the TNS name that contains the information for connecting to an Oracle instance.

### Declaration

```
// C#  
public string DataSource {get;}
```

### Property Value

The TNS name containing the connect information.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)
- [OracleException Members](#)

## Errors

This property specifies a collection of one or more `OracleError` objects that contain information about exceptions generated by the Oracle database.

### Declaration

```
// C#  
public OracleErrorCollection Errors {get;}
```

### Property Value

An `OracleErrorCollection`.

### Remarks

The `Errors` property contains at least one instance of `OracleError` objects.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)
- [OracleException Members](#)

## IsRecoverable

This property specifies whether the current operation producing this exception can succeed if retried.

**Declaration**

```
// C#  
public bool IsRecoverable {get;}
```

**Property Value**

A bool.

**Remarks**

When a database outage occurs, such as during a network failure, the session becomes unavailable and the client receives an error code. The client can have difficulty determining whether the in-flight operation committed or needs to be resubmitted. Oracle automatically determines whether an in-flight database operation can be recovered or not using the `IsRecoverable` property. If `IsRecoverable` returns true after an outage, then the application can retrieve the current operation status and complete the transaction. If `IsRecoverable` returns false, then the application can rollback the current operation and resubmit the transaction.

This property is often used in conjunction with Transaction Guard.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)
- [OracleException Members](#)
- [Using Transaction Guard to Prevent Logical Corruption](#)

## Message

Overrides Exception

This property specifies the error messages that occur in the exception.

**Declaration**

```
// C#  
public override string Message {get;}
```

**Property Value**

A string.

**Remarks**

Message is a concatenation of all errors in the Errors collection. Each error message is concatenated and is followed by a carriage return, except the last one.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)
- [OracleException Members](#)

## Number

This property specifies the Oracle error number.

**Declaration**

```
// C#  
public int Number {get;}
```

**Property Value**

The error number.

**Remarks**

This error number can be the topmost level of error generated by Oracle and can be a provider-specific error number.

**① Note**

ODP.NET error numbers have changed in version 23 to better align with standard Oracle error number ranges. ODP.NET-specific exceptions now use the ORA-500XXX error range.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)
- [OracleException Members](#)

## OracleLogicalTransaction

This property will returns an OracleLogicalTransaction object for a recoverable error when using Transaction Guard.

**Declaration**

```
// C#  
public OracleLogicalTransaction OracleLogicalTransaction {get;}
```

**Property Value**

An `OracleLogicalTransaction`.

**Remarks**

`OracleLogicalTransaction` is non-null when both of the following conditions are met:

- Transaction Guard is enabled on the service
- The exception is a recoverable error

`OracleLogicalTransaction` can be used to determine the transaction outcome by looking at the two properties that it exposes: `Committed` and `UserCallCompleted`. If the outcome is not known, then `Committed` and `UserCallCompleted` will be set to null.

If the outcome of a recoverable error could not be determined by ODP.NET and the connection have not participated in a distributed transaction, then the `OracleLogicalTransactionId` property of the `OracleLogicalTransaction` object will be non-null and it can be used to determine the outcome by having the application explicitly call the `OracleLogicalTransaction.GetOutcome` static method, if the database/service is up.

**① See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleException Class](#)
- [OracleException Members](#)
- [OracleLogicalTransaction Class](#)

## Procedure

This property specifies the stored procedure that caused the exception.

**Declaration**

```
// C#  
public string Procedure {get;}
```

**Property Value**

The stored procedure name.

**① See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleException Class](#)
- [OracleException Members](#)

Source

Overrides Exception

This property specifies the name of the data provider that generates the error.

Declaration

```
// C#
public override string Source {get;}
```

Property Value

The name of the data provider.

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)
- [OracleException Members](#)

OracleException Methods

OracleException methods are listed in [Table 6-128](#).

Table 6-128 OracleException Methods

| Method                        | Description                                                            |
|-------------------------------|------------------------------------------------------------------------|
| Equals                        | Inherited from System.Object (Overloaded)                              |
| GetBaseException              | Inherited from System.Exception                                        |
| GetHashCode                   | Inherited from System.Object                                           |
| <a href="#">GetObjectData</a> | Sets the serializable info object with information about the exception |
| GetType                       | Inherited from System.Object                                           |
| <a href="#">ToString</a>      | Returns the fully qualified name of this exception                     |

## GetObjectData

Overrides Exception

This method sets the serializable info object with information about the exception.

### Declaration

```
// C#  
public override void GetObjectData(SerializationInfo info, StreamingContext  
    context);
```

### Parameters

- *info*  
A SerializationInfo object.
- *context*  
A StreamingContext object.

### Remarks

The information includes DataSource, Message, Number, Procedure, Source, and StackTrace.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleException Class](#)
- [OracleException Members](#)

## ToString

Overrides Exception

This method returns the fully qualified name of this exception, the error message in the Message property, the InnerException.ToString() message, and the stack trace.

### Declaration

```
// C#  
public override string ToString();
```

### Return Value

The string representation of the exception.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class ToStringSample
```

```
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Create an OracleCommand object using the connection object
        OracleCommand cmd = con.CreateCommand();

        try
        {
            cmd.CommandText = "insert into notable values (99, 'MyText')";
            cmd.ExecuteNonQuery(); // This will throw an exception
        }
        catch (OracleException ex)
        {
            Console.WriteLine("Record is not inserted into the database table.");
            Console.WriteLine("ex.ToString() : " + ex.ToString());
        }
    }
}
```

## OracleInfoMessageEventArgs Class

The `OracleInfoMessageEventArgs` class provides event data for the `OracleConnection.InfoMessage` event. When any warning occurs in the database, the `OracleConnection.InfoMessage` event is triggered along with the `OracleInfoMessageEventArgs` object that stores the event data.

### Class Inheritance

`System.Object`

`System.EventArgs`

`Oracle.DataAccess.Client.OracleInfoMessageEventArgs`

### Declaration

```
// C#
public sealed class OracleInfoMessageEventArgs
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class InfoMessageSample
{
    public static void WarningHandler(object src,
        OracleInfoMessageEventArgs args)
    {
        Console.WriteLine("Source object is: " + src.GetType().Name);
        Console.WriteLine("InfoMessageArgs.Message is " + args.Message);
        Console.WriteLine("InfoMessageArgs.Source is " + args.Source);
    }
    static void Main()
    {
        OracleConnection con = new OracleConnection("User Id=scott;" +
            "Password=tiger;Data Source=oracle;");

        con.Open();

        OracleCommand cmd = con.CreateCommand();

        //Register to the InfoMessageHandler
        cmd.Connection.InfoMessage +=
            new OracleInfoMessageEventHandler(WarningHandler);

        cmd.CommandText =
            "create or replace procedure SelectWithNoInto( " +
            "  empname in VARCHAR2) AS " +
            "BEGIN " +
            "  select * from emp where ename = empname; " +
            "END SelectWithNoInto;";

        // Execute the statement that produces a warning
```

```
cmd.ExecuteNonQuery();

// Clean up
cmd.Dispose();
con.Dispose();
}
}
```

## OracleInfoMessageEventArgs Members

OracleInfoMessageEventArgs members are listed in the following tables.

### OracleInfoMessageEventArgs Static Methods

The OracleInfoMessageEventArgs static methods is listed in [Table 6-129](#).

**Table 6-129 OracleInfoMessageEventArgs Static Method**

| Method                 | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

### OracleInfoMessageEventArgs Properties

The OracleInfoMessageEventArgs properties are listed in [Table 6-130](#).

**Table 6-130 OracleInfoMessageEventArgs Properties**

| Property                | Description                                                     |
|-------------------------|-----------------------------------------------------------------|
| <a href="#">Errors</a>  | Specifies the collection of errors generated by the data source |
| <a href="#">Message</a> | Specifies the error text generated by the data source           |
| <a href="#">Source</a>  | Specifies the name of the object that generated the error       |

### OracleInfoMessageEventArgs Public Methods

The OracleInfoMessageEventArgs methods are listed in [Table 6-131](#).

**Table 6-131 OracleInfoMessageEventArgs Public Methods**

| Method                   | Description                                               |
|--------------------------|-----------------------------------------------------------|
| <code>Equals</code>      | Inherited from <code>System.Object</code> (Overloaded)    |
| <code>GetHashCode</code> | Inherited from <code>System.Object</code>                 |
| <code>GetType</code>     | Inherited from <code>System.Object</code>                 |
| <a href="#">ToString</a> | Returns the string representation of the current instance |

- [OracleInfoMessageEventArgs Members](#)

## OracleInfoMessageEventArgs Properties

The `OracleInfoMessageEventArgs` properties are listed in [Table 6-133](#).

**Table 6-133 OracleInfoMessageEventArgs Properties**

| Property                | Description                                                     |
|-------------------------|-----------------------------------------------------------------|
| <a href="#">Errors</a>  | Specifies the collection of errors generated by the data source |
| <a href="#">Message</a> | Specifies the error text generated by the data source           |
| <a href="#">Source</a>  | Specifies the name of the object that generated the error       |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleInfoMessageEventArgs Class](#)
- [OracleInfoMessageEventArgs Members](#)

## Errors

This property specifies the collection of errors generated by the data source.

### Declaration

```
// C#  
public OracleErrorCollection Errors {get;}
```

### Property Value

The collection of errors.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleInfoMessageEventArgs Class](#)
- [OracleInfoMessageEventArgs Members](#)

## Message

This property specifies the error text generated by the data source.

### Declaration

```
// C#  
public string Message {get;}
```

### Property Value

The error text.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleInfoMessageEventArgs Class](#)
- [OracleInfoMessageEventArgs Members](#)

Source

This property specifies the name of the object that generated the error.

Declaration

```
// C#  
public string Source {get;}
```

Property Value

The object that generated the error.

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleInfoMessageEventArgs Class](#)
- [OracleInfoMessageEventArgs Members](#)

OracleInfoMessageEventArgs Public Methods

The OracleInfoMessageEventArgs methods are listed in [Table 6-134](#).

Table 6-134 OracleInfoMessageEventArgs Public Methods

| Method                   | Description                                               |
|--------------------------|-----------------------------------------------------------|
| Equals                   | Inherited from System.Object (Overloaded)                 |
| GetHashCode              | Inherited from System.Object                              |
| GetType                  | Inherited from System.Object                              |
| <a href="#">ToString</a> | Returns the string representation of the current instance |

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleInfoMessageEventArgs Class](#)
- [OracleInfoMessageEventArgs Members](#)

ToString

Overrides Object

This method returns the string representation of the current instance.

Declaration

```
// C#
public override string ToString();
```

Return Value

Returns the OracleInfoMessageEventArgs value in a string representation.

Remarks

If the current instance has a null value, the returned string is null.

# OracleInfoMessageEventHandler Delegate

The OracleInfoMessageEventHandler represents the signature of the method that handles the OracleConnection.InfoMessage event.

Declaration

```
// C#
public delegate void OracleInfoMessageEventHandler(object sender,
    OracleInfoMessageEventArgs eventArgs);
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Parameters

- *sender*  
The source of the event.
- *eventArgs*  
The OracleInfoMessageEventArgs object that contains the event data.

# OracleLogicalTransaction Class

The OracleLogicalTransaction class provides detailed information about the logical transaction status. Applications can conclusively determine the outcome of the running transaction during the last database outage, then act accordingly to commit, complete, or rollback the transaction.

## Class Inheritance

System.Object

System.MarshalByRefObject

Oracle.DataAccess.Client.OracleLogicalTransaction

## Declaration

```
// C#
public sealed class OracleLogicalTransaction
```

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Members](#)
- [OracleLogicalTransaction Public Read-Only Properties](#)
- [OracleLogicalTransaction Methods](#)

## OracleLogicalTransaction Members

OracleLogicalTransaction members are listed in the following tables.

### OracleLogicalTransaction Public Read-Only Properties

OracleLoigcalTransaction public read-only properties are listed in [Table 6-135](#)

**Table 6-135 OracleLogicalTransaction Public Read-Only Properties**

| Property                             | Description                                                                                                                                |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Committed</a>            | Specifies if the transaction was committed or not                                                                                          |
| <a href="#">ConnectionString</a>     | Specifies a subset of the connection string used for the transaction running during the last database outage                               |
| <a href="#">LogicalTransactionId</a> | The logical transaction id is used to determine the commit outcome of the last transaction open in a database session following an outage. |
| <a href="#">UserCallCompleted</a>    | Specifies if the transaction completed and that the information returned may be incomplete and/or not all expected work was completed      |

### OracleLogicalTransaction Methods

OracleLoigcalTransaction methods are listed in [Table 6-136](#)

**Table 6-136 OracleLogicalTransaction Methods**

| Property                   | Description                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Dispose</a>    | This method releases any resources or memory allocated by the object                                                                                      |
| <a href="#">GetOutcome</a> | This method retrieves the transaction outcome from the database server. The method will determine whether the transaction committed and completed or not. |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Class](#)

## OracleLogicalTransaction Public Read-Only Properties

OracleLoigcalTransaction public read-only properties are listed in [Table 6-137](#)

**Table 6-137 OracleLogicalTransaction Public Read-Only Properties**

| Property                             | Description                                                                                                                                |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Committed</a>            | Specifies if the transaction was committed or not                                                                                          |
| <a href="#">ConnectionString</a>     | Specifies a subset of the connection string used for the transaction running during the last database outage                               |
| <a href="#">LogicalTransactionId</a> | The logical transaction id is used to determine the commit outcome of the last transaction open in a database session following an outage. |
| <a href="#">UserCallCompleted</a>    | Specifies if the transaction completed and that the information returned may be incomplete and/or not all expected work was completed      |

- [OracleLogicalTransaction Members](#)

## Committed

This property specifies if the transaction was committed or not.

### Declaration

```
// C#  
public bool? Committed {get;}
```

### Property Value

bool.

### Remarks

If `GetOutcome()` is not called, the this property holds a null value.

Once `GetOutcome()` is called, then this property will hold either true or false.

In some cases, `OracleLogicalTransaction.GetOutcome` will be called implicitly and populate this property with a non-null value automatically.

[Table 6-138](#) describes the possible outcomes of the `Committed` and `UserCallCompleted` properties.

**Table 6-138 Outcome of OracleLogicalTransaction Committed and UserCallCompleted Properties**

| Committed Value | UserCallCompleted Value | Outcome                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| false           | false                   | The call did not execute the commit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| true            | true                    | The call did execute the commit and there was no additional information to return and no more work to do if that call was a PL/SQL procedure.                                                                                                                                                                                                                                                                                                                                                                                    |
| true            | false                   | The transaction is committed, but the information returned may be incomplete and/or not all expected work was completed. Examples of incomplete information or incomplete work done include: the number of rows modified when using autocommit or commit on success, parameter and function results when calling PL/SQL procedures, or PL/SQL procedures with more work to do after the commit. In order to function correctly, .NET applications that use data returned from the commit must check the UserCallCompleted value. |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Class](#)
- [OracleLogicalTransaction Members](#)

## ConnectionString

This property specifies a subset of the connection string used for the transaction running during the last database outage.

**Declaration**

```
// C#
public string ConnectionString {get;}
```

**Property Value**

The data source as a string.

**Remarks**

This connection string can be useful if the outcome is not known at the time the exception is thrown due to a service that is down. In such a scenario, use the connection string from this property along with the LogicalTransactionId to determine the outcome of the logical transaction by invoking the static GetOutcome() method, once the database or service is back up.

The string returned by this property will contain only the following attributes: User Id, Proxy user Id (if not null/empty), Data Source, and Pooling (which will be set to false).

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Class](#)
- [OracleLogicalTransaction Members](#)

## LogicalTransactionId

The logical transaction id is used to determine the commit outcome of the last transaction open in a database session following an outage.

**Declaration**

```
// C#  
public byte LogicalTransactionId {get;}
```

**Property Value**

byte[]

**Remarks**

This logical transaction id can be useful if the outcome is not known at the time the exception is thrown due to a service that is down. In such a scenario, use the byte[] returned from this property (along with the ConnectionString) to determine the outcome of the logical transaction by invoking the static GetOutcome() method, once the database or service is back up.

This property will return a non-null value *only* when the outcome is not known. For example when database or service is down, then the outcome is not known.

LogicalTransactionId property will return null if the connection has participated in a distributed transaction.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Class](#)
- [OracleLogicalTransaction Members](#)

## UserCallCompleted

This property specifies if the transaction completed and that the information returned may be incomplete and/or not all expected work was completed.

**Declaration**

```
// C#  
public bool? UserCallCompleted {get;}
```

**Property Value**

bool

**Remarks**

If `GetOutcome()` is not called, the this property holds a null value.

Once `GetOutcome()` is called, then this property will hold either true or false.

In some cases, [GetOutcome](#) will be called implicitly and populate this property with a non-null value automatically

[Table 6-138](#) describes the possible outcomes of the `Committed` and `UserCallCompleted` properties.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Class](#)
- [OracleLogicalTransaction Members](#)

# OracleLogicalTransaction Methods

OracleLoigcalTransaction methods are listed in [Table 6-139](#)

**Table 6-139 OracleLogicalTransaction Methods**

| Property                   | Description                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Dispose</a>    | This method releases any resources or memory allocated by the object                                                                                      |
| <a href="#">GetOutcome</a> | This method retrieves the transaction outcome from the database server. The method will determine whether the transaction committed and completed or not. |

## Dispose

This method releases any resources or memory allocated by the object

**Declaration**

```
// C#
public void Dispose();
```

**Implements**

IDisposable

**Remarks**

The `Dispose` method also closes the `OracleLogicalTransaction` object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Class](#)
- [OracleLogicalTransaction Members](#)

## GetOutcome

The `GetOutcome` method retrieves the transaction outcome from the database server. The method will determine whether the transaction committed and completed or not.

**Overload List:**

- `GetOutcome(string constring, byte[] ltxid, out bool? bCommitted, out bool? bUserCallCompleted)`

The application can use this static method to determine the outcome if the outcome was not known when the exception was raised.

The application will need to obtain the connection string and logical transaction id from the `OracleException.OracleLogicalTransaction` object before calling this method.

The supplied connection string will be used to establish a connection to the database to determine the outcome of the provided logical transaction id.

ODP.NET implicitly calls `GetOutcome` under the following conditions:

- Transaction Guard is enabled on the service
- `OracleException` is raised
- The exception is a recoverable error

When all of the above is true, then the `OracleException.OracleLogicalTransaction` property will be non-null.

If a connection is involved in a distributed transaction, then `GetOutcome` is *not* called implicitly and the `OracleException.OracleLogicalTransaction.LogicalTransactionId` property returns null.

**① Note**

Once one server round-trip is incurred for the `GetOutcome()` invocation, the PL/SQL `ForceOutcome` is never invoked again against the server for a given `OracleLogicalTransaction` object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleLogicalTransaction Class](#)
- [OracleLogicalTransaction Members](#)

# OracleOnsServerCollection Class

The OracleOnsServerCollection class supports adding to and deleting from a collection of logical servers with their corresponding list of nodes where the Oracle Notification Service (ONS) daemons are talking to their remote clients.

In case of remote configuration, the application has to specify the <host>:<port> values for every potential database that it can connect to. The <host>:<port> value pairs represent the ports on the different nodes.

## Class Inheritance

System.Object  
  
Oracle.ManagedDataAccess.Client.OracleOnsServerCollection

## Declaration

```
// C#  
public static class OracleOnsServerCollection
```

## Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
using System;  
using Oracle.ManagedDataAccess.Client;  
  
namespace NetCoreApplication  
{  
    class OnsServersExample  
    {  
        static void Main(string[] args)  
        {  
            // Example to configure ONS Servers for the ODP.NET Core provider.  
  
            // Add server through Add method on OracleOnsServerCollection  
            OracleConfiguration.OracleOnsServers.Add("db1", "nodeList=host1:port1,  
host2:port2, host3:port3");  
  
            // Add server through indexer method on OracleOnsServerCollection  
            OracleConfiguration.OracleOnsServers["db2"] = "nodeList=m1:p1, m2:p2";  
        }  
    }  
}
```

```

// Get number of servers configured
int numServers = OracleConfiguration.OracleOnsServers.Count;

// Get OracleOnsServerCollection object
OracleOnsServerCollection serverColl = OracleConfiguration.OracleOnsServers;

// Add server through Add method on OracleOnsServerCollection
serverColl.Add("db3", "nodeList=host1:port1, host2:port2, host3:port3");

// Add server through indexer method on OracleOnsServerCollection
serverColl["db4"] = "nodeList=m1:p1, m2:p2";

// Remove a server
OracleConfiguration.OracleOnsServers.Remove("db2");

// Get number of servers configured
numServers = OracleConfiguration.OracleOnsServers.Count;

// Get value corresponding to a server.
string serverVal = OracleConfiguration.OracleOnsServers["db1"];

OracleConnection orclCon = null;

try
{
    // Open a test connection
    orclCon = new OracleConnection("user id=scott; password=tiger; data
source=oracle");

    orclCon.Open();
    orclCon.Close();
}
catch (OracleException ex)
{
    Console.WriteLine(ex);
}
finally
{
    // Close the connection
    if (null != orclCon)
        orclCon.Close();
}
}
}
}

```

## OracleOnsServerCollection Members

OracleOnsServerCollection members are listed in the following tables.

## OracleOnsServerCollection Methods

OracleOnsServerCollection methods are listed in [Table 6-140](#).

**Table 6-140 OracleOnsServerCollection Methods**

| Method                 | Description                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>    | Adds unique entries in the OracleOnsServerCollection using logical server names and it's corresponding list of nodes |
| <a href="#">Remove</a> | Removes an entry from an OracleOnsServerCollection                                                                   |

## OracleOnsServerCollection Properties

OracleOnsServerCollection properties are listed in [Table 6-141](#).

**Table 6-141 OracleOnsServerCollection Properties**

| Property              | Description                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------|
| <a href="#">Count</a> | Returns the number of OracleOnsServerCollection elements                                                      |
| <a href="#">This</a>  | Returns or sets the an entry for a unique logical server name, which is to be associated with a list of nodes |

# OracleOnsServerCollection Methods

OracleOnsServerCollection methods are listed in [Table 6-142](#).

**Table 6-142 OracleOnsServerCollection Methods**

| Method                 | Description                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>    | Adds unique entries in the OracleOnsServerCollection using logical server names and it's corresponding list of nodes |
| <a href="#">Remove</a> | Removes an entry from an OracleOnsServerCollection                                                                   |

## Add

This method adds unique entries in the OracleOnsServerCollection using logical server names and it's corresponding list of nodes.

**Declaration**

```
// C#  
public void Add(string serverName, string nodeList)
```

**Parameters**

- `serverName`
  - Type: `System.String`
  - A unique logical name for a list of nodes to be added
- `nodeList`
  - Type: `System.String`
  - Node names and remote ports for the list of nodes that ODP.NET shares ONS communication with using the following example format: `nodeList=racnode1:4200, racnode2:4200`

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOnsServerCollection Class](#)
- [OracleOnsServerCollection Members](#)

## Remove

This method removes an entry from an `OracleOnsServerCollection`.

**Declaration**

```
// C#  
public void Remove(string serverName)
```

**Parameters**

`serverName`

- Type: `System.String`
- A unique logical name for a list of nodes to be removed

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOnsServerCollection Class](#)
- [OracleOnsServerCollection Members](#)

# OracleOnsServerCollection Properties

OracleOnsServerCollection properties are listed in [Table 6-143](#).

**Table 6-143 OracleOnsServerCollection Properties**

| Property              | Description                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------|
| <a href="#">Count</a> | Returns the number of OracleOnsServerCollection elements                                                      |
| <a href="#">This</a>  | Returns or sets the an entry for a unique logical server name, which is to be associated with a list of nodes |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataSourceCollection Class](#)
- [OracleDataSourceCollection Members](#)

## Count

This is a read-only property that returns the number of OracleOnsServerCollection elements.

**Declaration**

```
// C#
public int Count { get; }
```

**Property Value**

Type: System.Int32

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOnsServerCollection Class](#)
- [OracleOnsServerCollection Members](#)

## This

This property returns or sets the an entry for a unique logical server name, which is to be associated with a list of nodes.

**Declaration**

```
// C#
public string this[string serverName] { get; set; }
```

Parameters

- `serverName`
  - Type: `System.String`
  - Unique logical server name to be added or updated
- `Value`
  - Type: `System.String`
  - Node names and remote ports for the list of nodes that ODP.NET shares ONS communication with using the following example format: `nodeList=racnode1:4200, racnode2:4200`

# OracleOpaqueString Class

This class securely obfuscates a series of characters, such as passwords. It is like .NET `SecureString` without `SecureString`'s known security weaknesses. Oracle recommends using `OracleOpaqueString` over .NET `SecureString`.

Class Inheritance

`System.Object`  
  
`Oracle.ManagedDataAccess.Client.OracleOpaqueString`

Declaration

```
// C#  
public class OracleOpaqueString
```

Requirements

| Provider       | ODP.NET, Managed Driver                      | ODP.NET Core                                 |
|----------------|----------------------------------------------|----------------------------------------------|
| Assembly       | <code>Oracle.ManagedDataAccess.dll</code>    | <code>Oracle.ManagedDataAccess.dll</code>    |
| Namespace      | <code>Oracle.ManagedDataAccess.Client</code> | <code>Oracle.ManagedDataAccess.Client</code> |
| .NET Framework | See <a href="#">System Requirements</a>      | -                                            |
| .NET (Core)    | -                                            | See <a href="#">System Requirements</a>      |

**See Also**

- [OracleOpaqueString Members](#)
- [OracleOpaqueString Constructor](#)
- [OracleOpaqueString Properties](#)
- [OracleOpaqueString Methods](#)

## OracleOpaqueString Members

OracleOpaqueString members are listed in the following tables.

### OracleOpaqueString Constructors

The OracleOpaqueString constructors are listed in [Table 6-144](#).

**Table 6-144 OracleOpaqueString Constructors**

| Constructors                                   | Description                                                      |
|------------------------------------------------|------------------------------------------------------------------|
| <a href="#">OracleOpaqueString Constructor</a> | Creates a new OracleOpaqueString instance to securely store text |

### OracleOpaqueString Methods

The OracleOpaqueString methods are listed in [Table 6-145](#).

**Table 6-145 OracleOpaqueString Methods**

| Method                       | Description                                                                 |
|------------------------------|-----------------------------------------------------------------------------|
| <a href="#">AppendChar</a>   | Obfuscates and appends a new character to the end of the OracleOpaqueString |
| <a href="#">Clear</a>        | Clears all the OracleOpaqueString characters                                |
| <a href="#">Copy</a>         | Creates a copy of the current OracleOpaqueString                            |
| <a href="#">Dispose</a>      | Scrubs and releases all OracleOpaqueString resources                        |
| <code>Equals(Object)</code>  | Inherited from System.Object(Overloaded)                                    |
| <a href="#">IsReadOnly</a>   | Indicates whether the OracleOpaqueString is read-only                       |
| <a href="#">MakeReadOnly</a> | Makes the OracleOpaqueString no longer modifiable                           |

### OracleOpaqueString Properties

The OracleOpaqueString properties are listed in [Table 6-146](#).

**Table 6-146 OracleOpaqueString Properties**

| Property               | Description                                                     |
|------------------------|-----------------------------------------------------------------|
| <a href="#">Length</a> | Returns the character length of the OracleOpaqueString instance |

## OracleOpaqueString Constructor

The OracleOpaqueString constructor creates a new OracleOpaqueString instance to securely store text.

### Declaration

```
// C#  
public OracleOpaqueString();
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

## OracleOpaqueString Properties

OracleOpaqueString properties are listed in [Table 6-147](#).

**Table 6-147 OracleOpaqueString Properties**

| Property               | Description                                                     |
|------------------------|-----------------------------------------------------------------|
| <a href="#">Length</a> | Returns the character length of the OracleOpaqueString instance |

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

## Length

This property returns the character length of the OracleOpaqueString instance.

Declaration

```
// C#  
public int Length {get;}
```

Property Value

The OracleOpaqueString character length

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

OracleOpaqueString Methods

OracleOpaqueString methods are listed in [Table 6-148](#).

Table 6-148 OracleOpaqueString Methods

| Method                       | Description                                                                 |
|------------------------------|-----------------------------------------------------------------------------|
| <a href="#">AppendChar</a>   | Obfuscates and appends a new character to the end of the OracleOpaqueString |
| <a href="#">Clear</a>        | Clears all the OracleOpaqueString characters                                |
| <a href="#">Copy</a>         | Creates a copy of the current OracleOpaqueString                            |
| <a href="#">Dispose</a>      | Scrubs and releases all OracleOpaqueString resources                        |
| <code>Equals(Object)</code>  | Inherited from System.Object(Overloaded)                                    |
| <a href="#">IsReadOnly</a>   | Indicates whether the OracleOpaqueString is read-only                       |
| <a href="#">MakeReadOnly</a> | Makes the OracleOpaqueString no longer modifiable                           |

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

AppendChar

This method obfuscates and appends a new character to the end of the OracleOpaqueString.

**Declaration**

```
// C#  
public void AppendChar(Char char)
```

**Parameters**

- char  
The character to append

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

## Clear

This method clears all the OracleOpaqueString characters.

**Declaration**

```
// C#  
public void Clear()
```

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

## Copy

This method creates a copy of the current OracleOpaqueString.

**Declaration**

```
// C#  
public OracleOpaqueString Copy()
```

**Return Value**

OracleOpaqueString

**Remarks**

This method does not have its char[] value in clear text at any point to preserve security.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

## Dispose

This method scrubs and releases all OracleOpaqueString resources.

**Declaration**

```
// C#  
public void Dispose()
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

## IsReadOnly

This method indicates whether the OracleOpaqueString is read-only.

**Declaration**

```
// C#  
public bool IsReadOnly()
```

**Remarks**

true if this string is marked read-only; otherwise, false.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

## MakeReadOnly

This method makes the OracleOpaqueString no longer modifiable.

Declaration

```
// C#
public void MakeReadOnly()
```

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleOpaqueString Class](#)
- [OracleOpaqueString Members](#)

OracleParameter Class

An OracleParameter object represents a parameter for an OracleCommand or a DataSet column.

Class Inheritance

Declaration

```
// C#
public sealed class OracleParameter : DbParameter, IDisposable, ICloneable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Exceptions

ArgumentException - The type binding is invalid.

## Binding Vector Parameters

The following input Vector parameter data types can be bound as various OracleDbType and OracleDbTypeEx types:

| Input Type         | OracleDbType Binding Type |
|--------------------|---------------------------|
| .NET numeric array | Vector                    |
|                    | Vector_Int8               |
|                    | Vector_Float32            |
|                    | Vector_Float64            |
| .NET byte array    | Vector                    |
|                    | Vector_Binary             |
|                    | Vector_Int8               |
|                    | Vector_Float32            |
|                    | Vector_Float64            |
| .NET string        | Vector                    |
|                    | Vector_Int8               |
|                    | Vector_Float32            |
|                    | Vector_Float64            |
|                    | Clob                      |
|                    | Varchar2                  |
| OracleString       | Vector                    |
|                    | Vector_Int8               |
|                    | Vector_Float32            |
|                    | Vector_Float64            |
|                    | Clob                      |
|                    | Varchar2                  |

## Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class OracleParameterSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleParameter[] prm = new OracleParameter[3];

        // Create OracleParameter objects through OracleParameterCollection
        OracleCommand cmd = con.CreateCommand();

        cmd.CommandText = "select max(empno) from emp";
        int maxno = int.Parse(cmd.ExecuteScalar().ToString());
    }
}
```

```
prm[0] = cmd.Parameters.Add("paramEmpno", OracleDbType.Decimal,
    maxno + 10, ParameterDirection.Input);
prm[1] = cmd.Parameters.Add("paramEname", OracleDbType.Varchar2,
    "Client", ParameterDirection.Input);
prm[2] = cmd.Parameters.Add("paramDeptNo", OracleDbType.Decimal,
    10, ParameterDirection.Input);
cmd.CommandText =
    "insert into emp(empno, ename, deptno) values(:1, :2, :3)";
cmd.ExecuteNonQuery();

Console.WriteLine("Record for employee id {0} has been inserted.",
    maxno + 10);
}
}
```

## OracleParameter Members

OracleParameter members are listed in the following tables.

### OracleParameter Constructors

OracleParameter constructors are listed in [Table 6-149](#).

**Table 6-149 OracleParameter Constructors**

| Constructor                                  | Description                                                       |
|----------------------------------------------|-------------------------------------------------------------------|
| <a href="#">OracleParameter Constructors</a> | Instantiates a new instance of OracleParameter class (Overloaded) |

### OracleParameter Static Methods

OracleParameter static methods are listed in [Table 6-150](#).

**Table 6-150 OracleParameter Static Methods**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

**OracleParameter Properties**

OracleParameter properties are listed in [Table 6-151](#).

**Table 6-151 OracleParameter Properties**

| Property                                | Description                                                                                                                                                                                                       |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ArrayBindSize</a>           | Specifies the input or output size of elements in Value property of a parameter before or after an Array Bind or PL/SQL Associative Array Bind execution                                                          |
| <a href="#">ArrayBindStatus</a>         | Specifies the input or output status of elements in Value property of a parameter before or after an Array Bind or PL/SQL Associative Array Bind execution                                                        |
| <a href="#">CollectionType</a>          | Specifies whether or not the OracleParameter represents a collection, and if so, specifies the collection type                                                                                                    |
| <a href="#">DbType</a>                  | Specifies the data type of the parameter using the Data.DbType enumeration type                                                                                                                                   |
| <a href="#">Direction</a>               | Specifies whether the parameter is input-only, output-only, bi-directional, or a stored function return value parameter                                                                                           |
| <a href="#">IsNullable</a>              | Not supported                                                                                                                                                                                                     |
| <a href="#">Offset</a>                  | Specifies the offset to the Value property or offset to the elements in the Value property                                                                                                                        |
| <a href="#">OracleDbType</a>            | Specifies the Oracle data type                                                                                                                                                                                    |
| <a href="#">OracleDbTypeEx</a>          | Specifies the Oracle data type to bind the parameter as, but returns a .NET type as output                                                                                                                        |
| <a href="#">ParameterName</a>           | Specifies the name of the parameter                                                                                                                                                                               |
| <a href="#">Precision</a>               | Specifies the maximum number of digits used to represent the Value property                                                                                                                                       |
| <a href="#">Scale</a>                   | Specifies the number of decimal places to which Value property is resolved                                                                                                                                        |
| <a href="#">Size</a>                    | Specifies the maximum size, in bytes or characters, of the data transmitted to or from the database. For PL/SQL Associative Array Bind, Size specifies the maximum number of elements in PL/SQL Associative Array |
| <a href="#">SourceColumn</a>            | Specifies the name of the DataTable Column of the DataSet                                                                                                                                                         |
| <a href="#">SourceColumnNullMapping</a> | Specifies a value which indicates whether the source column is nullable                                                                                                                                           |
| <a href="#">SourceVersion</a>           | Specifies the DataRowVersion value to use when loading the Value property of the parameter                                                                                                                        |
| <a href="#">Status</a>                  | Indicates the status of the execution related to the data in the Value property                                                                                                                                   |
| <a href="#">UdtTypeName</a>             | Specifies the Oracle user-defined type name if the parameter is a user-defined data type                                                                                                                          |
| <a href="#">Value</a>                   | Specifies the value of the Parameter                                                                                                                                                                              |

**OracleParameter Public Methods**

OracleParameter public methods are listed in [Table 6-152](#).

**Table 6-152 OracleParameter Public Methods**

| Public Method                     | Description                                                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <a href="#">Clone</a>             | Creates a shallow copy of an OracleParameter object                                                                |
| CreateObjRef                      | Inherited from System.MarshalByRefObject                                                                           |
| <a href="#">Dispose</a>           | Releases allocated resources                                                                                       |
| Equals                            | Inherited from System.Object (Overloaded)                                                                          |
| GetHashCode                       | Inherited from System.Object                                                                                       |
| GetLifetimeService                | Inherited from System.MarshalByRefObject                                                                           |
| GetType                           | Inherited from System.Object                                                                                       |
| InitializeLifetimeService         | Inherited from System.MarshalByRefObject                                                                           |
| <a href="#">ResetDbType</a>       | Resets the type associated with the parameter so that it can infer its type from the value passed in the parameter |
| <a href="#">ResetOracleDbType</a> | Resets the type associated with the parameter so that it can infer its type from the value passed in the parameter |
| <a href="#">ToString</a>          | Returns the string representation of the current instance                                                          |

## OracleParameter Constructors

OracleParameter constructors instantiate new instances of the OracleParameter class.

**Overload List:**

- [OracleParameter\(\)](#)  
This constructor instantiates a new instance of OracleParameter class.
- [OracleParameter\(string, OracleDbType\)](#)  
This constructor instantiates a new instance of OracleParameter class using the supplied parameter name and Oracle data type.
- [OracleParameter\(string, object\)](#)  
This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name and parameter value.
- [OracleParameter\(string, OracleDbType, ParameterDirection\)](#)  
This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, and parameter direction.
- [OracleParameter\(string, OracleDbType, object, ParameterDirection\)](#)  
This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, value, and direction.

- [OracleParameter\(string, OracleDbType, int\)](#)

This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, and size.

- [OracleParameter\(string, OracleDbType, int, string\)](#)

This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, size, and source column.

- [OracleParameter\(string, OracleDbType, int, ParameterDirection, bool, byte, byte, string, DataRowVersion, object\)](#)

This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, size, direction, null indicator, precision, scale, source column, source version and parameter value.

- [OracleParameter\(string, OracleDbType, int, object, ParameterDirection\)](#)

This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, size, value, and direction.

## OracleParameter()

This constructor instantiates a new instance of OracleParameter class.

### Declaration

```
// C#  
public OracleParameter();
```

### Remarks

#### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string
- ParameterName - Empty string
- Precision - 0
- Size - 0
- SourceColumn - Empty string

- SourceVersion - Current
- ArrayBindStatus - Success
- Value - null

#### See Also

## OracleParameter(string, OracleDbType)

This constructor instantiates a new instance of OracleParameter class using the supplied parameter name and Oracle data type.

### Declaration

```
// C#  
public OracleParameter(string parameterName, OracleDbType oraType);
```

### Parameters

- *parameterName*  
The parameter name.
- *oraType*  
The data type of the OracleParameter.

### Remarks

Changing the DbType implicitly changes the OracleDbType.

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string
- ParameterName - Empty string
- Precision - 0
- Size - 0

- SourceColumn - Empty string
- SourceVersion - Current
- ArrayBindStatus - Success
- Value - null

## OracleParameter(string, object)

This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name and parameter value.

### Declaration

```
// C#  
public OracleParameter(string parameterName, object obj);
```

### Parameters

- *parameterName*  
The parameter name.
- *obj*  
The value of the OracleParameter.

### Remarks

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string
- ParameterName - Empty string
- Precision - 0
- Size - 0

- SourceColumn - Empty string
- SourceVersion - Current
- ArrayBindStatus - Success
- Value - null

## OracleParameter(string, OracleDbType, ParameterDirection)

This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, and parameter direction.

### Declaration

```
// C#  
public OracleParameter(string parameterName, OracleDbType type,  
    ParameterDirection direction);
```

### Parameters

- *parameterName*  
The parameter name.
- *type*  
The data type of the OracleParameter.
- *direction*  
The direction of the OracleParameter.

### Remarks

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string

- `ParameterName` - Empty string
- `Precision` - 0
- `Size` - 0
- `SourceColumn` - Empty string
- `SourceVersion` - Current
- `ArrayBindStatus` - Success
- `Value` - null

## OracleParameter(string, OracleDbType, object, ParameterDirection)

This constructor instantiates a new instance of the `OracleParameter` class using the supplied parameter name, data type, value, and direction.

### Declaration

```
// C#
public OracleParameter(string parameterName, OracleDbType type, object obj,
    ParameterDirection direction);
```

### Parameters

- *parameterName*  
The parameter name.
- *type*  
The data type of the `OracleParameter`.
- *obj*  
The value of the `OracleParameter`.
- *direction*  
The `ParameterDirection` value.

### Remarks

Changing the `DbType` implicitly changes the `OracleDbType`.

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string
- ParameterName - Empty string
- Precision - 0
- Size - 0
- SourceColumn - Empty string
- SourceVersion - Current
- ArrayBindStatus - Success
- Value - null

## OracleParameter(string, OracleDbType, int)

This constructor instantiates a new instance of the `OracleParameter` class using the supplied parameter name, data type, and size.

### Declaration

```
// C#  
public OracleParameter(string parameterName, OracleDbType type,  
    int size);
```

### Parameters

- *parameterName*  
The parameter name.
- *type*  
The data type of the `OracleParameter`.
- *size*  
The size of the `OracleParameter` value.

### Remarks

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string
- ParameterName - Empty string
- Precision - 0
- Size - 0
- SourceColumn - Empty string
- SourceVersion - Current
- ArrayBindStatus - Success
- Value - null

## OracleParameter(string, OracleDbType, int, string)

This constructor instantiates a new instance of the OracleParameter class using the supplied parameter name, data type, size, and source column.

### Declaration

```
// C#  
public OracleParameter(string parameterName, OracleDbType type, int size,  
    string srcColumn);
```

### Parameters

- *parameterName*  
The parameter name.
- *type*

The data type of the `OracleParameter`.

- *size*

The size of the `OracleParameter` value.

- *srcColumn*

The name of the source column.

### Remarks

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- `DbType` - String
- `ParameterDirection` - Input
- `isNullable` - true
- `offset` - 0
- `OracleDbType` - Varchar2
- `ParameterAlias` - Empty string
- `ParameterName` - Empty string
- `Precision` - 0
- `Size` - 0
- `SourceColumn` - Empty string
- `SourceVersion` - Current
- `ArrayBindStatus` - Success
- `Value` - null

### ① See Also

`OracleParameter(string, OracleDbType, int, ParameterDirection, bool, byte, byte, string, DataRowVersion, object)`

This constructor instantiates a new instance of the `OracleParameter` class using the supplied parameter name, data type, size, direction, null indicator, precision, scale, source column, source version and parameter value.

### Declaration

```
// C#
public OracleParameter(string parameterName, OracleDbType oraType,
```

```
int size, ParameterDirection direction, bool isNullable, byte
precision, byte scale, string srcColumn, DataRowVersion srcVersion,
object obj);
```

### Parameters

- *parameterName*  
The parameter name.
- *oraType*  
The data type of the OracleParameter.
- *size*  
The size of the OracleParameter value.
- *direction*  
The ParameterDirection value.
- *isNullable*  
An indicator that specifies if the parameter value can be null.
- *precision*  
The precision of the parameter value.
- *scale*  
The scale of the parameter value.
- *srcColumn*  
The name of the source column.
- *srcVersion*  
The DataRowVersion value.
- *obj*  
The parameter value.

### Exceptions

ArgumentException - The supplied value does not belong to the type of Value property in any of the OracleTypes.

### Remarks

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string
- ParameterName - Empty string

- Precision - 0
- Size - 0
- SourceColumn - Empty string
- SourceVersion - Current
- ArrayBindStatus - Success
- Value - null

## OracleParameter(string, OracleDbType, int, object, ParameterDirection)

This constructor instantiates a new instance of the `OracleParameter` class using the supplied parameter name, data type, size, value, and direction.

### Declaration

```
// C#
public OracleParameter(string parameterName, OracleDbType type, int size,
    object obj, ParameterDirection direction);
```

### Parameters

- *parameterName*  
The parameter name.
- *type*  
The data type of the `OracleParameter`.
- *size*  
The size of the `OracleParameter` value.
- *obj*  
The value of the `OracleParameter`.
- *direction*  
The `ParameterDirection` value.

### Remarks

Changing the `DbType` implicitly changes the `OracleDbType`.

Unless explicitly set in the constructor, all the properties have the default values.

### Default Values:

- DbType - String
- ParameterDirection - Input
- isNullable - true
- offset - 0
- OracleDbType - Varchar2
- ParameterAlias - Empty string
- ParameterName - Empty string
- Precision - 0
- Size - 0
- SourceColumn - Empty string
- SourceVersion - Current
- ArrayBindStatus - Success
- Value - null

## OracleParameter Properties

OracleParameter properties are listed in [Table 6-154](#).

**Table 6-154 OracleParameter Properties**

| Property                                | Description                                                                                                                                                                                                       |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ArrayBindSize</a>           | Specifies the input or output size of elements in Value property of a parameter before or after an Array Bind or PL/SQL Associative Array Bind execution                                                          |
| <a href="#">ArrayBindStatus</a>         | Specifies the input or output status of elements in Value property of a parameter before or after an Array Bind or PL/SQL Associative Array Bind execution                                                        |
| <a href="#">CollectionType</a>          | Specifies whether or not the OracleParameter represents a collection, and if so, specifies the collection type                                                                                                    |
| <a href="#">DbType</a>                  | Specifies the data type of the parameter using the Data.DbType enumeration type                                                                                                                                   |
| <a href="#">Direction</a>               | Specifies whether the parameter is input-only, output-only, bi-directional, or a stored function return value parameter                                                                                           |
| <a href="#">IsNullable</a>              | Not supported                                                                                                                                                                                                     |
| <a href="#">Offset</a>                  | Specifies the offset to the Value property or offset to the elements in the Value property                                                                                                                        |
| <a href="#">OracleDbType</a>            | Specifies the Oracle data type                                                                                                                                                                                    |
| <a href="#">OracleDbTypeEx</a>          | Specifies the Oracle data type to bind the parameter as, but returns a .NET type as output                                                                                                                        |
| <a href="#">ParameterName</a>           | Specifies the name of the parameter                                                                                                                                                                               |
| <a href="#">Precision</a>               | Specifies the maximum number of digits used to represent the Value property                                                                                                                                       |
| <a href="#">Scale</a>                   | Specifies the number of decimal places to which Value property is resolved                                                                                                                                        |
| <a href="#">Size</a>                    | Specifies the maximum size, in bytes or characters, of the data transmitted to or from the database. For PL/SQL Associative Array Bind, Size specifies the maximum number of elements in PL/SQL Associative Array |
| <a href="#">SourceColumn</a>            | Specifies the name of the DataTable Column of the DataSet                                                                                                                                                         |
| <a href="#">SourceColumnNullMapping</a> | Specifies a value which indicates whether the source column is nullable                                                                                                                                           |
| <a href="#">SourceVersion</a>           | Specifies the DataRowVersion value to use when loading the Value property of the parameter                                                                                                                        |
| <a href="#">Status</a>                  | Indicates the status of the execution related to the data in the Value property                                                                                                                                   |
| <a href="#">UdtTypeName</a>             | Specifies the Oracle user-defined type name if the parameter is a user-defined data type                                                                                                                          |
| <a href="#">Value</a>                   | Specifies the value of the Parameter                                                                                                                                                                              |

## ArrayBindSize

This property specifies the maximum size, in bytes or characters, of the data for each array element transmitted to or from the database. This property is used for Array Bind or PL/SQL Associative Array execution.

**Declaration**

```
// C#  
public int[] ArrayBindSize {get; set; }
```

**Property Value**

An array of int values specifying the size.

**Remarks**

Default = null.

This property is only used for variable size element types for an Array Bind or PL/SQL Associative Array. For fixed size element types, this property is ignored.

Each element in the ArrayBindSize corresponds to the bind size of an element in the Value property. Before execution, ArrayBindSize specifies the maximum size of each element to be bound in the Value property. After execution, it contains the size of each element returned in the Value property.

For binding a PL/SQL Associative Array, whose elements are of a variable-length element type, as an InputOutput, Out, or ReturnValue parameter, this property must be set properly. The number of elements in ArrayBindSize must be equal to the value specified in the OracleParameter.Size property.

**Example**

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class ArrayBindSizeSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        OracleParameter[] prm = new OracleParameter[3];
```

```

// Create OracleParameter objects through OracleParameterCollection
OracleCommand cmd = con.CreateCommand();

cmd.CommandText = "select max(empno) from emp";
int maxno = int.Parse(cmd.ExecuteScalar().ToString());

// Set the ArrayBindCount for Array Binding
cmd.ArrayBindCount = 2;

prm[0] = cmd.Parameters.Add("paramEmpno", OracleDbType.Decimal,
    new int[2] {maxno + 10, maxno + 11}, ParameterDirection.Input);
prm[1] = cmd.Parameters.Add("paramEname", OracleDbType.Varchar2,
    new string[2] {"Client1xxx", "Client2xxx"}, ParameterDirection.Input);
prm[2] = cmd.Parameters.Add("paramDeptNo", OracleDbType.Decimal,
    new int[2] {10, 10}, ParameterDirection.Input);

// Set the ArrayBindSize for prm[1]
// These sizes indicate the maximum size of the elements in Value property
prm[1].ArrayBindSize = new int[2];
prm[1].ArrayBindSize[0] = 7; // Set ename = "Client1"
prm[1].ArrayBindSize[1] = 7; // Set ename = "Client2"

cmd.CommandText =
    "insert into emp(empno, ename, deptno) values(:1, :2, :3)";

cmd.ExecuteNonQuery();

Console.WriteLine("Record for employee id {0} has been inserted.",
    maxno + 10);
Console.WriteLine("Record for employee id {0} has been inserted.",
    maxno + 11);

prm[0].Dispose();
prm[1].Dispose();
prm[2].Dispose();
cmd.Dispose();

con.Close();
con.Dispose();
}
}

```

## ArrayBindStatus

This property specifies the input or output status of each element in the Value property before or after an Array Bind or PL/SQL Associative Array execution.

**Declaration**

```
// C#  
public OracleParameterStatus[] ArrayBindStatus { get; set; }
```

**Property Value**

An array of OracleParameterStatus enumerated values.

**Exceptions**

ArgumentOutOfRangeException - The Status value specified is invalid.

**Remarks**

Default = null.

ArrayBindStatus is used for Array Bind and PL/SQL Associative Array execution only.

Before execution, ArrayBindStatus indicates the bind status of each element in the Value property. After execution, it contains the execution status of each element in the Value property.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- ["ArrayBindSize "](#)

## CollectionType

This property specifies whether or not the OracleParameter represents a collection, and if so, specifies the collection type.

**Declaration**

```
// C#  
public OracleCollectionType CollectionType { get; set; }
```

**Property Value**

An OracleCollectionType enumerated value.

**Exceptions**

ArgumentException - The OracleCollectionType value specified is invalid.

**Remarks**

Default = `OracleCollectionType.None`. If `OracleParameter` is used to bind a PL/SQL Associative Array, then `CollectionType` must be set to `OracleCollectionType.PLSQLAssociativeArray`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## DbType

This property specifies the data type of the parameter using the `Data.DbType` enumeration type.

**Declaration**

```
// C#  
public override DbType DbType {get; set; }
```

**Property Value**

A `DbType` enumerated value.

**Implements**

`IDataParameter`

**Exceptions**

`ArgumentException` - The `DbType` value specified is invalid.

**Remarks**

Default = `DbType.String`

`DbType` is the data type of each element in the array if the `OracleParameter` object is used for Array Bind or PL/SQL Associative Array Bind execution.

Due to the link between `DbType` and `OracleDbType` properties, if the `DbType` property is set, the `OracleDbType` property is inferred from `DbType`.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)
- ["Inference of OracleDbType from DbType"](#)
- ["CollectionType"](#)

## Direction

This property specifies whether the parameter is input-only, output-only, bi-directional, or a stored function return value parameter.

### Declaration

```
// C#  
public override ParameterDirection Direction { get; set; }
```

### Property Value

A ParameterDirection enumerated value.

### Implements

IDataParameter

### Exceptions

ArgumentOutOfRangeException - The ParameterDirection value specified is invalid.

### Remarks

Default = ParameterDirection.Input

Possible values: Input, InputOutput, Output, and ReturnValue.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## IsNullable

This property is not supported.

### Declaration

```
// C#  
public override bool IsNullable { get; set; }
```

**Implements**

IDataParameter

**Property Value**

This property is not supported.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## Offset

This property specifies the offset to the Value property.

**Declaration**

```
// C#  
public int Offset { get; set; }
```

**Property Value**

An int that specifies the offset.

**Exceptions**

ArgumentOutOfRangeException - The Offset value specified is invalid.

**Remarks**

Default = 0

For Array Bind and PL/SQL Associative Array Bind, Offset applies to every element in the Value property.

The Offset property is used for binary and string data types. The Offset property represents the number of bytes for binary types and the number of characters for strings. The count for strings does not include the terminating character if a null is referenced. The Offset property is used by parameters of the following types:

- OracleDbType.BFile
- OracleDbType.Blob
- OracleDbType.LongRaw
- OracleDbType.Raw
- OracleDbType.Char
- OracleDbType.Clob
- OracleDbType.NClob

- `OracleDbType.NChar`
- `OracleDbType.NVarchar2`
- `OracleDbType.Varchar2`

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## OracleDbType

This property specifies the Oracle data type.

### Declaration

```
// C#  
public OracleDbType OracleDbType { get; set; }
```

### Property Value

An `OracleDbType` enumerated value.

### Remarks

Default = `OracleDbType.Varchar2`

If the `OracleParameter` object is used for Array Bind or PL/SQL Associative Array Bind execution, `OracleDbType` is the data type of each element in the array.

The `OracleDbType` property and `DbType` property are linked. Therefore, setting the `OracleDbType` property changes the `DbType` property to a supporting `DbType`.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)
- ["OracleDbType Enumeration"](#)
- ["Inference of DbType from OracleDbType"](#)
- ["CollectionType"](#)

## OracleDbTypeEx

This property specifies the Oracle data type to bind the parameter as, but returns a .NET type as output.

**Declaration**

```
// C#  
public OracleDbType OracleDbTypeEx { get; set; }
```

**Property Value**

An `OracleDbType` enumerated value.

**Remarks**

This property is used by applications that need to bind a parameter value as an Oracle type, but need a .NET type back for output. This property should be used with an output or input/output parameter. For an input parameter, using `OracleDbTypeEx` has the same affect as using `OracleDbType`. The .NET type that is returned for the output is the .NET type that the Oracle type closely maps to.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)
- ["OracleDbType Enumeration"](#)
- ["OracleDbType "](#)
- ["Inference of DbType from OracleDbType"](#)
- ["CollectionType"](#)

## ParameterName

This property specifies the name of the parameter.

**Declaration**

```
// C#  
public override string ParameterName { get; set; }
```

**Property Value**

String

**Implements**

`IDataParameter`

**Remarks**

Default = null

Oracle supports `ParameterName` up to 30 characters.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## Precision

This property specifies the maximum number of digits used to represent the Value property.

**Declaration**

```
// C#  
Public byte Precision { get; set; }
```

**Property Value**

byte

**Remarks**

Default = 0

The Precision property is used by parameters of type `OracleDbType.Decimal`.

Oracle supports Precision range from 0 to 38.

For Array Bind and PL/SQL Associative Array Bind, Precision applies to each element in the Value property.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)
- ["Value"](#)

## Scale

This property specifies the number of decimal places to which Value property is resolved.

**Declaration**

```
// C#  
public byte Scale { get; set; }
```

**Property Value**

byte

**Remarks**

Default = 0.

Scale is used by parameters of type `OracleDbType.Decimal`.

Oracle supports Scale between -84 and 127.

For Array Bind and PL/SQL Associative Array Bind, Scale applies to each element in the Value property.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)
- ["Value"](#)

## Size

This property specifies the maximum size, in bytes or characters, of the data transmitted to or from the database.

**Declaration**

```
// C#  
public override int Size { get; set;}
```

**Property Value**

int

**Exceptions**

`ArgumentOutOfRangeException` - The Size value specified is invalid.

`InvalidOperationException` - The Size = 0 when the `OracleParameter` object is used to bind a PL/SQL Associative Array.

**Remarks**

If Size is not explicitly set, it is inferred from the actual size of the specified parameter value when binding only for input parameters. Output parameters must have their size defined explicitly.

The default value is 0.

Before execution, this property specifies the maximum size to be bound in the Value property. After execution, it contains the size of the type in the Value property.

Size is used for parameters of the following types:

- `OracleDbType.Blob`
- `OracleDbType.Char`

- `OracleDbType.Clob`
- `OracleDbType.LongRaw`
- `OracleDbType.NChar`
- `OracleDbType.NClob`
- `OracleDbType.NVarchar2`
- `OracleDbType.Raw`
- `OracleDbType.Varchar2`

For the preceding types, the `Size` property describes the maximum amount of data transmitted to or from the database. For character data, `Size` is in number of characters and for binary data, it is in number of bytes.

For fixed length data types, the value of `Size` is ignored.

If the `Size` is not explicitly set, it is inferred from the actual size of the specified parameter value when binding.

#### Note

`Size` does not include the null terminating character for the string data.

If the `OracleParameter` object is used to bind a PL/SQL Associative Array, `Size` specifies the maximum number of elements in the PL/SQL Associative Array. Before the execution, this property specifies the maximum number of elements in the PL/SQL Associative Array. After the execution, it specifies the current number of elements returned in the PL/SQL Associative Array. For `Output` and `InputOutput` parameters and return values, `Size` specifies the maximum number of elements in the PL/SQL Associative Array.

ODP.NET does not support binding an empty PL/SQL Associative Array. Therefore, `Size` cannot be set to 0 when the `OracleParameter` object is used to bind a PL/SQL Associative Array.

#### See Also

- ["ArrayBindStatus"](#)
- ["Value"](#)

## SourceColumn

This property specifies the name of the DataTable Column of the DataSet.

### Declaration

```
// C#  
public override string SourceColumn { get; set; }
```

### Property Value

A string.

### Implements

IDataParameter

### Remarks

Default = empty string

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## SourceColumnNullMapping

This property specifies a value which indicates whether the source column is nullable.

### Declaration

```
// C#  
public bool SourceColumnNullMapping { get; set; }
```

### Property Value

Returns true if the source column can be nullified; otherwise, returns false.

### Remarks

The default value is false.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## SourceVersion

This property specifies the DataRowVersion value to use when loading the Value property of the parameter.

### Declaration

```
// C#  
public override DataRowVersion SourceVersion { get; set; }
```

### Property Value

DataRowVersion

### Implements

IDataParameter

### Exceptions

ArgumentOutOfRangeException - The DataRowVersion value specified is invalid.

### Remarks

Default = DataRowVersion.Current

SourceVersion is used by the OracleDataAdapter.UpdateCommand() during the OracleDataAdapter.Update to determine whether the original or current value is used for a parameter value. This allows primary keys to be updated. This property is ignored by the OracleDataAdapter.InsertCommand() and the OracleDataAdapter.DeleteCommand().

## Status

This property indicates the status of the execution related to the data in the Value property.

### Declaration

```
// C#  
public OracleParameterStatus Status { get; set; }
```

### Property Value

An OracleParameterStatus enumerated value.

### Exceptions

ArgumentOutOfRangeException - The Status value specified is invalid.

### Remarks

Default = `OracleParameterStatus.Success`

Before execution, this property indicates the bind status related to the `Value` property. After execution, it returns the status of the execution.

Status indicates if:

- A NULL is fetched from a column.
- Truncation has occurred during the fetch; then `Value` was not big enough to hold the data.
- A NULL is to be inserted into a database column; then `Value` is ignored, and a NULL is inserted into a database column.

This property is ignored for Array Bind and PL/SQL Associative Array Bind. Instead, `ArrayBindStatus` property is used.

## UdtTypeName

This property specifies the Oracle user-defined type name if the parameter is a user-defined data type.

### Declaration

```
// C#  
public string UdtTypeName {get; set;}
```

### Property Value

Name of the Oracle UDT.

### Remarks

The `UdtTypeName` property corresponds to the user-defined type name of the parameter. This property must always be specified if the parameter is a user-defined type. Note that when a custom object is provided as an input parameter value, it is converted to the Oracle UDT that is specified by the custom type mapping on the connection used to execute the command. The Oracle UDT specified by the custom type mapping and by the `OracleParameter.UdtTypeName` property differs if the application binds a custom object that represents a subtype of the parameter type.

## Value

This property specifies the value of the Parameter.

**Declaration**

```
// C#  
public override object Value { get; set; }
```

**Property Value**

An object.

**Implements**

IDataParameter

**Exceptions**

ArgumentException - The Value property specified is invalid.

InvalidArgumentException- The Value property specified is invalid.

**Remarks**

Default = null

If the OracleParameter object is used for Array Bind or PL/SQL Associative Array, Value is an array of parameter values.

The Value property can be overwritten by OracleDataAdapter.Update().

The provider attempts to convert any type of value if it supports the IConvertible interface. Conversion errors occur if the specified type is not compatible with the value.

When sending a null parameter value to the database, the user must specify DBNull, not null. The null value in the system is an empty object that has no value. DBNull is used to represent null values. The user can also specify a null value by setting Status to OracleParameterStatus.NullValue. In this case, the provider sends a null value to the database.

If neither OracleDbType nor DbType are set, their values can be inferred by Value. Please see the following for related information:

- Tables in section "[Inference of DbType and OracleDbType from Value](#)"
- "[ArrayBindCount](#) "
- "[ArrayBindSize](#) "
- "[ArrayBindStatus](#) "

- ["OracleDbType Enumeration"](#)

For input parameters the value is:

- Bound to the `OracleCommand` that is sent to the database.
- Converted to the data type specified in `OracleDbType` or `DbType` when the provider sends the data to the database.

For output parameters the value is:

- Set on completion of the `OracleCommand` (true for return value parameters also).
- Set to the data from the database, to the data type specified in `OracleDbType` or `DbType`.

When array binding is used with:

- Input parameter - Value should be set to an array of values. `OracleCommand.ArrayBindCount` should be set to a value that is greater than zero to indicate the number of elements to be bound.  
  
The number of elements in the array should be equal to the `OracleCommand.ArrayBindCount` property; otherwise, their minimum value is used to bind the elements in the array.
- Output parameter - `OracleCommand.ArrayBindCount` should be set to a value that is greater than zero to indicate the number of elements to be retrieved (for SELECT statements).

When PL/SQL Associative Array binding is used with:

- Input parameter – Value should be set to an array of values. `CollectionType` should be set to `OracleCollection.PLSQLAssociativeArray`. `Size` should be set to specify the possible maximum number of array elements in the PL/SQL Associative Array. If `Size` is smaller than the number of elements in `Value`, then `Size` specifies the number of elements in the `Value` property to be bound.
- Output parameter - `CollectionType` should be set to `OracleCollection.PLSQLAssociativeArray`. `Size` should be set to specify the maximum number of array elements in PL/SQL Associative Array.

Each parameter should have a value. To bind a parameter with a null value, set `Value` to `DBNull.Value`, or set `Status` to `OracleParameterStatus.NullInsert`.

If the data type specified is `OracleDbType.Decimal`, precision is not set or set to 0, and `OracleConfiguration` or `OracleConnection.SuppressGetDecimalInvalidCastException` is set to true, then a rounded-off 28 or 29 precision Oracle NUMBER value is return that can be represented as a .NET Decimal.

For vectors, if `OracleParameter.Value` is a .NET numeric type, then ODP.NET converts the value to the numeric format specified in the bind type (`OracleDbType.Vector*`) in `OracleParameter` unless it is a BINARY vector. In the BINARY case, the parameter values must be a .NET byte[] or string type, such as .NET string or `OracleString`.

OracleParameter Public Methods

OracleParameter public methods are listed in [Table 6-155](#).

Table 6-155 OracleParameter Public Methods

| Public Method                     | Description                                                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <a href="#">Clone</a>             | Creates a shallow copy of an OracleParameter object                                                                |
| CreateObjRef                      | Inherited from System.MarshalByRefObject                                                                           |
| <a href="#">Dispose</a>           | Releases allocated resources                                                                                       |
| Equals                            | Inherited from System.Object (Overloaded)                                                                          |
| GetHashCode                       | Inherited from System.Object                                                                                       |
| GetLifetimeService                | Inherited from System.MarshalByRefObject                                                                           |
| GetType                           | Inherited from System.Object                                                                                       |
| InitializeLifetimeService         | Inherited from System.MarshalByRefObject                                                                           |
| <a href="#">ResetDbType</a>       | Resets the type associated with the parameter so that it can infer its type from the value passed in the parameter |
| <a href="#">ResetOracleDbType</a> | Resets the type associated with the parameter so that it can infer its type from the value passed in the parameter |
| <a href="#">ToString</a>          | Returns the string representation of the current instance                                                          |

Clone

This method creates a shallow copy of an OracleParameter object.

**Declaration**

```
// C#  
public object Clone();
```

**Return Value**

An OracleParameter object.

**Implements**

ICloneable

**Remarks**

The cloned object has the same property values as that of the object being cloned.

**Example**

```
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class CloneSample  
{  
    static void Main()  
    {  
        OracleParameter prm1 = new OracleParameter();  
  
        // Prints "prm1.ParameterName = "  
        Console.WriteLine("prm1.ParameterName = " + prm1.ParameterName);  
  
        // Set the ParameterName before cloning  
        prm1.ParameterName = "MyParam";  
  
        // Clone the OracleParameter  
        OracleParameter prm2 = (OracleParameter) prm1.Clone();  
  
        // Prints "prm2.ParameterName = MyParam"  
        Console.WriteLine("prm2.ParameterName = " + prm2.ParameterName);  
  
        prm1.Dispose();  
        prm2.Dispose();  
    }  
}
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## Dispose

This method releases resources allocated for an OracleParameter object.

### Declaration

```
// C#  
public void Dispose();
```

### Implements

IDisposable

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## ResetDbType

This method resets the type associated with the parameter so that it can infer its type from the value passed in the parameter.

### Declaration

```
// C#  
public override void ResetDbType();
```

### Remarks

If an application does not set the DbType or OracleDbType properties of an OracleParameter object, then these values are inferred from the value set by the application to that OracleParameter object. Calling ResetDbType method resets these properties so that OracleParameter can again infer its type from the value passed into the OracleParameter. Calling this method affects both the DbType and OracleDbType properties of the OracleParameter object.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## ResetOracleDbType

This method resets the type associated with the parameter so that it can infer its type from the value passed in the parameter.

**Declaration**

```
// C#  
public override void ResetOracleDbType();
```

**Remarks**

If an application does not set the `DbType` or `OracleDbType` properties of an `OracleParameter` object, then these values are inferred from the value set by the application to that `OracleParameter` object. Calling the `ResetOracleDbType` method resets these properties so that `OracleParameter` can again infer its type from the value passed into the `OracleParameter`. Calling this method affects both the `DbType` and `OracleDbType` properties of the `OracleParameter` object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## ToString

Overrides `Object`

This method returns the string representation of the current instance.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

Returns the `OracleParameter` value in a string representation.

**Remarks**

If the current instance has a null value, the returned string is null.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameter Class](#)
- [OracleParameter Members](#)

## OracleParameterCollection Class

An `OracleParameterCollection` class represents a collection of all parameters relevant to an `OracleCommand` object and their mappings to `DataSet` columns.

Class Inheritance

System.Object  
    System.MarshalByRefObject  
        System.Data.Common.DbParameterCollection  
            Oracle.DataAccess.Client.OracleParameterCollection

Declaration

```
// C#
public sealed class OracleParameterCollection : DbParameterCollection,
    IDataParameterCollection, IList, ICollection, IEnumerable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

The position of an OracleParameter added into the OracleParameterCollection is the binding position in the SQL statement. Position is 0-based and is used only for positional binding. If named binding is used, the position of an OracleParameter in the OracleParameterCollection is ignored.

Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleParameterCollectionSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleParameter[] prm = new OracleParameter[3];
```

```
// Create OracleParameter objects through OracleParameterCollection
OracleCommand cmd = con.CreateCommand();

cmd.CommandText = "select max(empno) from emp";
int maxno = int.Parse(cmd.ExecuteScalar().ToString());

prm[0] = cmd.Parameters.Add("paramEmpno", OracleDbType.Decimal,
    maxno + 10, ParameterDirection.Input);
prm[1] = cmd.Parameters.Add("paramEname", OracleDbType.Varchar2,
    "Client", ParameterDirection.Input);
prm[2] = cmd.Parameters.Add("paramDeptNo", OracleDbType.Decimal,
    10, ParameterDirection.Input);
cmd.CommandText =
    "insert into emp(empno, ename, deptno) values(:1, :2, :3)";
cmd.ExecuteNonQuery();

Console.WriteLine("Record for employee id {0} has been inserted.",
    maxno + 10);

// Remove all parameters from OracleParameterCollection
cmd.Parameters.Clear();

prm[0].Dispose();
prm[1].Dispose();
prm[2].Dispose();
cmd.Dispose();

con.Close();
con.Dispose();
}
}
```

## OracleParameterCollection Members

OracleParameterCollection members are listed in the following tables.

### OracleParameterCollection Static Methods

OracleParameterCollection static methods are listed in [Table 6-156](#).

**Table 6-156 OracleParameterCollection Static Methods**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

**OracleParameterCollection Properties**

OracleParameterCollection properties are listed in [Table 6-157](#).

**Table 6-157 OracleParameterCollection Properties**

| Property                       | Description                                                                            |
|--------------------------------|----------------------------------------------------------------------------------------|
| <a href="#">Count</a>          | Specifies the number of OracleParameters in the collection                             |
| <a href="#">Item</a>           | Gets and sets the OracleParameter object (Overloaded)                                  |
| <a href="#">IsFixedSize</a>    | Gets a value that indicates whether the OracleParameterCollection has a fixed size     |
| <a href="#">IsReadOnly</a>     | Gets a value that indicates whether the OracleParameterCollection is read-only         |
| <a href="#">IsSynchronized</a> | Gets a value that indicates whether the OracleParameterCollection is synchronized.     |
| <a href="#">SyncRoot</a>       | Gets an object that can be used to synchronize access to the OracleParameterCollection |

**OracleParameterCollection Public Methods**

OracleParameterCollection public methods are listed in [Table 6-158](#).

**Table 6-158 OracleParameterCollection Public Methods**

| Public Method                 | Description                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>           | Adds objects to the collection (Overloaded)                                                                |
| <a href="#">AddRange</a>      | Adds elements to the end of the OracleParameterCollection                                                  |
| <a href="#">Clear</a>         | Removes all the OracleParameter objects from the collection                                                |
| <a href="#">Contains</a>      | Indicates whether or not objects exist in the collection (Overloaded)                                      |
| <a href="#">CopyTo</a>        | Copies OracleParameter objects from the collection, starting with the supplied index to the supplied array |
| CreateObjRef                  | Inherited from System.MarshalByRefObject                                                                   |
| Equals                        | Inherited from System.Object (Overloaded)                                                                  |
| <a href="#">GetEnumerator</a> | Returns an enumerator that iterates through the OracleParameterCollection                                  |
| GetHashCode                   | Inherited from System.Object                                                                               |
| GetLifetimeService            | Inherited from System.MarshalByRefObject                                                                   |
| GetType                       | Inherited from System.Object                                                                               |
| InitializeLifetimeService     | Inherited from System.MarshalByRefObject                                                                   |
| <a href="#">IndexOf</a>       | Returns the index of the objects in the collection (Overloaded)                                            |
| <a href="#">Insert</a>        | Inserts the supplied OracleParameter to the collection at the specified index                              |

**Table 6-158 (Cont.) OracleParameterCollection Public Methods**

| Public Method            | Description                                                  |
|--------------------------|--------------------------------------------------------------|
| <a href="#">Remove</a>   | Removes objects from the collection                          |
| <a href="#">RemoveAt</a> | Removes objects from the collection by location (Overloaded) |
| ToString                 | Inherited from System.Object                                 |

- [OracleParameterCollection Members](#)

Count

This property specifies the number of OracleParameter objects in the collection.

Declaration

```
// C#
public override int Count {get;}
```

Property Value

The number of OracleParameter objects.

Implements

ICollection

Remarks

Default = 0

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

Item

Item gets and sets the OracleParameter object.

**Overload List:**

- [Item\[int\]](#)  
This property gets and sets the OracleParameter object at the index specified by the supplied parameterIndex.
- [Item\[string\]](#)  
This property gets and sets the OracleParameter object using the parameter name specified by the supplied parameterName.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

**Item[int]**

This property gets and sets the OracleParameter object at the index specified by the supplied parameterIndex.

**Declaration**

```
// C#  
public object Item[int parameterIndex] {get; set;}
```

**Property Value**

An object.

**Implements**

IList

**Exceptions**

IndexOutOfRangeException - The supplied index does not exist.

**Remarks**

The OracleParameterCollection class is a zero-based index.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Item[string]

This property gets and sets the `OracleParameter` object using the parameter name specified by the supplied `parameterName`.

### Declaration

```
// C#  
public OracleParameter Item[string parameterName] {get; set;};
```

### Property Value

An `OracleParameter`.

### Implements

`IDataParameterCollection`

### Exceptions

`IndexOutOfRangeException` - The supplied parameter name does not exist.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## IsFixedSize

`IsFixedSize` gets a value that indicates whether the `OracleParameterCollection` has a fixed size.

### Declaration

```
// C#  
public override bool IsFixedSize { get; };
```

### Property Value

Returns true if the `OracleParameterCollection` has a fixed size; otherwise false.

### Implements

`IList`

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## IsReadOnly

IsReadOnly gets a value that indicates whether the OracleParameterCollection is read-only.

**Declaration**

```
// C#  
public override bool IsReadOnly { get; };
```

**Property Value**

Returns true if the OracleParameterCollection is read only; otherwise false.

**Implements**

ICollection

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## IsSynchronized

IsSynchronized gets a value that indicates whether the OracleParameterCollection is synchronized.

**Declaration**

```
// C#  
public override bool IsSynchronized { get; };
```

**Property Value**

Returns true if the OracleParameterCollection is synchronized; otherwise false.

**Implements**

ICollection

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

SyncRoot

SyncRoot gets an object that can be used to synchronize access to the OracleParameterCollection.

Declaration

```
// C#
public override Object SyncRoot { get; };
```

Property Value

An object that can be used to synchronize access to the OracleParameterCollection.

Implements

ICollection

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

OracleParameterCollection Public Methods

OracleParameterCollection public methods are listed in [Table 6-161](#).

Table 6-161 OracleParameterCollection Public Methods

| Public Method            | Description                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>      | Adds objects to the collection (Overloaded)                                                                |
| <a href="#">AddRange</a> | Adds elements to the end of the OracleParameterCollection                                                  |
| <a href="#">Clear</a>    | Removes all the OracleParameter objects from the collection                                                |
| <a href="#">Contains</a> | Indicates whether or not objects exist in the collection (Overloaded)                                      |
| <a href="#">CopyTo</a>   | Copies OracleParameter objects from the collection, starting with the supplied index to the supplied array |

**Table 6-161 (Cont.) OracleParameterCollection Public Methods**

| Public Method                 | Description                                                                   |
|-------------------------------|-------------------------------------------------------------------------------|
| CreateObjRef                  | Inherited from System.MarshalByRefObject                                      |
| Equals                        | Inherited from System.Object (Overloaded)                                     |
| <a href="#">GetEnumerator</a> | Returns an enumerator that iterates through the OracleParameterCollection     |
| GetHashCode                   | Inherited from System.Object                                                  |
| GetLifetimeService            | Inherited from System.MarshalByRefObject                                      |
| GetType                       | Inherited from System.Object                                                  |
| InitializeLifetimeService     | Inherited from System.MarshalByRefObject                                      |
| <a href="#">IndexOf</a>       | Returns the index of the objects in the collection (Overloaded)               |
| <a href="#">Insert</a>        | Inserts the supplied OracleParameter to the collection at the specified index |
| <a href="#">Remove</a>        | Removes objects from the collection                                           |
| <a href="#">RemoveAt</a>      | Removes objects from the collection by location (Overloaded)                  |
| ToString                      | Inherited from System.Object                                                  |

## Add

Add adds objects to the collection.

**Overload List:**

- [Add\(object\)](#)  
This method adds the supplied object to the collection.
- [Add\(OracleParameter\)](#)  
This method adds the supplied OracleParameter object to the collection.
- [Add\(string, object\)](#)  
This method adds an OracleParameter object to the collection using the supplied name and object value.
- [Add\(string, OracleDbType\)](#)  
This method adds an OracleParameter object to the collection using the supplied name and database type.

- [Add\(string, OracleDbType, ParameterDirection\)](#)  
This method adds an `OracleParameter` object to the collection using the supplied name, database type, and direction.
- [Add\(string, OracleDbType, object, ParameterDirection\)](#)  
This method adds an `OracleParameter` object to the collection using the supplied name, database type, parameter value, and direction.
- [Add\(string, OracleDbType, int, object, ParameterDirection\)](#)  
This method adds an `OracleParameter` object to the collection using the supplied name, database type, size, parameter value, and direction.
- [Add\(string, OracleDbType, int\)](#)  
This method adds an `OracleParameter` object to the collection using the supplied name, database type, and size.
- [Add \(string, OracleDbType, int, string\)](#)  
This method adds an `OracleParameter` object to the collection using the supplied name, database type, size, and source column.
- [Add\(string, OracleDbType, int, ParameterDirection, bool, byte, byte, string, DataRowVersion, object\)](#)  
This method adds an `OracleParameter` object to the collection using the supplied name, database type, size, direction, null indicator, precision, scale, source column, source version, and parameter value.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Add(object)

This method adds the supplied object to the collection.

### Declaration

```
// C#  
public override int Add(object obj);
```

### Parameters

- *obj*  
The supplied object.

### Return Value

The index at which the new `OracleParameter` is added.

**Implements**

IList

**Remarks**

InvalidCastException - The supplied *obj* cannot be cast to an OracleParameter object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Add(OracleParameter)

This method adds the supplied OracleParameter object to the collection.

**Declaration**

```
// C#  
public OracleParameter Add(OracleParameter paramObj);
```

**Parameters**

- *paramObj*  
The supplied OracleParameter object.

**Return Value**

The newly created OracleParameter object which was added to the collection.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Add(string, object)

This method adds an OracleParameter object to the collection using the supplied name and object value

**Declaration**

```
// C#  
public OracleParameter Add(string name, object val);
```

**Parameters**

- *name*  
The parameter name.
- *val*  
The OracleParameter value.

**Return Value**

The newly created OracleParameter object which was added to the collection.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Add(string, OracleDbType)

This method adds an OracleParameter object to the collection using the supplied name and database type.

**Declaration**

```
// C#  
public OracleParameter Add(string name, OracleDbType dbType);
```

**Parameters**

- *name*  
The parameter name.
- *dbType*  
The data type of the OracleParameter.

**Return Value**

The newly created OracleParameter object which was added to the collection.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Add(string, OracleDbType, ParameterDirection)

This method adds an `OracleParameter` object to the collection using the supplied name, database type, and direction.

### Declaration

```
// C#  
public OracleParameter Add(string name, OracleDbType dbType,  
    ParameterDirection direction);
```

### Parameters

- *name*  
The parameter name.
- *dbType*  
The data type of the `OracleParameter`.
- *direction*  
The `OracleParameter` direction.

### Return Value

The newly created `OracleParameter` object which was added to the collection.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)
- ["OracleDbType Enumeration"](#)

## Add(string, OracleDbType, object, ParameterDirection)

This method adds an `OracleParameter` object to the collection using the supplied name, database type, parameter value, and direction.

### Declaration

```
// C#  
public OracleParameter Add(string name, OracleDbType dbType, object val,  
    ParameterDirection dir);
```

### Parameters

- *name*  
The parameter name.
- *dbType*  
The data type of the `OracleParameter`.

- *val*  
The OracleParameter value.
- *dir*  
The ParameterDirection value.

### Return Value

The newly created OracleParameter object which was added to the collection.

### Example

```
// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class AddSample
{
    static void Main()
    {
        OracleCommand cmd = new OracleCommand();

        // Add parameter to the OracleParameterCollection
        OracleParameter prm = cmd.Parameters.Add(
            "MyParam", OracleDbType.Decimal, 1, ParameterDirection.Input);

        // Prints "cmd.Parameters.Count = 1"
        Console.WriteLine("cmd.Parameters.Count = " + cmd.Parameters.Count);

        prm.Dispose();
        cmd.Dispose();
    }
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)
- ["OracleDbType Enumeration"](#)

## Add(string, OracleDbType, int, object, ParameterDirection)

This method adds an OracleParameter object to the collection using the supplied name, database type, size, parameter value, and direction.

### Declaration

```
// C#
public OracleParameter Add(string name, OracleDbType dbType, int size,
    object val, ParameterDirection dir;
```

### Parameters

- *name*  
The parameter name.
- *dbType*  
The data type of the OracleParameter.
- *size*  
The size of OracleParameter.
- *val*  
The OracleParameter value.
- *dir*  
The ParameterDirection value.

### Return Value

The newly created OracleParameter object which was added to the collection.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)
- ["OracleDbType Enumeration"](#)

## Add(string, OracleDbType, int)

This method adds an OracleParameter object to the collection using the supplied name, database type, and size.

### Declaration

```
// C#  
public OracleParameter Add(string name, OracleDbType dbType, int size);
```

### Parameters

- *name*  
The parameter name.
- *dbType*  
The data type of the OracleParameter.
- *size*  
The size of OracleParameter.

### Return Value

The newly created OracleParameter object which was added to the collection.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;

class AddSample
{
    static void Main()
    {
        OracleCommand cmd = new OracleCommand();

        // Add parameter to the OracleParameterCollection
        OracleParameter prm = cmd.Parameters.Add(
            "MyParam", OracleDbType.Varchar2, 10);

        // Prints "cmd.Parameters.Count = 1"
        Console.WriteLine("cmd.Parameters.Count = " + cmd.Parameters.Count);

        prm.Dispose();
        cmd.Dispose();
    }
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Add (string, OracleDbType, int, string)

This method adds an OracleParameter object to the collection using the supplied name, database type, size, and source column.

### Declaration

```
// C#
public OracleParameter Add(string name, OracleDbType dbType, int size,
    string srcColumn);
```

### Parameters

- *name*  
The parameter name.
- *dbType*  
The data type of the OracleParameter.
- *size*

The size of `OracleParameter`.

- *srcColumn*

The name of the source column.

### Return Value

An `OracleParameter`.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Add(string, OracleDbType, int, ParameterDirection, bool, byte, byte, string, DataRowVersion, object)

This method adds an `OracleParameter` object to the collection using the supplied name, database type, size, direction, null indicator, precision, scale, source column, source version, and parameter value.

### Declaration

```
// C#
public OracleParameter Add(string name, OracleDbType dbType, int size,
    ParameterDirection dir, bool isNullable, byte precision,
    byte scale, string srcColumn, DataRowVersion version, object val);
```

### Parameters

- *name*  
The parameter name.
- *dbType*  
The data type of the `OracleParameter`.
- *size*  
The size of `OracleParameter`.
- *dir*  
The `ParameterDirection` value.
- *isNullable*  
An indicator that specifies if the parameter value can be null.
- *precision*  
The precision of the parameter value.
- *scale*  
The scale of the parameter value.

- *srcColumn*  
The name of the source column.
- *version*  
The DataRowVersion value.
- *val*  
The parameter value.

**Return Value**

The newly created OracleParameter object which was added to the collection.

**Exceptions**

ArgumentException - The type of supplied *val* does not belong to the type of Value property in any of the ODP.NET Types.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## AddRange

This method adds elements to the end of the OracleParameterCollection.

**Declaration**

```
// C#  
public override void AddRange(Array paramArray );
```

**Parameters**

*paramArray*

An array of OracleParameter objects.

**Exceptions**

ArgumentNullException - The input parameter is null.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Clear

This method removes all the OracleParameter objects from the collection.

### Declaration

```
// C#  
public override void Clear();
```

### Implements

ICollection

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class ClearSample  
{  
    static void Main()  
    {  
        OracleCommand cmd = new OracleCommand();  
  
        // Add parameter to the OracleParameterCollection  
        OracleParameter prm = cmd.Parameters.Add("MyParam", OracleDbType.Decimal);  
  
        // Prints "cmd.Parameters.Count = 1"  
        Console.WriteLine("cmd.Parameters.Count = " + cmd.Parameters.Count);  
  
        // Clear all parameters in the OracleParameterCollection  
        cmd.Parameters.Clear();  
  
        // Prints "cmd.Parameters.Count = 0"  
        Console.WriteLine("cmd.Parameters.Count = " + cmd.Parameters.Count);  
  
        prm.Dispose();  
        cmd.Dispose();  
    }  
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Contains

Contains indicates whether or not the supplied object exists in the collection.

**Overload List:**

- [Contains\(object\)](#)  
This method indicates whether or not the supplied object exists in the collection.
- [Contains\(string\)](#)  
This method indicates whether or not an OracleParameter object exists in the collection using the supplied string.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Contains(object)

This method indicates whether or not the supplied object exists in the collection.

**Declaration**

```
// C#  
public override bool Contains(object obj)
```

**Parameters**

- *obj*  
The object.

**Return Value**

A bool that indicates whether or not the OracleParameter specified is inside the collection.

**Implements**

ICollection

**Exceptions**

InvalidCastException - The supplied *obj* is not an OracleParameter object.

**Remarks**

Returns true if the collection contains the OracleParameter object; otherwise, returns false.

**Example**

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class ContainsSample  
{
```

```
static void Main()
{
    OracleCommand cmd = new OracleCommand();

    // Add parameter to the OracleParameterCollection
    OracleParameter prm1 = cmd.Parameters.Add("MyParam", OracleDbType.Decimal);

    // Check if the OracleParameterCollection contains prm1
    bool bContains = cmd.Parameters.Contains(prm1);

    // Prints "bContains = True"
    Console.WriteLine("bContains = " + bContains);

    OracleParameter prm2 = new OracleParameter();

    // Check if the OracleParameterCollection contains prm2
    bContains = cmd.Parameters.Contains(prm2);

    // Prints "bContains = False"
    Console.WriteLine("bContains = " + bContains);

    prm1.Dispose();
    prm2.Dispose();
    cmd.Dispose();
}
}
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Contains(string)

This method indicates whether or not an `OracleParameter` object exists in the collection using the supplied string.

### Declaration

```
// C#
public override bool Contains(string name);
```

### Parameters

- *name*  
The name of `OracleParameter` object.

### Return Value

Returns `true` if the collection contains the `OracleParameter` object with the specified parameter name; otherwise, returns `false`.

### Implements

`IDataParameterCollection`

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;

class ContainsSample
{
    static void Main()
    {
        OracleCommand cmd = new OracleCommand();

        // Add parameter to the OracleParameterCollection
        OracleParameter prm = cmd.Parameters.Add("MyParam", OracleDbType.Decimal);

        // Check if the OracleParameterCollection contains "MyParam"
        bool bContains = cmd.Parameters.Contains("MyParam");

        // Prints "bContains = True"
        Console.WriteLine("bContains = " + bContains);

        // Check if the OracleParameterCollection contains "NoParam"
        bContains = cmd.Parameters.Contains("NoParam");

        // Prints "bContains = False"
        Console.WriteLine("bContains = " + bContains);

        prm.Dispose();
        cmd.Dispose();
    }
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## CopyTo

This method copies `OracleParameter` objects from the collection, starting with the supplied index to the supplied array.

### Declaration

```
// C#
public override void CopyTo(Array array, int index);
```

### Parameters

- *array*  
The specified array.
- *index*

The array index.

### Implements

ICollection

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## GetEnumerator

GetEnumerator returns an enumerator that iterates through the OracleParameterCollection.

### Declaration

```
// C#  
public override IEnumerator GetEnumerator();
```

### Implements

IEnumerable

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## IndexOf

IndexOf returns the index of the OracleParameter object in the collection.

### Overload List:

- [IndexOf\(object\)](#)

This method returns the index of the OracleParameter object in the collection.

- [IndexOf\(String\)](#)

This method returns the index of the OracleParameter object with the specified name in the collection.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## IndexOf(object)

This method returns the index of the `OracleParameter` object in the collection.

**Declaration**

```
// C#  
public override int IndexOf(object obj);
```

**Parameters**

- *obj*

The specified object.

**Return Value**

Returns the index of the `OracleParameter` object in the collection.

**Implements**

`IList`

**Exceptions**

`InvalidCastException` - The supplied *obj* cannot be cast to an `OracleParameter` object.

**Remarks**

Returns the index of the supplied `OracleParameter` *obj* in the collection.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## IndexOf(String)

This method returns the index of the `OracleParameter` object with the specified name in the collection.

**Declaration**

```
// C#  
public override int IndexOf(String name);
```

**Parameters**

- *name*

The name of parameter.

**Return Value**

Returns the index of the supplied `OracleParameter` in the collection.

**Implements**

`IDataParameterCollection`

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Insert

This method inserts the supplied `OracleParameter` object to the collection at the specified index.

**Declaration**

```
// C#  
public override void Insert(int index, object obj);
```

**Parameters**

- *index*

The specified index.

- *obj*

The `OracleParameter` object.

**Implements**

`IList`

**Remarks**

An `InvalidCastException` is thrown if the supplied *obj* cannot be cast to an `OracleParameter` object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## Remove

This method removes the supplied `OracleParameter` from the collection.

### Declaration

```
// C#  
public override void Remove(object obj);
```

### Parameters

- *obj*  
The specified object to remove.

### Implements

`IList`

### Exceptions

`InvalidCastException` - The supplied *obj* cannot be cast to an `OracleParameter` object.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class RemoveSample  
{  
    static void Main()  
    {  
        OracleCommand cmd = new OracleCommand();  
  
        // Add 2 parameters to the OracleParameterCollection  
        OracleParameter prm1 = cmd.Parameters.Add("MyParam1", OracleDbType.Decimal);  
        OracleParameter prm2 = cmd.Parameters.Add("MyParam2", OracleDbType.Decimal);  
  
        // Prints "cmd.Parameters.Count = 2"  
        Console.WriteLine("cmd.Parameters.Count = " + cmd.Parameters.Count);  
  
        // Remove the 1st parameter from the OracleParameterCollection  
        cmd.Parameters.Remove(prm1);  
  
        // Prints "cmd.Parameters.Count = 1"  
        Console.WriteLine("cmd.Parameters.Count = " + cmd.Parameters.Count);  
  
        // Prints "cmd.Parameters[0].ParameterName = MyParam2"  
        Console.WriteLine("cmd.Parameters[0].ParameterName = " +
```

```
        cmd.Parameters[0].ParameterName);  
  
        prm1.Dispose();  
        prm2.Dispose();  
        cmd.Dispose();  
    }  
}
```

## RemoveAt

RemoveAt removes the OracleParameter object from the collection by location.

#### Overload List:

- [RemoveAt\(int\)](#)

This method removes from the collection the OracleParameter object located at the index specified by the supplied index.

- [RemoveAt\(String\)](#)

This method removes from the collection the OracleParameter object specified by the supplied name.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## RemoveAt(int)

This method removes from the collection the OracleParameter object located at the index specified by the supplied index.

#### Declaration

```
// C#  
public override void RemoveAt(int index);
```

#### Parameters

- *index*

The specified index from which the OracleParameter is to be removed.

**Implements**

IList

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## RemoveAt(String)

This method removes from the collection the `OracleParameter` object specified by the supplied name.

**Declaration**

```
// C#  
public override void RemoveAt(String name);
```

**Parameters**

- *name*

The name of the `OracleParameter` object to be removed from the collection.

**Implements**

IDataParameterCollection

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleParameterCollection Class](#)
- [OracleParameterCollection Members](#)

## OraclePermission Class

An `OraclePermission` object enables ODP.NET to enforce imperative security and helps ensure that a user has a security level adequate for accessing data.

**Class Inheritance**

System.Object

System.Security.CodeAccessPermission

System.Data.Common.DbDataPermission

Oracle.DataAccess.Client.OraclePermission

Declaration

```
// C#  
public class OraclePermission: DBDataPermission
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

OraclePermission Members

OraclePermission members are listed in the following tables.

OraclePermission Constructors

The OraclePermission constructor is listed in [Table 6-162](#).

Table 6-162 OraclePermission Constructor

| Constructor                                  | Description                                                |
|----------------------------------------------|------------------------------------------------------------|
| <a href="#">OraclePermission Constructor</a> | Instantiates a new instance of the OraclePermission class. |

OraclePermission Static Methods

The OraclePermission static methods are listed in [Table 6-163](#).

**Table 6-163 OraclePermission Static Methods**

| Static Method    | Description                         |
|------------------|-------------------------------------|
| Equals           | Inherited from System.Object        |
| ReferenceEquals  | Inherited from System.Object        |
| RevertAll        | Inherited from CodeAccessPermission |
| RevertAssert     | Inherited from CodeAccessPermission |
| RevertDeny       | Inherited from CodeAccessPermission |
| RevertPermitOnly | Inherited from CodeAccessPermission |

**OraclePermission Public Properties**

The OraclePermission public methods are listed in [Table 6-167](#).

**Table 6-164 OraclePermission Public Properties**

| Public Properties  | Description                                                                         |
|--------------------|-------------------------------------------------------------------------------------|
| AllowBlankPassword | Inherited from DBDataPermission<br>OraclePermission does not support this property. |

**OraclePermission Public Methods**

The OraclePermission public methods are listed in [Table 6-165](#).

**Table 6-165 OraclePermission Public Methods**

| Public Method              | Description                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>        | Adds a new connection string fragment and a list of restricted keywords to the OraclePermission object            |
| Assert                     | Inherited from CodeAccessPermission                                                                               |
| <a href="#">Copy</a>       | Returns a copy of the current permission object                                                                   |
| Demand                     | Inherited from CodeAccessPermission                                                                               |
| Deny                       | Inherited from CodeAccessPermission                                                                               |
| Equals                     | Inherited from CodeAccessPermission                                                                               |
| FromXml                    | Inherited from DBDataPermission                                                                                   |
| GetHashCode                | Inherited from CodeAccessPermission                                                                               |
| GetType                    | Inherited from System.Object                                                                                      |
| Intersect                  | Inherited from DBDataPermission                                                                                   |
| <a href="#">IsSubsetOf</a> | Returns a boolean value that indicates whether or not the current permission is a subset of the target permission |
| IsUnrestricted             | Inherited from DBDataPermission                                                                                   |
| PermitOnly                 | Inherited from CodeAccessPermission                                                                               |
| ToString                   | Inherited from CodeAccessPermission                                                                               |
| ToXml                      | Inherited from DBDataPermission                                                                                   |

**Table 6-165 (Cont.) OraclePermission Public Methods**

| Public Method | Description                     |
|---------------|---------------------------------|
| Union         | Inherited from DBDataPermission |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OraclePermission Class](#)

## OraclePermission Constructor

The OraclePermission constructor instantiates a new instance of the OraclePermission class.

**Declaration**

```
// C#  
public OraclePermission (PermissionState state);
```

**Parameters**

- *state*

The *state* parameter takes one of the following two values: `PermissionState.None` or `PermissionState.Unrestricted`.

**Exceptions**

`ArgumentException` - The `PermissionState` value is invalid.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OraclePermission Class](#)
- [OraclePermission Members](#)

## OraclePermission Static Methods

The OraclePermission static methods are listed in [Table 6-166](#).

**Table 6-166 OraclePermission Static Methods**

| Static Method   | Description                               |
|-----------------|-------------------------------------------|
| Equals          | Inherited from <code>System.Object</code> |
| ReferenceEquals | Inherited from <code>System.Object</code> |

**Table 6-166 (Cont.) OraclePermission Static Methods**

| Static Method    | Description                         |
|------------------|-------------------------------------|
| RevertAll        | Inherited from CodeAccessPermission |
| RevertAssert     | Inherited from CodeAccessPermission |
| RevertDeny       | Inherited from CodeAccessPermission |
| RevertPermitOnly | Inherited from CodeAccessPermission |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## Add

This method adds a new connection string fragment and a list of restricted keywords to the OraclePermission object.

### Declaration

```
// C#
public void Add(string connStr, string keyRestrict,
    KeyRestrictionBehavior behavior);
```

### Parameters

- *connStr*  
The connection string fragment.
- *keyRestrict*  
The key restrictions.

- *behavior*

One of the following KeyRestrictionBehavior enumerations:

- AllowOnly
- PreventUsage

### Exceptions

ArgumentException - The KeyRestrictionBehavior value or the format of the *connStr* or *keyRestrict* string is invalid.

### Remarks

The Add method configures the connection strings allowed or disallowed by the permission object.

Opening an OracleConnection is allowed or denied based upon the connection string fragment, key restrictions combination, and the key restriction behavior.

In the following example, KeyRestrictionBehavior.AllowOnly allows connection strings that use orcl as the Data Source with any User Id and Password combination but no other connection string keywords. Connection string keywords other than User Id and Password cause security exceptions.

```
orclPermission.Add("Data Source=orcl;", "User Id=;Password=;",  
    KeyRestrictionBehavior.AllowOnly);
```

In the next example, KeyRestrictionBehavior.PreventUsage restricts connection strings that use the keyword Pooling. Use of the Pooling keyword causes an exception.

```
orclPermission.Add("Data Source=orcl;", "Pooling=;",  
    KeyRestrictionBehavior.PreventUsage)
```

As a general rule, in an unrestricted environment, any connection string that is not allowed is restricted and throws a security exception.

If a connection string fragment contains key-value pairs for the password and proxy password attributes, then values for these attributes are ignored. However, the presence of the attributes themselves is still checked. This means that the connection is allowed only if the password and proxy attributes keywords are allowed in the connection string.

## Copy

This method returns a copy of the current permission object.

### Declaration

```
// C#  
public override IPermission Copy();
```

**Return Value**

A copy of the `OraclePermission` object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OraclePermission Class](#)
- [OraclePermission Members](#)

## IsSubsetOf

This method returns a boolean value that indicates whether or not the current permission is a subset of the target permission.

**Declaration**

```
// C#  
public override bool IsSubsetOf(IPermission target);
```

**Parameters**

- *target*  
A permission that must be of type `OraclePermission`.

**Return Value**

A `bool` value that indicates whether or not the current permission is a subset of the target permission.

**Exceptions**

`ArgumentException` - The permission is not of the `OraclePermission` type.

**Remarks**

The `AllowBlankPassword` property is ignored when evaluating whether or not the current permission is a subset of the target permission.

# OraclePermissionAttribute Class

An OraclePermissionAttribute object enables ODP.NET to enforce declarative security and helps ensure that a user has a security level adequate for accessing data.

## Class Inheritance

## Declaration

```
// C#
[Serializable, AttributeUsage(AttributeTargets.Method |
AttributeTargets.Constructor | AttributeTargets.Class | AttributeTargets.Struct |
AttributeTargets.Assembly, AllowMultiple = true, Inherited = false)]
public sealed class OraclePermissionAttribute: DBDataPermissionAttribute
```

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OraclePermissionAttribute Members

OraclePermissionAttribute members are listed in the following tables.

### OraclePermissionAttribute Constructor

The OraclePermissionAttribute constructor is listed in [Table 6-169](#).

**Table 6-169 OraclePermission Constructor**

| Constructor                                           | Description                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------|
| <a href="#">OraclePermissionAttribute Constructor</a> | Instantiates a new instance of the OraclePermissionAttribute class. |

### OraclePermissionAttribute Static Methods

The OraclePermissionAttribute static methods are listed in [Table 6-170](#).

**Table 6-170 OraclePermissionAttribute Static Methods**

| Static Methods      | Description                                  |
|---------------------|----------------------------------------------|
| GetCustomAttribute  | Inherited from System.Attribute (Overloaded) |
| GetCustomAttributes | Inherited from System.Attribute(Overloaded)  |
| IsDefined           | Inherited from System.Attribute(Overloaded)  |
| ReferenceEquals     | Inherited from System.Object                 |

### OraclePermissionAttribute Public Properties

The OraclePermissionAttribute public properties are listed in [Table 6-171](#).

**Table 6-171 OraclePermissionAttribute Public Properties**

| Public Properties      | Description                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Action                 | Inherited from SecurityAttribute                                                                                                                                                       |
| AllowBlankPassword     | Inherited from DBDataPermissionAttribute.<br>OraclePermissionAttribute ignores this property.<br>Any value set for this property, for an OraclePermissionAttribute object, is ignored. |
| ConnectionString       | Inherited from DBDataPermissionAttribute                                                                                                                                               |
| KeyRestrictionBehavior | Inherited from DBDataPermissionAttribute                                                                                                                                               |
| KeyRestrictions        | Inherited from DBDataPermissionAttribute                                                                                                                                               |
| TypeId                 | Inherited from System.Attribute                                                                                                                                                        |
| Unrestricted           | Inherited from SecurityAttribute                                                                                                                                                       |

### OraclePermissionAttribute Public Methods

The OraclePermissionAttribute public methods are listed in [Table 6-172](#).

Table 6-172 OraclePermissionAttribute Public Methods

| Public Methods                   | Description                                                                                   |
|----------------------------------|-----------------------------------------------------------------------------------------------|
| <a href="#">CreatePermission</a> | Returns a new OraclePermissionAttribute object that is configured based on the attributes set |
| Equals                           | Inherited from System.Attribute                                                               |
| GetHashCode                      | Inherited from System.Attribute                                                               |
| GetType                          | Inherited from System.Attribute                                                               |
| IsDefaultAttribute               | Inherited from System.Attribute                                                               |
| Match                            | Inherited from System.Attribute                                                               |
| ShouldSerializeConnectionString  | Inherited from DBDataPermissionAttribute                                                      |
| ShouldSerializeKeyRestrictions   | Inherited from DBDataPermissionAttribute                                                      |
| ToString                         | Inherited from System.Object                                                                  |

## OraclePermissionAttribute Constructor

The OraclePermissionAttribute constructor instantiates new instances of the OraclePermissionAttribute class.

**Declaration**

```
// C#
public OraclePermissionAttribute (SecurityAction action);
```

**Parameters**

- *action*

A System.Security.Permissions.SecurityAction value representing an action that can be performed using declarative security.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OraclePermissionAttribute Class](#)
- [OraclePermissionAttribute Members](#)

## OraclePermissionAttribute Static Methods

The OraclePermissionAttribute static methods are listed in [Table 6-173](#).

**Table 6-173 OraclePermissionAttribute Static Methods**

| Static Methods      | Description                                  |
|---------------------|----------------------------------------------|
| GetCustomAttribute  | Inherited from System.Attribute (Overloaded) |
| GetCustomAttributes | Inherited from System.Attribute(Overloaded)  |
| IsDefined           | Inherited from System.Attribute(Overloaded)  |
| ReferenceEquals     | Inherited from System.Object                 |

# CreatePermission

This method returns a new OraclePermissionAttribute object that is configured based on the attributes set.

**Declaration**

```
// C#
public override IPermission CreatePermission();
```

**Return Value**

An OraclePermission object.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OraclePermissionAttribute Class](#)
- [OraclePermissionAttribute Members](#)

# OracleRefreshAccessTokenEventArgs Class

The OracleRefreshAccessTokenEventArgs class provides a way for the application to return the refreshed signature token. When the token is about to expire, the callback registered using RefreshAccessToken event is triggered along with the OracleRefreshAccessTokenEventArgs object. The application is expected to provide the refreshed token with a new expiration within this object.

**Class Inheritance**

**Declaration**

```
// C#
public sealed class OracleRefreshAccessTokenEventArgs
```

**Requirements**

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

## OracleRefreshAccessTokenEventArgs Members

OracleRefreshAccessTokenEventArgs members are listed in the following tables.

OracleRefreshAccessTokenEventArgs Properties

OracleRefreshAccessTokenEventArgs properties are listed in [Table 6-200](#).

Table 6-176 OracleRefreshAccessTokenEventArgs Properties

| Property                   | Description                                            |
|----------------------------|--------------------------------------------------------|
| <a href="#">DbToken</a>    | Sets the new/refreshed signature token in this object  |
| <a href="#">PrivateKey</a> | Sets the refreshed private key in this object          |
| <a href="#">Token</a>      | Sets the new or refreshed access token in this object. |

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRefreshAccessTokenEventArgs Class](#)

OracleRefreshAccessTokenEventArgs Properties

The OracleRefreshAccessTokenEventArgs properties are listed in [Table 6-187](#).

Table 6-177 OracleRefreshAccessTokenEventArgs Properties

| Property                   | Description                                            |
|----------------------------|--------------------------------------------------------|
| <a href="#">DbToken</a>    | Sets the new/refreshed signature token in this object  |
| <a href="#">PrivateKey</a> | Sets the refreshed private key in this object          |
| <a href="#">Token</a>      | Sets the new or refreshed access token in this object. |

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRefreshAccessTokenEventArgs Class](#)
- [OracleRefreshAccessTokenEventArgs Members](#)

DbToken

This property sets the new/refreshed signature token in this object.

Declaration

```
// C#
public char[] DbToken { set; }
```

**Description**

The char[] used to set the value of this property will be cleared by ODP.NET. Applications should not depend on this char[] once this property is called.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleRefreshAccessTokenEventArgs Class](#)
- [OracleRefreshAccessTokenEventArgs Members](#)

## PrivateKey

This property sets the refreshed private key in this object.

**Declaration**

```
// C#  
public char[] PrivateKey { set; }
```

**Description**

The char[] used to set the value of this property will be cleared by ODP.NET. Applications should not depend on this char[] once this property is called.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleRefreshAccessTokenEventArgs Class](#)
- [OracleRefreshAccessTokenEventArgs Members](#)

## Token

This property sets the new or refreshed access token in this object.

**Declaration**

```
// C#  
public char[] Token { set; }
```

**Description**

This property can hold an access token.

The char[] used to set the value of this property will be cleared by ODP.NET for security reasons. The application should not depend on this char[] once this property is called.

- [OracleRefreshAccessTokenEventArgs Members](#)

# OracleRoleCollection Class

The OracleRoleCollection class represents a collection of roles that can be set on new connections or connections retrieved from a connection pool programmatically.

### Class Inheritance

System.Object  
  
Oracle.ManagedDataAccess.Client.OracleRoleCollection

### Declaration

```
// C#  
public sealed class OracleRoleCollection
```

### Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

Instance methods do not guarantee thread safety.

### Remarks

Database role names are case sensitive. If a name without double-quotes is specified in the database, it automatically converts all its characters to upper case. If double quotes are specified, the upper and lower case letters are maintained in the database. Oracle does not allow starting a role name with single quote.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## OracleRoleCollection Members

OracleRoleCollection members are listed in the following tables.

### OracleRoleCollection Methods

The OracleSessionlessTransactionOptions methods are listed in [Table 6-178](#).

**Table 6-178 OracleRoleCollection Methods**

| Methods                  | Description                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>      | Adds a role to the role list (Overloaded)                                                                                                                           |
| <a href="#">Clear</a>    | Clears all the roles in the roles collection                                                                                                                        |
| <a href="#">Contains</a> | Verifies whether a role is present in the roles collection or a role is enabled on a connection if the connection is open depending on the Oracle software versions |
| <a href="#">Remove</a>   | Removes a role from the roles list                                                                                                                                  |

### OracleRoleCollection Properties

The OracleRoleCollection properties are listed in [Table 6-179](#).

**Table 6-179 OracleRoleCollection Properties**

| Property                     | Description                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">Count</a>        | Specifies the number of roles in the OracleRoleCollection object or enabled on the current session |
| <a href="#">Item</a>         | Retrieves a role in the OracleRoleCollection object using an index value                           |
| <a href="#">UseAllExcept</a> | Specifies enabling all non-password-based roles except those added in OracleRoleCollection         |

## OracleRoleCollection Methods

OracleRoleCollection methods are listed in [Table 6-180](#).

**Table 6-180 OracleRoleCollection Methods**

| Method                   | Description                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>      | Adds a role to the role list (Overloaded)                                                                                                                           |
| <a href="#">Clear</a>    | Clears all the roles in the roles collection                                                                                                                        |
| <a href="#">Contains</a> | Verifies whether a role is present in the roles collection or a role is enabled on a connection if the connection is open depending on the Oracle software versions |
| <a href="#">Remove</a>   | Removes a role from the roles list                                                                                                                                  |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## Add

The Add method adds a new role to the role list.

**Overloaded List:**

- [Add\(string\)](#)  
This method adds a role to the roles list and sets it on a on a newly created connection or a connection coming from connection pool.
- [Add\(string, OracleOpaqueString\)](#)  
This method adds a role with a password to the roles list and sets it on a on a newly created connection or a connection coming from connection pool.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## Add(string)

This method adds a role to the roles list and sets it on a on a newly created connection or a connection coming from connection pool.

**Declaration**

```
// C#  
public void Add(string Role);
```

## Parameters

*Role* - Role name that will be set on a connection.

## Exceptions

`ArgumentNullException` - It is thrown when role name is provided as Null.

`ArgumentException` - It is thrown when role name is provided as empty string.

`ArgumentException` - It is thrown when case sensitive role name is not enclosed properly within double quotes.

`InvalidOperationException` - It is thrown when the connection is already open.

## Remarks

The user must already be granted the database roles before adding those roles to the `OracleRoleCollection` object. Otherwise, an error occurs indicating the role is not granted or does not exist. The database roles not added to the ODP.NET collection are disabled for the session, except when no roles are added to the collection. In this case, the default roles are enabled in the database session.

To modify an existing connection's enabled roles, close the connection, modify the `OracleRoleCollection` instance associated with the connection instance, and reopen the connection.

To enable all roles granted, except roles with passwords, add ALL to the `OracleRoleCollection` instance. To disable all roles including default roles, add NONE to the `OracleRoleCollection` instance. ALL and NONE are reserved keywords for role names. When using ALL or NONE, make sure no other role names are added to the collection. Otherwise, it results in errors.

Once the session is created after inserting the ALL reserved keyword or when `OracleRoleCollection.UseAllExcept` property is set to true, ODP.NET does not modify the session's enabled roles if the database modifies the default roles until the `OracleRoleCollection` is itself modified. This holds true even for the connections which are checked into the pool.

To enable all previously granted user roles except for a particular collection, set `OracleRoleCollection.UseAllExcept` to true. It enables all the roles except those which are added in `OracleRoleCollection` object associated with `OracleConnection` object. If this property is set to True, then the password-based roles are not enabled on the connection. If `OracleRoleCollection.UseAllExcept` is true and nothing is added in the `OracleRoleCollection` object, then ODP.NET will not enable or disable any roles on the connection. The connection state with respect to roles enabled remains unchanged.

### Note

For DRCP connections, because random sessions are checked out from server pool and it can have any set of roles enabled on the session, it is necessary to add the ALL keyword in the `OracleRoleCollection` object associated with the `OracleConnection` object, if you want to enable all the non-password based roles on the upcoming session.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## Add(string, OracleOpaqueString)

This method adds a role with a password to the roles list and sets it on a on a newly created connection or a connection coming from connection pool.

**Declaration**

```
// C#  
public void Add(string Role, OracleOpaqueString Password);
```

**Parameters**

- *Role* - Role name that will be set on a connection.
- *Password* - Password of Role

**Exceptions**

ArgumentNullException - It is thrown when role name is provided as Null.

ArgumentException - It is thrown when role name is provided as empty string.

ArgumentException - It is thrown when case sensitive role name is not enclosed properly within double quotes.

InvalidOperationException - It is thrown when the connection is already open.

**Remarks**

The user must already be granted the database roles before adding those roles to the OracleRoleCollection object. Otherwise, an error occurs indicating the role is not granted or does not exist. The database roles not added to the ODP.NET collection are disabled for the session, except when no roles are added to the collection. In this case, the non-password-based roles are enabled in the database session.

To modify an existing connection's enabled roles, close the connection, modify the OracleRoleCollection instance associated with the connection instance, and reopen the connection.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## Clear

This method clears all the roles in the roles collection.

### Declaration

```
// C#  
public void clear();
```

### Exceptions

InvalidOperationException - It is thrown when the connection is already open.

### Remarks

This method only clears entries from the `OracleRoleCollection` object associated with the `OracleConnection` object. After clearing the roles and then opening a connection, ODP.NET does not enable nor disable any session roles due to the empty `OracleRoleCollection` object. For a session to have no roles enabled, add `NONE` to the `OracleRoleCollection` object.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## Contains

This method verifies whether a role is present in the roles collection or a role is enabled on a connection if the connection is open depending on the Oracle software versions.

### Declaration

```
// C#  
public bool Contains(string Role)
```

### Parameters

*Role* - Role name to check for presence in the roles collection.

### Return Value

A Boolean value indicating if the role is present in the ODP.NET roles collection or that role is enabled in the current session. The exact behavior depends on the database version.

### Exceptions

ArgumentNullException - It is thrown when role name is provided as Null.

ArgumentException - It is thrown when role name is provided as empty string.

ArgumentException - It is thrown when case sensitive role name is not enclosed properly within double quotes.

## Remarks

For Oracle AI Database 26ai, 23.8 and earlier versions, this method only checks for roles specified in the `OracleConnection.Roles` property regardless whether the connection is open or closed.

For Oracle Database and ODP.NET versions 23.9 and later, this method checks if a given role is enabled on the current session, which requires the connection to be open. This method still returns true for roles not specified using `OracleRoleCollection.Add` but still are enabled on the current session. An example are default roles, which are enabled on the session as soon as it establishes.

For DRCP connections, until a session attaches to the `OracleConnection` object, this method searches the role name specified in the `OracleRoleCollection` object.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## Remove

This method removes a role from the roles list.

### Declaration

```
// C#  
public bool Remove(string Role);
```

### Parameters

*Role* - Role name to be removed from role list.

### Return Value

A Boolean value indicating whether the specified role was removed from the list (true) or not (false).

### Exceptions

`ArgumentNullException` - It is thrown when role name is provided as Null.

`ArgumentException` - It is thrown when role name is provided as empty string.

`ArgumentException` - It is thrown when case sensitive role name is not enclosed properly within double quotes.

`InvalidOperationException` - It is thrown when the connection is already open.

### Remarks

A password-based role can also be removed from the collection by providing its name to the method.

## OracleRoleCollection Properties

OracleRoleCollection properties are listed in [Table 6-181](#).

**Table 6-181 OracleRoleCollection Properties**

| Property                     | Description                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">Count</a>        | Specifies the number of roles in the OracleRoleCollection object or enabled on the current session |
| <a href="#">Item</a>         | Retrieves a role in the OracleRoleCollection object using an index value                           |
| <a href="#">UseAllExcept</a> | Specifies enabling all non-password-based roles except those added in OracleRoleCollection         |

❗ See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

### Count

This property specifies the number of roles in the OracleRoleCollection object or enabled on the current session.

**Declaration**

```
// C#  
public int Count{get;}
```

**Property Value**

Number of roles in this OracleRoleCollection object or enabled on current session.

**Remarks**

For Oracle AI Database 26ai, 23.8 and earlier versions, this property only returns the total number of roles specified in the OracleConnection.Roles property regardless whether the connection is open or closed.

For Oracle Database and ODP.NET versions 23.9 and later, this property returns the number of roles enabled on a connection when the connection is open.

When a reserved keyword for roles, such as ALL or NONE, is part of the `OracleRoleCollection` object, the property value is the total items added to the object when the connection is closed. When the connection is open, this property returns the total number of roles enabled on the session.

For DRCP connections, until a session attaches to the `OracleConnection` object, this property returns the total roles specified in `OracleRoleCollection` object.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## Item

This property retrieves a role in the `OracleRoleCollection` object using an index value.

### Declaration

```
// C#  
public string Item[int index] {get;}
```

### Parameters

- *index* - An integer that represents the index value for role name retrieval.

### Property Value

A string for the role name

### Exceptions

`ArgumentOutOfRangeException` - Index is outside the range of valid indexes.

### Remarks

Roles are stored in alphabetical order by role name. To fetch the role name, the index value should be less than the `OracleRoleCollection.Count` value. Otherwise, it results in an `ArgumentOutOfRangeException`.

For Oracle AI Database 26ai, 23.8 and earlier versions, this property only returns roles specified in `OracleConnection.Roles` property regardless whether the connection is open or closed.

For Oracle AI Database and ODP.NET versions 23.9 and later, this property returns the default session roles names enabled on the session when the connection is open.

When a reserved keyword for roles, such as ALL or NONE, is part of the `OracleRoleCollection` object, this property returns the items added in the roles collection when the connection is closed. When the connection is open, this property returns the session-enabled role names. Similarly, when `OracleRoleCollection.UseAllExcept` property is set to true and connection is

closed, this property returns the `OracleRoleCollection` item names. When the connection is open, this property returns session-enabled role names.

For DRCP connections, this property returns the role names specified in the `OracleRoleCollection` object until the connection opens and a session is attached to it.

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRoleCollection Class](#)
- [OracleRoleCollection Members](#)

## UseAllExcept

This property specifies enabling all non-password-based roles except those added in `OracleRoleCollection`.

#### Declaration

```
// C#  
public bool UseAllExcept{get;set;}
```

#### Property Value

A Boolean specifying whether to enable all non-password-based roles except those added in `OracleRoleCollection`.

#### Remarks

The roles in `OracleRoleCollection` must be directly granted to the database user. They cannot be the roles granted to that user via other roles.

## OracleRowUpdatedEventArgs Class

The `OracleRowUpdatedEventArgs` class provides event data for the `OracleDataAdapter.RowUpdated` event.

#### Class Inheritance

`System.Object`

`System.EventArgs`

`System.RowUpdatedEventArgs`

System.OracleRowUpdatedEventArgs

Declaration

```
// C#
public sealed class OracleRowUpdatedEventArgs : RowUpdatedEventArgs
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Example

The example for the RowUpdated event shows how to use OracleRowUpdatedEventArgs. See RowUpdated event "[Example](#)".

# OracleRowUpdatedEventArgs Constructor

The OracleRowUpdatedEventArgs constructor creates a new OracleRowUpdatedEventArgs instance.

**Declaration**

```
// C#
public OracleRowUpdatedEventArgs(DataRow row, IDbCommand command,
    StatementType statementType, DataTableMapping tableMapping);
```

**Parameters**

- *row*  
The DataRow sent for Update.
- *command*  
The IDbCommand executed during the Update.
- *statementType*  
The StatementType Enumeration value indicating the type of SQL statement executed.
- *tableMapping*  
The DataTableMapping used for the Update.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

Command

This property specifies the OracleCommand that is used when OracleDataAdapter.Update() is called.

Declaration

```
// C#
public new OracleCommand Command {get;}
```

Property Value

The OracleCommand executed when Update is called.

❶ See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRowUpdatedEventArgs Class](#)
- [OracleRowUpdatedEventArgs Members](#)

## OracleRowUpdatedEventArgs Public Methods

The OracleRowUpdatedEventArgs properties are listed in [Table 6-188](#).

**Table 6-188 OracleRowUpdatedEventArgs Public Methods**

| Public Method | Description                               |
|---------------|-------------------------------------------|
| Equals        | Inherited from System.Object (Overloaded) |
| GetHashCode   | Inherited from System.Object              |
| GetType       | Inherited from System.Object              |
| ToString      | Inherited from System.Object              |

## OracleRowUpdatedEventHandler Delegate

The OracleRowUpdatedEventHandler delegate represents the signature of the method that handles the OracleDataAdapter.RowUpdated event.

### Declaration

```
// C#
public delegate void OracleRowUpdatedEventHandler(object sender,
    OracleRowUpdatedEventArgs eventArgs);
```

### Requirements

| Provider  | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------|---------------------------------|---------------------------------|
| Assembly  | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.DataAccess.Client  | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Parameters

- *sender*  
The source of the event.
- *eventArgs*  
The OracleRowUpdatedEventArgs object that contains the event data.

### Remarks

Event callbacks can be registered through this event delegate for applications that wish to be notified after a row is updated.

In the .NET framework, the convention of an event delegate requires two parameters: the object that raises the event and the event data.

#### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- "[RowUpdated](#)"

## OracleRowUpdatingEventArgs Class

The OracleRowUpdatingEventArgs class provides event data for the OracleDataAdapter.RowUpdating event.

### Class Inheritance

System.Object

System.EventArgs

System.RowUpdatingEventArgs

System.OracleRowUpdatingEventArgs

### Declaration

```
// C#
public sealed class OracleRowUpdatingEventArgs : RowUpdatingEventArgs
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |

| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

The example for the RowUpdated event shows how to use OracleRowUpdatingEventArgs. See RowUpdated event "[Example](#)".

# OracleRowUpdatingEventArgs Members

OracleRowUpdatingEventArgs members are listed in the following tables.

## OracleRowUpdatingEventArgs Constructors

OracleRowUpdatingEventArgs constructors are listed in [Table 6-189](#).

**Table 6-189 OracleRowUpdatingEventArgs Constructors**

| Constructor                                            | Description                                                                  |
|--------------------------------------------------------|------------------------------------------------------------------------------|
| <a href="#">OracleRowUpdatingEventArgs Constructor</a> | Instantiates a new instance of OracleRowUpdatingEventArgs class (Overloaded) |

## OracleRowUpdatingEventArgs Static Methods

The OracleRowUpdatingEventArgs static methods are listed in [Table 6-190](#).

**Table 6-190 OracleRowUpdatingEventArgs Static Methods**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

## OracleRowUpdatingEventArgs Properties

The OracleRowUpdatingEventArgs properties are listed in [Table 6-191](#).

**Table 6-191 OracleRowUpdatingEventArgs Properties**

| Property                | Description                                                                            |
|-------------------------|----------------------------------------------------------------------------------------|
| <a href="#">Command</a> | Specifies the OracleCommand that is used when the OracleDataAdapter.Update() is called |
| Errors                  | Inherited from System.Data.Common.RowUpdatingEventArgs                                 |
| Row                     | Inherited from System.Data.Common.RowUpdatingEventArgs                                 |
| StatementType           | Inherited from System.Data.Common.RowUpdatingEventArgs                                 |
| Status                  | Inherited from System.Data.Common.RowUpdatingEventArgs                                 |
| TableMapping            | Inherited from System.Data.Common.RowUpdatingEventArgs                                 |

## OracleRowUpdatingEventArgs Public Methods

The OracleRowUpdatingEventArgs public methods are listed in [Table 6-192](#).

**Table 6-192 OracleRowUpdatingEventArgs Public Methods**

| Public Method | Description                               |
|---------------|-------------------------------------------|
| Equals        | Inherited from System.Object (Overloaded) |
| GetHashCode   | Inherited from System.Object              |
| GetType       | Inherited from System.Object              |
| ToString      | Inherited from System.Object              |

## OracleRowUpdatingEventArgs Constructor

The `OracleRowUpdatingEventArgs` constructor creates a new instance of the `OracleRowUpdatingEventArgs` class using the supplied data row, `IDbCommand`, type of SQL statement, and table mapping.

### Declaration

```
// C#  
public OracleRowUpdatingEventArgs(DataRow row, IDbCommand command,  
    StatementType statementType, DataTableMapping tableMapping);
```

### Parameters

- *row*  
The `DataRow` sent for Update.
- *command*  
The `IDbCommand` executed during the Update.
- *statementType*  
The `StatementType` enumeration value indicating the type of SQL statement executed.
- *tableMapping*  
The `DataTableMapping` used for the Update.

## Command

This property specifies the OracleCommand that is used when the OracleDataAdapter.Update() is called.

**Declaration**

```
// C#
public new OracleCommand Command {get; set;}
```

**Property Value**

The OracleCommand executed when Update is called.

❗ See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRowUpdatingEventArgs Class](#)
- [OracleRowUpdatingEventArgs Members](#)

## OracleRowUpdatingEventArgs Public Methods

The OracleRowUpdatingEventArgs public methods are listed in [Table 6-195](#).

**Table 6-195 OracleRowUpdatingEventArgs Public Methods**

| Public Method | Description                               |
|---------------|-------------------------------------------|
| Equals        | Inherited from System.Object (Overloaded) |
| GetHashCode   | Inherited from System.Object              |
| GetType       | Inherited from System.Object              |
| ToString      | Inherited from System.Object              |

❗ See Also

## OracleRowUpdatingEventHandler Delegate

The OracleRowUpdatingEventHandler delegate represents the signature of the method that handles the OracleDataAdapter.RowUpdating event.

### Declaration

```
// C#
public delegate void OracleRowUpdatingEventHandler (object sender,
    OracleRowUpdatingEventArgs eventArgs);
```

### Requirements

| Provider  | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------|---------------------------------|---------------------------------|
| Assembly  | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.DataAccess.Client  | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Parameters

- *sender*  
The source of the event.
- *eventArgs*  
The `OracleRowUpdatingEventArgs` object that contains the event data.

### Remarks

Event callbacks can be registered through this event delegate for applications that wish to be notified after a row is updated.

In the .NET framework, the convention of an event delegate requires two parameters: the object that raises the event and the event data.

## OracleSessionlessTransactionOptions Class

The `OracleSessionlessTransactionOption` class specifies the options to operate on a transaction that can span across multiple sessions. This transaction type is called an Oracle sessionless transaction.

### Class Inheritance

`System.Object`

`Oracle.ManagedDataAccess.Client.OracleSessionlessTransactionOption`

### Declaration

```
// C#
public class OracleSessionlessTransactionOptions
```

## Requirements

| Provider              | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | See <a href="#">System Requirements</a> |

## OracleSessionlessTransactionOptions Members

OracleSessionlessTransactionOptions members are listed in the following tables.

### OracleSessionlessTransactionOptions Constructors

The OracleSessionlessTransactionOptions constructors are listed in [Table 6-196](#).

**Table 6-196 OracleSessionlessTransactionOptions Constructors**

| Constructors                                                     | Description                                                               |
|------------------------------------------------------------------|---------------------------------------------------------------------------|
| <a href="#">OracleSessionlessTransactionOptions Constructors</a> | Instantiate new instances of an OracleSessionlessTransactionOptions class |

### OracleSessionlessTransactionOptions Properties

The OracleSessionlessTransactionOptions properties are listed in [Table 6-197](#).

**Table 6-197 OracleSessionlessTransactionOptions Properties**

| Property                              | Description                                                                                                                |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ResumeBehavior</a>        | Specifies sessionless transaction resume behavior in <code>OracleConnection.ResumeSessionlessTransaction()</code>          |
| <a href="#">StartBehavior</a>         | Specifies sessionless transaction start behavior in <code>OracleConnection.BeginSessionlessTransaction()</code>            |
| <a href="#">SuspendAfterExecution</a> | Specifies whether the active sessionless transaction should be suspended after an <code>OracleCommand</code> SQL execution |

**Table 6-197 (Cont.) OracleSessionlessTransactionOptions Properties**

| Property                | Description                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">Timeout</a> | Specifies the time, in seconds, to wait for a transaction to become active after it is detached or suspended |

## OracleSessionlessTransactionOptions Constructors

OracleSessionlessTransactionOptions constructors instantiate new instances of an OracleSessionlessTransactionOptions class.

### Overload List:

- [OracleSessionlessTransactionOptions\(\)](#)  
This constructor instantiates a new instance of the OracleSessionlessTransactionOptions class using default property values.
- [OracleSessionlessTransactionOptions\(int, OracleSessionlessTransactionStartBehavior, OracleSessionlessTransactionStartBehavior, bool\)](#)  
This constructor instantiates a new instance of the OracleSessionlessTransactionOptions class with the provided transaction options.

### ① See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleSessionlessTransactionOptions Class](#)
- [OracleSessionlessTransactionOptions Members](#)

## OracleSessionlessTransactionOptions()

This constructor instantiates a new instance of the OracleSessionlessTransactionOptions class using default property values.

### Declaration

```
// C#  
public OracleSessionlessTransactionOptions();
```

### Remarks

OracleSessionlessTransactionOptions properties have the following default values:

- Timeout = 60 seconds
- StartBehavior = OracleSessionlessTransactionStartBehavior.StartBeforeExecute
- ResumeBehavior = OracleSessionlessTransactionStartBehavior.StartBeforeExecute
- SuspendSessionlessTransactionAfterExecution = false

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSessionlessTransactionOptions Class](#)
- [OracleSessionlessTransactionOptions Members](#)

## OracleSessionlessTransactionOptions(int, OracleSessionlessTransactionStartBehavior, OracleSessionlessTransactionStartBehavior, bool)

This constructor instantiates a new instance of the `OracleSessionlessTransactionOptions` class with the provided transaction options.

**Declaration**

```
// C#
public OracleSessionlessTransactionOptions(int timeout,
OracleSessionlessTransactionStartBehavior startBehavior,
OracleSessionlessTransactionStartBehavior resumeBehavior,
bool suspendAfterExecution);
```

**Parameters**

- *timeout* : time, in seconds, to wait for a transaction to become active after it is detached or suspended. If a non-active sessionless transaction is not resumed, committed, or rolled back within the timeout period, it is aborted. The timeout value must be set greater than 0.
- *startBehavior* : determines if the sessionless transaction should start immediately in `OracleConnection.BeginSessionlessTransaction()` or upon an `OracleCommand` SQL execution.
- *resumeBehavior* : determines if the sessionless transaction should resume immediately in `OracleConnection.ResumeSessionlessTransaction()` or upon an `OracleCommand` SQL execution.
- *suspendAfterExecution* : determines if the active sessionless transaction should be suspended after an `OracleCommand` SQL execution.

**Exceptions**

`ArgumentOutOfRangeException` - specified timeout is equal or smaller than zero.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSessionlessTransactionOptions Class](#)
- [OracleSessionlessTransactionOptions Members](#)

## OracleSessionlessTransactionOptions Properties

OracleSessionlessTransactionOptions properties are listed in [Table 6-198](#).

**Table 6-198 OracleSessionlessTransactionOptions Properties**

| Property                              | Description                                                                                                                |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ResumeBehavior</a>        | Specifies sessionless transaction resume behavior in <code>OracleConnection.ResumeSessionlessTransaction()</code>          |
| <a href="#">StartBehavior</a>         | Specifies sessionless transaction start behavior in <code>OracleConnection.BeginSessionlessTransaction()</code>            |
| <a href="#">SuspendAfterExecution</a> | Specifies whether the active sessionless transaction should be suspended after an <code>OracleCommand</code> SQL execution |
| <a href="#">Timeout</a>               | Specifies the time, in seconds, to wait for a transaction to become active after it is detached or suspended               |

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSessionlessTransactionOptions Class](#)
- [OracleSessionlessTransactionOptions Members](#)

## ResumeBehavior

This property specifies sessionless transaction resume behavior in `OracleConnection.ResumeSessionlessTransaction()`.

### Declaration

```
// C#  
public OracleSessionlessTransactionStartBehavior ResumeBehavior { get; set; }
```

### Property Value

The `OracleSessionlessTransactionStartBehavior` enum specifies the behavior to resume a sessionless transaction.

### Remarks

When `ResumeBehavior` is set to `OracleSessionlessTransactionStartBehavior.StartBeforeExecution`, the connection is associated with the sessionless transaction in `OracleConnection.ResumeSessionlessTransaction()`. However, the transaction will only resume upon the first `OracleCommand` SQL execution.

When `ResumeBehavior` is set to `OracleSessionlessTransactionStartBehavior.StartImmediate`, the sessionless transaction resumes immediately when `OracleConnection.ResumeSessionlessTransaction()` is invoked.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSessionlessTransactionOptions Class](#)
- [OracleSessionlessTransactionOptions Members](#)

## StartBehavior

This property specifies sessionless transaction start behavior in `OracleConnection.BeginSessionlessTransaction()`.

**Declaration**

```
// C#  
public OracleSessionlessTransactionStartBehavior StartBehavior { get; set; }
```

**Property Value**

The `OracleSessionlessTransactionStartBehavior` enum that specifies sessionless transaction start behavior.

**Remarks**

When `StartBehavior` is set to `OracleSessionlessTransactionStartBehavior.StartBeforeExecution`, the connection is associated with the sessionless transaction in `OracleConnection.BeginSessionlessTransaction()`. However, the transaction will only start upon the first `OracleCommand` SQL execution.

When `StartBehavior` is set to `OracleSessionlessTransactionStartBehavior.StartImmediate`, the sessionless transaction starts immediately when `OracleConnection.BeginSessionlessTransaction()` is invoked.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSessionlessTransactionOptions Class](#)
- [OracleSessionlessTransactionOptions Members](#)

## SuspendAfterExecution

This property specifies whether the active sessionless transaction should be suspended after an `OracleCommand` SQL execution.

**Declaration**

```
// C#  
public bool SuspendAfterExecution { get; set; }
```

**Property Value**

The boolean indicates if the sessionless transaction should be suspended after the OracleCommand SQL execution.

**Remarks**

When SuspendAfterExecution is set to true, then the active sessionless transaction is suspended upon the first OracleCommand SQL execution.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSessionlessTransactionOptions Class](#)
- [OracleSessionlessTransactionOptions Members](#)

## Timeout

This property specifies the time, in seconds, to wait for a transaction to become active after it is detached or suspended.

**Declaration**

```
// C#  
public int Timeout { get; set; }
```

**Property Value**

The integer specifies the sessionless transaction timeout.

**Exceptions**

ArgumentOutOfRangeException - specified timeout is equal or smaller than zero.

**Remarks**

If a non-active sessionless transaction is not resumed, committed, or rolled back within the timeout period, then it is aborted. The timeout value must be set greater than 0.

**① See Also**

## OracleShardingKey Class

An OracleShardingKey object can represent either a sharding key or a super sharding key.

## Class Inheritance

System.Object

Oracle.DataAccess.Client.OracleShardingKey

## Declaration

```
// C#
public class OracleShardingKey : IDisposable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Example

```
// C#

using System;
using Oracle.DataAccess.Client;

class Sharding
{
    static void Main()
    {
        OracleConnection con = new OracleConnection("user id=hr;password=hr;DataSource=orcl;");
        //Setting a shard key
        OracleShardingKey shardingKey = new OracleShardingKey(OracleDbType.Int32, 123);
        //Setting a second shard key value for a composite key
        shardingKey.SetShardingKey(OracleDbType.Varchar2, "gold");
        //Creating and setting the super shard key
        OracleShardingKey superShardingKey = new OracleShardingKey();
        superShardingKey.SetShardingKey(OracleDbType.Int32, 1000);

        //Setting super sharding key and sharding key on the connection
        con.SetShardingKey(shardingKey, superShardingKey);
        con.Open();

        //perform SQL query
    }
}
```

## OracleShardingKey Members

OracleShardingKey members are listed in the following tables.

### OracleShardingKey Constructors

OracleShardingKey constructors are listed in [Table 6-199](#).

**Table 6-199 OracleShardingKey Constructors**

| Constructor                                    | Description                                                         |
|------------------------------------------------|---------------------------------------------------------------------|
| <a href="#">OracleShardingKey Constructors</a> | Instantiates a new instance of OracleShardingKey class (Overloaded) |

### OracleShardingKey Instance Methods

OracleShardingKey instance methods are listed in [Table 6-200](#).

**Table 6-200 OracleShardingKey Instance Methods**

| Method                                               | Description                                                             |
|------------------------------------------------------|-------------------------------------------------------------------------|
| <a href="#">SetShardingKey(OracleDbType, object)</a> | Enables applications to set a key within the OracleShardingKey object   |
| <a href="#">Dispose</a>                              | Enables applications to explicitly dispose the OracleShardingKey object |

### ① See Also

## OracleShardingKey Constructors

OracleShardingKey constructors instantiate new instances of the OracleShardingKey class.

### Overload List:

- [OracleShardingKey\(\)](#)

This constructor instantiates a new instance of `OracleShardingKey` class.

- [OracleShardingKey\(OracleDbType, object\)](#)

This constructor instantiates a new instance of the `OracleShardingKey` class using the supplied data type and key.

#### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleShardingKey Class](#)
- [OracleShardingKey Members](#)

## OracleShardingKey()

This constructor enables applications to construct the `OracleShardingKey` object.

### Declaration

```
// C#  
public OracleShardingKey();
```

### Exceptions

None

### Remarks

This constructs an `OracleShardingKey` without any keys set.

#### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleShardingKey Class](#)
- [OracleShardingKey Members](#)

## OracleShardingKey(OracleDbType, object)

This constructor enables applications to construct the `OracleShardingKey` object with the supplied key.

### Declaration

```
// C#  
public OracleShardingKey(OracleDbType type, object key);
```

### Exceptions

`InvalidArgumentException` – The supplied argument is invalid

**Remarks**

This constructs an OracleShardingKey with the supplied key set.

Acceptable OracleDbType enumeration values are Byte, Decimal, Double, Int16, Int32, Int64, Single, Varchar2, String, Date, TimeStamp, and Raw.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleShardingKey Class](#)
- [OracleShardingKey Members](#)

## OracleShardingKey Instance Methods

OracleShardingKey instance methods are listed in [Table 6-201](#).

**Table 6-201 OracleShardingKey Instance Methods**

| Instance Method                                           | Description                                                             |
|-----------------------------------------------------------|-------------------------------------------------------------------------|
| <a href="#">SetShardingKey(OracleDbType type, object)</a> | Enables applications to set a key within the OracleShardingKey object   |
| <a href="#">Dispose</a>                                   | Enables applications to explicitly dispose the OracleShardingKey object |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleShardingKey Class](#)
- [OracleShardingKey Members](#)

## SetShardingKey(OracleDbType, object)

This instance method enables applications to set a key within the OracleShardingKey object.

**Declaration**

```
// C#  
public void SetShardingKey(OracleDbType type, object key);
```

**Exceptions**

InvalidArgumentException – The supplied argument is invalid

**Remarks**

This method sets a key within the OracleShardingKey object.

Acceptable OracleDbType enumeration values are Byte, Decimal, Double, Int16, Int32, Int64, Single, Varchar2, String, Date, TimeStamp, and Raw.

This can be called multiple times to construct a composite key.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleShardingKey Class](#)
- [OracleShardingKey Members](#)

## Dispose

This instance method enables applications to explicitly dispose the OracleShardingKey object.

### Declaration

```
// C#  
public void Dispose();
```

### Exceptions

None

### Remarks

This method disposes the OracleShardingKey object.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleShardingKey Class](#)
- [OracleShardingKey Members](#)

## OracleSparseVector Class

An OracleSparseVector object represents a sparse Oracle VECTOR.

### Class Inheritance

System.Object

Oracle.DataAccess.Types.OracleVector

Oracle.DataAccess.Types.OracleSparseVector

### Declaration

```
// C#  
public class OracleSparseVector : OracleVector
```

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

OracleSparseVector Members

OracleSparseVector members are listed in the following tables.

OracleSparseVector Constructors

The OracleSparseVector constructors is listed in [Table 6-202](#).

Table 6-202 OracleSparseVector Constructors

| Constructor                                     | Description                                                                                         |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">OracleSparseVector Constructors</a> | OracleSparseVector constructors instantiate new instances of OracleSparseVector class. (Overloaded) |

OracleSparseVector Properties

OracleSparseVector properties are listed in [Table 6-203](#).

**Table 6-203 OracleSparseVector Properties**

| Property                     | Description                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">Dimensions</a>   | Returns the number of dimensions of the OracleSparseVector                                 |
| <a href="#">VectorType</a>   | Returns the vector type                                                                    |
| <a href="#">ProviderType</a> | Returns the OracleDbType value of the OracleSparseVector provider type                     |
| <a href="#">Value</a>        | Returns a .NET numeric array representing the sparse vector values at the non-zero indices |
| <a href="#">Indices</a>      | Returns a long[] of the zero-based sparse vector's non-zero indices                        |
| <a href="#">Item</a>         | Obtains the element in an OracleSparseVector at the specified index                        |
| <a href="#">IsNull</a>       | Indicates whether the current instance has a null value                                    |

**OracleSparseVector Static Field**

OracleSparseVector static fields are listed in [Table 6-204](#).

**Table 6-204 OracleSparseVector Static Field**

| Static Field | Description                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------|
| Null         | static readonly OracleSparseVector Null represents a null value that can be assigned to an OracleSparseVector instance. |

**OracleSparseVector Instance Methods**

OracleSparseVector Instance methods are listed in [Table 6-205](#).

**Table 6-205 OracleSparseVector Instance Methods**

| Instance Method                        | Description                                                            |
|----------------------------------------|------------------------------------------------------------------------|
| <a href="#">ToInt16Array()</a>         | Returns a short[] value of the OracleSparseVector instance             |
| <a href="#">ToFloatArray()</a>         | Returns a float[] value of the OracleSparseVector instance             |
| <a href="#">ToDoubleArray()</a>        | Returns a double[] value of this OracleSparseVector instance           |
| <a href="#">ToNonZeroInt16Array()</a>  | Returns a short[] of the sparse vector values at the non-zero indices  |
| <a href="#">ToNonZeroFloatArray()</a>  | Returns a float[] of the sparse vector values at the non-zero indices  |
| <a href="#">ToNonZeroDoubleArray()</a> | Returns a double[] of the sparse vector values at the non-zero indices |
| <a href="#">ToString()</a>             | Returns the OracleSparseVector string representation                   |
| <a href="#">Dispose()</a>              | Releases resources allocated by this object                            |

## OracleSparseVector Constructors

OracleSparseVector constructors instantiate new instances of OracleSparseVector class.

**Overload List:**

- [OracleSparseVector\(sparseVectorString\)](#)  
This constructor creates an instance of the OracleSparseVector class with the string representation of a sparse vector.
- [OracleSparseVector\(sparseVectorString, providerType\)](#)  
This constructor creates an instance of the OracleSparseVector class with the string representation of a sparse vector.
- [OracleSparseVector\(dimensions, indices\)](#)  
This constructor creates an instance of the OracleSparseVector class with a specified number of dimensions and the non-zero indices stored in a long[].
- [OracleSparseVector\(dimensions, indices, sparseValue\)](#)  
This constructor creates an instance of the OracleSparseVector class with a specified number of dimensions and non-zero vector values stored in a short[].
- [OracleSparseVector\(dimensions, indices, sparseValue\)](#)  
This constructor creates an instance of the OracleSparseVector class with a specified number of dimensions and non-zero vector values stored in a float[].
- [OracleSparseVector\(dimensions, indices, sparseValue\)](#)  
This constructor creates an instance of the OracleSparseVector class with a specified number of dimensions and non-zero vector values stored in a double[].

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

### OracleSparseVector(sparseVectorString)

This constructor creates an instance of the OracleSparseVector class with the string representation of a sparse vector.

**Declaration**

```
// C#  
public OracleSparseVector(string sparseVectorString);
```

**Parameters**

sparseVectorString

The string representation of a sparse vector

**Exceptions**

ArgumentException - The parameter is an invalid string representation of an OracleSparseVector.

ArgumentNullException - The parameter is null.

**Remarks**

The ProviderType is OracleDbType.Vector\_Float32 unless it is in binary sparse vector format. If that is the case, the ProviderType is OracleDbType.Vector\_Binary.

If the vector parameter has a length of zero, then the constructed instance will have null value and IsNull will be true.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## OracleSparseVector(sparseVectorString, providerType)

This constructor creates an instance of the OracleSparseVector class with the string representation of a sparse vector.

**Declaration**

```
// C#  
public OracleSparseVector(string sparseVectorString, OracleDbType providerType);
```

**Parameters**

- sparseVectorString  
The string representation of a sparse vector
- providerType  
The OracleDbType of the resulting OracleSparseVector.

**Exceptions**

ArgumentException - The parameter is an invalid string or binary representation of an OracleSparseVector or the providerType is not an OracleDbType.Vector\*.

ArgumentNullException - The parameter is null.

### Remarks

The allowed providerType values are:

- OracleDbType.Vector
- OracleDbType.Vector\_Binary
- OracleDbType.Vector\_Int8
- OracleDbType.Vector\_Float32
- OracleDbType.Vector\_Float64

If the vector parameter has a length of zero, then the constructed instance will have null value and IsNull will be true.

When providerType is OracleDbType.Vector and if sparseVectorString is in binary sparse vector format, then the OracleSparseVector ProviderType becomes OracleDbType.Vector\_Binary; otherwise, it becomes OracleDbType.Vector\_Float32 for other vector formats.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## OracleSparseVector(dimensions, indices)

This constructor creates an instance of the OracleSparseVector class with a specified number of dimensions and the non-zero indices stored in a long[].

### Declaration

```
// C#  
public OracleSparseVector(long dimensions, long[] indices);
```

### Parameters

- dimensions  
The number of dimensions of the sparse vector
- indices  
The long[] for the zero-based sparse vector's non-zero indices

### Exceptions

ArgumentOutOfRangeException - index is less than 0, or an element in indices is less than 0 or greater than or equal to dimensions.

ArgumentNullException - The indices parameter is null.

ArgumentException - The dimensions are not a multiple of 8 or are less than the length of indices.

**Remarks**

The `ProviderType` is `OracleDbType.Vector_Binary`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## OracleSparseVector(dimensions, indices, sparseValue)

This constructor creates an instance of the `OracleSparseVector` class with a specified number of dimensions and non-zero vector values stored in a `short[]`.

**Declaration**

```
// C#  
public OracleSparseVector(long dimensions, long[] indices, short[] sparseValue);
```

**Parameters**

- `dimensions`  
The number of sparse vector dimensions.
- `indices`  
The `long[]` for the zero-based sparse vector's non-zero indices.
- `sparseValue`  
The `short[]` for the vector values of the non-zero indices.

**Exceptions**

`ArgumentOutOfRangeException` - `dimensions` index is less than zero; an `indices` element is less than zero or greater than or equal to `dimensions`; or a vector value is either too large or too small for a signed byte (`INT8`).

`ArgumentNullException` - The `indices` or `sparseValue` parameter is null.

`ArgumentException` - The `dimensions` are fewer than the length of `indices` or `sparseValue`, or the length of `indices` and `sparseValue` are not equal.

**Remarks**

The `ProviderType` is `OracleDbType.Vector_Int8`.

If the vector parameter has a length of zero, then the constructed instance will have null value and `IsNull` will be true.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## OracleSparseVector(dimensions, indices, sparseValue)

This constructor creates an instance of the `OracleSparseVector` class with a specified number of dimensions and non-zero vector values stored in a `float[]`.

**Declaration**

```
// C#  
public OracleSparseVector(long dimensions, long[] indices, float[] sparseValue);
```

**Parameters**

- **dimensions**  
The number of sparse vector dimensions.
- **indices**  
The `long[]` for the zero-based sparse vector's non-zero indices.
- **sparseValue**  
The `float[]` for the vector values of the non-zero indices.

**Exceptions**

`ArgumentOutOfRangeException` – `dimensions` index is less than zero, or an element in `indices` is less than zero or greater than or equal to `dimensions`.

`ArgumentNullException` - The `indices` or `sparseValue` parameter is null.

`ArgumentException` - The `dimensions` are fewer than the length of `indices` or `sparseValue`, or the length of `indices` and `sparseValue` are not equal.

**Remarks**

The `ProviderType` is `OracleDbType.Vector_Float32`.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## OracleSparseVector(dimensions, indices, sparseValue)

This constructor creates an instance of the `OracleSparseVector` class with a specified number of dimensions and non-zero vector values stored in a `double[]`.

Declaration

```
// C#
public OracleSparseVector(long dimensions, long[] indices, double[] sparseValue);
```

Parameters

- dimensions  
The number of sparse vector dimensions.
- indices  
The long[] for the zero-based sparse vector's non-zero indices.
- sparseValue  
The double[] for the vector values of the non-zero indices.

Exceptions

ArgumentOutOfRangeException – dimensions index is less than zero, or an element in indices is less than zero or greater than or equal to dimensions.

ArgumentNullException - The indices or sparseValue parameter is null.

ArgumentException - The dimensions are fewer than the length of indices or sparseValue, or the length of indices and sparseValue are not equal.

Remarks

The ProviderType is OracleDbType.Vector\_Float64.

OracleSparseVector Properties

OracleSparseVector properties are listed in [Table 6-206](#).

Table 6-206 OracleSparseVector Properties

| Property                     | Description                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">Dimensions</a>   | Returns the number of dimensions of the OracleSparseVector                                 |
| <a href="#">VectorType</a>   | Returns the vector type                                                                    |
| <a href="#">ProviderType</a> | Returns the OracleDbType value of the OracleSparseVector provider type                     |
| <a href="#">Value</a>        | Returns a .NET numeric array representing the sparse vector values at the non-zero indices |

Table 6-206 (Cont.) OracleSparseVector Properties

| Property                | Description                                                                      |
|-------------------------|----------------------------------------------------------------------------------|
| <a href="#">Indices</a> | Returns a <code>long[]</code> of the zero-based sparse vector's non-zero indices |
| <a href="#">Item</a>    | Obtains the element in an <code>OracleSparseVector</code> at the specified index |
| <a href="#">IsNull</a>  | Indicates whether the current instance has a null value                          |

 **See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

Dimensions

This property returns the number of dimensions of the `OracleSparseVector`.

**Declaration**

```
// C#  
public long Dimensions {get;}
```

**Property Value**

A long value

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

**Remarks**

Inherits `OracleVector` `Dimensions` property.

 **See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

VectorType

This property returns the vector type.

**Declaration**

```
// C#  
public OracleVectorType VectorType {get;}
```

**Property Value**

OracleSparseVector always returns as type OracleVectorType.Sparse.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

**Remarks**

Inherits OracleVector VectorType property.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## ProviderType

This property returns the OracleDbType value of the OracleSparseVector provider type.

**Declaration**

```
// C#  
public OracleDbType ProviderType {get;}
```

**Property Value**

The vector's provider type corresponds to its numeric format.

Possible values include:

- OracleDbType.Vector\_Binary
- OracleDbType.Vector\_Int8
- OracleDbType.Vector\_Float32
- OracleDbType.Vector\_Float64

**Exceptions**

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

Value

This property returns a .NET numeric array representing the sparse vector values at the non-zero indices.

Declaration

```
// C#
public Array Value {get;}
```

Property Value

A .NET numeric array representing the sparse vector values at the non-zero indices. This array can be byte[], Int16[], float[], or double[] depending on the sparse vector's numeric format.

Exceptions

- OracleNullValueException - The current instance has a null value.
- ObjectDisposedException - The object is already disposed.

Remarks

This property's return type varies depending on the sparse vector's numeric format.

| Numeric Format              | Return Type |
|-----------------------------|-------------|
| OracleDbType.Vector_Binary  | byte[]      |
| OracleDbType.Vector_Int8    | short[]     |
| OracleDbType.Vector_Float32 | float[]     |
| OracleDbType.Vector_Float64 | double[]    |

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

Indices

This property returns a long[] of the zero-based sparse vector's non-zero indices.

**Declaration**

```
// C#  
public long[] Indices {get;}
```

**Property Value**

A long[] of the zero-based sparse vector's non-zero indices.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## Item

This property obtains the element in an OracleSparseVector at the specified index.

**Declaration**

```
// C#  
public object this [long index] {get;}
```

**Parameters**

index

The zero-based index of the element to get from the OracleSparseVector

**Property Value**

An object value of bool, short, float, or double at the specified index depending on the sparse vector's numeric format.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - Index is less than zero or index is equal to or greater than number of dimensions.

ObjectDisposedException - The object is already disposed.

**Remarks**

This property's return type varies depending on the sparse vector's numeric format.

| Numeric Format              | Return Type |
|-----------------------------|-------------|
| OracleDbType.Vector_Binary  | bool        |
| OracleDbType.Vector_Int8    | short       |
| OracleDbType.Vector_Float32 | float       |
| OracleDbType.Vector_Float64 | double      |

❶ See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

IsNull

This property indicates whether the current instance has a null value.

Declaration

```
// C#
public bool IsNull {get;}
```

Property Value

Returns true if the current instance has a null value; otherwise, returns false.

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

OracleSparseVector Instance Methods

OracleSparseVector instance methods are listed in [Table 6-207](#).

Table 6-207 OracleSparseVector Instance Methods

| Instance Method                       | Description                                                           |
|---------------------------------------|-----------------------------------------------------------------------|
| <a href="#">ToInt16Array()</a>        | Returns a short[] value of the OracleSparseVector instance            |
| <a href="#">ToFloatArray()</a>        | Returns a float[] value of the OracleSparseVector instance            |
| <a href="#">ToDoubleArray()</a>       | Returns a double[] value of this OracleSparseVector instance          |
| <a href="#">ToNonZeroInt16Array()</a> | Returns a short[] of the sparse vector values at the non-zero indices |

**Table 6-207 (Cont.) OracleSparseVector Instance Methods**

| Instance Method                        | Description                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">ToNonZeroFloatArray()</a>  | Returns a <code>float[]</code> of the sparse vector values at the non-zero indices  |
| <a href="#">ToNonZeroDoubleArray()</a> | Returns a <code>double[]</code> of the sparse vector values at the non-zero indices |
| <a href="#">ToString()</a>             | Returns the <code>OracleSparseVector</code> string representation                   |

## ToInt16Array()

The method returns a `short[]` value of this `OracleSparseVector` instance.

**Declaration**

```
// C#  
public short[] ToInt16Array();
```

**Return Value**

A `short[]` representing the whole sparse vector in dense vector form.

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

**Remarks**

If the vector's numeric format is not `OracleDbType.Vector_Int8`, then this method implicitly converts the vector values to short types.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## ToFloatArray()

The method returns a `float[]` value of this `OracleSparseVector` instance.

### Declaration

```
// C#  
public float[] ToFloatArray();
```

### Return Value

A `float[]` representing the whole sparse vector in dense vector form.

### Expections

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Float32`, then this method implicitly converts the vector values to float types.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## ToDoubleArray()

The method returns a `double[]` value of this `OracleSparseVector` instance.

### Declaration

```
// C#  
public double[] ToDoubleArray();
```

### Return Value

A `double[]` representing the whole sparse vector in dense vector form.

### Expections

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Float64`, then this method implicitly converts the vector values to double types.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## ToNonZeroInt16Array()

The method returns a `short[]` of the sparse vector values at the non-zero indices.

**Declaration**

```
// C#  
public short[] ToNonZeroInt16Array();
```

**Return Value**

A `short[]` of the sparse vector values at the non-zero indices.

**Expections**

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

**Remarks**

If the vector's numeric format is not `OracleDbType.Vector_Int8`, then this method implicitly converts the vector values to short types.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## ToNonZeroFloatArray()

The method returns a `float[]` of the sparse vector values at the non-zero indices.

**Declaration**

```
// C#  
public float[] ToNonZeroFloatArray();
```

**Return Value**

A `float[]` of the sparse vector values at the non-zero indices.

**Expections**

`OracleNullValueException` - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Float32`, then this method implicitly converts the vector values to float types.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## ToNonZeroDoubleArray()

The method returns a `double[]` of the sparse vector values at the non-zero indices.

### Declaration

```
// C#  
public double[] ToNonZeroDoubleArray();
```

### Return Value

A `double[]` of the sparse vector values at the non-zero indices.

### Exceptions

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Float64`, then this method implicitly converts the vector values to double types.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## ToString()

This method returns the `OracleSparseVector` string representation

### Declaration

```
// C#  
public string ToString();
```

**Return Value**

Returns the sparse vector representation as a JSON format string.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

For BINARY sparse vectors, the JSON format string has 2 elements: dimensions and indices. For sparse vectors of all other numeric formats, the JSON format string has 3 elements: dimensions, indices, and sparse values.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## Dispose()

This instance method releases resources allocated by this object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

**Remarks**

The object cannot be reused after being disposed. Although some properties can still be accessed, their values cannot be accountable. Since resources are freed, method calls can lead to exceptions.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleSparseVector Class](#)
- [OracleSparseVector Members](#)

## OracleTransaction Class

An OracleTransaction object represents a local transaction.

Class Inheritance

System.Object  
    System.MarshalByRefObject  
        System.Data.Common.DbTransaction  
            Oracle.DataAccess.Client.OracleTransaction

Declaration

```
// C#  
public sealed class OracleTransaction : DbTransaction  
  
// C#  
public sealed class OracleTransaction : MarshalByRefObject,  
    IDbTransaction, IDisposable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

The application calls BeginTransaction on the OracleConnection object to create an OracleTransaction object. The OracleTransaction object can be created in Read Committed mode only. Any other mode results in an exception.

The execution of a [DDL](#) statement in the context of a transaction is not recommended since it results in an implicit commit that is not reflected in the state of the OracleTransaction object.

All operations related to [savepoints](#) pertain to the current local transaction. Operations like commit and rollback performed on the transaction have no effect on data in any existing DataSet.

Example

```
// Database Setup, if you have not done so yet.  
/*  
connect scott/tiger@oracle  
DROP TABLE MyTable;  
CREATE TABLE MyTable (MyColumn NUMBER);  
--CREATE TABLE MyTable (MyColumn NUMBER PRIMARY KEY);
```

```
*/

// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class OracleTransactionSample
{
    static void Main()
    {
        // Drop & Create MyTable as indicated Database Setup, at beginning

        // This sample starts a transaction and inserts two records with the same
        // value for MyColumn into MyTable.
        // If MyColumn is not a primary key, the transaction will commit.
        // If MyColumn is a primary key, the second insert will violate the
        // unique constraint and the transaction will rollback.

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleCommand cmd = con.CreateCommand();

        // Check the number of rows in MyTable before transaction
        cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
        int myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

        // Print the number of rows in MyTable
        Console.WriteLine("myTableCount = " + myTableCount);

        // Start a transaction
        OracleTransaction txn = con.BeginTransaction(
            IsolationLevel.ReadCommitted);

        try
        {
            // Insert the same row twice into MyTable
            cmd.CommandText = "INSERT INTO MyTable VALUES (1)";
            cmd.ExecuteNonQuery();
            cmd.ExecuteNonQuery(); // This may throw an exception
            txn.Commit();
        }
        catch (Exception e)
        {
            // Print the exception message
            Console.WriteLine("e.Message = " + e.Message);

            // Rollback the transaction
            txn.Rollback();
        }

        // Check the number of rows in MyTable after transaction
        cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
        myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

        // Prints the number of rows
        // If MyColumn is not a PRIMARY KEY, the value should increase by two.
    }
}
```

```
// If MyColumn is a PRIMARY KEY, the value should remain same.
Console.WriteLine("myTableCount = " + myTableCount);

txn.Dispose();
cmd.Dispose();

con.Close();
con.Dispose();
}
}
```

## OracleTransaction Members

OracleTransaction members are listed in the following tables.

### OracleTransaction Static Methods

The OracleTransaction static method is listed in [Table 6-208](#).

**Table 6-208 OracleTransaction Static Method**

| Method                 | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

### OracleTransaction Properties

OracleTransaction properties are listed in [Table 6-209](#).

**Table 6-209 OracleTransaction Properties**

| Property                       | Description                                                      |
|--------------------------------|------------------------------------------------------------------|
| <a href="#">IsolationLevel</a> | Specifies the isolation level for the transaction                |
| <a href="#">Connection</a>     | Specifies the connection that is associated with the transaction |

### OracleTransaction Public Methods

OracleTransaction public methods are listed in [Table 6-210](#).

**Table 6-210 OracleTransaction Public Methods**

| Public Method          | Description                      |
|------------------------|----------------------------------|
| <a href="#">Commit</a> | Commits the database transaction |

**Table 6-210 (Cont.) OracleTransaction Public Methods**

| Public Method             | Description                                              |
|---------------------------|----------------------------------------------------------|
| CreateObjRef              | Inherited from System.MarshalByRefObject                 |
| <a href="#">Dispose</a>   | Frees the resources used by the OracleTransaction object |
| Equals                    | Inherited from System.Object (Overloaded)                |
| GetHashCode               | Inherited from System.Object                             |
| GetLifetimeService        | Inherited from System.MarshalByRefObject                 |
| GetType                   | Inherited from System.Object                             |
| InitializeLifetimeService | Inherited from System.MarshalByRefObject                 |
| <a href="#">Rollback</a>  | Rolls back a database transaction (Overloaded)           |
| <a href="#">Save</a>      | Creates a savepoint within the current transaction       |
| ToString                  | Inherited from System.Object                             |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleTransaction Class](#)

## OracleTransaction Static Methods

The OracleTransaction static method is listed in [Table 6-211](#).

**Table 6-211 OracleTransaction Static Method**

| Method | Description                               |
|--------|-------------------------------------------|
| Equals | Inherited from System.Object (Overloaded) |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## OracleTransaction Properties

OracleTransaction properties are listed in [Table 6-212](#).

**Table 6-212 OracleTransaction Properties**

| Property                       | Description                                                      |
|--------------------------------|------------------------------------------------------------------|
| <a href="#">IsolationLevel</a> | Specifies the isolation level for the transaction                |
| <a href="#">Connection</a>     | Specifies the connection that is associated with the transaction |

**① See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## IsolationLevel

This property specifies the isolation level for the transaction.

**Declaration**

```
// C#  
public override IsolationLevel IsolationLevel {get;}
```

**Property Value**

IsolationLevel

**Implements**

IDbTransaction

**Exceptions**

InvalidOperationException - The transaction has already completed.

**Remarks**

Default = IsolationLevel.ReadCommitted

**① See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## Connection

This property specifies the connection that is associated with the transaction.

Declaration

```
// C#
public OracleConnection Connection {get;}
```

Property Value

Connection

Implements

IDbTransaction

Remarks

This property indicates the OracleConnection object that is associated with the transaction.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

OracleTransaction Public Methods

OracleTransaction public methods are listed in [Table 6-213](#).

Table 6-213 OracleTransaction Public Methods

| Public Method             | Description                                              |
|---------------------------|----------------------------------------------------------|
| <a href="#">Commit</a>    | Commits the database transaction                         |
| CreateObjRef              | Inherited from System.MarshalByRefObject                 |
| <a href="#">Dispose</a>   | Frees the resources used by the OracleTransaction object |
| Equals                    | Inherited from System.Object (Overloaded)                |
| GetHashCode               | Inherited from System.Object                             |
| GetLifetimeService        | Inherited from System.MarshalByRefObject                 |
| GetType                   | Inherited from System.Object                             |
| InitializeLifetimeService | Inherited from System.MarshalByRefObject                 |
| <a href="#">Rollback</a>  | Rolls back a database transaction (Overloaded)           |
| <a href="#">Save</a>      | Creates a savepoint within the current transaction       |
| ToString                  | Inherited from System.Object                             |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## Commit

This method commits the database transaction.

### Declaration

```
// C#  
public override void Commit();
```

### Implements

IDbTransaction

### Exceptions

InvalidOperationException - The transaction has already been completed successfully, has been rolled back, or the associated connection is closed.

### Remarks

Upon a successful commit, the transaction enters a completed state.

Upon `Commit()`, `AutoCommit` and `IsolationLevel` return to the respective values specified on the `OracleConnection` object.

### Example

```
// Database Setup, if you have not done so yet  
/*  
connect scott/tiger@oracle  
DROP TABLE MyTable;  
CREATE TABLE MyTable (MyColumn NUMBER);  
--CREATE TABLE MyTable (MyColumn NUMBER PRIMARY KEY);  
  
*/  
  
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class CommitSample  
{  
    static void Main()  
    {  
        // Drop & Create MyTable as indicated in Database Setup, at beginning  
  
        // This sample starts a transaction and inserts two records with the same  
        // value for MyColumn into MyTable.  
        // If MyColumn is not a primary key, the transaction will commit.
```

```
// If MyColumn is a primary key, the second insert will violate the
// unique constraint and the transaction will rollback.

string constr = "User Id=scott;Password=tiger;Data Source=oracle";
OracleConnection con = new OracleConnection(constr);
con.Open();

OracleCommand cmd = con.CreateCommand();

// Check the number of rows in MyTable before transaction
cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
int myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

// Print the number of rows in MyTable
Console.WriteLine("myTableCount = " + myTableCount);

// Start a transaction
OracleTransaction txn = con.BeginTransaction(
    IsolationLevel.ReadCommitted);

try
{
    // Insert the same row twice into MyTable
    cmd.CommandText = "INSERT INTO MyTable VALUES (1)";
    cmd.ExecuteNonQuery();
    cmd.ExecuteNonQuery(); // This may throw an exception
    txn.Commit();
}
catch (Exception e)
{
    // Print the exception message
    Console.WriteLine("e.Message = " + e.Message);

    // Rollback the transaction
    txn.Rollback();
}

// Check the number of rows in MyTable after transaction
cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

// Prints the number of rows
// If MyColumn is not a PRIMARY KEY, the value should increase by two.
// If MyColumn is a PRIMARY KEY, the value should remain same.
Console.WriteLine("myTableCount = " + myTableCount);

txn.Dispose();
cmd.Dispose();

con.Close();
con.Dispose();
}
}
```

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## Dispose

This method frees the resources used by the OracleTransaction object.

### Declaration

```
// C#  
public void Dispose();
```

### Implements

IDisposable

### Remarks

This method releases both the managed and unmanaged resources held by the OracleTransaction object. If the transaction is not in a completed state, an attempt to rollback the transaction is made.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## Rollback

Rollback rolls back a database transaction.

### Overload List:

- [Rollback\(\)](#)  
This method rolls back a database transaction.
- [Rollback\(string\)](#)  
This method rolls back a database transaction to a [savepoint](#) within the current transaction.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## Rollback()

This method rolls back a database transaction.

**Declaration**

```
// C#  
public override void Rollback();
```

**Implements**

IDbTransaction

**Exceptions**

InvalidOperationException - The transaction has already been completed successfully, has been rolled back, or the associated connection is closed.

**Remarks**

After a Rollback(), the OracleTransaction object can no longer be used because the Rollback ends the transaction.

Upon Rollback(), AutoCommit and IsolationLevel return to the respective values specified on the OracleConnection object.

**Example**

```
// Database Setup, if you have not done so yet.  
/*  
connect scott/tiger@oracle  
DROP TABLE MyTable;  
CREATE TABLE MyTable (MyColumn NUMBER);  
  
*/  
  
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
  
class RollbackSample  
{  
    static void Main()  
    {  
        // Drop & Create MyTable as indicated previously in Database Setup  
  
        // This sample starts a transaction and inserts one record into MyTable.  
        // It then rollsback the transaction, the number of rows remains the same
```

```
string constr = "User Id=scott;Password=tiger;Data Source=oracle";
OracleConnection con = new OracleConnection(constr);
con.Open();

OracleCommand cmd = con.CreateCommand();

// Check the number of rows in MyTable before transaction
cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
int myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

// Print the number of rows in MyTable
Console.WriteLine("myTableCount = " + myTableCount);

// Start a transaction
OracleTransaction txn = con.BeginTransaction(
    IsolationLevel.ReadCommitted);

// Insert a row into MyTable
cmd.CommandText = "INSERT INTO MyTable VALUES (1)";
cmd.ExecuteNonQuery();

// Rollback the transaction
txn.Rollback();

// Check the number of rows in MyTable after transaction
cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

// Prints the number of rows, should remain the same
Console.WriteLine("myTableCount = " + myTableCount);

txn.Dispose();
cmd.Dispose();

con.Close();
con.Dispose();
}
}
```

#### 📘 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## Rollback(string)

This method rolls back a database transaction to a [savepoint](#) within the current transaction.

### Declaration

```
// C#
public override void Rollback(string savepointName);
```

### Parameters

- *savepointName*

The name of the savepoint to rollback to, in the current transaction.

### Exceptions

`InvalidOperationException` - The transaction has already been completed successfully, has been rolled back, or the associated connection is closed.

### Remarks

After a rollback to a savepoint, the current transaction remains active and can be used for further operations.

The *savepointName* specified does not have to match the case of the *savepointName* created using the `Save` method, since savepoints are created in the database in a case-insensitive manner.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleTransaction Class](#)
- [OracleTransaction Members](#)

## Save

This method creates a [savepoint](#) within the current transaction.

### Declaration

```
// C#  
public void Save(string savepointName);
```

### Parameters

- *savepointName*  
The name of the savepoint being created in the current transaction.

### Exceptions

`InvalidOperationException` - The transaction has already been completed.

### Remarks

After creating a savepoint, the transaction does not enter a completed state and can be used for further operations.

The *savepointName* specified is created in the database in a case-insensitive manner. Calling the `Rollback` method rolls back to *savepointName*. This allows portions of a transaction to be rolled back, instead of the entire transaction.

### Example

```
// Database Setup, if you have not done so yet.  
/*  
connect scott/tiger@oracle  
DROP TABLE MyTable;
```

```
CREATE TABLE MyTable (MyColumn NUMBER);

*/

// C#

using System;
using System.Data;
using Oracle.DataAccess.Client;

class SaveSample
{
    static void Main()
    {
        // Drop & Create MyTable as indicated in Database Setup, at beginning

        // This sample starts a transaction and creates a savepoint after
        // inserting one record into MyTable.
        // After inserting the second record it rollsback to the savepoint
        // and commits the transaction. Only the first record will be inserted

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleCommand cmd = con.CreateCommand();

        // Check the number of rows in MyTable before transaction
        cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
        int myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

        // Print the number of rows in MyTable
        Console.WriteLine("myTableCount = " + myTableCount);

        // Start a transaction
        OracleTransaction txn = con.BeginTransaction(
            IsolationLevel.ReadCommitted);

        // Insert a row into MyTable
        cmd.CommandText = "INSERT INTO MyTable VALUES (1)";
        cmd.ExecuteNonQuery();

        // Create a savepoint
        txn.Save("MySavePoint");

        // Insert another row into MyTable
        cmd.CommandText = "insert into mytable values (2)";
        cmd.ExecuteNonQuery();

        // Rollback to the savepoint
        txn.Rollback("MySavePoint");

        // Commit the transaction
        txn.Commit();

        // Check the number of rows in MyTable after transaction
        cmd.CommandText = "SELECT COUNT(*) FROM MyTable";
        myTableCount = int.Parse(cmd.ExecuteScalar().ToString());

        // Prints the number of rows, should have increased by 1
        Console.WriteLine("myTableCount = " + myTableCount);
    }
}
```

```
        txn.Dispose();  
        cmd.Dispose();  
  
        con.Close();  
        con.Dispose();  
    }  
}
```

# OracleVector Class

An OracleVector object represents a dense Oracle VECTOR. It is the base class for all Oracle VECTOR types.

**Class Inheritance**

System.Object  
  
Oracle.DataAccess.Types.OracleVector

**Declaration**

```
// C#  
public class OracleVector : INullable, IXmlSerializable, IDisposable
```

**Requirements**

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [Artificial Intelligence Vectors and Semantic Search](#)
- [OracleVector Members](#)

## OracleVector Members

OracleVector members are listed in the following tables.

### OracleVector Constructors

The OracleVector constructors is listed in [Table 6-214](#).

**Table 6-214 OracleVector Constructors**

| Constructor                               | Description                                                                             |
|-------------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">OracleVector Constructors</a> | OracleVector constructors instantiate new instances of OracleVector class. (Overloaded) |

### OracleVector Properties

OracleVector properties are listed in [Table 6-215](#).

**Table 6-215 OracleVector Properties**

| Property                     | Description                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Dimensions</a>   | Returns the number of dimensions of the OracleVector                                         |
| <a href="#">VectorType</a>   | Returns the vector's storage format                                                          |
| <a href="#">ProviderType</a> | Returns the OracleDbType value of the OracleVector provider type                             |
| <a href="#">Value</a>        | Returns a .NET array representing the vector                                                 |
| <a href="#">Item[long]</a>   | Obtains the element in an OracleVector at the specified index                                |
| IsNull                       | bool IsNull returns true if the current instance has a null value; otherwise, returns false. |

### OracleVector Static Field

OracleVector static fields are listed in [Table 6-216](#).

**Table 6-216 OracleVector Static Field**

| Static Field | Description                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------|
| Null         | static readonly OracleVector Null represents a null value that can be assigned to an OracleVector instance |

**OracleVector Instance Methods**

OracleVector Instance methods are listed in [Table 6-217](#).

**Table 6-217 OracleVector Instance Methods**

| Instance Method                 | Description                                            |
|---------------------------------|--------------------------------------------------------|
| <a href="#">ToInt16Array()</a>  | Returns a short[] value of the OracleVector instance   |
| <a href="#">ToFloatArray()</a>  | Returns a float[] value of the OracleVector instance   |
| <a href="#">ToDoubleArray()</a> | Returns a double[] value of this OracleVector instance |
| <a href="#">ToByteArray()</a>   | Returns a byte[] value of this OracleVector instance   |
| <a href="#">ToString()</a>      | Returns the OracleVector string representation         |
| <a href="#">Dispose()</a>       | Releases resources allocated by this object            |

## OracleVector Constructors

OracleVector constructors instantiate new instances of OracleVector class.

**Overload List:**

- [OracleVector\(vectorString\)](#)  
This constructor creates an instance of the OracleVector class with the string representation of a vector.
- [OracleVector\(vectorString, providerType\)](#)  
This constructor creates an instance of the OracleVector class with the string representation of a vector.
- [OracleVector\(vectorValues\)](#)  
This constructor creates an instance of the OracleVector class with a vector in the short[].
- [OracleVector\(vectorValues\)](#)  
This constructor creates an instance of the OracleVector class with a vector in the float[].

- [OracleVector\(vectorValues\)](#)

This constructor creates an instance of the `OracleVector` class with a vector in the `double[]`.

- [OracleVector\(vectorValues\)](#)

This constructor creates an instance of the `OracleVector` class with a vector in the `byte[]`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## OracleVector(vectorString)

This constructor creates an instance of the `OracleVector` class with the string representation of a vector.

### Declaration

```
// C#  
public OracleVector(string vectorString);
```

### Parameters

*vectorString*

The string representation of a vector

### Exceptions

`ArgumentException` - The string parameter is an invalid string representation of an `OracleVector`.

`ArgumentNullException` - The string parameter is null.

### Remarks

The `ProviderType` is `OracleDbType.Vector_Float32`.

If the parameter value is an empty string, then the constructed instance will have null value and `IsNull` will be true.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## OracleVector(vectorString, providerType)

This constructor creates an instance of the `OracleVector` class with the string representation of a vector.

### Declaration

```
// C#  
public OracleVector(string vectorString, OracleDbType providerType);
```

### Parameters

- *vectorString*  
The string representation of a vector
- *providerType*  
The `OracleDbType` of the resulting `OracleVector`.

### Exceptions

`ArgumentException` - The vector string parameter is an invalid string representation of an `OracleVector` or the `providerType` is not a `OracleDbType.Vector*`

`ArgumentNullException` - The string parameter is null.

### Remarks

The allowed `providerType` values are:

- `OracleDbType.Vector`
- `OracleDbType.Vector_Int8`
- `OracleDbType.Vector_Float32`
- `OracleDbType.Vector_Float64`
- `OracleDbType.Vector_Binary`

If `providerType` is `OracleDbType.Vector`, then the `OracleSparseVector` `ProviderType` will be `OracleDbType.Vector_Float32`.

If the parameter value is an empty string, then the constructed instance will have null value and `IsNull` will be true.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## OracleVector(vectorValues)

This constructor creates an instance of the `OracleVector` class with a vector in the `short[]`.

**Declaration**

```
// C#  
public OracleVector(short[] vectorValues);
```

**Parameters**

*vectorValues*

A short[] that represents a vector.

**Exceptions**

ArgumentNullException - The parameter is null.

ArgumentOutOfRangeException - A value in the parameter vector is either too large or too small for a signed byte (INT8).

**Remarks**

The ProviderType is OracleDbType.Vector\_Int8.

If the vector parameter has a length of zero, then the constructed instance will have null value and IsNull will be true.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## OracleVector(vectorValues)

This constructor creates an instance of the OracleVector class with a vector in the float[].

**Declaration**

```
// C#  
public OracleVector(float[] vectorValues);
```

**Parameters**

*vectorValues*

A float[] that represents a vector.

**Exceptions**

ArgumentNullException - The parameter is null.

**Remarks**

The ProviderType is OracleDbType.Vector\_Float32.

If the vector parameter has a length of zero, then the constructed instance will have null value and IsNull will be true.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## OracleVector(vectorValues)

This constructor creates an instance of the `OracleVector` class with a vector in the `double[]`.

**Declaration**

```
// C#  
public OracleVector(double[] vectorValues);
```

**Parameters**

*vectorValues*

A `double[]` that represents a vector.

**Exceptions**

`ArgumentNullException` - The parameter is null.

**Remarks**

The `ProviderType` is `OracleDbType.Vector_Float64`.

If the vector parameter has a length of zero, then the constructed instance will have null value and `IsNull` will be true.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## OracleVector(vectorValues)

This constructor creates an instance of the `OracleVector` class with a vector in the `byte[]`.

**Declaration**

```
// C#  
public OracleVector(byte[] vectorValues);
```

**Parameters**

*vectorValues*

A `byte[]` that represents a vector with BINARY numeric format.

Exceptions

ArgumentNullException - The parameter is null.

Remarks

The ProviderType is OracleDbType.Vector\_Binary.

If the vector parameter has a length of zero, then the constructed instance will have null value and IsNull will be true.

OracleVector Properties

OracleVector properties are listed in [Table 6-218](#).

Table 6-218 OracleVector Properties

| Property                     | Description                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Dimensions</a>   | Returns the number of dimensions of the OracleVector                                         |
| <a href="#">VectorType</a>   | Returns the vector's storage format                                                          |
| <a href="#">ProviderType</a> | Returns the OracleDbType value of the OracleVector provider type                             |
| <a href="#">Value</a>        | Returns a .NET array representing the vector                                                 |
| <a href="#">Item[long]</a>   | Obtains the element in an OracleVector at the specified index                                |
| IsNull                       | bool IsNull returns true if the current instance has a null value; otherwise, returns false. |

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

Dimensions

This property returns the number of dimensions of the OracleVector.

**Declaration**

```
// C#  
public long Dimensions {get;}
```

**Property Value**

A long value

**Exceptions**

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## VectorType

This property returns the vector's storage format.

**Declaration**

```
// C#  
public OracleVectorType VectorType {get;}
```

**Property Value**

The OracleVectorType representing the storage format of the OracleVector.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

**Remarks**

OracleVector will always return the vector value in dense format regardless of whether the vector is dense or sparse. To retrieve sparse values, cast the OracleVector to OracleSparseVector and use the OracleSparseVector APIs.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## ProviderType

This property returns the `OracleDbType` value of the `OracleVector` provider type.

### Declaration

```
// C#  
public OracleDbType ProviderType {get;}
```

### Property Value

The vector's provider type corresponds to its numeric format.

Possible values:

- `OracleDbType.Vector_Int8`
- `OracleDbType.Vector_Float32`
- `OracleDbType.Vector_Float64`
- `OracleDbType.Vector_Binary`

### Exceptions

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## Value

This property returns a .NET array representing the vector.

### Declaration

```
// C#  
public Array Value {get;}
```

### Property Value

A .NET array representing the vector. This array can be `Int16[]`, `float[]`, `double[]`, or `byte[]` depending on the vector numeric format.

### Exceptions

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

Remarks

The property return type varies based on the vector numeric format.

| Numeric Format              | Return Type |
|-----------------------------|-------------|
| OracleDbType.Vector_Int8    | short[]     |
| OracleDbType.Vector_Float32 | float[]     |
| OracleDbType.Vector_Float64 | double[]    |
| OracleDbType.Vector_Binary  | byte[]      |

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

Item[long]

This property obtains the element in an OracleVector at the specified index.

Declaration

```
// C#
public object this [long index] {get;}
```

Parameters

index

The zero-based index of the element to retrieve from the OracleVector

Property Value

A short, float, double, or bool object at the specified index depending on the vector numeric format.

Exceptions

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - Index is less than zero or index is equal to or greater than vector dimensions.

ObjectDisposedException - The object is already disposed.

Remarks

The property return type varies based on the vector numeric format.

| Numeric Format           | Return Type |
|--------------------------|-------------|
| OracleDbType.Vector_Int8 | short       |

| Numeric Format              | Return Type |
|-----------------------------|-------------|
| OracleDbType.Vector_Float32 | float       |
| OracleDbType.Vector_Float64 | double      |
| OracleDbType.Vector_Binary  | bool        |

 **See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## OracleVector Instance Methods

OracleVector instance methods are listed in [Table 6-219](#).

**Table 6-219 OracleVector Instance Methods**

| Instance Method                 | Description                                            |
|---------------------------------|--------------------------------------------------------|
| <a href="#">ToInt16Array()</a>  | Returns a short[] value of the OracleVector instance   |
| <a href="#">ToFloatArray()</a>  | Returns a float[] value of the OracleVector instance   |
| <a href="#">ToDoubleArray()</a> | Returns a double[] value of this OracleVector instance |
| <a href="#">ToByteArray()</a>   | Returns a byte[] value of this OracleVector instance   |
| <a href="#">ToString()</a>      | Returns the OracleVector string representation         |
| <a href="#">Dispose()</a>       | Releases resources allocated by this object            |

 **See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

### ToInt16Array()

The method returns a short[] value of the OracleVector instance.

**Declaration**

```
// C#  
public short[] ToInt16Array();
```

**Return Value**

A short[] representing the vector

### Exceptions

InvalidCastException - The vector numeric format is binary.

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Int8`, then this method implicitly converts the vector values to short types.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## ToFloatArray()

The method returns a `float[]` value of the `OracleVector` instance.

### Declaration

```
// C#  
public float[] ToFloatArray();
```

### Return Value

A `float[]` representing the vector

### Exceptions

InvalidCastException - The vector numeric format is binary.

OracleNullValueException - The current instance has a null value.

ObjectDisposedException - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Float32`, then this method implicitly converts the vector values to float types.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## ToDoubleArray()

The method returns a `double[]` value of this `OracleVector` instance.

### Declaration

```
// C#  
public double[] ToDoubleArray();
```

### Return Value

A `double[]`

### Exceptions

`InvalidCastException` - The vector numeric format is binary.

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Float64`, then this method implicitly converts the vector values to double types.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## ToByteArray()

The method returns a `byte[]` value of this `OracleVector` instance.

### Declaration

```
// C#  
public byte[] ToByteArray();
```

### Return Value

A `byte[]`

### Exceptions

`OracleNullValueException` - The current instance has a null value.

`ObjectDisposedException` - The object is already disposed.

### Remarks

If the vector's numeric format is not `OracleDbType.Vector_Binary`, then this method implicitly converts the vector values to byte types.

This is the only valid `To*Array()` method for Binary format vectors. Binary sparse vectors are returned as dense vector byte arrays.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## ToString()

Returns the `OracleVector` string representation.

#### Declaration

```
// C#  
public string ToString();
```

#### Return Value

Returns the vector representation as a JSON format string.

#### Remarks

If the vector is sparse, then `OracleVector.ToString()` will return a JSON string in dense format.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleVector Class](#)
- [OracleVector Members](#)

## Dispose()

This instance method releases resources allocated by this object.

#### Declaration

```
// C#  
public void Dispose();
```

#### Implements

`IDisposable`

#### Remarks

The object cannot be reused after being disposed. Although some properties can still be accessed, their values cannot be accountable. Since resources are freed, further method calls can lead to exceptions.

# OracleCollectionType Enumeration

OracleCollectionType enumerated values specify whether or not the OracleParameter object represents a collection, and if so, specifies the collection type.

[Table 6-221](#) lists all the OracleCollectionType enumeration values with a description of each enumerated value.

**Table 6-221 OracleCollectionType Enumeration Values**

| Member Name           | Description                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------|
| None                  | Is not a collection type                                                                    |
| PLSQLAssociativeArray | Indicates that the collection type is a PL/SQL Associative Array (or PL/SQL Index-By Table) |

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|

# OracleConnectionOpenReason Enumeration

This enumeration's values specify the reason for triggering a ConnectionOpen event. Applications can retrieve the reason through the OracleConnectionOpenEventArgs Reason property

[Table 6-222](#) lists all the OracleConnectionOpenReason enumeration values with a description of each enumerated value.

**Table 6-222 OracleConnectionOpenReason Enumeration Values**

| Member Name | Description                                                                              |
|-------------|------------------------------------------------------------------------------------------|
| HardConnect | Indicates a hard connect to the database. A new connection has been created.             |
| SoftConnect | Indicates a soft connect to the database. A connection from the pool has been dispensed. |

A connection created for Application Continuity replay has an enumeration value of HardConnect.

**Requirements**

| Provider              | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | See <a href="#">System Requirements</a> |

## OracleConnectionType Enumeration

OracleConnectionType enumerated values specify whether a particular connection object is associated with an Oracle database connection, a TimesTen database connection, or no physical connection at all.

[Table 6-223](#) lists all the OracleConnectionType enumeration values with a description of each enumerated value.

**Table 6-223 OracleConnectionType Enumeration Values**

| Member Name | Description                                                         |
|-------------|---------------------------------------------------------------------|
| Undefined   | No connection is associated with the OracleConnection object.       |
| Oracle      | The OracleConnection object is associated with an Oracle database.  |
| TimesTen    | The OracleConnection object is associated with a TimesTen database. |

Requirements

|                |                                         |
|----------------|-----------------------------------------|
| Provider       | ODP.NET, Unmanaged Driver               |
| Assembly       | Oracle.DataAccess.dll                   |
| Namespace      | Oracle.DataAccess.Client                |

OracleDBAPrivilege Enumeration

OracleDBAPrivilege enumerated values are used to explicitly specify the DBA Privilege required while creating the OracleCredential object.

[Table 6-223](#) lists all the OracleDBAPrivilege enumeration values with a description of each enumerated value.

Table 6-224 OracleDBAPrivilege Enumeration Values

| Member Name | Description                          |
|-------------|--------------------------------------|
| None        | Default value, no DBA privilege set. |
| SYSASM      | SYSASM connection                    |
| SYSBACKUP   | SYSBACKUP connection                 |
| SYSDBA      | SYSDBA connection                    |
| SYSDBG      | SYSDBG connection                    |
| SYSKM       | SYSKM connection                     |
| SYSOPER     | SYSOPER connection                   |
| SYSRAC      | SYSRAC connection                    |

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                    |
|----------------|-----------------------------------------|-----------------------------------------|---------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll    |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                               |

| Provider    | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver | ODP.NET Core                            |
|-------------|---------------------------|-------------------------|-----------------------------------------|
| .NET (Core) | -                         | -                       | See <a href="#">System Requirements</a> |

## OracleDBShutdownMode Enumeration

OracleDBShutdownMode enumerated values specify the database shutdown options.

[Table 6-226](#) lists all the OracleDBShutdownMode enumeration values with a description of each enumerated value.

**Table 6-225 OracleDBShutdownMode Enumeration Values**

| Member Name        | Description                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default            | Refuses new connections and waits for existing connections to end.                                                                                         |
| Transactional      | Refuses new connections and does not allow any new transactions. Waits for active transactions to commit.                                                  |
| TransactionalLocal | Refuses new connections and does not allow any new transactions. Waits for only local transactions to commit.                                              |
| Immediate          | Does not wait for current calls to complete or users to disconnect from the database. All uncommitted transactions are terminated and rolled back.         |
| Final              | Shuts down the database. Used in the second call for shutdown after the database has been closed and dismounted.                                           |
| Abort              | Does not wait for current calls to complete or users to disconnect from the database. All uncommitted transactions are terminated and are not rolled back. |

#### Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                    |
|-----------------------|-----------------------------------------|-----------------------------------------|---------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll    |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                               |

| Provider    | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver | ODP.NET Core                            |
|-------------|---------------------------|-------------------------|-----------------------------------------|
| .NET (Core) | -                         | -                       | See <a href="#">System Requirements</a> |

# OracleDBStartupMode Enumeration

OracleDBStartupMode enumerated values specify the database startup options.

[Table 6-226](#) lists all the OracleDBStartupMode enumeration values with a description of each enumerated value.

**Table 6-226 OracleDBStartupMode Enumeration Values**

| Member Name   | Description                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NoRestriction | Starts the database and allows access to all users.                                                                                                                                          |
| Restrict      | Starts the database and allows database access only to users having the CREATE SESSION and RESTRICTED SESSION privileges. These privileges are normally assigned to database administrators. |
| Force         | Shuts down a running instance in abort mode and starts a new instance.                                                                                                                       |

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## OracleDbType Enumeration

OracleDbType enumerated values are used to explicitly specify the OracleDbType of an OracleParameter.

[Table 6-227](#) lists all the OracleDbType enumeration values with a description of each enumerated value.

**Table 6-227 OracleDbType Enumeration Values**

| Member Name  | Description                                |
|--------------|--------------------------------------------|
| Array        | Oracle Collection (VArray or Nested Table) |
| BFile        | Oracle BFILE type                          |
| BinaryFloat  | Oracle BINARY_FLOAT type                   |
| BinaryDouble | Oracle BINARY_DOUBLE type                  |
| Blob         | Oracle BLOB type                           |
| Boolean      | Oracle BOOLEAN type                        |
| Byte         | byte type                                  |
| Char         | Oracle CHAR type                           |
| Clob         | Oracle CLOB type                           |
| Date         | Oracle DATE type                           |
| Decimal      | Oracle NUMBER type                         |
| Double       | 8-byte FLOAT type                          |
| Int16        | 2-byte INTEGER type                        |
| Int32        | 4-byte INTEGER type                        |
| Int64        | 8-byte INTEGER type                        |
| IntervalDS   | Oracle INTERVAL DAY TO SECOND type         |
| IntervalYM   | Oracle INTERVAL YEAR TO MONTH type         |
| Long         | Oracle LONG type                           |
| Json         | Oracle JSON type                           |
| LongRaw      | Oracle LONG RAW type                       |
| NChar        | Oracle NCHAR type                          |
| NClob        | Oracle NCLOB type                          |
| NVarChar2    | Oracle NVARCHAR2 type                      |
| Object       | Oracle Object                              |
| Raw          | Oracle RAW type                            |

Table 6-227 (Cont.) OracleDbType Enumeration Values

| Member Name    | Description                                                  |
|----------------|--------------------------------------------------------------|
| Ref            | Oracle REF                                                   |
| RefCursor      | Oracle REF CURSOR type                                       |
| Single         | 4-byte FLOAT type, supports 6 precisions                     |
| TimeStamp      | Oracle TIMESTAMP type                                        |
| TimeStampLTZ   | Oracle TIMESTAMP WITH LOCAL TIME ZONE type                   |
| TimeStampTZ    | Oracle TIMESTAMP WITH TIME ZONE type                         |
| Varchar2       | Oracle VARCHAR2 type                                         |
| Vector         | Numeric format type vector. Either INT8, FLOAT32, or FLOAT64 |
| Vector_Int8    | INT8 numeric format type vector                              |
| Vector_Float32 | FLOAT32 numeric format type vector                           |
| Vector_Float64 | FLOAT64 numeric format type vector                           |
| XmlType        | Oracle XMLType type                                          |

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |

OracleDRCPPurity Enumeration

OracleDRCPPurity enumerated values specify the session purity.

[Table 6-228](#) lists all the OracleDRCPPurity enumeration values with a description of each enumerated value.

**Table 6-228 OracleDRCPPurity Enumeration Values**

| Member Name | Description                                                                            |
|-------------|----------------------------------------------------------------------------------------|
| New         | The application requires a session without any previously set session state.           |
| Pooled      | An application can reuse a pooled session (i.e. the session can have been used before) |

**Requirements**

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |

## OracleIdentityType Enumeration

The OracleIdentityType enumeration specifies how Oracle identity column values are generated.

[Table 6-229](#) lists all the OracleIdentityType enumeration values with a description of each enumerated value.

**Table 6-229 OracleIdentityType Members**

| Member Name              | Description                                                                                                                                                  |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GeneratedAlways          | Indicates that unique values are generated for every insertion. No updates or inserts are allowed for this identity column.                                  |
| GeneratedByDefault       | Indicates that the values are generated only if no explicit value is provided for the identity column. Null values are not allowed for this identity column. |
| GeneratedByDefaultOnNull | Indicates that the values are generated only if no explicit value is provided or a NULL is inserted for the identity column.                                 |

Requirements

|                |                                         |
|----------------|-----------------------------------------|
| Provider       | ODP.NET, Unmanaged Driver               |
| Assembly       | Oracle.DataAccess.dll                   |
| Namespace      | Oracle.DataAccess.Client                |

OracleParameterStatus Enumeration

The OracleParameterStatus enumeration type indicates whether a NULL value is fetched from a column, or truncation has occurred during the fetch, or a NULL value is to be inserted into a database column.

[Table 6-230](#) lists all the OracleParameterStatus enumeration values with a description of each enumerated value.

Table 6-230 OracleParameterStatus Members

| Member Name | Description                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Success     | Indicates that (for input parameters) the input value has been assigned to the column. For output parameter, it indicates that the provider assigned an intact value to the parameter. |
| NullFetched | Indicates that a NULL value has been fetched from a column or an OUT parameter.                                                                                                        |
| NullInsert  | Indicates that a NULL value is to be inserted into a column.                                                                                                                           |
| Truncation  | Indicates that truncation has occurred when fetching the data from the column.                                                                                                         |

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                        |
|----------------|-----------------------------------------|-----------------------------------------|-------------------------------------|

# OracleTokenAuth Enumeration

OracleTokenAuth enumerated values are used to explicitly specify which TOKEN\_AUTH mode needs to be enabled for token authentication. Possible values for this enumeration are:

[Table 6-233](#) lists all the OracleTokenAuth enumeration values with a description of each enumerated value.

Table 6-233 OracleTokenAuth Members

| Member Name          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Disabled             | Default value. Token authentication is DISABLED.                                                                                                                                                                                                                                                                                                                                                                                                       |
| OciApiKey            | Token authentication using OCI_API_KEY authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                                       |
| OciInstancePrincipal | Token authentication using OCI_INSTANCE_PRINCIPAL authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                            |
| OciDelegationToken   | Token authentication using OCI_DELEGATION_TOKEN authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                              |
| OciInteractive       | Token authentication using OCI_INTERACTIVE authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i>                                                                                                                                                                                                                                                                                                                                   |
| OciDefault           | Token authentication using the most appropriate method depending on the application environment. ODP.NET first attempts to retrieve the token using the OCI API key. If that fails, then ODP.NET checks whether it is in a Cloud Shell environment to attempt to get the token using delegation token authentication flow. Lastly, it attempts to use the instance principal authentication flow.<br><i>Not available in ODP.NET, Unmanaged Driver</i> |
| OciToken             | Token authentication is enabled for Oracle Identity and Access Management.                                                                                                                                                                                                                                                                                                                                                                             |
| OAuth                | Token authentication enabled for Microsoft Entra ID.                                                                                                                                                                                                                                                                                                                                                                                                   |

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |

# Oracle Data Provider for .NET XML-Related Classes

This chapter describes ODP.NET XML-related classes and enumerations.

This chapter contains these topics:

- [OracleXmlCommandType Enumeration](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlSaveProperties Class](#)
- [OracleXmlStream Class](#)
- [OracleXmlType Class](#)

All offsets are 0-based for OracleXmlStream object parameters.

## OracleXmlCommandType Enumeration

The OracleXmlCommandType enumeration specifies the values that are allowed for the XmlCommandType property of the OracleCommand class. It is used to specify the type of XML operation.

[Table 7-1](#) lists all the OracleXmlCommandType enumeration values with a description of each enumerated value.

**Table 7-1 OracleXmlCommandType Members**

| Member Name | Description                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------|
| None        | No XML operation is desired                                                                                                  |
| Query       | The command text is a SQL query and the result of the query is an XML document. The SQL query needs to be a select statement |
| Insert      | The command text is an XML document containing rows to insert.                                                               |
| Update      | The command text is an XML document containing rows to update.                                                               |
| Delete      | The command text is an XML document containing rows to delete.                                                               |

### Requirements

# OracleXmlQueryProperties Class

An OracleXmlQueryProperties object represents the XML properties used by the OracleCommand class when the XmlCommandType property is Query.

## Class Inheritance

System.Object  
    System.OracleXmlQueryProperties

## Declaration

public sealed class OracleXmlQueryProperties : ICloneable

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Remarks

OracleXmlQueryProperties can be accessed, and modified using the XmlQueryProperties property of the OracleCommand class. Each OracleCommand object has its own instance of the OracleXmlQueryProperties class in the XmlQueryProperties property.

Use the default constructor to get a new instance of the OracleXmlQueryProperties. Use the OracleXmlQueryProperties.Clone() method to get a copy of an OracleXmlQueryProperties instance.

## Example

This example retrieves relational data as XML.

```
// C#

using System;
using System.IO;
using System.Data;
using System.Xml;
using System.Text;
using Oracle.DataAccess.Client;

class OracleXmlQueryPropertiesSample
{
    static void Main()
    {
        int rows = 0;
        StreamReader sr = null;

        // Define the XSL document for doing the transform.
        string xslstr = "<?xml version='1.0'?>\n" +
            "<xsl:stylesheet version='1.0'\n" +
            "  xmlns:xsl='http://www.w3.org/1999/XSL/Transform'\n" +
            "  <xsl:output encoding='utf-8'/>\n" +
            "  <xsl:template match='/'>\n" +
            "    <EMPLOYEES>\n" +
            "      <xsl:apply-templates select='ROWSET'/>\n" +
            "    </EMPLOYEES>\n" +
            "  </xsl:template>\n" +
            "  <xsl:template match='ROWSET'\n" +
            "    <xsl:apply-templates select='ROW'/>\n" +
            "  </xsl:template>\n" +
            "  <xsl:template match='ROW'\n" +
            "    <EMPLOYEE>\n" +
            "      <EMPLOYEE_ID>\n" +
            "        <xsl:apply-templates select='EMPNO'/>\n" +
            "      </EMPLOYEE_ID>\n" +
            "      <EMPLOYEE_NAME>\n" +
            "        <xsl:apply-templates select='ENAME'/>\n" +
            "      </EMPLOYEE_NAME>\n" +
            "      <HIRE_DATE>\n" +
            "        <xsl:apply-templates select='HIREDATE'/>\n" +
            "      </HIRE_DATE>\n" +
            "      <JOB_TITLE>\n" +
            "        <xsl:apply-templates select='JOB'/>\n" +
            "      </JOB_TITLE>\n" +
            "    </EMPLOYEE>\n" +
            "  </xsl:template>\n" +
            "</xsl:stylesheet>\n";

        // Create the connection.
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Set the date, and timestamp formats for Oracle 9i Release 2, or later.
        // This is just needed for queries.
        if (!con.ServerVersion.StartsWith("9.0") &&
            !con.ServerVersion.StartsWith("8.1"))
        {
            OracleGlobalization sessionParams = con.GetSessionInfo();
```

```
        sessionParams.DateFormat = "YYYY-MM-DD\"T\"HH24:MI:SS";
        sessionParams.TimeStampFormat = "YYYY-MM-DD\"T\"HH24:MI:SS.FF3";
        sessionParams.TimeStampTZFormat = "YYYY-MM-DD\"T\"HH24:MI:SS.FF3";
        con.SetSessionInfo(sessionParams);
    }

    // Create the command.
    OracleCommand cmd = new OracleCommand("", con);

    // Set the XML command type to query.
    cmd.XmlCommandType = OracleXmlCommandType.Query;

    // Set the SQL query.
    cmd.CommandText = "select * from emp e where e.empno = :empno";

    // Set command properties that affect XML query behaviour.
    cmd.BindByName = true;

    // Bind values to the parameters in the SQL query.
    Int32 empNum = 7369;
    cmd.Parameters.Add("empno", OracleDbType.Int32, empNum,
        ParameterDirection.Input);

    // Set the XML query properties.
    cmd.XmlQueryProperties.MaxRows = 1;
    cmd.XmlQueryProperties.RootTag = "ROWSET";
    cmd.XmlQueryProperties.RowTag = "ROW";
    cmd.XmlQueryProperties.Xslt = xslstr;

    // Test query execution without returning a result.
    Console.WriteLine("SQL query: select * from emp e where e.empno = 7369");
    Console.WriteLine("Maximum rows: all rows (-1)");
    Console.WriteLine("Return Value from OracleCommand.ExecuteNonQuery():");
    rows = cmd.ExecuteNonQuery();
    Console.WriteLine(rows);
    Console.WriteLine("\n");

    // Get the XML document as an XmlReader.
    Console.WriteLine("SQL query: select * from emp e where e.empno = 7369");
    Console.WriteLine("Maximum rows: all rows (-1)");
    Console.WriteLine("XML Document from OracleCommand.ExecuteXmlReader():");

    XmlReader xmlReader = cmd.ExecuteXmlReader();
    XmlDocument xmlDocument = new XmlDocument();
    xmlDocument.PreserveWhitespace = true;
    xmlDocument.Load(xmlReader);
    Console.WriteLine(xmlDocument.OuterXml);
    Console.WriteLine("\n");

    // Change the SQL query, and set the maximum number of rows to 2.
    cmd.CommandText = "select * from emp e";
    cmd.Parameters.Clear();
    cmd.XmlQueryProperties.MaxRows = 2;

    // Get the XML document as a Stream.
    Console.WriteLine("SQL query: select * from emp e");
    Console.WriteLine("Maximum rows: 2");
    Console.WriteLine("XML Document from OracleCommand.ExecuteStream():");
    Stream stream = cmd.ExecuteStream();
    sr = new StreamReader(stream, Encoding.Unicode);
    Console.WriteLine(sr.ReadToEnd());
    Console.WriteLine("\n");
```

```
// Get all the rows.
cmd.XmlQueryProperties.MaxRows = -1;

// Append the XML document to an existing Stream.
Console.WriteLine("SQL query: select * from emp e");
Console.WriteLine("Maximum rows: all rows (-1)");
Console.WriteLine("XML Document from OracleCommand.ExecuteToStream():");
MemoryStream mstream = new MemoryStream(32);
cmd.ExecuteToStream(mstream);
mstream.Seek(0, SeekOrigin.Begin);
sr = new StreamReader(mstream, Encoding.Unicode);
Console.WriteLine(sr.ReadToEnd());
Console.WriteLine("\n");

// Clean up.
cmd.Dispose();
con.Close();
con.Dispose();
}
}
```

## OracleXmlQueryProperties Members

OracleXmlQueryProperties members are listed in the following tables.

### OracleXmlQueryProperties Constructors

The OracleXmlQueryProperties constructors are listed in [Table 7-2](#).

**Table 7-2 OracleXmlQueryProperties Constructors**

| Constructor                                          | Description                                                       |
|------------------------------------------------------|-------------------------------------------------------------------|
| <a href="#">OracleXmlQueryProperties Constructor</a> | Instantiates a new instance of the OracleXmlQueryProperties class |

### OracleXmlQueryProperties Properties

The OracleXmlQueryProperties properties are listed in [Table 7-3](#).

**Table 7-3 OracleXmlQueryProperties Properties**

| Name                       | Description                                                                                                              |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxRows</a>    | Specifies the maximum number of rows from the result set of the query that can be represented in the result XML document |
| <a href="#">RootTag</a>    | Specifies the root element of the result XML document                                                                    |
| <a href="#">RowTag</a>     | Specifies the value of the XML element which identifies a row of data from the result set in an XML document             |
| <a href="#">Xslt</a>       | Specifies the XSL document used for XML transformation using XSLT                                                        |
| <a href="#">XsltParams</a> | Specifies parameters for the XSL document                                                                                |

**OracleXmlQueryProperties Public Methods**

The OracleXmlQueryProperties public methods are listed in [Table 7-4](#).

**Table 7-4 OracleXmlQueryProperties Public Methods**

| Name                  | Description                                          |
|-----------------------|------------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleXmlQueryProperties object |

**See Also**

## OracleXmlQueryProperties Constructor

The OracleXmlQueryProperties constructor instantiates a new instance of the OracleXmlQueryProperties class.

**Declaration**

```
// C#  
public OracleXmlQueryProperties();
```

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

## OracleXmlQueryProperties Properties

The OracleXmlQueryProperties properties are listed in [Table 7-5](#).

**Table 7-5 OracleXmlQueryProperties Properties**

| Name                       | Description                                                                                                              |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxRows</a>    | Specifies the maximum number of rows from the result set of the query that can be represented in the result XML document |
| <a href="#">RootTag</a>    | Specifies the root element of the result XML document                                                                    |
| <a href="#">RowTag</a>     | Specifies the value of the XML element which identifies a row of data from the result set in an XML document             |
| <a href="#">Xslt</a>       | Specifies the XSL document used for XML transformation using XSLT                                                        |
| <a href="#">XsltParams</a> | Specifies parameters for the XSL document                                                                                |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

## MaxRows

This property specifies the maximum number of rows from the result set of the query that can be represented in the result XML document.

### Declaration

```
// C#  
public int MaxRows {get; set;}
```

### Property Value

The maximum number of rows.

### Exceptions

ArgumentException - The new value for MaxRows is not valid.

### Remarks

Default value is -1.

Possible values are:

- -1 (all rows).
- A number greater than or equal to 0.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

## RootTag

This property specifies the root element of the result XML document.

### Declaration

```
// C#  
public string RootTag {get; set;}
```

### Property Value

The root element of the result XML document.

### Remarks

The default root tag is ROWSET.

To indicate that no root tag is to be used in the result XML document, set this property to null or "" or String.Empty.

If both RootTag and RowTag are set to null, an XML document is returned only if the result set returns one row and one column.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

## RowTag

This property specifies the value of the XML element which identifies a row of data from the result set in an XML document.

### Declaration

```
// C#  
public string RowTag {get; set;}
```

### Property Value

The value of the XML element.

**Remarks**

The default is ROW.

To indicate that no row tag is be used in the result XML document, set this property to null or "" or String.Empty.

If both RootTag and RowTag are set to null, an XML document is returned only if the result set returns one row and one column.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

## Xslt

This property specifies the XSL document used for XML transformation using XSLT.

**Declaration**

```
// C#  
public string Xslt {get; set;}
```

**Property Value**

The XSL document used for XML transformation.

**Remarks**

Default value is null.

The XSL document is used for XML transformation of the XML document generated from the result set of the query.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

## XsltParams

This property specifies parameters for the XSL document.

**Declaration**

```
// C#  
public string XsltParams {get; set;}
```

**Property Value**

The parameters for the XSL document.

**Remarks**

Default value is null.

The parameters are specified as a string of "name=value" pairs of the form "param1=value1; param2=value2; ..." delimited by semicolons.

 **See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

# OracleXmlQueryProperties Public Methods

The OracleXmlQueryProperties public methods are listed in [Table 7-6](#).

**Table 7-6 OracleXmlQueryProperties Public Methods**

| Name                  | Description                                          |
|-----------------------|------------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleXmlQueryProperties object |

## Clone

This method creates a copy of an OracleXmlQueryProperties object.

**Declaration**

```
// C#  
public object Clone();
```

**Return Value**

An OracleXmlQueryProperties object

**Implements**

ICloneable

 **See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlQueryProperties Class](#)
- [OracleXmlQueryProperties Members](#)

# OracleXmlSaveProperties Class

An OracleXmlSaveProperties object represents the XML properties used by the OracleCommand class when the XmlCommandType property is Insert, Update, or Delete.

## Class Inheritance

System.Object

System.OracleXmlSaveProperties

## Declaration

```
public sealed class OracleXmlSaveProperties : ICloneable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Remarks

OracleXmlSaveProperties can be accessed and modified using the XmlSaveProperties property of the OracleCommand class. Each OracleCommand object has its own instance of the OracleXmlSaveProperties class in the XmlSaveProperties property.

Use the default constructor to get a new instance of OracleXmlSaveProperties. Use the OracleXmlSaveProperties.Clone() method to get a copy of an OracleXmlSaveProperties instance.

## Example

This sample demonstrates how to do inserts, updates, and deletes to a relational table or view using an XML document.

```
// C#
/* -- If HR account is being locked, you need to log on as a DBA
   -- to unlock the account first. Unlock a locked users account:

ALTER USER hr ACCOUNT UNLOCK;
*/

using System;
```

```

using Oracle.DataAccess.Client;

class OracleXmlSavePropertiesSample
{
    static void Main()
    {
        string[] KeyColumnsList = null;
        string[] UpdateColumnsList = null;
        int rows = 0;

        // Create the connection.
        string constr = "User Id=hr;Password=hr;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Create the command.
        OracleCommand cmd = new OracleCommand("", con);

        // Set the XML command type to insert.
        cmd.XmlCommandType = OracleXmlCommandType.Insert;

        // Set the XML document.
        cmd.CommandText = "<?xml version='1.0'?'>\n" +
            "<ROWSET>\n" +
            "  <MYROW num = \"1\">\n" +
            "    <EMPLOYEE_ID>1234</EMPLOYEE_ID>\n" +
            "    <LAST_NAME>Smith</LAST_NAME>\n" +
            "    <EMAIL>Smith@Oracle.com</EMAIL>\n" +
            "    <HIRE_DATE>1982-01-23T00:00:00.000</HIRE_DATE>\n" +
            "    <JOB_ID>IT_PROG</JOB_ID>\n" +
            "  </MYROW>\n" +
            "  <MYROW num = \"2\">\n" +
            "    <EMPLOYEE_ID>1235</EMPLOYEE_ID>\n" +
            "    <LAST_NAME>Barney</LAST_NAME>\n" +
            "    <EMAIL>Barney@Oracle.com</EMAIL>\n" +
            "    <HIRE_DATE>1982-01-23T00:00:00.000</HIRE_DATE>\n" +
            "    <JOB_ID>IT_PROG</JOB_ID>\n" +
            "  </MYROW>\n" +
            "</ROWSET>\n";

        // Set the XML save properties.
        KeyColumnsList = new string[1];
        KeyColumnsList[0] = "EMPLOYEE_ID";
        UpdateColumnsList = new string[5];
        UpdateColumnsList[0] = "EMPLOYEE_ID";
        UpdateColumnsList[1] = "LAST_NAME";
        UpdateColumnsList[2] = "EMAIL";
        UpdateColumnsList[3] = "HIRE_DATE";
        UpdateColumnsList[4] = "JOB_ID";
        cmd.XmlSaveProperties.KeyColumnsList = KeyColumnsList;
        cmd.XmlSaveProperties.RowTag = "MYROW";
        cmd.XmlSaveProperties.Table = "employees";
        cmd.XmlSaveProperties.UpdateColumnsList = UpdateColumnsList;
        cmd.XmlSaveProperties.Xslt = null;
        cmd.XmlSaveProperties.XsltParams = null;

        // Do the inserts.
        rows = cmd.ExecuteNonQuery();
        Console.WriteLine("rows: " + rows);

        // Set the XML command type to update.
        cmd.XmlCommandType = OracleXmlCommandType.Update;
    }
}

```

```

// Set the XML document.
cmd.CommandText = "<?xml version=\"1.0\"?>\n" +
    "<ROWSET>\n" +
    "  <MYROW num = \"1\">\n" +
    "    <EMPLOYEE_ID>1234</EMPLOYEE_ID>\n" +
    "    <LAST_NAME>Adams</LAST_NAME>\n" +
    "  </MYROW>\n" +
    "</ROWSET>\n";

// Set the XML save properties.
KeyColumnsList = new string[1];
KeyColumnsList[0] = "EMPLOYEE_ID";
UpdateColumnsList = new string[1];
UpdateColumnsList[0] = "LAST_NAME";

## OracleXmlSaveProperties Members

OracleXmlSaveProperties members are listed in the following tables.

### OracleXmlSaveProperties Constructor

OracleXmlSaveProperties constructors are listed in [Table 7-7](#)

**Table 7-7 OracleXmlSaveProperties Constructor**

| Constructor                                         | Description                                                      |
|-----------------------------------------------------|------------------------------------------------------------------|
| <a href="#">OracleXmlSaveProperties Constructor</a> | Instantiates a new instance of the OracleXmlSaveProperties class |

### OracleXmlSaveProperties Properties

The OracleXmlSaveProperties properties are listed in [Table 7-8](#).

**Table 7-8 OracleXmlSaveProperties Properties**

| Name                              | Description                                                                                                    |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| <a href="#">KeyColumnsList</a>    | Specifies the list of columns used as a key to locate existing rows for update or delete using an XML document |
| <a href="#">RowTag</a>            | Specifies the value for the XML element that identifies a row of data in an XML document                       |
| <a href="#">Table</a>             | Specifies the name of the table or view to which changes are saved                                             |
| <a href="#">UpdateColumnsList</a> | Specifies the list of columns to update or insert                                                              |
| <a href="#">Xslt</a>              | Specifies the XSL document used for XML transformation using XSLT                                              |
| <a href="#">XsltParams</a>        | Specifies the parameters for the XSLT document specified in the Xslt property                                  |

### OracleXmlSaveProperties Public Methods

The OracleXmlSaveProperties public methods are listed in [Table 7-9](#).

**Table 7-9 OracleXmlSaveProperties Public Methods**

| Name                  | Description                                         |
|-----------------------|-----------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleXmlSaveProperties object |

## OracleXmlSaveProperties Constructor

The OracleXmlSaveProperties constructor instantiates a new instance of OracleXmlSaveProperties class.

**Declaration**

```
// C#  
public OracleXmlSaveProperties;
```

- [OracleXmlSaveProperties Members](#)

## OracleXmlSaveProperties Properties

The OracleXmlSaveProperties properties are listed in [Table 7-10](#).

**Table 7-10 OracleXmlSaveProperties Properties**

| Name                              | Description                                                                                                    |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| <a href="#">KeyColumnsList</a>    | Specifies the list of columns used as a key to locate existing rows for update or delete using an XML document |
| <a href="#">RowTag</a>            | Specifies the value for the XML element that identifies a row of data in an XML document                       |
| <a href="#">Table</a>             | Specifies the name of the table or view to which changes are saved                                             |
| <a href="#">UpdateColumnsList</a> | Specifies the list of columns to update or insert                                                              |
| <a href="#">Xslt</a>              | Specifies the XSL document used for XML transformation using XSLT                                              |
| <a href="#">XsltParams</a>        | Specifies the parameters for the XSLT document specified in the Xslt property                                  |

## KeyColumnsList

This property specifies the list of columns used as a key to locate existing rows for update or delete using an XML document.

### Declaration

```
// C#  
public string[] KeyColumnsList {get; set;}
```

### Property Value

The list of columns.

### Remarks

Default value is null.

The first null value (if any) terminates the list.

KeyColumnsList usage with XMLCommandType property values:

- Insert - KeyColumnsList is ignored and can be null.
- Update - KeyColumnsList must be specified; it identifies the columns to use to find the rows to be updated.
- Delete - If KeyColumnsList is null, all the column values in each row element in the XML document are used to locate the rows to delete. Otherwise, KeyColumnsList specifies the columns used to identify the rows to delete.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlSaveProperties Class](#)
- [OracleXmlSaveProperties Members](#)

## RowTag

This property specifies the value for the XML element that identifies a row of data in an XML document.

### Declaration

```
// C#  
public string RowTag {get; set;}
```

**Property Value**

An XML element name.

**Remarks**

The default value is ROW.

Each element in the XML document identifies one row in a table or view.

If RowTag is set to "" or null, no row tag is used in the XML document. In this case, the XML document is assumed to contain only one row.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlSaveProperties Class](#)
- [OracleXmlSaveProperties Members](#)

## Table

This property specifies the name of the table or view to which changes are saved.

**Declaration**

```
// C#  
public string Table {get; set;}
```

**Property Value**

A table name.

**Remarks**

Default value is null.

The property must be set to a valid table or view name.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlSaveProperties Class](#)
- [OracleXmlSaveProperties Members](#)

## UpdateColumnsList

This property specifies the list of columns to update or insert.

**Declaration**

```
// C#  
public string[] UpdateColumnsList {get; set;}
```

**Property Value**

A list of columns.

**Remarks**

Default value is null.

The first null value (if any) terminates the list.

UpdateColumnList usage with XMLCommandType property values:

- Insert - UpdateColumnList indicates which columns are assigned values when a new row is created. If UpdateColumnList is null, then all columns are assigned values. If a column is on the UpdateColumnList, but no value is specified for the row in the XML file, then NULL is used. If a column is not on the UpdateColumnList, then the default value for that column is used.
- Update - UpdateColumnList specifies columns to modify for each row of data in the XML document. If UpdateColumnList is null, all the values in each XML element in the XML document are used to modify the columns.
- Delete - UpdateColumnsList is ignored and can be null.

- [OracleXmlSaveProperties Class](#)
- [OracleXmlSaveProperties Members](#)

## Xslt

This property specifies the XSL document used for XML transformation using XSLT.

**Declaration**

```
// C#  
public string Xslt {get; set;}
```

**Property Value**

The XSL document used for XML transformation.

**Remarks**

Default = null.

The XSL document is used for XSLT transformation of a given XML document. The transformed XML document is used to save changes to the table or view.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleXmlSaveProperties Class](#)
- [OracleXmlSaveProperties Members](#)

XsltParams

This property specifies the parameters for the XSLT document specified in the Xslt property.

Declaration

```
// C#
public string XsltParams {get; set;}
```

Property Value

The parameters for the XSLT document.

Remarks

Default is null.  
This property is a string delimited by semicolons in "name=value" pairs of the form "param1=value1; param2=value2; ...".

OracleXmlSaveProperties Public Methods

The OracleXmlSaveProperties public methods are listed in [Table 7-11](#).

Table 7-11 OracleXmlSaveProperties Public Methods

| Name                  | Description                                         |
|-----------------------|-----------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleXmlSaveProperties object |

Clone

This method creates a copy of an OracleXmlSaveProperties object.

Declaration

```
// C#
public object Clone();
```

Return Value

An OracleXmlSaveProperties object

Implements

ICloneable

# OracleXmlStream Class

An OracleXmlStream object represents a read-only stream of XML data stored in an OracleXmlType object.

Class Inheritance

Declaration

```
// C#
public sealed class OracleXmlStream : IDisposable, ICloneable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OracleXmlStream Members

OracleXmlStream members are listed in the following tables.

### OracleXmlStream Constructors

The OracleXmlStream constructors are listed in [Table 7-12](#).

**Table 7-12 OracleXmlStream Constructors**

| Constructor                                 | Description                                                                                                                        |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleXmlStream Constructor</a> | Creates an instance of an OracleXmlStream object which provides a Stream representation of the XML data stored in an OracleXmlType |

### OracleXmlStream Static Methods

The OracleXmlStream static methods are listed in [Table 7-13](#).

**Table 7-13 OracleXmlStream Static Methods**

| Methods | Description                               |
|---------|-------------------------------------------|
| Equals  | Inherited from System.Object (Overloaded) |

### OracleXmlStream Instance Properties

The OracleXmlStream instance properties are listed in [Table 7-14](#).

**Table 7-14 OracleXmlStream Instance Properties**

| Properties              | Description                                         |
|-------------------------|-----------------------------------------------------|
| <a href="#">CanRead</a> | Indicates whether or not the XML stream can be read |

**Table 7-14 (Cont.) OracleXmlStream Instance Properties**

| Properties                 | Description                                                                       |
|----------------------------|-----------------------------------------------------------------------------------|
| <a href="#">CanSeek</a>    | Indicates whether or not forward and backward seek operation can be performed     |
| <a href="#">CanWrite</a>   | OracleXmlStream is a sequential read only, forward only stream.                   |
| <a href="#">Connection</a> | Indicates the OracleConnection that is used to retrieve the XML data              |
| <a href="#">Length</a>     | Indicates the number of bytes in the XML stream                                   |
| <a href="#">Position</a>   | Gets or sets the byte position within the stream                                  |
| <a href="#">Value</a>      | Returns the XML data, starting from the first character in the stream as a string |

**OracleXmlStream Instance Methods**

The OracleXmlStream instance methods are listed in [Table 7-15](#).

**Table 7-15 OracleXmlStream Instance Methods**

| Methods                   | Description                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| BeginRead                 | Inherited from System.IO.Stream                                                                                                                          |
| BeginWrite                | Inherited from System.IO.Stream                                                                                                                          |
| <a href="#">Clone</a>     | Creates a copy of an OracleXmlStream object                                                                                                              |
| <a href="#">Close</a>     | Closes the current stream and releases any resources associated with it                                                                                  |
| <a href="#">Dispose</a>   | Releases resources allocated by this object                                                                                                              |
| EndRead                   | Inherited from System.IO.Stream                                                                                                                          |
| EndWrite                  | Inherited from System.IO.Stream                                                                                                                          |
| Equals                    | Inherited from System.Object                                                                                                                             |
| <a href="#">Flush</a>     | <i>Not Supported</i>                                                                                                                                     |
| GetHashCode               | Inherited from System.Object                                                                                                                             |
| GetLifetimeService        | Inherited from System.MarshalByRefObject                                                                                                                 |
| GetType                   | Inherited from System.Object                                                                                                                             |
| InitializeLifetimeService | Inherited from System.MarshalByRefObject                                                                                                                 |
| <a href="#">Read</a>      | Reads a specified amount from the current stream instance and populates the array buffer (Overloaded)                                                    |
| <a href="#">ReadAsync</a> | Returns a Task-based asynchronous version of OracleXmlStream.Read( ), which reads a specified amount of data and populates the array buffer (Overloaded) |
| ReadByte                  | Inherited from System.IO.Stream                                                                                                                          |
| <a href="#">Seek</a>      | Sets the position within the current stream and returns the new position within the current stream                                                       |
| <a href="#">SetLength</a> | <i>Not Supported</i>                                                                                                                                     |
| ToString                  | Inherited from System.Object                                                                                                                             |
| <a href="#">Write</a>     | <i>Not Supported</i>                                                                                                                                     |

Table 7-15 (Cont.) OracleXmlStream Instance Methods

| Methods                   | Description          |
|---------------------------|----------------------|
| WriteByte                 | <i>Not Supported</i> |
| <a href="#">WriteLine</a> | <i>Not Supported</i> |

**See Also**

## OracleXmlStream Constructor

This constructor creates an instance of an `OracleXmlStream` object which provides a `Stream` representation of the XML data stored in an `OracleXmlType` object.

**Declaration**

```
// C#  
public OracleXmlStream(OracleXmlType xmlType);
```

**Parameters**

- *xmlType*  
The `OracleXmlType` object.

**Remarks**

The `OracleXmlStream` implicitly uses the `OracleConnection` object from the `OracleXmlType` object from which it was constructed.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## OracleXmlStream Static Methods

The `OracleXmlStream` static methods are listed in [Table 7-16](#).

**Table 7-16 OracleXmlStream Static Methods**

| Methods                | Description                                            |
|------------------------|--------------------------------------------------------|
| <a href="#">Equals</a> | Inherited from <code>System.Object</code> (Overloaded) |

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## OracleXmlStream Instance Properties

The `OracleXmlStream` instance properties are listed in [Table 7-17](#).

**Table 7-17 OracleXmlStream Instance Properties**

| Properties                 | Description                                                                       |
|----------------------------|-----------------------------------------------------------------------------------|
| <a href="#">CanRead</a>    | Indicates whether or not the XML stream can be read                               |
| <a href="#">CanSeek</a>    | Indicates whether or not forward and backward seek operation can be performed     |
| <a href="#">CanWrite</a>   | <code>OracleXmlStream</code> is a sequential read only, forward only stream.      |
| <a href="#">Connection</a> | Indicates the <code>OracleConnection</code> that is used to retrieve the XML data |
| <a href="#">Length</a>     | Indicates the number of bytes in the XML stream                                   |
| <a href="#">Position</a>   | Gets or sets the byte position within the stream                                  |
| <a href="#">Value</a>      | Returns the XML data, starting from the first character in the stream as a string |

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## CanRead

Overrides `Stream`

This property indicates whether or not the XML stream can be read.

**Declaration**

```
// C#  
public override bool CanRead{get;}
```

**Property Value**

If the XML stream is can be read, returns true; otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## CanSeek

Overrides Stream

This property indicates whether or not forward and backward seek operation can be performed.

**Declaration**

```
// C#  
public override bool CanSeek{get;}
```

**Property Value**

If forward and backward seek operations can be performed, this property returns true. Otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## CanWrite

Overrides Stream

OracleXmlStream is a sequential read only, forward only stream.

**Declaration**

```
// C#  
public override bool CanWrite{get;}
```

**Property Value**

Always returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Connection

This instance property indicates the `OracleConnection` that is used to retrieve the XML data.

**Declaration**

```
// C#  
public OracleConnection Connection {get;}
```

**Property Value**

An `OracleConnection`.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Length

Overrides `Stream`

This property indicates the number of bytes in the XML stream.

**Declaration**

```
// C#  
public override Int64 Length{get;}
```

**Property Value**

An `Int64` value representing the number of bytes in the XML stream. An empty stream has a length of 0 bytes.

## Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Position

Overrides Stream

This property gets or sets the byte position within the stream.

### Declaration

```
// C#  
public override Int64 Position{get; set;}
```

### Property Value

An Int64 that indicates the current position in the stream.

## Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The Position is less than 0.

### Remarks

The beginning of the stream is represented by position 0. Seeking to any location beyond the length of the stream is supported.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Value

This property returns the XML data, starting from the first character of the stream as a string.

### Declaration

```
// C#  
public string Value{get; set;}
```

### Property Value

A string.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

### Remarks

The value of `Position` is neither used nor changed by using this property.

The maximum length of the string that can be returned by this property is 2 GB.

## OracleXmlStream Instance Methods

The `OracleXmlStream` instance methods are listed in [Table 7-18](#).

**Table 7-18 OracleXmlStream Instance Methods**

| Methods                 | Description                                                             |
|-------------------------|-------------------------------------------------------------------------|
| <code>BeginRead</code>  | Inherited from <code>System.IO.Stream</code>                            |
| <code>BeginWrite</code> | Inherited from <code>System.IO.Stream</code>                            |
| <a href="#">Clone</a>   | Creates a copy of an <code>OracleXmlStream</code> object                |
| <a href="#">Close</a>   | Closes the current stream and releases any resources associated with it |
| <a href="#">Dispose</a> | Releases resources allocated by this object                             |
| <code>EndRead</code>    | Inherited from <code>System.IO.Stream</code>                            |
| <code>EndWrite</code>   | Inherited from <code>System.IO.Stream</code>                            |
| <code>Equals</code>     | Inherited from <code>System.Object</code>                               |

**Table 7-18 (Cont.) OracleXmlStream Instance Methods**

| Methods                   | Description                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flush                     | <i>Not Supported</i>                                                                                                                                    |
| GetHashCode               | Inherited from System.Object                                                                                                                            |
| GetLifetimeService        | Inherited from System.MarshalByRefObject                                                                                                                |
| GetType                   | Inherited from System.Object                                                                                                                            |
| InitializeLifetimeService | Inherited from System.MarshalByRefObject                                                                                                                |
| <a href="#">Read</a>      | Reads a specified amount from the current XML stream instance and populates the array buffer (Overloaded)                                               |
| <a href="#">ReadAsync</a> | Returns a Task-based asynchronous version of OracleXmlStream.Read(), which reads a specified amount of data and populates the array buffer (Overloaded) |
| ReadByte                  | Inherited from System.IO.Stream                                                                                                                         |
| <a href="#">Seek</a>      | Sets the position within the current stream and returns the new position within the current stream                                                      |
| SetLength                 | <i>Not Supported</i>                                                                                                                                    |
| ToString                  | Inherited from System.Object                                                                                                                            |
| Write                     | <i>Not Supported</i>                                                                                                                                    |
| WriteByte                 | <i>Not Supported</i>                                                                                                                                    |
| WriteLine                 | <i>Not Supported</i>                                                                                                                                    |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Clone

This method creates a copy of an OracleXmlStream object.

**Declaration**

```
// C#
public object Clone();
```

**Return Value**

An OracleXmlStream object.

**Implements**

ICloneable

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The cloned object has the same property values as that of the object being cloned.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Close

Overrides Stream

This method closes the current stream and releases any resources associated with it.

**Declaration**

```
// C#  
public override void Close();
```

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Dispose

This public method releases resources allocated by this object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

## Remarks

The object cannot be reused after being disposed. Although some properties can still be accessed, their values cannot be accountable. Since resources are freed, method calls can lead to exceptions.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Flush

This method is not supported.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Read

This method reads a specified amount from the current XML stream instance and populates the array buffer.

### Overload List:

- [Read\(byte\[\], int, int\)](#)  
This method reads a specified amount of unicode bytes from the current instance, advances the position within the stream, and populates the byte array buffer.
- [Read\(char\[\], int, int\)](#)  
This method reads a specified amount of characters from the current instance, advances the position within the stream, and populates the character array buffer.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Read(byte[], int, int)

Overrides Stream

This method reads a specified amount of unicode bytes from the current instance, advances the position within the stream, and populates the byte array buffer.

### Declaration

```
// C#  
public override int Read(byte[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The byte array buffer that is populated.
- *offset*  
The zero-based offset (in bytes) at which the buffer is populated.
- *count*  
The maximum amount of bytes to be read.

### Return Value

The number of unicode bytes read into the given byte[] buffer or 0 if the end of the stream has been reached.

### Remarks

This method reads a maximum of *count* bytes from the current stream and stores them in buffer beginning at *offset*. The current position within the stream is advanced by the number of bytes read. However, if an exception occurs, the current position within the stream remains unchanged.

The XML data is read starting from the position specified by the *Position* property.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## Read(char[], int, int)

Overrides Stream

This method reads a specified amount of characters from the current instance, advances the position within the stream, and populates the character array buffer.

### Declaration

```
// C#  
public override int Read(char[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The character array buffer to be populated.
- *offset*  
The zero-based offset (in characters) in the buffer at which the buffer is populated.
- *count*  
The maximum amount of characters to be read from the stream.

### Return Value

The return value indicates the number of characters read from the stream or 0 if the end of the stream has been reached.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

### Remarks

This method requires that the `Position` on the stream instance be zero or an even number.

The XML data is read starting from the position specified by the `Position` property.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## ReadAsync

This method returns a Task-based asynchronous version of `OracleXmlStream.Read()`, which reads a specified amount of data and populates the array buffer.

### Overload List:

- [ReadAsync\(byte\[\], int, int, CancellationToken\)](#)  
This method returns a Task-based asynchronous version of `OracleXmlStream.Read()`
- [ReadAsync\(char\[\], int, int\)](#)

This method returns a Task-based asynchronous version of `OracleXmlStream.Read()`

- [ReadAsync\(char\[\], int, int, CancellationToken\)](#)

This method returns a Task-based asynchronous version of `OracleXmlStream.Read()`

- [ReadAsync\(byte\[\], int, int\)](#)

This method returns a Task-based asynchronous version of `OracleXmlStream.Read()`

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## ReadAsync(byte[], int, int, CancellationToken)

### Declaration

```
// C#
public override Task<int> ReadAsync(byte[] buffer, int offset, int count,
CancellationToken cancellationToken);
```

### Parameters

- *buffer*  
The byte array buffer that is populated.
- *offset*  
The zero-based offset (in bytes) at which the buffer is populated.
- *count*  
The maximum amount of bytes to be read.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<int>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

Stream

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:

- The offset or the count parameter is less than 0.
- The offset is greater than or equal to the `buffer.Length`.
- The offset and the count together are greater than the `buffer.Length`.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## ReadAsync(char[], int, int)

This will call into the `ReadAsync` implementation with argument `cancellationToken` passed as `CancellationToken.None`.

### Declaration

```
// C#  
public Task<int> ReadAsync(char[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The character array buffer to be populated.
- *offset*  
The zero-based offset (in characters) at which the buffer is populated.
- *count*  
The maximum amount of characters to be read.

### Return Value

`Task<int>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

`Stream`

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:

- The offset or the count parameter is less than 0.
- The offset is greater than or equal to the `buffer.Length`.
- The offset and the count together are greater than the `buffer.Length`.

**① See Also**

## ReadAsync(char[], int, int, CancellationToken)

**Declaration**

```
// C#  
public Task<int> ReadAsync(char[] buffer, int offset, int count, CancellationToken  
cancellationToken);
```

**Parameters**

- *buffer*  
The character array buffer to be populated.
- *offset*  
The zero-based offset (in characters) at which the buffer is populated.
- *count*  
The maximum amount of characters to be read.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task.

**Return Value**

Task<int> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Implements**

Stream

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - This exception is thrown if any of the following conditions exist:

- The offset or the count parameter is less than 0.
- The offset is greater than or equal to the buffer.Length.
- The offset and the count together are greater than the buffer.Length.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlStream Class](#)
- [OracleXmlStream Members](#)

## ReadAsync(byte[], int, int)

This will call into the ReadAsync implementation with argument `cancellationToken` passed as `CancellationToken.None`.

**Declaration**

```
// C#  
public Task<int> ReadAsync(byte[] buffer, int offset, int count);
```

**Parameters**

- *buffer*  
The byte array buffer to be populated.
- *offset*  
The zero-based offset (in bytes) at which the buffer is populated.
- *count*  
The maximum amount of bytes to be read.

**Return Value**

`Task<int>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Implements**

Stream

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:

- The offset or the count parameter is less than 0.
- The offset is greater than or equal to the `buffer.Length`.
- The offset and the count together are greater than the `buffer.Length`.

- [OracleXmlStream Members](#)

## Seek

Overrides Stream.

This method sets the position within the current stream and returns the new position within the current stream.

### Declaration

```
// C#  
public long Seek(long offset, SeekOrigin origin);
```

### Parameters

- *offset*  
A byte offset relative to origin.
  - If *offset* is negative, the new position precedes the position specified by *origin* by the number of bytes specified by *offset*.
  - If offset is zero, the new position is the position specified by *origin*.
  - If *offset* is positive, the new position follows the position specified by *origin* by the number of bytes specified by *offset*.
- *origin*  
A value of type `SeekOrigin` indicating the reference point used to obtain the new position.

### Return Value

The new Position within the current stream.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object

### Remarks

Use the `CanSeek` property to determine whether or not the current instance supports seeking. Seeking to any location beyond the length of the stream is supported.

# OracleXmlType Class

An `OracleXmlType` object represents an Oracle XMLType instance.

Class Inheritance

System.Object  
    System.OracleXmlType

Declaration

```
// C#  
public sealed class OracleXmlType : IDisposable, INullable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

OracleXmlType objects can be used for well-formed XML documents with or without XML schemas or XML fragments.

① See Also

OracleXmlType Members

OracleXmlType members are listed in the following tables.

## OracleXmlType Constructors

The OracleXmlType constructors are listed in [Table 7-19](#).

**Table 7-19 OracleXmlType Constructors**

| Constructor                                | Description                                                 |
|--------------------------------------------|-------------------------------------------------------------|
| <a href="#">OracleXmlType Constructors</a> | Creates an instance of the OracleXmlType class (Overloaded) |

## OracleXmlType Static Methods

The OracleXmlType static methods are listed in [Table 7-20](#).

**Table 7-20 OracleXmlType Static Methods**

| Methods                | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

## OracleXmlType Static Fields

The OracleXmlType static field is listed in [Table 7-21](#).

**Table 7-21 OracleXmlType Static Field**

| Static Field         | Description                                                               |
|----------------------|---------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an OracleXmlType instance |

## OracleXmlType Instance Properties

The OracleXmlType instance properties are listed in [Table 7-22](#).

**Table 7-22 OracleXmlType Instance Properties**

| Properties                    | Description                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">Connection</a>    | Indicates the OracleConnection that is used to retrieve and store XML data in the OracleXmlType          |
| <a href="#">IsEmpty</a>       | Indicates whether or not the OracleXmlType is empty                                                      |
| <a href="#">IsFragment</a>    | Indicates whether the XML data is a collection of XML elements or a well-formed XML document             |
| <a href="#">IsNull</a>        | Indicates whether or not the OracleXmlType is null                                                       |
| <a href="#">IsSchemaBased</a> | Indicates whether or not the XML data represented by the OracleXmlType is based on an XML schema         |
| <a href="#">RootElement</a>   | Represents the name of the top-level element of the schema-based XML data contained in the OracleXmlType |
| <a href="#">Schema</a>        | Represents the XML schema of the XML data contained in the OracleXmlType                                 |
| <a href="#">SchemaUrl</a>     | Represents in the database for the XML schema of the XML data contained in the OracleXmlType.            |

**Table 7-22 (Cont.) OracleXmlType Instance Properties**

| Properties            | Description                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------|
| <a href="#">Value</a> | Returns the XML data starting from the first character in the current instance as a string |

**OracleXmlType Instance Methods**

The OracleXmlType instance methods are listed in [Table 7-23](#).

**Table 7-23 OracleXmlType Instance Methods**

| Methods                        | Description                                                                                                                    |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Clone</a>          | Creates a copy of the OracleXmlType instance                                                                                   |
| <a href="#">Dispose</a>        | Releases the resources allocated by this OracleXmlType object                                                                  |
| <a href="#">Equals</a>         | Inherited from System.Object                                                                                                   |
| <a href="#">Extract</a>        | Extracts a subset from the XML data using the given XPath expression (Overloaded)                                              |
| <a href="#">GetHashCode</a>    | Inherited from System.Object                                                                                                   |
| <a href="#">GetStream</a>      | Returns an instance of OracleXmlStream which provides a read-only stream of the XML data stored in this OracleXmlType instance |
| <a href="#">GetType</a>        | Inherited from System.Object                                                                                                   |
| <a href="#">GetXmlDocument</a> | Returns a XmlDocument object containing the XML data stored in this OracleXmlType instance                                     |
| <a href="#">GetXmlReader</a>   | Returns a XmlTextReader object that can be used to manipulate XML data directly using the .NET Framework classes and methods   |
| <a href="#">IsExists</a>       | Checks for the existence of a particular set of nodes identified by the given XPath expression in the XMLdata (Overloaded)     |
| <a href="#">ToString</a>       | Inherited from System.Object                                                                                                   |
| <a href="#">Transform</a>      | Transforms the OracleXmlType into another OracleXmlType instance using the given XSL document (Overloaded)                     |
| <a href="#">Update</a>         | Updates the XML node or fragment identified by the given XPath expression in the current OracleXmlType instance (Overloaded)   |
| <a href="#">Validate</a>       | Validates whether or not the XML data in the OracleXmlType object conforms to the given XML schema.                            |

**See Also**

- [OracleXmlType Class](#)

## OracleXmlType Constructors

OracleXmlType constructors create instances of the OracleXmlType class.

**Overload List:**

- [OracleXmlType\(OracleClob\)](#)  
This constructor creates an instance of the OracleXmlType class using the XML data contained in an OracleClob object.
- [OracleXmlType\(OracleConnection, string\)](#)  
This constructor creates an instance of the OracleXmlType class using the XML data contained in the .NET String.
- [OracleXmlType\(OracleConnection, XmlReader\)](#)  
This constructor creates an instance of the OracleXmlType class using the contents of the .NET XmlReader object.
- [OracleXmlType\(OracleConnection, XmlDocument\)](#)  
This constructor creates an instance of the OracleXmlType object using the contents of the XML [DOM](#) document in the .NET XmlDocument object.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType(OracleClob)

This constructor creates an instance of the OracleXmlType class using the XML data contained in an OracleClob object.

**Declaration**

```
// C#  
public OracleXmlType(OracleClob oraClob);
```

**Parameters**

- *oraClob*  
An OracleClob object.

**Exceptions**

ArgumentNullException - The OracleClob object is null.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The CLOB data depends on a valid connection object and the new OracleXMLType uses the OracleConnection in the OracleClob object to store data for the current instance.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType(OracleConnection, string)

This constructor creates an instance of the `OracleXmlType` class using the XML data contained in the .NET String.

**Declaration**

```
// C#  
public OracleXmlType(OracleConnection con, string xmlData);
```

**Parameters**

- *con*  
An `OracleConnection` object.
- *xmlData*  
A string containing the XML data.

**Exceptions**

`ArgumentNullException` - The `OracleConnection` object is null.

`ArgumentException` - The `xmlData` argument is an empty string.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

**Remarks**

The new `OracleXmlType` uses the given `OracleConnection` object to store data for the current instance.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType(OracleConnection, XmlReader)

This constructor creates an instance of the `OracleXmlType` class using the contents of the .NET `XmlReader` object.

**Declaration**

```
// C#  
public OracleXmlType(OracleConnection con, XmlReader reader);
```

**Parameters**

- *con*  
An OracleConnection object.
- *reader*  
An XmlReader object.

**Exceptions**

ArgumentNullException - The OracleConnection object is null.

ArgumentException - The *reader* argument contains no data.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The new OracleXMLType uses the given OracleConnection object to store data for the current instance.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType(OracleConnection, XmlDocument)

This constructor creates an instance of the OracleXmlType object using the contents of the XML [DOM](#) document in the .NET XmlDocument object.

**Declaration**

```
// C#  
public OracleXmlType(OracleConnection con, XmlDocument domDoc);
```

**Parameters**

- *con*  
An OracleConnection object.
- *domDoc*  
An XML document.

### Exceptions

ArgumentNullException - The OracleConnection object is null.

ArgumentException - The *domDoc* argument contains no data.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

The new OracleXMLType uses the given OracleConnection object to store data for the current instance.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType Static Methods

The OracleXmlType static methods are listed in [Table 7-24](#).

**Table 7-24 OracleXmlType Static Methods**

| Methods | Description                               |
|---------|-------------------------------------------|
| Equals  | Inherited from System.Object (Overloaded) |

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType Static Fields

The OracleXmlType static field is listed in [Table 7-25](#).

**Table 7-25 OracleXmlType Static Field**

| Static Field         | Description                                                               |
|----------------------|---------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an OracleXmlType instance |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Null

This static field represents a null value that can be assigned to an `OracleXmlType` instance.

### Declaration

```
// C#  
public static readonly OracleXmlType Null;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType Instance Properties

The `OracleXmlType` instance properties are listed in [Table 7-26](#).

**Table 7-26 OracleXmlType Instance Properties**

| Properties                    | Description                                                                                                                   |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Connection</a>    | Indicates the <code>OracleConnection</code> that is used to retrieve and store XML data in the <code>OracleXmlType</code>     |
| <a href="#">IsEmpty</a>       | Indicates whether or not the <code>OracleXmlType</code> is empty                                                              |
| <a href="#">IsFragment</a>    | Indicates whether the XML data is a collection of XML elements or a well-formed XML document                                  |
| <a href="#">IsNull</a>        | Indicates whether or not the <code>OracleXmlType</code> is null                                                               |
| <a href="#">IsSchemaBased</a> | Indicates whether or not the XML data represented by the <code>OracleXmlType</code> is based on an XML schema                 |
| <a href="#">Null</a>          | Represents a null value that can be assigned to an <code>OracleXmlType</code> instance                                        |
| <a href="#">RootElement</a>   | Represents the name of the top-level element of the schema-based XML data contained in the <code>OracleXmlType</code>         |
| <a href="#">Schema</a>        | Represents the XML schema of the XML data contained in the <code>OracleXmlType</code>                                         |
| <a href="#">SchemaUrl</a>     | Represents <a href="#">URL</a> in the database for the XML schema of the XML data contained in the <code>OracleXmlType</code> |

**Table 7-26 (Cont.) OracleXmlType Instance Properties**

| Properties            | Description                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------|
| <a href="#">Value</a> | Returns the XML data starting from the first character in the current instance as a string |

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Connection

This property indicates the `OracleConnection` that is used to retrieve and store XML data in the `OracleXmlType`.

**Declaration**

```
// C#  
public OracleConnection Connection {get;}
```

**Property Value**

An `OracleConnection` object.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

**Remarks**

The connection must explicitly be opened by the user before creating or using `OracleXmlType`.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## IsEmpty

This property indicates whether or not the `OracleXmlType` is empty.

**Declaration**

```
// C#  
public bool IsEmpty {get;}
```

### Property Value

Returns true if the OracleXmlType represents an empty XML document. Returns false otherwise.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## IsFragment

This property indicates whether the XML data is a collection of XML elements or a well-formed XML document.

### Declaration

```
// C#  
public bool IsFragment {get;}
```

### Property Value

Returns true if the XML data contained in the OracleXmlType object is a collection of XML elements with no root element. Returns false otherwise.

### Exceptions

ObjectDisposedException - The object is already disposed.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## IsNull

This property indicates whether or not the OracleXmlType is null.

**Declaration**

```
// C#  
public bool IsNull {get;}
```

**Property Value**

Returns true if the OracleXmlType represents a null value. Returns false otherwise.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## IsSchemaBased

This property indicates whether or not the XML data represented by the OracleXmlType is based on an XML schema.

**Declaration**

```
// C#  
public bool IsSchemaBased {get;}
```

**Property Value**

Returns true if the XML data represented by the OracleXmlType is based on an XML schema. Returns false otherwise.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## RootElement

This property represents the name of the top-level or root element of the schema-based XML data contained in the `OracleXmlType`.

### Declaration

```
// C#  
public string RootElement{get;}
```

### Property Value

A string that represents the name of the top-level or root element of the XML data contained in the `OracleXmlType`.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

### Remarks

If the `OracleXmlType` instance contains non-schema based XML data, this property returns an empty string.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Schema

This property represents the XML schema for the XML data contained in the `OracleXmlType`.

### Declaration

```
// C#  
public OracleXmlType Schema {get;}
```

### Property Value

An `OracleXmlType` instance that represents the XML schema for the XML data contained in the `OracleXmlType`.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

### Remarks

If the `OracleXmlType` instance contains non-schema based XML data, this property returns an `OracleXmlType` instance representing an empty XML document.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## SchemaUrl

This property represents the XML schema in the database for the XML schema of the XML data contained in the `OracleXmlType`.

### Declaration

```
// C#  
public string SchemaUrl {get;}
```

### Property Value

A string that represents the URL in the database for the XML schema of the XML data.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

### Remarks

If the `OracleXmlType` instance contains non-schema based XML data, this property returns an empty string.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Value

This property returns the XML data starting from the first character in the current instance as a string.

### Declaration

```
// C#  
public string Value{get;}
```

### Property Value

The entire XML data as a string.

## Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## OracleXmlType Instance Methods

The `OracleXmlType` instance methods are listed in [Table 7-27](#).

**Table 7-27 OracleXmlType Instance Methods**

| Methods                        | Description                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Clone</a>          | Creates a copy of the <code>OracleXmlType</code> instance                                                                                                |

## Clone

This method creates a copy of this OracleXmlType instance.

**Declaration**

```
// C#  
public object Clone();
```

**Implements**

ICloneable

**Return Value**

An OracleXmlType object.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Dispose

This method releases the resources allocated by this object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Extract

This method extracts a subset from the XML data using the given XPath expression.

### Overload List:

- [Extract\(string, string\)](#)  
This method extracts a subset from the XML data represented by the `OracleXmlType` object using the given XPath expression and a string parameter for namespace resolution.
- [Extract\(string, XmlNamespaceManager\)](#)  
This method extracts a subset from the XML data represented by the `OracleXmlType` object, using the given XPath expression and a .NET `XmlNamespaceManager` object for namespace resolution.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Extract(string, string)

This method extracts a subset from the XML data represented by the `OracleXmlType` object using the given XPath expression and a string parameter for namespace resolution.

### Declaration

```
// C#  
public OracleXmlType Extract(string xpathExpr, string nsMap);
```

### Parameters

- *xpathExpr*  
The XPath expression.
- *nsMap*  
The string parameter used for namespace resolution of the XPath expression. *nsMap* has zero or more namespaces separated by spaces. *nsMap* can be null. For example:

```
xmlns:ns1="http://www.company1.com" xmlns:ns2="http://www.company2.com"
```

**Return Value**

An OracleXmlType object.

**Exceptions**

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Extract(string, XmlNamespaceManager)

This public method extracts a subset from the XML data represented by the OracleXmlType object, using the given XPath expression and a .NET XmlNamespaceManager object for namespace resolution.

**Declaration**

```
// C#  
public OracleXmlType Extract(string xpathExpr, XmlNamespaceManager nsMgr);
```

**Parameters**

- *xpathExpr*  
The XPath expression.
- *nsMgr*  
The .NET XmlNamespaceManager object used for namespace resolution of the XPath expression. *nsMgr* can be null.

**Return Value**

An OracleXmlType.

**Exceptions**

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The default namespace is ignored if its value is an empty string.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## GetStream

This public method returns an instance of `OracleXmlStream` which provides a read-only stream of the XML data stored in this `OracleXmlType` instance.

**Declaration**

```
// C#  
public Stream GetStream();
```

**Return Value**

A `Stream` object.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## GetXmlDocument

This public method returns a `XmlDocument` object containing the XML data stored in this `OracleXmlType` instance.

**Declaration**

```
// C#  
public XmlDocument GetXmlDocument();
```

**Return Value**

An XmlDocument object.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The XML data in the XmlDocument object is a copy of the XML data in the OracleXmlType instance and modifying it does not automatically modify the XML data in the OracleXmlType instance. The XmlDocument instance returned has the PreserveWhitespace property set to true.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## GetXmlReader

This public method returns a XmlTextReader object that can be used to manipulate XML data directly using the .NET Framework classes and methods.

**Declaration**

```
// C#  
public XmlTextReader GetXmlReader();
```

**Return Value**

An XmlTextReader object.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The XmlTextReader is a read-only, forward-only representation of the XML data stored in the OracleXmlType instance.

### ① See Also

- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## IsExists

IsExists checks for the existence of a particular set of nodes identified by the XPath expression in the XML data.

### Overload List:

- [IsExists\(string, string\)](#)  
This method checks for the existence of a particular set of nodes identified by the XPath expression in the XML data represented by the current `OracleXmlType` instance using a string parameter for namespace resolution.
- [IsExists\(string, XmlNamespaceManager\)](#)  
This method checks for the existence of a particular set of nodes identified by the XPath expression in the XML document represented by the current `OracleXmlType` instance using a .NET `XmlNamespaceManager` object for namespace resolution.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## IsExists(string, string)

This method checks for the existence of a particular set of nodes identified by the XPath expression in the XML data represented by the current `OracleXmlType` instance using a string parameter for namespace resolution.

### Declaration

```
// C#  
public bool IsExists(string xpathExpr, string nsMap);
```

### Parameters

- *xpathExpr*  
The XPath expression.
- *nsMap*  
The string parameter used for namespace resolution of the XPath expression. *nsMap* has zero or more namespaces separated by spaces. *nsMap* can be null.

**Return Value**

Returns true if the required set of nodes exists; otherwise, returns false.

**Exceptions**

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The default namespace is ignored if its value is an empty string.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## IsExists(string, XmlNamespaceManager)

This method checks the existence of a particular set of nodes identified by the XPath expression in the XML document represented by the current OracleXmlType instance using a .NET XmlNamespaceManager object for namespace resolution.

**Declaration**

```
// C#  
public bool IsExists(string xpathExpr, XmlNamespaceManager nsMgr);
```

**Parameters**

- *xpathExpr*  
The XPath expression.
- *nsMgr*  
The .NET XmlNamespaceManager object used for namespace resolution of the XPath expression. *nsMgr* can be null.

**Return Value**

Returns true if the required set of nodes exists; otherwise, returns false.

**Exceptions**

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

#### Remarks

The default namespace is ignored if its value is an empty string.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)

## Transform

This method transforms the OracleXmlType into another OracleXmlType instance using the given XSL document.

#### Overload List:

- [Transform\(OracleXmlType, string\)](#)  
This method transforms the current OracleXmlType instance into another OracleXmlType instance using the given XSL document (as an OracleXmlType object) and a string of XSLT parameters.
- [Transform\(string, string\)](#)  
This public method transforms the current OracleXmlType instance into another OracleXmlType instance using the given XSL document and a string of XSLT parameters.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Transform(OracleXmlType, string)

This method transforms the current OracleXmlType instance into another OracleXmlType instance using the given XSL document and a string of XSLT parameters.

#### Declaration

```
// C#  
public OracleXmlType Transform(OracleXmlType xslDoc, string paramMap);
```

#### Parameters

- *xslDoc*

The XSL document as an `OracleXmlType` object.

- *paramMap*

A string which provides the parameters for the XSL document.

For this release, *paramMap* is ignored.

### Return Value

An `OracleXmlType` object containing the transformed XML document.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`ArgumentNullException` - The *xslDoc* parameter is null.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Transform(string, string)

This method transforms the current `OracleXmlType` instance into another `OracleXmlType` instance using the given XSL document and a string of XSLT parameters.

### Declaration

```
// C#  
public OracleXmlType Transform(string xslDoc, string paramMap);
```

### Parameters

- *xslDoc*

The XSL document to be used for XSLT.

- *paramMap*

A string which provides the parameters for the XSL document.

For this release, *paramMap* is ignored.

### Return Value

An `OracleXmlType` object containing the transformed XML document.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`ArgumentNullException` - The *xslDoc* parameter is null.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Update

This method updates the XML node or fragment identified by the given XPath expression in the current OracleXmlType instance.

#### Overload List:

- [Update\(string, string, string\)](#)  
This method updates the XML nodes identified by the given XPath expression with the given string value and a string parameter for namespace resolution.
- [Update\(string, XmlNamespaceManager, string\)](#)  
This method updates the XML nodes identified by the given XPath expression with the given string value and a .NET XmlNamespaceManager object for namespace resolution.
- [Update\(string, string, OracleXmlType\)](#)  
This method updates the XML nodes identified by the given XPath expression with the XML data stored in the given OracleXmlType value and a string parameter for namespace resolution.
- [Update\(string, XmlNamespaceManager, OracleXmlType\)](#)  
This method updates the XML nodes identified by the given XPath expression with the XML data stored in the given OracleXmlType value and a .NET XmlNamespaceManager object for namespace resolution.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Update(string, string, string)

This method updates the XML nodes identified by the given XPath expression with the given string value and a string parameter for namespace resolution.

### Declaration

```
// C#  
public void Update(string xpathExpr, string nsMap, string value);
```

### Parameters

- *xpathExpr*  
The XPath expression that identifies the nodes to update.
- *nsMap*  
The string parameter used for namespace resolution of the XPath expression. *nsMap* has zero or more namespaces separated by spaces. *nsMap* can be null. For example:  
`xmlns:ns1="http://www.company1.com" xmlns:ns2="http://www.company2.com"`
- *value*  
The new value as a string.

### Exceptions

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

The default namespace is ignored if its value is an empty string.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Update(string, XmlNamespaceManager, string)

This method updates the XML nodes identified by the given XPath expression with the given string value and a .NET *XmlNamespaceManager* object for namespace resolution.

### Declaration

```
// C#  
public void Update(string xpathExpr, XmlNamespaceManager nsMgr, string  
    value);
```

### Parameters

- *xpathExpr*  
The XPath expression that identifies the nodes to update.

- *nsMgr*  
The .NET XmlNamespaceManager object used for namespace resolution of the XPath expression. *nsMgr* can be null.
- *value*  
The new value as a string.

### Exceptions

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

The default namespace is ignored if its value is an empty string.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Update(string, string, OracleXmlType)

This method updates the XML nodes identified by the given XPath expression with the XML data stored in the given OracleXmlType value and a string parameter for namespace resolution.

### Declaration

```
// C#  
public void Update(string xpathExpr, string nsMap, OracleXmlType value);
```

### Parameters

- *xpathExpr*  
The XPath expression that identifies the nodes to update.
- *nsMap*  
The string parameter used for namespace resolution of the XPath expression. *nsMap* has zero or more namespaces separated by spaces. *nsMap* can be null.
- *value*  
The new value as an OracleXmlType object.

### Exceptions

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The *OracleConnection* is not open or has been closed during the lifetime of the object.

### Remarks

The default namespace is ignored if its value is an empty string.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Update(string, XmlNamespaceManager, OracleXmlType)

This method updates the XML nodes identified by the given XPath expression with the XML data stored in the given *OracleXmlType* value and a .NET *XmlNamespaceManager* object for namespace resolution.

### Declaration

```
// C#  
public void Update(string xpathExpr, XmlNamespaceManager nsMgr, OracleXmlType value);
```

### Parameters

- *xpathExpr*  
The XPath expression that identifies the nodes to update.
- *nsMgr*  
The .NET *XmlNamespaceManager* object used for namespace resolution of the XPath expression. *nsMgr* can be null.
- *value*  
The new value as an *OracleXmlType* object.

### Exceptions

ObjectDisposedException - The object is already disposed.

ArgumentNullException - The *xpathExpr* is null or zero-length.

InvalidOperationException - The *OracleConnection* is not open or has been closed during the lifetime of the object.

### Remarks

The default namespace is ignored if its value is an empty string.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleXmlType Class](#)
- [OracleXmlType Members](#)

## Validate

This methods validates whether or not the XML data in the `OracleXmlType` object conforms to the given XML schema.

**Declaration**

```
// C#  
public bool Validate(String schemaUrl);
```

**Parameters**

- `schemaUrl`  
A string representing the [URL](#) in the database of the XML schema.

**Return Value**

Returns true if the XML data conforms to the XML schema; otherwise, returns false.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentNullException` - The `schemaUrl` argument is null or an empty string.

## Oracle Data Provider for .NET HA Event Classes

This chapter describes the following ODP.NET HA event class and enumerations:

- [OracleHAEventArgs Class](#)
- [OracleHAEventHandler Delegate](#)
- [OracleHAEventSource Enumeration](#)
- [OracleHAEventStatus Enumeration](#)

### OracleHAEventArgs Class

The `OracleHAEventArgs` class provides event data for the `OracleConnection.HAEvent` event.

#### Class Inheritance

`System.Object`

`System.EventArgs`

`Oracle.DataAccess.Client.OracleHAEventArgs`

#### Declaration

```
// C#  
public sealed class OracleHAEventArgs
```

#### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

#### Thread Safety

All public methods are thread-safe, although instance methods do not guarantee thread safety.

#### Remarks

When any HA event occurs for a service, service member, host, node, or instance that an `OracleConnection` object is set to with "ha\_events=true", the `OracleConnection.HAEvent` is

triggered and passes an instance of `OracleHAEventArgs` to all the delegates that have registered with the event.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Members](#)
- [OracleHAEventArgs Properties](#)
- ["OracleConnection Class"](#)
- ["HAEvent"](#)

## OracleHAEventArgs Members

`OracleHAEventArgs` members are listed in the following table.

### OracleHAEventArgs Properties

The `OracleHAEventArgs` properties are listed in [Table 8-2](#).

**Table 8-1 OracleHAEventArgs Properties**

| Name                               | Description                                                                                           |
|------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">DatabaseDomainName</a> | Specifies the domain name of the database affected by the HAEvent                                     |
| <a href="#">DatabaseName</a>       | Specifies the database affected by the HAEvent                                                        |
| <a href="#">DrainTimeout</a>       | Indicates the number of seconds allowed for resource draining to be completed during a planned outage |
| <a href="#">HostName</a>           | Specifies the host that triggered the event                                                           |
| <a href="#">InstanceName</a>       | Specifies the instance that triggered the event                                                       |
| <a href="#">Reason</a>             | Specifies the reason for which the HA event was sent by the server                                    |
| <a href="#">ServiceName</a>        | Specifies the service that triggered the event                                                        |
| <a href="#">Source</a>             | Specifies the source that triggered the event                                                         |
| <a href="#">Status</a>             | Specifies the status of the source that triggered the event                                           |
| <a href="#">Time</a>               | Specifies the time when the event was triggered on the server                                         |

#### See Also

## DatabaseDomainName

This property specifies the domain name of the database that is affected by the HA event.

### Declaration

```
// C#  
public string DatabaseDomainName {get;}
```

### Property Value

The domain name of the database that is affected by the HA Event.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

## DatabaseName

This property specifies the database that is affected by the HA event.

**Declaration**

```
// C#  
public string DatabaseName {get;}
```

**Property Value**

This property specifies the database name that is affected by the HA event.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

## DrainTimeout

An integer value indicating the maximum time period in seconds that ODP.NET waits for the service to drain connections from the database service from when the Fast Application Notification SERVICE\_DOWN event is received.

**Declaration**

```
// C#  
public int DrainTimeout {get;}
```

**Property Value**

The number of seconds allowed for resource draining to be completed during a planned outage

**Remarks**

When connecting to Oracle Data Guard in Oracle Database 12c Release 2 or later, database administrators can set their own timeout value, `drain_timeout`, to indicate the number of seconds allowed for resource draining to be completed during a planned outage. The `drain_timeout` value populates `OracleHAEventArgs.DrainTimeout.drain_timeout`. `drain_timeout` can be

used by the ODP.NET ServiceRelocationConnectionTimeout to wait for a service to be relocated before attempting new connections.

- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)
- [ServiceRelocationConnectionTimeout](#)

## HostName

This property specifies the host that triggered the HA event.

#### Declaration

```
// C#  
public string HostName {get;}
```

#### Property Value

The host that is affected by the HA Event.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

## InstanceName

This property specifies the instance that triggered the HA event.

#### Declaration

```
// C#  
public string InstanceName {get;}
```

#### Property Value

The instance that is affected by the HA Event.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

## Reason

This property specifies reason for which the HA event was sent by the server.

### Declaration

```
// C#  
public string Reason {get;}
```

### Property Value

The reason the HA Event was triggered. Possible values include Data\_Guard\_Failover, Failure, Dependency, User, Autostart, and Restart.

The value User is indicative of a planned outage. All other values are indicative of an unplanned outage.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

## ServiceName

This property specifies the service that triggered the HA event.

### Declaration

```
// C#  
public string ServiceName {get;}
```

### Property Value

The service that is affected by the HA Event.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

## Source

This property specifies the source that triggered the HA event.

### Declaration

```
// C#  
public OracleHAEventSource Source {get;}
```

### Property Value

The source that triggered the HA Event.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

## Status

This property specifies the status of the source that triggered the HA event.

### Declaration

```
// C#  
public OracleHAEventStatus Status {get;}
```

### Property Value

The status of the source that triggered the HA Event.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

Time

This property specifies the time when the HA event was triggered on the server.

Declaration

```
// C#
public DateTime Time {get;}
```

Property Value

The time that the HA Event was triggered.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleHAEventArgs Class](#)
- [OracleHAEventArgs Members](#)
- ["HAEvent"](#)

OracleHAEventHandler Delegate

The OracleHAEventHandler delegate represents the signature of the method that handles the OracleConnection.HAEvent event.

Declaration

```
// C#
public delegate void OracleHAEventHandler(OracleHAEventArgs eventArgs);
```

Requirements

| Provider  | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------|---------------------------------|---------------------------------|
| Assembly  | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.DataAccess.Client  | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

#### Parameters

- *sender*  
The source of the event.
- *EventArgs*  
The OracleHAEvEntArgs object that contains the event data.

#### ① See Also

## OracleHAEvEntSource Enumeration

The OracleHAEvEntSource enumeration indicates the source of the HA event.

[Table 8-3](#) lists all the OracleHAEvEntSource enumeration values with a description of each enumerated value.

**Table 8-3 OracleHAEvEntSource Enumeration Member Values**

| Member Name   | Description                                     |
|---------------|-------------------------------------------------|
| Service       | The source of the HA Event is a service.        |
| ServiceMember | The source of the HA Event is a service member. |
| Database      | The source of the HA Event is a database.       |
| Host          | The source of the HA Event is a host.           |
| Instance      | The source of the HA Event is an instance.      |
| Node          | The source of the HA Event is a node.           |

#### Requirements

| Provider | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver      | ODP.NET Core                 |
|----------|---------------------------|------------------------------|------------------------------|
| Assembly | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll | Oracle.ManagedDataAccess.dll |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|

## OracleHAEventStatus Enumeration

The OracleHAEventStatus enumeration indicates the status of the HA event source.

[Table 8-4](#) lists all the OracleHAEventStatus enumeration values with a description of each enumerated value.

**Table 8-4 OracleHAEventStatus Enumeration Values**

| Member Name | Description                         |
|-------------|-------------------------------------|
| Up          | The source of the HA Event is up.   |
| Down        | The source of the HA Event is down. |

#### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

# Continuous Query Notification Classes

This chapter describes Oracle Data Provider for .NET Continuous Query Notification Classes, Event Delegates, and Enumerations.

## See Also

["Continuous Query Notification Support"](#)

This chapter contains these topics:

- [OracleDependency Class](#)
- [OracleNotificationRequest Class](#)
- [OracleNotificationEventArgs Class](#)
- [OnChangeEventHandler Delegate](#)
- [OracleRowidInfo Enumeration](#)
- [OracleNotificationType Enumeration](#)
- [OracleNotificationSource Enumeration](#)
- [OracleNotificationInfo Enumeration](#)

## OracleDependency Class

An `OracleDependency` class represents a dependency between an application and an Oracle database, enabling the application to get notifications whenever the data of interest or the state of the Oracle database changes.

### Class Inheritance

`System.Object`

`Oracle.DataAccess.Client.OracleDependency`

### Declaration

```
// C#
public sealed class OracleDependency
```

### Requirements

| Provider | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver      | ODP.NET Core                 |
|----------|---------------------------|------------------------------|------------------------------|
| Assembly | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll | Oracle.ManagedDataAccess.dll |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although methods do not guarantee thread safety.

- [OracleDependency Properties](#)
- [OracleDependency Events](#)

OracleDependency Members

OracleDependency members are listed in the following tables.

OracleDependency Constructors

OracleDependency constructors are listed in [Table 9-1](#).

Table 9-1 OracleDependency Constructors

| Constructors                                  | Description                                                        |
|-----------------------------------------------|--------------------------------------------------------------------|
| <a href="#">OracleDependency Constructors</a> | Instantiates a new instance of OracleDependency class (Overloaded) |

OracleDependency Static Fields

The OracleDependency static fields are listed in [Table 9-2](#).

**Table 9-2 OracleDependency Static Fields**

| Static Field            | Description                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Address</a> | Indicates the address that the notification listener listens on, for database notifications<br>Supported in ODP.NET Core only |
| <a href="#">Port</a>    | Indicates the port number that the notification listener listens on, for database notifications                               |

### OracleDependency Static Methods

OracleDependency static methods are listed in [Table 9-3](#).

**Table 9-3 OracleDependency Static Methods**

| Static Methods                      | Description                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------|
| <code>Equals</code>                 | Inherited from <code>System.Object</code>                                                  |
| <a href="#">GetOracleDependency</a> | Returns an <code>OracleDependency</code> instance based on the specified unique identifier |

### OracleDependency Properties

OracleDependency properties are listed in [Table 9-4](#).

**Table 9-4 OracleDependency Properties**

| Properties                             | Description                                                                                                                  |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DataSource</a>             | Indicates the data source associated with the <code>OracleDependency</code> instance                                         |
| <a href="#">HasChanges</a>             | Indicates whether or not there is any change in the database associated with this dependency                                 |
| <a href="#">Id</a>                     | Represents the unique identifier for the <code>OracleDependency</code> instance                                              |
| <a href="#">IsEnabled</a>              | Specifies whether or not the dependency is enabled between the application and the database                                  |
| <a href="#">QueryBasedNotification</a> | Specifies whether the change notification registration is object-based or query-based                                        |
| <a href="#">RegisteredQueryIDs</a>     | Provides a list of <code>CHANGE_NOTIFICATION_QUERY_IDS</code>                                                                |
| <a href="#">RegisteredResources</a>    | Indicates the database resources that are registered in the notification registration                                        |
| <a href="#">RowidInfo</a>              | Specifies whether or not ROWID information is part of change notification events fired whenever data changes on the database |
| <a href="#">UserName</a>               | Indicates the database user name associated with the <code>OracleDependency</code> instance                                  |

### OracleDependency Methods

OracleDependency methods are listed in [Table 9-5](#).

**Table 9-5 OracleDependency Methods**

| Methods                              | Description                                                                 |
|--------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">AddCommandDependency</a> | Binds the OracleDependency instance to the specified OracleCommand instance |
| Equals                               | Inherited from System.Object                                                |
| GetHashCode                          | Inherited from System.Object                                                |
| GetType                              | Inherited from System.Object                                                |
| <a href="#">RemoveRegistration</a>   | Removes the specified dependency between the application and the database   |
| ToString                             | Inherited from System.Object                                                |

### OracleDependency Events

The OracleDependency event is listed in [Table 9-6](#).

**Table 9-6 OracleDependency Events**

| Event                    | Description                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------|
| <a href="#">OnChange</a> | An event that is sent when a database notification associated with the dependency is received from the database |

#### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDependency Class](#)

## OracleDependency Constructors

OracleDependency constructors create instances of the OracleDependency class.

### Overload List:

- [OracleDependency \( \)](#)  
This constructor creates an instance of the OracleDependency class.
- [OracleDependency\(OracleCommand\)](#)  
This constructor creates an instance of the OracleDependency class and binds it to the specified OracleCommand instance.
- [OracleDependency\(OracleCommand, bool, int, bool\)](#)  
This constructor creates an instance of the OracleDependency class and binds it to the specified OracleCommand instance, specifying whether or not a notification is to be removed upon notification, the timeout value of the notification registration, and the persistence of the notification.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## OracleDependency ( )

This constructor creates an instance of the `OracleDependency` class.

### Declaration

```
// C#  
public OracleDependency ( )
```

### Remarks

Using this constructor does not bind any `OracleCommand` to the newly constructed `OracleDependency`. Use the `AddCommandDependency` method to do so.

### ① Note

The dependency between the application and the database is not established when the `OracleDependency` instance is created. The dependency is established when the command that is associated with this dependency is executed.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## OracleDependency(OracleCommand)

This constructor creates an instance of the `OracleDependency` class and binds it to an `OracleCommand` instance.

### Declaration

```
// C#  
public OracleDependency (OracleCommand cmd)
```

### Parameters

- *cmd*

The command that the `OracleDependency` object binds to.

## Exceptions

`ArgumentNullException` - The `cmd` parameter is null.

`InvalidOperationException` - The specified `OracleCommand` instance already contains a notification request.

## Remarks

When this `OracleDependency` constructor binds the `OracleCommand` instance to an `OracleDependency` instance, it causes the creation of an `OracleNotificationRequest` instance and then sets that `OracleNotificationRequest` instance to the `OracleCommand.Notification` property.

The Continuous Query Notification is registered with the database, when the command is executed. Any of the command execution methods (for example, `ExecuteNonQuery`, `ExecuteReader`, and so on) will register the notification request. An `OracleDependency` may be bound to more than one `OracleCommand`. When one of these `OracleCommand` object statements is executed, the statement is registered with the associated `OracleCommand`. Although the registration happens on each `OracleCommand` separately, one `OracleDependency` can be responsible for detecting and sending notifications that occur for all `OracleCommand` objects that the `OracleDependency` is associated with. The `OnChangeEventArgs` that is passed to the application for the `OnChange` event provides information on what has changed in the database.

The `OracleNotificationRequest` instance that is created by this constructor has the following default property values:

- `IsNotifiedOnce` is set to the value `True`.
- `Timeout` is set to 50,000 seconds.
- `IsPersistent` is set to the value `False`, that is, the invalidation message is not persistent, but is stored in an in-memory queue before delivery.

## OracleDependency(OracleCommand, bool, int, bool)

This constructor creates an instance of the `OracleDependency` class and binds it to the specified `OracleCommand` instance, while specifying whether or not a registration is to be removed upon notification, the timeout value of the notification registration, and the persistence of the notification.

## Declaration

```
// C#
public OracleDependency (OracleCommand cmd, bool isNotifiedOnce, long timeout,
    bool isPersistent)
```

### Parameters

- *cmd*  
The command associated with the Continuous Query Notification request.
- *isNotifiedOnce*  
An indicator that specifies whether or not the registration is removed automatically once the notification occurs.
- *timeout*  
The amount of time, in seconds, that the registration stays active. When *timeout* is set to 0, the registration never expires. The valid values for *timeout* are between 0 and 4294967295.
- *isPersistent*  
Indicates whether or not the invalidation message should be queued persistently in the database before delivery. If the *isPersistent* parameter is set to True, the message is queued persistently in the database and cannot be lost upon database failures or shutdowns. If the *isPersistent* property is set to False, the message is stored in an in-memory queue before delivery and might be lost.  
  
Database performance is faster if the message is stored in an in-memory queue rather than in the database queue.

### Exceptions

ArgumentNullException - The *cmd* parameter is null.

ArgumentOutOfRangeException - The specified *timeout* is invalid.

InvalidOperationException - The specified *OracleCommand* instance already contains a notification request.

### Remarks

When this *OracleDependency* constructor binds the *OracleCommand* instance to an *OracleDependency* instance, it causes the creation of an *OracleNotificationRequest* instance and then sets that *OracleNotificationRequest* instance to the *OracleCommand.Notification* property.

The Continuous Query Notification is registered with the database, when the command is executed. Any of the command execution methods (for example, *ExecuteNonQuery*, *ExecuteReader*, and so on) will register the notification request. An *OracleDependency* may be bound to more than one *OracleCommand*. When one of these *OracleCommand* object statements is executed, the statement is registered with the associated *OracleCommand*. Although the registration happens on each *OracleCommand* separately, one *OracleDependency* can be responsible for detecting and sending notifications that occur for all *OracleCommand* objects that the *OracleDependency* is associated with. The *OnChangeEventArgs* that is passed to the application for the *OnChange* event provides information on what has changed in the database.

The *OracleNotificationRequest* instance that is created by this constructor has the following default property values:

- *IsNotifiedOnce* is set to the specified value.
- *Timeout* is set to the specified value.
- *IsPersistent* is set to the specified value.

## OracleDependency Static Fields

The OracleDependency static fields are listed in [Table 9-7](#).

**Table 9-7 OracleDependency Static Fields**

| Static Field            | Description                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Address</a> | Indicates the address that the notification listener listens on, for database notifications<br>Supported in ODP.NET Core only |
| <a href="#">Port</a>    | Indicates the port number that the notification listener listens on, for database notifications                               |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## Address

This static field indicates the address that the notification listener listens on, for database notifications.

**Declaration**

```
// C#  
public static string Address{get; set}
```

**Property Value**

A string value that represents the address that listens for the database notifications.

If the address is not set, then `OracleConfiguration.DBNotificationAddress` will be used if set. If `OracleDependency.Address` is explicitly set to `string.Empty` or `null`, then the hostname will be used.

**Remarks**

This property allows specifying a particular IPv4 or IPv6 address to use, such as the case with a machine that contains multiple network cards. The address can be set to any valid

hostname, IPv4, or IPv6 address, which is associated with the machine on which the ODP.NET application is running on, which will be listening for notifications.

The address specified by the `OracleDependency.Address` static field is used by the notification listener that runs within the same application domain as ODP.NET. This address receives Continuous Query Notifications from the database. One notification listener is capable of listening to all Continuous Query Notifications and therefore, only one notification listener is created for each application domain.

The notification listener is created when a command associated with an `OracleDependency` object is executed for the first time during the application domain lifetime. The address specified for the `OracleDependency.Address` static field is used by the listener for its lifetime. The `OracleDependency.Address` static field can be changed after the creation of the notification listener, but doing so does not affect the actual address that the notification listener listens on.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## Port

This static field indicates the port number that the notification listener listens on, for database notifications.

### Declaration

```
// C#  
public static int Port{get; set;}
```

### Property Value

An `int` value that represents the number of the port that listens for the database notifications. If the port number is set to -1, a random port number is assigned for the listener when the listener is started. Otherwise, the specified port number is used to start the listener.

### Exceptions

`ArgumentOutOfRangeException` - The port number is set to a negative value.

`InvalidOperationException` - The port number is being changed after the listener has started.

### Remarks

The port number specified by the `OracleDependency.Port` static field is used by the notification listener that runs within the same application domain as ODP.NET. This port number receives Continuous Query Notifications from the database. One notification listener is capable of listening to all Continuous Query Notifications and therefore, only one notification listener is created for each application domain.

The notification listener is created when a command associated with an `OracleDependency` object is executed for the first time during the application domain lifetime. The port number specified for the `OracleDependency.Port` static field is used by the listener for its lifetime. The

OracleDependency.Port static field can be changed after the creation of the notification listener, but doing so does not affect the actual port number that the notification listener listens on.

## OracleDependency Static Methods

OracleDependency static methods are listed in [Table 9-8](#).

**Table 9-8 OracleDependency Static Methods**

| Static Methods                      | Description                                                                   |
|-------------------------------------|-------------------------------------------------------------------------------|
| Equals                              | Inherited from System.Object                                                  |
| <a href="#">GetOracleDependency</a> | Returns an OracleDependency instance based on the specified unique identifier |

#### 📘 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- [OracleDependency Members](#)

## GetOracleDependency

This static method returns an OracleDependency instance based on the specified unique identifier.

### Declaration

```
// C#  
public static OracleDependency GetOracleDependency(string guid)
```

### Parameters

- *guid*  
The string representation of the unique identifier of an OracleDependency instance.

### Exceptions

ArgumentException - The specified unique identifier cannot locate an OracleDependency instance.

### Return Value

An OracleDependency instance that has the specified *guid* parameter.

## OracleDependency Properties

OracleDependency properties are listed in [Table 9-9](#).

**Table 9-9 OracleDependency Properties**

| Properties                             | Description                                                                                                                  |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DataSource</a>             | Indicates the data source associated with the OracleDependency instance                                                      |
| <a href="#">HasChanges</a>             | Indicates whether or not there is any change in the database associated with this dependency                                 |
| <a href="#">Id</a>                     | Represents the unique identifier for the OracleDependency instance                                                           |
| <a href="#">IsEnabled</a>              | Specifies whether or not the dependency is enabled between the application and the database                                  |
| <a href="#">QueryBasedNotification</a> | Specifies whether the change notification registration is object-based or query-based                                        |
| <a href="#">RegisteredQueryIDs</a>     | Provides a list of CHANGE_NOTIFICATION_QUERY_IDs                                                                             |
| <a href="#">RegisteredResources</a>    | Indicates the database resources that are registered in the notification registration                                        |
| <a href="#">RowidInfo</a>              | Specifies whether or not ROWID information is part of change notification events fired whenever data changes on the database |
| <a href="#">UserName</a>               | Indicates the database user name associated with the OracleDependency instance                                               |

#### See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## DataSource

This property indicates the data source associated with the OracleDependency instance.

**Declaration**

```
// C#  
public string DataSource{get;}
```

**Property Value**

A string that indicates the data source associated with the `OracleDependency` instance.

**Remarks**

The `DataSource` property is populated with the data source once the `OracleCommand` associated with the `OracleDependency` executes and registers for the notification successfully.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## HasChanges

This property indicates whether or not there is any change in the database associated with this dependency.

**Declaration**

```
// C#  
public bool HasChanges{get;}
```

**Property Value**

A `bool` value that returns `True` if the database has detected changes that are associated with this dependency; otherwise, returns `False`.

**Remarks**

As an alternative to using the `OnChange` event, applications can check the `HasChanges` property to determine if there are any changes in the database associated with this dependency.

Once the `HasChanges` property is accessed, its value is reset to `False` so that the next notification can then be acknowledged.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## Id

This property represents the unique identifier for the OracleDependency instance.

### Declaration

```
// C#  
public string Id{get;}
```

### Property Value

A string that represents the unique identifier that was generated for the OracleDependency instance when it was created.

### Remarks

This property is set when the OracleDependency instance is created.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## IsEnabled

This property specifies whether or not the dependency is enabled between the application and the database.

### Declaration

```
// C#  
public bool IsEnabled {get;}
```

### Property Value

A bool value that specifies whether or not dependency is enabled between the application and the database.

### Remarks

The dependency between the application and the database is not established when the OracleDependency instance is created. The dependency is established when the command that is associated with this dependency is executed, at which time the notification request is registered with the database. The dependency ends when the notification registration is removed from the database or when it times out.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## QueryBasedNotification

This instance property specifies whether the change notification registration is object-based or query-based.

### Declaration

```
// C#  
public bool QueryBasedNotification{get; set;}
```

### Property Value

Specifies whether the change notification registration is object-based or not.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

### Remarks

This property value will be ignored if it is set after the command execution that registers the command for change notification.

By default, this property is true.

ODP.NET developers can register their queries on the row level, not just the object level, beginning with Oracle Data Provider for .NET release 11.1 and Oracle Database 11g release 1 (11.1). The application only receives notification when the selected row or rows change. Query-based notifications provide developers more granularity for using client-side cached data, as they can be more specific about what changes the application needs to be notified of.

`OracleNotificationType` enumeration is set to `Query` for query-based notifications.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## RegisteredQueryIDs

This instance property provides a list of `CHANGE_NOTIFICATION_QUERY_IDS`.

**Declaration**

```
// C#  
public ArrayList RegisteredQueryIDs {get;}
```

**Property Value**

This property is an ArrayList of CHANGE\_NOTIFICATION\_QUERY\_IDs.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

This property provides a list of CHANGE\_NOTIFICATION\_QUERY\_IDs that uniquely identify the query that has been registered for change notification. The notification returned from the database will also contain these IDs, allowing applications to determine the query that the notifications are for.

The QueryId at index *n* in RegisteredQueryIDs is for the statement at index *n* the RegisteredResources at index *n*.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## RegisteredResources

This property indicates the database resources that are registered in the notification registration.

**Declaration**

```
// C#  
public ArrayList RegisteredResources{get;}
```

**Property Value**

The registered resources in the notification registration.

**Remarks**

The ArrayList contains all the command statement or statements that are registered for notification through this OracleDependency object. It is appropriately updated when the Continuous Query Notification is registered by a command execution.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## RowidInfo

This property specifies whether or not ROWID information is part of change notification events fired whenever data changes on the database.

### Declaration

```
// C#  
public OracleRowidInfo RowidInfo {get; set;};
```

### Property Value

An `OracleRowidInfo` enumeration type that determines the inclusion of ROWID in the change notification event.

### Remarks

There are three `OracleRowidInfo` enumeration types that are valid for this property:

- `Default` includes ROWID information in the change notification event only if `OracleCommand.AddRowid` property is set to true or if ROWID is in the select list of the query that is registered for change notification.
- `Include` includes ROWID information regardless of whether or not ROWID is in the select-list for the query.
- `Exclude` excludes ROWID information regardless of whether or not ROWID is in the select-list.

For change notification registrations that involve stored procedure executions, change notification events related to the REF CURSOR contain ROWID information only if `RowidInfo` property is set to `OracleRowidInfo.Include`.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)
- ["OracleRowidInfo Enumeration"](#)

## UserName

This property indicates the database user name associated with the `OracleDependency` instance.

### Declaration

```
// C#  
public string UserName{get;}
```

### Property Value

A string that indicates the database user name associated with the OracleDependency instance. This database user registers the Continuous Query Notification request with the database.

### Remarks

The UserName property is populated with the user name once the OracleCommand associated with the OracleDependency executes and registers for the notification successfully. Only the database user who creates the notification registration, or the database system administrator, can remove the registration.

The user specified by this property must have the CHANGE NOTIFICATION privilege to register successfully for the Continuous Query Notification with the database.

## OracleDependency Methods

OracleDependency methods are listed in [Table 9-10](#).

**Table 9-10 OracleDependency Methods**

| Methods                              | Description                                                                 |
|--------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">AddCommandDependency</a> | Binds the OracleDependency instance to the specified OracleCommand instance |
| Equals                               | Inherited from System.Object                                                |
| GetHashCode                          | Inherited from System.Object                                                |
| GetType                              | Inherited from System.Object                                                |
| <a href="#">RemoveRegistration</a>   | Removes the specified dependency between the application and the database   |
| ToString                             | Inherited from System.Object                                                |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## AddCommandDependency

This instance method binds the `OracleDependency` instance to the specified `OracleCommand` instance.

### Declaration

```
// C#  
Public void AddCommandDependency (OracleCommand cmd);
```

### Parameters

- *cmd*

The command that is to be bound to the `OracleDependency` object.

### Exceptions

`ArgumentNullException` - The *cmd* parameter is null.

`InvalidOperationException` - The specified `OracleCommand` instance already contains a notification request.

### Remarks

An `OracleDependency` instance can bind to multiple `OracleCommand` instances.

While it binds an existing `OracleDependency` instance to an `OracleCommand` instance, the `AddCommandDependency` method creates an `OracleNotificationRequest` instance, and sets it to the specified `OracleCommand.Notification` property.

When this method creates an `OracleNotificationRequest` instance, the following `OracleNotificationRequest` properties are set:

- `IsNotifiedOnce` is set to the value `True`.
- `Timeout` is set to 50,000 seconds.
- `IsPersistent` is set to the value `False`, indicating that the invalidation message is stored in an in-memory queue before delivery.

With this method, multiple commands can be associated with a single Continuous Query Notification registration request. Furthermore, the `OracleNotificationRequest` attribute values assigned to the `OracleCommand` can be changed once the association between the `OracleCommand` and the `OracleDependency` is established.

However, when multiple `OracleCommand` objects are associated with a single `OracleDependency` object, the `OracleNotificationRequest` attributes (`Timeout`, `IsPersistent`, and `IsNotifiedOnce`) of the first executed `OracleCommand` object are used for registration, the attributes associated with subsequent `OracleCommand` executions will be ignored.

Furthermore, once a command associated with an `OracleDependency` is executed and registered, all other subsequent command executions and registration associated with the same `OracleDependency` must use a connection with the same "User Id" and "Data Source" connection string attribute value settings.

Otherwise, an exception will be thrown.

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)
- ["OracleDependency\(OracleCommand\)"](#) for `OracleNotificationRequest` property value

## RemoveRegistration

This instance method removes the specified dependency between the application and the database. Once the registration of the dependency is removed from the database, the `OracleDependency` is no longer able to detect any changes that the database undergoes.

### Declaration

```
// C#  
public void RemoveRegistration(OracleConnection con)
```

### Parameters

- *con*  
The connection associated with the `OracleDependency` instance.

### Exceptions

`InvalidOperationException` - The associated connection is not open.

### Remarks

The notification registration associated with the `OracleDependency` instance is removed from the database.

The `OracleConnection` parameter must be in an *opened state*. This instance method does not open the connection implicitly for the application.

An exception is thrown if the dependency is not valid.

# OracleDependency Events

The OracleDependency event is listed in [Table 9-11](#).

**Table 9-11 OracleDependency Event**

| Event                    | Description                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------|
| <a href="#">OnChange</a> | An event that is sent when a database notification associated with the dependency is received from the database |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDependency Class](#)
- [OracleDependency Members](#)

## OnChange

The OnChange event is sent when a database notification associated with the dependency is received from the database. The information related to the notification is stored in the OracleChangeNotificationEventArgs class.

**Declaration**

```
// C#
public event OnChangeEventHandler OnChange;
```

**Remarks**

The OnChange event occurs if any result set associated with the dependency changes. For objects that are part of a Transaction, notifications will be received for each modified object. This event also occurs for other actions related to database or registration status, such as database shutdowns and startups, or registration timeouts.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

# OracleNotificationRequest Class

An OracleNotificationRequest class represents a notification request to be subscribed in the database. It contains information about the request and the characteristics of the notification.

Using the `OracleNotificationRequest` class, Oracle Data Provider for .NET can create the notification registration in the database.

**Class Inheritance**

`System.Object`

`Oracle.DataAccess.Client.OracleNotificationRequest`

**Declaration**

```
// C#
public sealed class OracleNotificationRequest
```

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although methods do not guarantee thread safety.

 **See Also**

- [OracleNotificationRequest Properties](#)
- [OracleNotificationRequest Methods](#)

# OracleNotificationRequest Members

`OracleNotificationRequest` members are listed in the following tables.

**OracleNotificationRequest Static Method**

The `OracleNotificationRequest` static method is listed in [Table 9-12](#).

**Table 9-12 OracleNotificationRequest Static Method**

| Static Method | Description                  |
|---------------|------------------------------|
| Equals        | Inherited from System.Object |

**OracleNotificationRequest Properties**

OracleNotificationRequest properties are listed in [Table 9-13](#).

**Table 9-13 OracleNotificationRequest Properties**

| Properties                                  | Description                                                                                                     |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <a href="#">IsNotifiedOnce</a>              | Indicates whether or not the registration is to be removed upon notification                                    |
| <a href="#">IsPersistent</a>                | Indicates whether or not the notification message should be queued persistently in the database before delivery |
| <a href="#">Timeout</a>                     | Specifies the time that the registration remains alive                                                          |
| <a href="#">GroupingNotificationEnabled</a> | Specifies whether grouping notification is enabled or not                                                       |
| <a href="#">GroupingType</a>                | Specifies the type of grouping notification                                                                     |
| <a href="#">GroupingInterval</a>            | Specifies the interval between grouping notifications, in seconds                                               |

**OracleNotificationRequest Methods**

OracleNotificationRequest methods are listed in [Table 9-14](#).

**Table 9-14 OracleNotificationRequest Methods**

| Methods     | Description                  |
|-------------|------------------------------|
| Equals      | Inherited from System.Object |
| GetHashCode | Inherited from System.Object |
| GetType     | Inherited from System.Object |
| ToString    | Inherited from System.Object |

**See Also**

## OracleNotificationRequest Properties

The `OracleNotificationRequest` properties are listed in [Table 9-16](#).

**Table 9-16 OracleNotificationRequest Properties**

| Properties                                  | Description                                                                                                     |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <a href="#">IsNotifiedOnce</a>              | Indicates whether or not the registration is to be removed upon notification                                    |
| <a href="#">IsPersistent</a>                | Indicates whether or not the notification message should be queued persistently in the database before delivery |
| <a href="#">Timeout</a>                     | Specifies the time that the registration remains alive                                                          |
| <a href="#">GroupingNotificationEnabled</a> | Specifies whether grouping notification is enabled or not                                                       |
| <a href="#">GroupingType</a>                | Specifies the type of grouping notification                                                                     |
| <a href="#">GroupingInterval</a>            | Specifies the interval between grouping notifications, in seconds                                               |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

- [OracleNotificationRequest Class](#)

## IsNotifiedOnce

This property indicates whether or not the registration is to be removed upon notification.

**Declaration**

```
// C#  
public bool IsNotifiedOnce{get; set;}
```

**Property Value**

A bool value that indicates whether or not the registration is to be removed upon notification.

**Remarks**

The default value is false for AQ. This is different from change notification where the default value is true.

Modifying this property after the completion of a successful registration has no effect.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationRequest Members](#)
- [OracleNotificationRequest Class](#)

## IsPersistent

This property indicates whether or not the notification message should be queued persistently in the database until delivery.

**Declaration**

```
// C#  
public bool IsPersistent{get; set;}
```

**Property Value**

A bool value that indicates whether or not the notifications should be stored persistently in the database until delivery.

When the IsPersistent property is set to True, the message is queued persistently in the database and cannot be lost upon database failures or shutdowns. When the IsPersistent property is set to False, the message is stored in an in-memory queue before delivery and could be lost.

This property does not apply to NotificationRegistration which is always persistent.

This property only applies to the notification message after it has been sent.

**Remarks**

The default value is false.

The database performs faster if the message is stored in an in-memory queue rather than a database queue.

Modifying this property after the completion of a successful registration has no effect.

This property is ignored for grouping notifications.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationRequest Members](#)
- [OracleNotificationRequest Class](#)

## Timeout

This property specifies the time, in seconds, that the registration remains alive.

### Declaration

```
// C#  
public long Timeout{get; set}
```

### Property Value

A long value that specifies the time, in seconds, that the registration remains alive. The valid values for the Timeout property are between 0 and 4294967295.

### Exceptions

ArgumentOutOfRangeException - The specified Timeout is invalid.

### Remarks

The default value is 0 (infinite) for AQ and 50000 for change notification. If the Timeout property is set to 0, then the registration does not expire.

If the registration is removed because the Timeout value has been reached, then the database sends a notification indicating the expiration.

Modifying this property after the completion of a successful registration has no effect.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationRequest Members](#)
- [OracleNotificationRequest Class](#)

## GroupingNotificationEnabled

This property specifies whether to group notifications together by time is enabled or not.

### Declaration

```
// C#  
public bool GroupingNotificationEnabled {get; set}
```

**Property Value**

A true value indicates that grouping notification is enabled. A false value indicates that grouping notification is disabled.

**Remarks**

The default value is false.

Modifying this property after the completion of a successful registration has no effect.

If enabled, then ODP.NET will group notifications together that occur during the same time period. The time period is defined by `OracleNotificationRequest.GroupingInterval`.

If disabled, then notifications will be generated immediately after the event that triggers them.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationRequest Members](#)
- [OracleNotificationRequest Class](#)

## GroupingType

This property specifies the type of grouping notification, which can summarize all notifications during the time period or only the last notification.

**Declaration**

```
// C#  
public OracleAQNotificationGroupingType GroupingType {get; set;}
```

**Property Value**

An `OracleAQNotificationGroupingType` enum value. The possible enum values are `OracleAQNotificationGroupingType.Summary` and `OracleAQNotificationGroupingType.Last`.

**Remarks**

The default value is `OracleAQNotificationGroupingType.Summary`.

Modifying this property after the completion of a successful registration has no effect.

`OracleAQNotificationGroupingType.Summary` : All notifications in the group are summarized into a single notification.

**① Note**

The single notification does not include ROWIDs, even if ROWID information was requested to be returned.

OracleAQNotificationGroupingType.Last : Only the last notification in the group is published. The earlier ones discarded.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationRequest Members](#)
- [OracleNotificationRequest Class](#)

## GroupingInterval

This property specifies the interval of grouping notification in seconds. The group notifications are delivered at intervals specified by this property.

#### Declaration

```
// C#  
public int GroupingInterval {get; set}
```

#### Property Value

An integer specifying the grouping interval in seconds.

#### Remarks

If this value is 900, then notifications generated in the same 15 minute interval are grouped together into a single notification. The default value is 600 seconds.

The range of GroupingInterval is from 1 to Int32.MaxValue.

Modifying this property after the completion of a successful registration has no effect.

# OracleNotificationEventArgs Class

The OracleNotificationEventArgs class provides event data for a notification.

**Class Inheritance**

**Declaration**

```
// C#
public sealed class OracleNotificationEventArgs
```

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although methods do not guarantee thread safety.

## OracleNotificationEventArgs Members

OracleNotificationEventArgs members are listed in the following tables.

### OracleNotificationEventArgs Static Fields

The OracleNotificationEventArgs static field is listed in [Table 9-18](#).

**Table 9-18 OracleNotificationEventArgs Static Field**

| Static Field | Description                     |
|--------------|---------------------------------|
| Empty        | Inherited from System.EventArgs |

### OracleNotificationEventArgs Static Methods

The OracleNotificationEventArgs static method is listed in [Table 9-19](#).

**Table 9-19 OracleNotificationEventArgs Static Method**

| Static Method | Description                  |
|---------------|------------------------------|
| Equals        | Inherited from System.Object |

### OracleNotificationEventArgs Properties

OracleNotificationEventArgs properties are listed in [Table 9-20](#).

**Table 9-20 OracleNotificationEventArgs Properties**

| Properties                    | Description                                                          |
|-------------------------------|----------------------------------------------------------------------|
| <a href="#">Details</a>       | Contains detailed information about the current notification         |
| <a href="#">Info</a>          | Indicates the database events for the notification                   |
| <a href="#">ResourceNames</a> | Indicates the database resources related to the current notification |
| <a href="#">Source</a>        | Returns the database event source for the notification               |
| <a href="#">Type</a>          | Returns the database event type for the notification                 |

## OracleNotificationEventArgs Methods

OracleNotificationEventArgs methods are listed in [Table 9-21](#).

**Table 9-21 OracleNotificationEventArgs Methods**

| Methods     | Description                  |
|-------------|------------------------------|
| Equals      | Inherited from System.Object |
| GetHashCode | Inherited from System.Object |
| GetType     | Inherited from System.Object |
| ToString    | Inherited from System.Object |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationEventArgs Class](#)

## OracleNotificationEventArgs Static Fields

The OracleNotificationEventArgs static field is listed in [Table 9-22](#).

**Table 9-22 OracleNotificationEventArgs Static Field**

| Static Field | Description                     |
|--------------|---------------------------------|
| Empty        | Inherited from System.EventArgs |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationEventArgs Class](#)
- [OracleNotificationEventArgs Members](#)

## OracleNotificationEventArgs Static Methods

The OracleNotificationEventArgs static method is listed in [Table 9-23](#).

**Table 9-23 OracleNotificationEventArgs Static Method**

| Static Method | Description                  |
|---------------|------------------------------|
| Equals        | Inherited from System.Object |

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## Details

This property contains detailed information about the current notification.

**Declaration**

```
// C#
Public DataTable Details{get;}
```

**Property Value**

A DataTable instance that contains detailed information about the current notification.

**Remarks**

The returned DataTable object contains column data about the current notification in order as shown in [Table 9-25](#).

**Table 9-25 DataTable Object Column Data**

| Name         | Type                   | Description                                                                           |
|--------------|------------------------|---------------------------------------------------------------------------------------|
| ResourceName | System.String          | The resource name of the invalidated object in the format <Schema_name>.<object_name> |
| Info         | OracleNotificationInfo | The information about the database event that occurs on a resource                    |
| Rowid        | System.String          | The rowid for the invalidated table row                                               |
| QueryId      | Int32                  | The CHANGE_NOTIFICATION_QUERY_ID                                                      |

The QueryId column contains the CHANGE\_NOTIFICATION\_QUERY\_ID that corresponds to the pseudo-column that may have been retrieved by a SELECT statement at the time of the query-based notification. Also, the OracleDependency object maintains all the CHANGE\_NOTIFICATION\_QUERY\_IDS that are registered with it.

For Continuous Query Notification:

- The Details property indicates changes for each invalidated object in the notification in the data table.
- If ROWID information is requested, then the ROWID information is populated into the Rowid column. However, if many rows are modified in a table, then the whole table is invalidated, and ROWID information is not provided. Therefore, the Rowid column contains all Null values.
- If the database event is related to a DDL change of the table or a table drop, then the Rowid column is set to Null.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationEventArgs Class](#)
- [OracleNotificationEventArgs Members](#)

## Info

This property indicates the database events for the notification.

### Declaration

```
// C#
public OracleNotificationInfo Info{get;}
```

### Property Value

An OracleNotificationInfo value that indicates the database event for the notification.

### Remarks

The OracleNotificationInfo value is an enumeration type. If several events are received from the invalidation message, the Info property is set to one of the OracleNotificationInfo enumeration values associated with the database events. For example, if a table has been

altered and a new row has been inserted into another table, the Info property is set to either OracleNotificationInfo.Altered or OracleNotificationInfo.Insert.

To obtain more detailed information from the invalidation message, use the Details and the ResourceNames properties.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationEventArgs Class](#)
- [OracleNotificationEventArgs Members](#)
- ["Details"](#)
- ["ResourceNames"](#)
- ["OracleNotificationInfo Enumeration"](#)

## ResourceNames

This property indicates the database resources related to the current notification.

#### Declaration

```
// C#  
public string[] ResourceNames{get;}
```

#### Property Value

A string array that indicates the database resources related to the current notification.

#### Remarks

For Continuous Query Notification, the ResourceNames property contains information about the invalidated object names in the format <schema\_name>.<object \_name>. To obtain more detailed information about the changes for invalidated objects, use the Details property.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationEventArgs Class](#)
- [OracleNotificationEventArgs Members](#)
- ["Details"](#)

## Source

This property returns the database event source for the notification.

## Declaration

```
// C#  
public OracleNotificationSource Source{get;}
```

## Property Value

The OracleNotificationSource value for the notification.

## Remarks

The OracleNotificationSource value is an enumeration type. If several event sources are received from the notification message, the Source property is set to one of the OracleNotificationSource enumeration values related to the database event source. For example, if a table has been altered (by the ALTER TABLE command) and a new row has been inserted into the same table, the Source property is set to either OracleNotificationSource.Object or OracleNotificationSource.Data.

For Continuous Query Notification:

- When the Source property is set to OracleNotificationSource.Data:
  - The Info property is set to one of the following:
    - \* OracleNotificationInfo.Insert
    - \* OracleNotificationInfo.Delete
    - \* OracleNotificationInfo.Update
  - The ResourceNames property is set, and the elements are set to the invalidated object names.
  - The Details property contains detailed information on the change of each invalidated table.
- When the Source property is set to OracleNotificationSource.Database:
  - The Info property is set to one of the following:
    - \* OracleNotificationInfo.Startup
    - \* OracleNotificationInfo.Shutdown
    - \* OracleNotificationInfo.Shutdown\_Any
    - \* OracleNotificationInfo.Dropped
- When the Source property is set to OracleNotificationSource.Object:
  - The Info property is set to either OracleNotificationInfo.Altered or OracleNotificationInfo.Dropped.
  - The ResourceNames property is set, and the array elements of the ResourceNames property are set to the object names that have been altered or dropped.
  - The Details property contains detailed information on the changes of the object.
- When the Source property is set to OracleNotificationSource.Subscription:
  - The Info property is set to the following:
    - \* OracleNotificationInfo.End

Type

This property returns the database event type for the notification.

Declaration

```
// C#
public OracleNotificationType Type{get;}
```

Property Value

An OracleNotificationType enumeration value that represents the type of the database event notification.

Remarks

The OracleNotificationType value is an enumeration type. If several event types are received from the notification message, then the Type property is set to one of the OracleNotificationType enumeration values related to the database event type.

# OnChangeEventHandler Delegate

The OnChangeEventHandler delegate represents the signature of the method that handles the notification.

## Declaration

```
// C#
public delegate void OnChangeEventHandler(object sender,
    OracleNotificationEventArgs args);
```

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Parameters

- *sender*  
The source of the event.
- *args*  
The OracleNotificationEventArgs instance that contains the event data.

❗ See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleNotificationEventArgs Class](#)

## OracleRowidInfo Enumeration

OracleRowidInfo enumeration values specify whether ROWID information is included as part of the ChangeNotificationEventArgs or not.

[Table 9-28](#) lists all the OracleRowidInfo enumeration values with a description of each enumerated value.

**Table 9-27 OracleRowidInfo Members**

| Member Name | Description                                                                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default     | ROWID information is included only if <code>OracleCommand.AddRowid</code> property is set to true or if ROWID column is explicitly included in the query. |
| Include     | ROWID information is included regardless of whether ROWID is included in the select-list of the query or not.                                             |
| Exclude     | ROWID information is not included regardless of whether ROWID is included in the select-list of the query or not.                                         |

### Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |

## OracleNotificationType Enumeration

OracleNotificationType enumerated values specify the different types that cause the notification.

[Table 9-28](#) lists all the OracleNotificationType enumeration values with a description of each enumerated value.

**Table 9-28 OracleNotificationType Members**

| Member Name | Description                                  |
|-------------|----------------------------------------------|
| Change      | A change occurs in the database.             |
| Subscribe   | A change occurs in the subscription.         |
| Query       | A query-based change occurs in the database. |

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**See Also**

## OracleNotificationSource Enumeration

OracleNotificationSource enumerated values specify the different sources that cause notification.

[Table 9-29](#) lists all the OracleNotificationSource enumeration values with a description of each enumerated value.

**Table 9-29 OracleNotificationSource Members**

| Member Name  | Description                                                     |
|--------------|-----------------------------------------------------------------|
| Data         | The data in a table has changed.                                |
| Database     | A database event such as a database startup or shutdown occurs. |
| Object       | A database object is altered or dropped.                        |
| Subscription | The subscription is changed.                                    |

**Requirements**

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## OracleNotificationInfo Enumeration

OracleNotificationInfo enumerated values specify the database event that causes the notification.

[Table 9-30](#) lists all the OracleNotificationInfo enumeration values with a description of each enumerated value.

**Table 9-30 OracleNotificationInfo Members**

| Member Name  | Description                                                                            |
|--------------|----------------------------------------------------------------------------------------|
| Insert       | A row is inserted.                                                                     |
| Delete       | A row is deleted.                                                                      |
| Update       | A row is updated.                                                                      |
| Startup      | A database starts.                                                                     |
| Shutdown     | A database shuts down.                                                                 |
| Shutdown_any | A database instance in a Real Application Cluster (Oracle RAC) environment shuts down. |
| Alter        | An object is altered.                                                                  |
| Drop         | An object or database is dropped.                                                      |
| End          | A registration is removed.                                                             |
| Error        | A notification error occurs.                                                           |

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |

# Oracle Data Provider for .NET Globalization Classes

This chapter describes the ODP.NET globalization classes.

This chapter contains these topics:

- [OracleGlobalization Class](#)
- [OracleDatabaseCharset Enumeration](#)
- [OracleDatabaseNCharset Enumeration](#)

## OracleGlobalization Class

The OracleGlobalization class is used to obtain and set the Oracle globalization settings of the session, thread, and local computer (read-only).

Class Inheritance

System.Object

Oracle.DataAccess.Client.OracleGlobalization

### Declaration

public sealed class OracleGlobalization : ICloneable, IDisposable

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

An exception is thrown for invalid property values. All newly set property values are validated, except the TimeZone property.

Changing the OracleGlobalization object properties does not change the globalization settings of the session or the thread. Either the SetSessionInfo method of the OracleConnection object or the SetThreadInfo method of the OracleGlobalization object must be called to alter the session's and thread's globalization settings, respectively.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;

class OracleGlobalizationSample
{
    static void Main()
    {
        // Get thread's globalization info
        OracleGlobalization glob = OracleGlobalization.GetThreadInfo();

        // Prints "glob.Language = AMERICAN"
        Console.WriteLine("glob.Language = " + glob.Language);

        // Set language on thread's globalization info
        glob.Language = "FRENCH";
        OracleGlobalization.SetThreadInfo(glob);
        OracleGlobalization.GetThreadInfo(glob);

        // Prints "glob.Language = FRENCH"
        Console.WriteLine("glob.Language = " + glob.Language);

        glob.Dispose();
    }
}
```

## OracleGlobalization Members

OracleGlobalization members are listed in the following tables.

### OracleGlobalization Static Methods

The OracleGlobalization static methods are listed in [Table 10-1](#).

**Table 10-1 OracleGlobalization Static Methods**

| Name                          | Description                                                                                                                                                                                               |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GetClientInfo</a> | Returns an OracleGlobalization object that represents the Oracle globalization settings of the local computer (Overloaded)<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>            |
| <a href="#">GetThreadInfo</a> | Returns or refreshes an OracleGlobalization instance that represents Oracle globalization settings of the current thread (Overloaded)<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">SetThreadInfo</a> | Sets Oracle globalization parameters to the current thread<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                                                                            |

**OracleGlobalization Properties**

The OracleGlobalization properties are listed in [Table 10-2](#).

**Table 10-2 OracleGlobalization Properties**

| Name                                     | Description                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Calendar</a>                 | Specifies the calendar system                                                                                           |
| <a href="#">ClientCharacterSet</a>       | Specifies a client character set<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                    |
| <a href="#">Comparison</a>               | Specifies a method of comparison for WHERE clauses and comparison in PL/SQL blocks                                      |
| <a href="#">Currency</a>                 | Specifies the string to use as a local currency symbol for the L number format element                                  |
| <a href="#">DateFormat</a>               | Specifies the date format for Oracle Date type as a string                                                              |
| <a href="#">DateLanguage</a>             | Specifies the language used to spell day and month names and date abbreviations                                         |
| <a href="#">DualCurrency</a>             | Specifies the dual currency symbol, such as <i>Euro</i> , for the U number format element                               |
| <a href="#">ISOCurrency</a>              | Specifies the string to use as an international currency symbol for the C number format element                         |
| <a href="#">Language</a>                 | Specifies the default language of the database                                                                          |
| <a href="#">LengthSemantics</a>          | Enables creation of CHAR and VARCHAR2 columns using either byte or character (default) length semantics                 |
| <a href="#">NCharConversionException</a> | Determines whether or not data loss during an implicit or explicit character type conversion reports an error           |
| <a href="#">NumericCharacters</a>        | Specifies the characters used for the decimal character and the group separator character for numeric values in strings |
| <a href="#">Sort</a>                     | Specifies the collating sequence for ORDER by clause                                                                    |
| <a href="#">Territory</a>                | Specifies the name of the territory                                                                                     |
| <a href="#">TimeStampFormat</a>          | Specifies the string format for TimeStamp types                                                                         |
| <a href="#">TimeStampTZFormat</a>        | Specifies the string format for TimeStampTZ types                                                                       |
| <a href="#">TimeZone</a>                 | Specifies the time zone region name                                                                                     |

## OracleGlobalization Public Methods

OracleGlobalization public methods are listed in [Table 10-3](#).

**Table 10-3 OracleGlobalization Public Methods**

| Public Method           | Description                                              |
|-------------------------|----------------------------------------------------------|
| <a href="#">Clone</a>   | Creates a copy of an OracleGlobalization object          |
| <a href="#">Dispose</a> | Releases any resources or memory allocated by the object |

## GetClientInfo

GetClientInfo returns an OracleGlobalization object instance that represents the Oracle globalization settings of the local computer.

**Overload List:**

- [GetClientInfo\(\)](#)  
This method returns an OracleGlobalization instance that represents the globalization settings of the local computer.
- [GetClientInfo\(OracleGlobalization\)](#)  
This method refreshes the provided OracleGlobalization object with the globalization settings of the local computer.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## GetClientInfo()

This method returns an OracleGlobalization instance that represents the globalization settings of the local computer.

**Declaration**

```
// C#  
public static OracleGlobalization GetClientInfo();
```

**Return Value**

An OracleGlobalization instance.

**Example**

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class GetClientInfoSample  
{  
    static void Main()  
    {  
        // Get client's globalization info  
        OracleGlobalization glob = OracleGlobalization.GetClientInfo();  
  
        // Prints "glob.Language = AMERICAN"  
        Console.WriteLine("glob.Language = " + glob.Language);  
  
        glob.Dispose();  
    }  
}
```

- [OracleGlobalization Members](#)

## GetClientInfo(OracleGlobalization)

This method refreshes the provided `OracleGlobalization` object with the globalization settings of the local computer.

**Declaration**

```
// C#  
public static void GetClientInfo(OracleGlobalization oraGlob);
```

**Parameters**

- *oraGlob*

The `OracleGlobalization` object being updated.

**Example**

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
  
class GetClientInfoSample  
{  
    static void Main()  
    {  
        // Get client's globalization info  
        OracleGlobalization glob = OracleGlobalization.GetClientInfo();  
  
        // Prints "glob.Language = AMERICAN"  
        Console.WriteLine("glob.Language = " + glob.Language);  
  
        // Get client's globalization info using overload  
        OracleGlobalization.GetClientInfo(glob);  
  
        // Prints "glob.Language = AMERICAN"  
        Console.WriteLine("glob.Language = " + glob.Language);  
  
        glob.Dispose();  
    }  
}
```

## GetThreadInfo

GetThreadInfo returns or refreshes an OracleGlobalization instance.

### Overload List:

- [GetThreadInfo\(\)](#)  
This method returns an OracleGlobalization object instance of the current thread.
- [GetThreadInfo\(OracleGlobalization\)](#)  
This method refreshes the OracleGlobalization object instance with the globalization settings of the current thread.

## GetThreadInfo()

This method returns an OracleGlobalization instance of the current thread.

### Declaration

```
// C#  
public static OracleGlobalization GetThreadInfo();
```

### Return Value

An OracleGlobalization instance.

### Remarks

Initially, GetThreadInfo() returns an OracleGlobalization object that has the same property values as that returned by GetClientInfo(), unless the application changes it by invoking SetThreadInfo().

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;
```

```
class GetThreadInfoSample
{
    static void Main()
    {
        // Get thread's globalization info
        OracleGlobalization glob = OracleGlobalization.GetThreadInfo();

        // Prints "glob.Language = AMERICAN"
        Console.WriteLine("glob.Language = " + glob.Language);

        // Get thread's globalization info using overloaded
        OracleGlobalization.GetThreadInfo(glob);

        // Prints "glob.Language = AMERICAN"
        Console.WriteLine("glob.Language = " + glob.Language);

        glob.Dispose();
    }
}
```

## GetThreadInfo(OracleGlobalization)

This method refreshes the `OracleGlobalization` object with the globalization settings of the current thread.

### Declaration

```
// C#
public static void GetThreadInfo(OracleGlobalization oraGlob);
```

### Parameters

- *oraGlob*  
The `OracleGlobalization` object being updated.

### Remarks

Initially `GetThreadInfo()` returns an `OracleGlobalization` object that has the same property values as that returned by `GetClientInfo()`, unless the application changes it by invoking `SetThreadInfo()`.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;

class GetThreadInfoSample
```

```
{
    static void Main()
    {
        // Get thread's globalization info
        OracleGlobalization glob = OracleGlobalization.GetThreadInfo();

        // Prints "glob.Language = AMERICAN"
        Console.WriteLine("glob.Language = " + glob.Language);

        // Get thread's globalization info using overloaded
        OracleGlobalization.GetThreadInfo(glob);

        // Prints "glob.Language = AMERICAN"
        Console.WriteLine("glob.Language = " + glob.Language);

        glob.Dispose();
    }
}
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

- [OracleGlobalization Members](#)

## SetThreadInfo

This method sets Oracle globalization parameters to the current thread.

### Declaration

```
// C#
public static void SetThreadInfo(OracleGlobalization oraGlob);
```

### Parameters

- *oraGlob*  
An OracleGlobalization object.

### Remarks

Any .NET string conversions to and from ODP.NET Types, as well as ODP.NET Type constructors, use the globalization property values where applicable. For example, when constructing an OracleDate structure from a .NET string, that string is expected to be in the format specified by the OracleGlobalization.DateFormat property of the thread.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;

class SetThreadInfoSample
{
    static void Main()
```

```

{
    // Get thread's globalization info
    OracleGlobalization glob1 = OracleGlobalization.GetThreadInfo();

    // Prints "glob1.Language = AMERICAN"
    Console.WriteLine("glob1.Language = " + glob1.Language);

    // Set language on thread's globalization info
    glob1.Language = "FRENCH";
    OracleGlobalization.SetThreadInfo(glob1);
    OracleGlobalization glob2 = OracleGlobalization.GetThreadInfo();

    // Prints "glob2.Language = FRENCH"
    Console.WriteLine("glob2.Language = " + glob2.Language);

    glob1.Dispose();
    glob2.Dispose();
}
}

```

## OracleGlobalization Properties

The OracleGlobalization properties are listed in [Table 10-5](#).

**Table 10-5 OracleGlobalization Properties**

| Name                               | Description                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------|
| <a href="#">Calendar</a>           | Specifies the calendar system                                                                        |
| <a href="#">ClientCharacterSet</a> | Specifies a client character set<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">Comparison</a>         | Specifies a method of comparison for WHERE clauses and comparison in PL/SQL blocks                   |
| <a href="#">Currency</a>           | Specifies the string to use as a local currency symbol for the L number format element               |
| <a href="#">DateFormat</a>         | Specifies the date format for Oracle Date type as a string                                           |
| <a href="#">DateLanguage</a>       | Specifies the language used to spell day and month names and date abbreviations                      |
| <a href="#">DualCurrency</a>       | Specifies the dual currency symbol, such as <i>Euro</i> , for the U number format element            |
| <a href="#">ISOCurrency</a>        | Specifies the string to use as an international currency symbol for the C number format element      |
| <a href="#">Language</a>           | Specifies the default language of the database                                                       |

**Table 10-5 (Cont.) OracleGlobalization Properties**

| Name                                     | Description                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <a href="#">LengthSemantics</a>          | Enables creation of CHAR and VARCHAR2 columns using either byte or character (default) length semantics                 |
| <a href="#">NCharConversionException</a> | Determines whether or not data loss during an implicit or explicit character type conversion reports an error           |
| <a href="#">NumericCharacters</a>        | Specifies the characters used for the decimal character and the group separator character for numeric values in strings |
| <a href="#">Sort</a>                     | Specifies the collating sequence for ORDER by clause                                                                    |
| <a href="#">Territory</a>                | Specifies the name of the territory                                                                                     |
| <a href="#">TimeStampFormat</a>          | Specifies the string format for TimeStamp types                                                                         |
| <a href="#">TimeStampTZFormat</a>        | Specifies the string format for TimeStampTZ types                                                                       |
| <a href="#">TimeZone</a>                 | Specifies the time zone region name                                                                                     |

## Calendar

This property specifies the calendar system.

**Declaration**

```
// C#  
public string Calendar {get; set;}
```

**Property Value**

A string representing the Calendar.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_CALENDAR setting of the local computer. This value is the same regardless of whether or not the OracleGlobalization object represents the settings of the client, thread, or session.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## ClientCharacterSet

This property specifies a client character set.

### Declaration

```
// C#  
public string ClientCharacterSet {get;}
```

### Property Value

A string that the provides the name of the character set of the local computer.

### Remarks

The default value is the character set of the local computer.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## Comparison

This property represents a method of comparison for WHERE clauses and comparison in PL/SQL blocks.

### Declaration

```
// C#  
public string Comparison {get; set;}
```

### Property Value

A string that provides the name of the method of comparison.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

The default value is the NLS\_COMP setting of the local computer.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## Currency

This property specifies the string to use as a local currency symbol for the L number format element.

### Declaration

```
// C#  
public string Currency {get; set;}
```

### Property Value

The string to use as a local currency symbol for the L number format element.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

The default value is the NLS\_CURRENCY setting of the local computer.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)
- *Oracle AI Database SQL Language Reference* for further information on the L number format element

## DateFormat

This property specifies the date format for Oracle Date type as a string.

### Declaration

```
// C#  
public string DateFormat {get; set;}
```

### Property Value

The date format for Oracle Date type as a string

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_DATE\_FORMAT setting of the local computer.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## DateLanguage

This property specifies the language used to spell names of days and months, and date abbreviations (for example: a.m., p.m., AD, BC).

**Declaration**

```
// C#  
public string DateLanguage {get; set;}
```

**Property Value**

A string specifying the language.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_DATE\_LANGUAGE setting of the local computer.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## DualCurrency

This property specifies the dual currency symbol, such as *Euro*, for the U number format element.

**Declaration**

```
// C#  
public string DualCurrency {get; set;}
```

**Property Value**

A string that provides the dual currency symbol.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_DUAL\_CURRENCY setting of the local computer.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)
- *Oracle AI Database SQL Language Reference* for further information on the U number format element

## ISOCurrency

This property specifies the string to use as an international currency symbol for the C number format element.

**Declaration**

```
// C#  
public string ISOCurrency {get; set;}
```

**Property Value**

The string used as an international currency symbol.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_ISO\_CURRENCY setting of the local computer.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)
- *Oracle AI Database SQL Language Reference* for further information on the C number format element

## Language

This property specifies the default language of the database.

### Declaration

```
// C#  
public string Language {get; set;}
```

### Property Value

The default language of the database.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

### Remarks

The default value is the NLS\_LANGUAGE setting of the local computer.

Language is used for messages, day and month names, and sorting algorithms. It also determines NLS\_DATE\_LANGUAGE and NLS\_SORT parameter values.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## LengthSemantics

This property indicates whether or not CHAR and VARCHAR2 columns use byte or character (default) length semantics.

### Declaration

```
// C#  
public string LengthSemantics {get; set;}
```

**Property Value**

A string that indicates either byte or character length semantics.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_LENGTH\_SEMANTICS setting of the local computer.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## NCharConversionException

This property determines whether or not data loss during an implicit or explicit character type conversion reports an error.

**Declaration**

```
// C#  
public bool NCharConversionException {get; set;}
```

**Property Value**

A string that indicates whether or not a character type conversion causes an error message.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value of NLS\_NCHAR\_CONV\_EXCP is False, unless it is overridden by a setting in the INIT.ORA file.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## NumericCharacters

This property specifies the characters used for the decimal character and the group separator character for numeric values in strings.

### Declaration

```
// C#  
public string NumericCharacters {get; set;}
```

### Property Value

A string that represents the characters used.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

The default value is the NLS\_NUMERIC\_CHARACTERS setting of the local computer.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## Sort

This property specifies the collating sequence for ORDER by clause.

### Declaration

```
// C#  
public string Sort {get; set;}
```

### Property Value

A string that indicates the collating sequence.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

The default value is the NLS\_SORT setting of the local computer.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## Territory

This property specifies the name of the territory.

**Declaration**

```
// C#  
public string Territory {get; set;}
```

**Property Value**

A string that provides the name of the territory.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_TERRITORY setting of the local computer.

Changing this property changes other globalization properties.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)
- *Oracle AI Database Globalization Support Guide.*

## TimeStampFormat

This property specifies the string format for TimeStamp types.

**Declaration**

```
// C#  
public string TimeStampFormat {get; set;}
```

**Property Value**

The string format for TimeStamp types.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_TIMESTAMP\_FORMAT setting of the local computer.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## TimeStampTZFormat

This property specifies the string format for TimeStampTZ types.

**Declaration**

```
// C#  
public string TimeStampTZFormat {get; set;}
```

**Property Value**

The string format for TimeStampTZ types.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The default value is the NLS\_TIMESTAMP\_TZ\_FORMAT setting of the local computer.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## TimeZone

This property specifies the time zone region name or hour offset.

**Declaration**

```
// C#  
public string TimeZone {get; set;}
```

**Property Value**

The string represents the time zone region name or the time zone offset.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

**Remarks**

The default value is the time zone region name of the local computer

`TimeZone` is only used when the thread constructs one of the `TimeStamp` structures. `TimeZone` has no effect on the session.

`TimeZone` can be either an hour offset, for example, 7:00, or a valid time zone region name that is provided in `V$TIMEZONE_NAMES`, such as `US/Pacific`. Time zone abbreviations are not supported.

**Note**

PST is a time zone region name as well as a time zone abbreviation; therefore it is accepted by `OracleGlobalization`.

This property returns an empty string if the `OracleGlobalization` object is obtained using `GetSessionInfo()` or `GetSessionInfo(OracleGlobalization)`. Initially, by default, the time zone of the session is identical to the time zone of the thread. Therefore, given that the session time zone is not changed by invoking `ALTER SESSION` calls, the session time zone can be fetched from the client's globalization settings.

## OracleGlobalization Public Methods

`OracleGlobalization` public methods are listed in [Table 10-6](#).

**Table 10-6 OracleGlobalization Public Methods**

| Public Method           | Description                                                  |
|-------------------------|--------------------------------------------------------------|
| <a href="#">Clone</a>   | Creates a copy of an <code>OracleGlobalization</code> object |
| <a href="#">Dispose</a> | Releases any resources or memory allocated by the object     |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## Clone

This method creates a copy of an OracleGlobalization object.

**Declaration**

```
// C#  
public object Clone();
```

**Return Value**

An OracleGlobalization object.

**Implements**

ICloneable

**Remarks**

The cloned object has the same property values as that of the object being cloned.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleGlobalization Class](#)
- [OracleGlobalization Members](#)

## Dispose

This method releases any resources or memory allocated by the object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

**Remarks**

The Dispose method also closes the OracleGlobalization object.

OracleDatabaseNCharset Enumeration

The OracleDatabaseNCharset enumeration specifies the Oracle NCHAR character set. Possible values for this enumeration are:

Table 10-8 OracleDatabaseNCharset Enumeration

| Member Name | Description                                                    |
|-------------|----------------------------------------------------------------|
| AL16UTF16   | Unicode 15.0 Universal character set, UTF-16BE encoding scheme |
| UTF8        | Unicode 3.0 Universal character set, CESU-8 encoding scheme    |

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

# Oracle Data Provider for .NET Transparent Application Failover Classes

This chapter describes the ODP.NET Transparent Application Failover(TAF) classes and enumerations.

This chapter contains these topics:

- [OracleFailoverEventArgs Class](#)
- [OracleTAFMode Class](#)
- [OracleFailoverEventHandler Delegate](#)
- [FailoverEvent Enumeration](#)
- [FailoverReturnCode Enumeration](#)
- [FailoverType Enumeration](#)
- [OracleFailoverEvent Enumeration](#)
- [OracleFailoverRestore Enumeration](#)
- [OracleFailoverReturnCode Enumeration](#)
- [OracleFailoverType Enumeration](#)

## OracleFailoverEventArgs Class

The `OracleFailoverEventArgs` class provides event data for the `OracleConnection.Failover` event. When database failover occurs, the `OracleConnection.Failover` event is triggered along with the `OracleFailoverEventArgs` object that stores the event data.

### Class Inheritance

`System.Object`

`System.EventArgs`

`Oracle.DataAccess.Client.OracleFailoverEventArgs`

### Declaration

```
// C#
public sealed class OracleFailoverEventArgs
```

### Requirements

| Provider | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver      | ODP.NET Core                 |
|----------|---------------------------|------------------------------|------------------------------|
| Assembly | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll | Oracle.ManagedDataAccess.dll |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example (Oracle.DataAccess.Client only)

```
// Transparent Application Failover (TAF) Setup
// Refer Oracle® Database Net Services Administrator's Guide

// C#

using System;
using System.Threading;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class FailoverSample
{
    static void Main(string[] args)
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Register the event handler OnFailover
        con.Failover += new OracleFailoverEventHandler(OnFailover);

        Console.WriteLine("Wait for a failover for 5 seconds");
        Thread.Sleep(5000);

        con.Close();
        con.Dispose();
    }

    // TAF callback function
    static FailoverReturnCode OnFailover(object sender,
        OracleFailoverEventArgs eventArgs)
    {
        switch (eventArgs.FailoverEvent)
        {
            case FailoverEvent.Begin:
            {
                Console.WriteLine("FailoverEvent.Begin - Failover is starting");
                Console.WriteLine("FailoverType = " + eventArgs.FailoverType);
                break;
            }
            case FailoverEvent.End:
            {
                Console.WriteLine("FailoverEvent.End - Failover was successful");
            }
        }
    }
}
```

```
        break;
    }
    case FailoverEvent.Reauth:
    {
        Console.WriteLine("FailoverEvent.Reauth - User reauthenticated");
        break;
    }
    case FailoverEvent.Error:
    {
        Console.WriteLine("FailoverEvent.Error - Failover was unsuccessful");

        // Sleep for 3 sec and Retry
        Thread.Sleep(3000);
        return FailoverReturnCode.Retry;
    }
    case FailoverEvent.Abort:
    {
        Console.WriteLine("FailoverEvent.Abort - Failover was unsuccessful");
        break;
    }
    default:
    {
        Console.WriteLine("Invalid FailoverEvent : " + eventArgs.FailoverEvent);
        break;
    }
}
return FailoverReturnCode.Success;
}
```

## OracleFailoverEventArgs Members

OracleFailoverEventArgs members are listed in the following tables.

### OracleFailoverEventArgs Static Methods

The OracleFailoverEventArgs static methods are listed in [Table 11-1](#).

**Table 11-1 OracleFailoverEventArgs Static Methods**

| Methods | Description                               |
|---------|-------------------------------------------|
| Equals  | Inherited from System.Object (Overloaded) |

## OracleFailoverEventArgs Properties

The OracleFailoverEventArgs properties are listed in [Table 11-2](#).

**Table 11-2 OracleFailoverEventArgs Properties**

| Name                                | Description                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">FailoverEvent</a>       | Indicates the state of the failover                                                                          |
| <a href="#">FailoverType</a>        | Specifies the type of failover the client has requested                                                      |
| <a href="#">OracleFailoverEvent</a> | Indicates the state of the failover<br><i>Not available in ODP.NET, Unmanaged Driver</i>                     |
| <a href="#">OracleFailoverType</a>  | Specifies the type of failover the client has requested<br><i>Not available in ODP.NET, Unmanaged Driver</i> |

## OracleFailoverEventArgs Public Methods

The OracleFailoverEventArgs public methods are listed in [Table 11-3](#).

**Table 11-3 OracleFailoverEventArgs Public Methods**

| Name        | Description                               |
|-------------|-------------------------------------------|
| Equals      | Inherited from System.Object (Overloaded) |
| GetHashCode | Inherited from System.Object              |
| GetType     | Inherited from System.Object              |
| ToString    | Inherited from System.Object              |

# OracleTAFMode Class

An OracleTAFMode object sets the Oracle Transparent Application Failover parameters for the connection.

**Class Inheritance**

System.Object  
  
Oracle.ManagedDataAccess.OracleTAFMode

**Declaration**

```
// C#  
public sealed class OracleTAFMode
```

**Requirements**

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe.

- [OracleTAFMode Constructors](#)

# OracleTAFMode Constructors

OracleTAFMode constructors instantiates new instances of the OracleTAFMode class.

**Overload List:**

- `OracleTAFMode()`  
This constructor instantiates a new instance of the `OracleTAFMode` class using default property values.
- `OracleTAFMode(OracleFailoverType, OracleFailoverRestore)`  
This constructor instantiates a new instance of the `OracleTAFMode` class using the provided failover type and restore level.
- `OracleTAFMode(OracleFailoverType, OracleFailoverRestore, int, int)`  
This constructor instantiates a new instance of the `OracleTAFMode` class using the provided failover type, restore level, retries, and delay.

**Arguments:**

- `failoverType`: Specifies the type of failover. Possible values are:
  - `NONE`: This is the default. No failover functionality is used. This can also be explicitly specified to prevent failover from happening.
  - `SESSION`: Fails over the session. For example, if a user's connection is lost, then a new session is automatically created for the user. This type of failover does not attempt to recover selects.
- `failoverRestore`: Specifies the session restore level. Possible values are:
  - `NONE`: This is the default. No session state will be restored.
  - `LEVEL1`: Restores basic session state along with NLS parameters.
- `failoverRetries`: Specifies the number of times to attempt to connect after a failover. Default value is 0.
- `failoverDelay`: Specifies the amount of time in seconds to wait between connect attempts. Default value is 0.

**Exception**

`ArgumentException` is thrown if negative value is provided for `failoverRetries` or `failoverDelay` arguments in the constructor.

## OracleFailoverEventHandler Delegate

The `OracleFailoverEventHandler` represents the signature of the method that handles the `OracleConnection.Failover` event.

**Declaration**

```
// C#
public delegate FailoverReturnCode OracleFailoverEventHandler(object sender,
    OracleFailoverEventArgs eventArgs);
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Parameter

- *sender*  
The source of the event.
- *eventArgs*  
The OracleFailoverEventArgs object that contains the event data.

## Return Type

An int.

## Remarks

To receive failover notifications, a callback function can be registered as follows:

```
ConObj.Failover += new OracleFailoverEventHandler(OnFailover);
```

The definition of the callback function OnFailover can be as follows:

```
public FailoverReturnCode OnFailover(object sender, OracleFailoverEventArgs eventArgs)
```

# FailoverEvent Enumeration

FailoverEvent enumerated values are used to specify the state of the failover.

[Table 11-7](#) lists all the FailoverEvent enumeration values with a description of each enumerated value.

**Table 11-7 FailoverEvent Enumeration Values**

| Member Names                      | Description                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>FailoverEvent.Begin</code>  | Indicates that failover has detected a lost connection and that failover is starting.                                                                                                                                                                                                                                                                                                      |
| <code>FailoverEvent.End</code>    | Indicates successful completion of failover.                                                                                                                                                                                                                                                                                                                                               |
| <code>FailoverEvent.Abort</code>  | Indicates that failover was unsuccessful, and there is no option of retrying.                                                                                                                                                                                                                                                                                                              |
| <code>FailoverEvent.Error</code>  | Indicates that failover was unsuccessful, and it gives the application the opportunity to handle the error and retry failover. The application can retry failover by returning <code>FailoverReturnCode.Retry</code> for the event notification.                                                                                                                                           |
| <code>FailoverEvent.Reauth</code> | Indicates that a user handle has been reauthenticated. This applies to the situation where a client has multiple user sessions on a single server connection. During the initial failover, only the active user session is failed over. Other sessions are failed over when the application tries to use them. This is the value passed to the callback during these subsequent failovers. |

No significant database operation should occur immediately after a `FailoverEvent.Begin` event. SQL and major database operations should wait until the `FailoverEvent.End` event. `FailoverEvent.Begin` is primarily used to reject failover or to trace it. `FailoverEvent.Begin` can also be used for non-database application operations, such as informing the end user a failover is in progress and to wait until it completes before proceeding. Transactions can be used in the `FailoverEvent.End` callback phase, such as to file fault tickets or audit. These transactions must be committed before the callback completes.

### Requirements

|                       |                                         |
|-----------------------|-----------------------------------------|
| <b>Provider</b>       | <b>ODP.NET, Unmanaged Driver</b>        |
| <b>Assembly</b>       | <code>Oracle.DataAccess.dll</code>      |

## FailoverReturnCode Enumeration

FailoverReturnCode enumerated values are passed back by the application to the ODP.NET provider to request a retry in case of a failover error, or to continue in case of a successful failover.

[Table 11-8](#) lists the FailoverReturnCode enumeration values with a description of each enumerated value.

**Table 11-8 FailoverReturnCode Enumeration Values**

| Member Names               | Description                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------|
| FailoverReturnCode.Retry   | Requests ODP.NET to retry failover in case FailoverEvent.Error is passed to the application |
| FailoverReturnCode.Success | Requests ODP.NET to proceed so that the application receive more notifications, if any      |

### Requirements

|                |                                         |
|----------------|-----------------------------------------|
| Provider       | ODP.NET, Unmanaged Driver               |
| Assembly       | Oracle.DataAccess.dll                   |
| Namespace      | Oracle.DataAccess.Client                |

## OracleFailoverEvent Enumeration

OracleFailoverEvent enumerated values are used to specify the state of the failover.

OracleFailoverEvent Enumeration Values lists all the OracleFailoverEvent enumeration values with a description of each enumerated value.

**Table 11-10 OracleFailoverEvent Enumeration Values**

| Member Names              | Description                                                                                                                                                                                                                                            |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OracleFailoverEvent.Begin | Indicates that failover has detected a lost connection and that failover is starting.                                                                                                                                                                  |
| OracleFailoverEvent.End   | Indicates successful completion of failover.                                                                                                                                                                                                           |
| OracleFailoverEvent.Abort | Indicates that failover was unsuccessful, and there is no option of retrying.                                                                                                                                                                          |
| OracleFailoverEvent.Error | Indicates that failover was unsuccessful, and it gives the application the opportunity to handle the error and retry failover. The application can retry failover by returning <code>OracleFailoverReturnCode.Retry</code> for the event notification. |

Table 11-10 (Cont.) OracleFailoverEvent Enumeration Values

| Member Names               | Description                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OracleFailoverEvent.Reauth | Indicates that a user handle has been reauthenticated. This applies to the situation where a client has multiple user sessions on a single server connection. During the initial failover, only the active user session is failed over. Other sessions are failed over when the application tries to use them. This is the value passed to the callback during these subsequent failovers. |

No significant database operation should occur immediately after a OracleFailoverEvent.Begin event. SQL and major database operations should wait until the OracleFailoverEvent.End event. OracleFailoverEvent.Begin is primarily used to reject failover or to trace it. OracleFailoverEvent.Begin can also be used for non-database application operations, such as informing the end user a failover is in progress and to wait until it completes before proceeding. Transactions can be used in the OracleFailoverEvent.End callback phase, such as to file fault tickets or audit. These transactions must be committed before the callback completes.

# OracleFailoverRestore Enumeration

OracleFailoverRestore enumerated values are used to indicates whether ODP.NET must restore session state after failover for Transparent Application Failover.

OracleFailoverRestore Enumeration Values lists all the OracleFailoverRestore enumeration values with a description of each enumerated value.

**Table 11-11 OracleFailoverRestore Enumeration Values**

| Member Names            | Description                                         |
|-------------------------|-----------------------------------------------------|
| OracleFailoverRestore.N | No session state will be restored after failover    |
| OracleFailoverRestore.L | Basic session state will be restored after failover |
| level1                  |                                                     |

Basic session state (Level 1) restored includes:

- Action
- Call collect time
- Client identifier
- Client info
- Container
- Current schema
- Database operation
- Edition
- Error on overlap time
- Execution context identifier
- Execution context sequence
- Module
- Row archival visibility
- Service
- SQL translation profile
- Time zone
- NLS parameters
  - NLS\_LANGUAGE
  - NLS\_TERRITORY
  - NLS\_CURRENCY
  - NLS\_ISO\_CURRENCY
  - NLS\_NUMERIC\_CHARACTERS
  - NLS\_CALENDAR
  - NLS\_DATE\_FORMAT
  - NLS\_DATE\_LANGUAGE
  - NLS\_SORT
  - NLS\_COMP
  - NLS\_DUAL\_CURRENCY
  - NLS\_TIME\_FORMAT

- NLS\_TIMESTAMP\_FORMAT
- NLS\_TIME\_TZ\_FORMAT
- NLS\_TIMESTAMP\_TZ\_FORMAT

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

# OracleFailoverReturnCode Enumeration

OracleFailoverReturnCode enumerated values are passed back by the application to the ODP.NET provider to request a retry in case of a failover error, or to continue in case of a successful failover.

OracleFailoverReturnCode Enumeration Values lists the OracleFailoverReturnCode enumeration values with a description of each enumerated value.

Table 11-12 OracleFailoverReturnCode Enumeration Values

| Member Names                     | Description                                                                                       |
|----------------------------------|---------------------------------------------------------------------------------------------------|
| OracleFailoverReturnCode.Retry   | Requests ODP.NET to retry failover in case OracleFailoverEvent.Error is passed to the application |
| OracleFailoverReturnCode.Success | Requests ODP.NET to proceed so that the application receives more notifications, if any           |

Requirements

| Provider  | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------------|---------------------------------|
| Assembly  | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

# OracleFailoverType Enumeration

OracleFailoverType enumerated values are used to indicate the type of failover event that was raised.

OracleFailoverType Enumeration Values lists all the OracleFailoverType enumeration values with a description of each enumerated value.

**Table 11-13 OracleFailoverType Enumeration Values**

| Member Names               | Description                                                |
|----------------------------|------------------------------------------------------------|
| OracleFailoverType.None    | Indicates the user has requested no failover functionality |
| OracleFailoverType.Session | Indicates the user has requested only session failover     |

**Requirements**

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

## Oracle Database Advanced Queuing and Transactional Event Queues Classes

This chapter describes the following Oracle Data Provider for .NET classes:

- [OracleAQAgent Class](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQEnqueueOptions Class](#)
- [OracleAQMessage Class](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventHandler Delegate](#)
- [OracleAQQueue Class](#)
- [OracleAQDequeueMode Enumeration](#)
- [OracleAQMessageDeliveryMode Enumeration](#)
- [OracleAQMessageState Enumeration](#)
- [OracleAQMessageType Enumeration](#)
- [OracleAQNavigationMode Enumeration](#)
- [OracleAQNotificationGroupingType Enumeration](#)
- [OracleAQNotificationType Enumeration](#)
- [OracleAQVisibilityMode Enumeration](#)
- [OracleTxEventQNotificationDirective Enumeration](#)

### OracleAQAgent Class

The `OracleAQAgent` class represents agents that may be senders or recipients of a message.

#### Class Inheritance

`System.Object`

`OracleAQAgent`

#### Declaration

```
// C#  
public sealed class OracleAQAgent
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Remarks

An agent may be a consumer, another queue, or a consumer of another queue. The queue may be either local or remote. A remote queue is specified through a database link.

### ① See Also

- [OracleAQAgent Properties](#)

# OracleAQAgent Members

OracleAQAgent members are listed in the following tables.

## OracleAQAgent Constructors

OracleAQAgent constructors are listed in [Table 12-1](#).

**Table 12-1 OracleAQAgent Constructors**

| Constructor                                | Description                                                          |
|--------------------------------------------|----------------------------------------------------------------------|
| <a href="#">OracleAQAgent Constructors</a> | Instantiates a new instance of the OracleAQAgent class (Overloaded). |

## OracleAQAgent Properties

OracleAQAgent properties are listed in [Table 12-2](#).

**Table 12-2 OracleAQAgent Properties**

| Property                | Description                         |
|-------------------------|-------------------------------------|
| <a href="#">Address</a> | Specifies the address of the agent. |
| <a href="#">Name</a>    | Specifies the name of the agent.    |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleAQAgent Class](#)

## OracleAQAgent Constructors

OracleAQAgent constructors instantiate new instances of the OracleAQAgent class.

**Overload List:**

- [OracleAQAgent \(string\)](#)  
This constructor instantiates the OracleAQAgent class using the specified name.
- [OracleAQAgent \(string, string\)](#)  
This constructor instantiates the OracleAQAgent class using the specified name and address.

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleAQAgent Class](#)
- [OracleAQAgent Members](#)

## OracleAQAgent (string)

This constructor instantiates the OracleAQAgent class using the specified name.

**Declaration**

```
// C#  
public OracleAQAgent(string name);
```

**Parameters**

- *name*  
The name of the agent.

### Exceptions

ArgumentNullException - The *name* parameter is null.

ArgumentException - The *name* parameter is empty.

### Remarks

The agent name signifies the name of a producer or consumer of a message. In the context of functionality exposed by `Listen`, an agent name corresponds to the name of a consumer for which a message is expected on a multiconsumer queue. It may also be set on a message to signify sender identification or intended recipients of the message.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQAgent Class](#)
- [OracleAQAgent Members](#)

## OracleAQAgent (string, string)

This constructor instantiates the `OracleAQAgent` class using the specified name and address.

### Declaration

```
// C#  
public OracleAQAgent(string name, string address);
```

### Parameters

- *name*  
The name of the agent.
- *address*  
The address is of the form `[schema].queue[@dblink]`.

### Exceptions

ArgumentNullException - The *address* parameter is null.

ArgumentException - The *address* parameter is empty.

### Remarks

The agent name signifies the name of a producer or consumer of a message. In the context of functionality exposed by `Listen`, an agent name corresponds to the name of a consumer for which a message is expected on a multiconsumer queue. For multiconsumer queue, the agent name must be a non null value.

The *name* parameter can be specified as `null` in this constructor. In such a scenario, the agent only has an *address*.

The *address* parameter signifies the name of the queue against which this agent listens for new messages. The *address* represents a queue at a local or remote database. The validity of

the *address* is not checked implicitly. The exceptions due to wrong *address* are thrown only during database operations such as Listen.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQAgent Class](#)
- [OracleAQAgent Members](#)

## OracleAQAgent Properties

OracleAQAgent properties are listed in [Table 12-3](#).

**Table 12-3 OracleAQAgent Properties**

| Property                | Description                         |
|-------------------------|-------------------------------------|
| <a href="#">Address</a> | Specifies the address of the agent. |
| <a href="#">Name</a>    | Specifies the name of the agent.    |

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQAgent Class](#)
- [OracleAQAgent Members](#)

## Address

This instance property specifies the address of the agent.

### Declaration

```
// C#  
public string Address {get; }
```

### Property Value

A string that specifies the agent address.

### Remarks

The address represents a queue at a local or remote database. The default value is null. The address of the agent is of the form *[schema.]queue[dbLink]*. The string length can be up to 1024 characters.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQAgent Class](#)
- [OracleAQAgent Members](#)

## Name

This instance property specifies the name of the agent.

**Declaration**

```
// C#  
public string Name {get; }
```

**Property Value**

A string.

**Remarks**

The default is null. The string length can be up to 128 characters. A non-null value implies that this agent name either corresponds to a consumer name in a multiconsumer queue, or a recipient as specified in message properties.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQAgent Class](#)

## OracleAQDequeueOptions Class

An OracleAQDequeueOptions object represents the options available when dequeuing a message from an OracleAQQueue object.

**Class Inheritance**

System.Object

OracleAQDequeueOptions

**Declaration**

```
// C#  
public sealed class OracleAQDequeueOptions : ICloneable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### ① See Also

## OracleAQDequeueOptions Members

OracleAQDequeueOptions members are listed in the following tables.

### OracleAQDequeueOptions Constructor

The OracleAQDequeueOptions constructor is listed in [Table 12-4](#).

**Table 12-4 OracleAQDequeueOptions Constructor**

| Constructor                                        | Description                                                     |
|----------------------------------------------------|-----------------------------------------------------------------|
| <a href="#">OracleAQDequeueOptions Constructor</a> | Instantiates a new instance of the OracleAQDequeueOptions class |

### OracleAQDequeueOptions Properties

OracleAQDequeueOptions properties are listed in [Table 12-5](#).

**Table 12-5 OracleAQDequeueOptions Properties**

| Property                             | Description                                                                                                |
|--------------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">ConsumerName</a>         | Specifies the consumer name for which to dequeue the message                                               |
| <a href="#">Correlation</a>          | Specifies the correlation identifier of the message to be dequeued                                         |
| <a href="#">DeliveryMode</a>         | Specifies the expected delivery mode of the message being dequeued                                         |
| <a href="#">DequeueMode</a>          | Specifies the locking behavior associated with the dequeue operation                                       |
| <a href="#">MessageId</a>            | Specifies the message identifier of the message to be dequeued                                             |
| <a href="#">NavigationMode</a>       | Specifies the position of the message that will be retrieved                                               |
| <a href="#">ProviderSpecificType</a> | Specifies whether the payload of a dequeued message is provided as an ODP.NET specific type or a .NET type |
| <a href="#">Visibility</a>           | Specifies whether or not the new message is dequeued as part of the current transaction                    |
| <a href="#">Wait</a>                 | Specifies the wait time, in seconds, for a message that matches the search criteria                        |

**OracleAQDequeueOptions Public Methods**

OracleAQDequeueOptions public methods are listed in [Table 12-6](#).

**Table 12-6 OracleAQDequeueOptions Public Methods**

| Public Method         | Description                                         |
|-----------------------|-----------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleAQDequeueOptions object. |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleAQDequeueOptions Class](#)

## OracleAQDequeueOptions Constructor

The OracleAQDequeueOptions constructor creates an instance of the OracleAQDequeueOptions class and sets all its properties to their default values.

**Declaration**

```
// C#  
public OracleAQDequeueOptions();
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## OracleAQDequeueOptions Properties

OracleAQDequeueOptions properties are listed in [Table 12-7](#).

**Table 12-7 OracleAQDequeueOptions Properties**

| Property                             | Description                                                                                                |
|--------------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">ConsumerName</a>         | Specifies the consumer name for which to dequeue the message                                               |
| <a href="#">Correlation</a>          | Specifies the correlation identifier of the message to be dequeued                                         |
| <a href="#">DeliveryMode</a>         | Specifies the expected delivery mode of the message being dequeued                                         |
| <a href="#">DequeueMode</a>          | Specifies the locking behavior associated with the dequeue operation                                       |
| <a href="#">MessageId</a>            | Specifies the message identifier of the message to be dequeued                                             |
| <a href="#">NavigationMode</a>       | Specifies the position of the message that will be retrieved                                               |
| <a href="#">ProviderSpecificType</a> | Specifies whether the payload of a dequeued message is provided as an ODP.NET specific type or a .NET type |
| <a href="#">Visibility</a>           | Specifies whether or not the new message is dequeued as part of the current transaction                    |
| <a href="#">Wait</a>                 | Specifies the wait time, in seconds, for a message that matches the search criteria                        |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## ConsumerName

This instance property specifies the consumer name for which to dequeue the message.

**Declaration**

```
// C#  
public string ConsumerName {get;set;}
```

**Property Value**

A string.

**Remarks**

The ConsumerName property only accesses those messages that match the consumer name. If a queue is not set up for multiple consumers, then this field should be set to null.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## Correlation

This instance property specifies the correlation identifier of the message to be dequeued.

**Declaration**

```
// C#  
public string Correlation {get;set;}
```

**Property Value**

A string.

**Remarks**

This property specifies the identification of the message to be dequeued. Special pattern matching characters, such as the percent sign (%) and the underscore (\_) can be used. If more than one message satisfies the pattern, then the order of dequeuing is undetermined.

The maximum length of Correlation is 128.

MessageId and Correlation are two independent identifiers. While MessageId is unique for a message, a group of messages can be assigned the same Correlation. Also, pattern matching is possible only with Correlation.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## DeliveryMode

This instance property specifies the expected delivery mode of the message being dequeued.

**Declaration**

```
// C#  
public OracleAQMessageDeliveryMode DeliveryMode {get;set;}
```

**Property Value**

An `OracleAQMessageDeliveryMode` enumerated value.

**Remarks**

This property specifies the type of messages to be dequeued. It can be set to dequeue either persistent or buffered messages, or both from a queue. The following values are valid:

- `OracleAQMessageDeliveryMode.Persistent`
- `OracleAQMessageDeliveryMode.Buffered`
- `OracleAQMessageDeliveryMode.PersistentOrBuffered`

The default value is `OracleAQMessageDeliveryMode.Persistent`.

`OracleAQMessageDeliveryMode.Buffered` is not supported for AQ and TxEventQ operations, the workaround is to use `OracleAQMessageDeliveryMode.Persistent`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## DequeueMode

This instance property specifies the locking behavior associated with the dequeue operation.

**Declaration**

```
// C#  
public OracleAQDequeueMode DequeueMode {get;set;}
```

**Property Value**

An `OracleAQDequeueMode` enumerated value.

**Exceptions**

`ArgumentOutOfRangeException` - The specified `DequeueMode` value is invalid.

**Remarks**

The default value is `OracleAQDequeueMode.Remove`.

`OracleAQDequeueMode.RemoveNoData` is not supported for TxEventQ . In case of AQ, it is not supported with JSON data type.

OracleAQDequeueMode.Locked is not supported with Visibility = Immediate for AQ and TxEventQ, the workaround is to use OracleAQDequeueMode.Locked with Visibility = OnCommit.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## MessageId

This instance property specifies the message identifier of the message to be dequeued.

### Declaration

```
// C#  
public byte[] MessageId {get;set;}
```

### Property Value

A byte[ ].

### Remarks

The dequeue operation succeeds only if the message ID of the message being dequeued matches with the message ID specified.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## NavigationMode

This instance property specifies the position of the message that will be retrieved.

### Declaration

```
// C#  
public OracleAQNavigationMode NavigationMode {get;set;}
```

### Property Value

An OracleAQNavigationMode enumerated value.

### Exceptions

ArgumentOutOfRangeException - The specified NavigationMode value is invalid.

**Remarks**

The default value is `OracleAQNavigationMode.NextMessage`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## ProviderSpecificType

This property specifies whether the payload of a dequeued message is provided as an ODP.NET specific type or a .NET type.

**Declaration**

```
// C#  
public bool ProviderSpecificType {get;set;}
```

**Property Value**

A `bool`.

**Remarks**

The default value of this property is `false`. For a discussion of how this property affects payload type, refer to ["MessageType"](#) under the `OracleAQQueue` class.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)
- ["MessageType"](#)

## Visibility

This instance property specifies whether or not the new message is dequeued as part of the current transaction.

**Declaration**

```
// C#  
public OracleAQVisibilityMode Visibility {get;set;}
```

**Property Value**

An `OracleAQVisibilityMode` enumerated value.

## Exceptions

`ArgumentOutOfRangeException` - The `Visibility` value specified is invalid.

## Remarks

The default value is `OracleAQVisibilityMode.OnCommit`. You must use transactions when using the default value for this property. This ensures that applications do not lose messages and the messages are appropriately removed from the queue after the dequeue operation is successful. If transactions are not used when using the default visibility mode of `OracleAQVisibilityMode.OnCommit`, then messages are not removed from the queue.

Using the alternative visibility mode value, `OracleAQVisibilityMode.Immediate` can eliminate the need to create, commit, and rollback a transaction. However, if an error occurs during the dequeue operation, then the message may be lost.

The visibility parameter is ignored when `DequeueMode` is set to `OracleAQDequeueMode.Browse`.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## Wait

This instance property specifies the wait time, in seconds, for a message that matches the search criteria.

## Declaration

```
// C#  
public int Wait {get;set;}
```

## Property Value

Any positive integer value or 0 or -1.

## Exceptions

`ArgumentOutOfRangeException` - The specified `Wait` value is invalid.

## Remarks

The default value is -1, which implies an infinite wait. The following values are valid:

- Positive integer: Wait time in seconds.
- -1: Wait forever.
- 0: Do not wait.

A value of less than -1 raises an `ArgumentOutOfRangeException`.

This parameter is ignored if messages in the same group are being dequeued.

# OracleAQDequeueOptions Public Methods

The OracleAQDequeueOptions public method is listed in [Table 12-8](#).

**Table 12-8 OracleAQDequeueOptions Public Methods**

| Public Method         | Description                                        |
|-----------------------|----------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleAQDequeueOptions object |

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

## Clone

This method creates a copy of an OracleAQDequeueOptions object.

**Declaration**

```
// C#  
public object Clone();
```

**Return Value**

An OracleAQDequeueOptions object.

**Implements**

ICloneable.

**Remarks**

The cloned object has the same property values as the object being cloned.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQDequeueOptions Class](#)
- [OracleAQDequeueOptions Members](#)

# OracleAQEnqueueOptions Class

The OracleAQEnqueueOptions class represents the options available when enqueueing a message to an OracleAQQueue.

**Class Inheritance**

**Declaration**

```
// C#
public sealed class OracleAQEnqueueOptions : ICloneable
```

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OracleAQEnqueueOptions Members

The OracleAQEnqueueOptions members are listed in the following tables.

### OracleAQEnqueueOptions Constructor

OracleAQEnqueueOptions constructor is listed in [Table 12-9](#).

**Table 12-9 OracleAQEnqueueOptions Constructor**

| Constructor                                        | Description                                                      |
|----------------------------------------------------|------------------------------------------------------------------|
| <a href="#">OracleAQEnqueueOptions Constructor</a> | Instantiates a new instance of the OracleAQEnqueueOptions class. |

### OracleAQEnqueueOptions Properties

OracleAQEnqueueOptions properties are listed in [Table 12-10](#).

**Table 12-10 OracleAQEnqueueOptions Properties**

| Property                     | Description                                                                              |
|------------------------------|------------------------------------------------------------------------------------------|
| <a href="#">DeliveryMode</a> | Specifies the delivery mode of the message being enqueued.                               |
| <a href="#">Visibility</a>   | Specifies whether or not the new message is enqueued as part of the current transaction. |

### OracleAQEnqueueOptions Public Methods

The OracleAQEnqueueOptions public method is listed in [Table 12-11](#).

**Table 12-11 OracleAQEnqueueOptions Public Methods**

| Public Method         | Description                                         |
|-----------------------|-----------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleAQEnqueueOptions object. |

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQEnqueueOptions Class](#)

## OracleAQEnqueueOptions Constructor

This constructor creates an instance of the OracleAQEnqueueOptions class with default property values.

### Declaration

```
// C#  
public OracleAQEnqueueOptions();
```

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQEnqueueOptions Class](#)
- [OracleAQEnqueueOptions Members](#)

## OracleAQEnqueueOptions Properties

OracleAQEnqueueOptions properties are listed in [Table 12-12](#).

**Table 12-12 OracleAQEnqueueOptions Properties**

| Property                     | Description                                                                              |
|------------------------------|------------------------------------------------------------------------------------------|
| <a href="#">DeliveryMode</a> | Specifies the delivery mode of the message being enqueued.                               |
| <a href="#">Visibility</a>   | Specifies whether or not the new message is enqueued as part of the current transaction. |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQEnqueueOptions Class](#)
- [OracleAQEnqueueOptions Members](#)

## DeliveryMode

This instance property specifies the delivery mode of the message being enqueued.

### Declaration

```
// C#  
public OracleAQMessageDeliveryMode DeliveryMode {get;set;}
```

### Exceptions

ArgumentOutOfRangeException - The specified Visibility value is invalid.

### Remarks

The valid values can be any of the following enumerated values:

- `OracleAQMessageDeliveryMode.Persistent`
- `OracleAQMessageDeliveryMode.Buffered`

The default is `OracleAQMessageDeliveryMode.Persistent`.

`OracleAQMessageDeliveryMode.PersistentOrBuffered` cannot be set on this property.

OracleAQMessageDeliveryMode.Buffered is not supported for AQ and TxEventQ operations, workaround is to use OracleAQMessageDeliveryMode.Persistent.

#### ① See Also

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"
- [OracleAQEnqueueOptions Class](#)
- [OracleAQEnqueueOptions Members](#)

## Visibility

This instance property specifies whether or not the new message is enqueued as part of the current transaction.

### Declaration

```
// C#  
public OracleAQVisibilityMode Visibility {get;set;}
```

### Property Value

An OracleAQVisibilityMode enumerated value.

### Exceptions

ArgumentOutOfRangeException - The specified Visibility value is invalid.

### Remarks

The default value is OracleAQVisibilityMode.OnCommit. You must use transactions when using the default value. If transactions are not used when using the default visibility mode of OracleAQVisibilityMode.OnCommit, then messages are not enqueued to the queue.

Using the alternative visibility mode value, OracleAQVisibilityMode.Immediate eliminates the need to use a transaction. The queue is not affected in case the enqueue operation fails. The message does not get enqueued to the queue for such cases.

## OracleAQEnqueueOptions Public Methods

OracleAQEnqueueOptions public method is listed in [Table 12-13](#).

Table 12-13 OracleAQEnqueueOptions Public Methods

| Public Method         | Description                                         |
|-----------------------|-----------------------------------------------------|
| <a href="#">Clone</a> | Creates a copy of an OracleAQEnqueueOptions object. |

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQEnqueueOptions Class](#)
- [OracleAQEnqueueOptions Members](#)

Clone

This method creates a copy of an OracleAQEnqueueOptions object.

Declaration

```
// C#
public object Clone();
```

Return Value

An OracleAQEnqueueOptions object.

Implements

ICloneable.

Remarks

The cloned object has the same property values as that of the object being cloned.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQEnqueueOptions Class](#)
- [OracleAQEnqueueOptions Members](#)

OracleAQMessage Class

An OracleAQMessage object represents a message to be enqueued and dequeued.

Class Inheritance

Declaration

```
// C#
public sealed class OracleAQMessage
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

An OracleAQMessage object consists of control information (metadata) and Payload (data). The control information is exposed by various properties on the OracleAQMessage object and is used by Oracle Database Advanced Queuing to manage messages. The payload is the information stored in the queue.

❗ Note

An instance of OracleAQMessage cannot be re-used across multiple operations of OracleAQQueue public method [Enqueue\(\)](#) or [EnqueueArray\(\)](#), if the payload is an XmlReader. This is a direct consequence of the forward-only semantics of the XmlReader, as an [Enqueue\(\)](#) or [EnqueueArray\(\)](#) operation internally invokes a read operation on the XmlReader to extract the data to be enqueued.

❗ See Also

## OracleAQMessage Members

OracleAQMessage members are listed in the following tables.

### OracleAQMessage Constructor

OracleAQMessage constructors are listed in [Table 12-14](#).

**Table 12-14 OracleAQMessage Constructors**

| Constructor                                  | Description                                                            |
|----------------------------------------------|------------------------------------------------------------------------|
| <a href="#">OracleAQMessage Constructors</a> | Instantiates a new instance of the OracleAQMessage class (Overloaded). |

### OracleAQMessage Properties

OracleAQMessage properties are listed in [Table 12-15](#).

**Table 12-15 OracleAQMessage Properties**

| Property                          | Description                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">Correlation</a>       | Specifies an identification for the message.                                                                |
| <a href="#">Delay</a>             | Specifies the duration, in seconds, after which an enqueued message is available for dequeuing.             |
| <a href="#">DeliveryMode</a>      | Specifies the delivery mode of the dequeued message.                                                        |
| <a href="#">DequeueAttempts</a>   | Returns the number of attempts that have been made to dequeue the message.                                  |
| <a href="#">EnqueueTime</a>       | Specifies the time when the message was enqueued.                                                           |
| <a href="#">ExceptionQueue</a>    | Specifies the name of the queue that the message should be moved to if it cannot be processed successfully. |
| <a href="#">Expiration</a>        | Specifies the duration, in seconds, for which an enqueued message is available for dequeuing.               |
| <a href="#">MessageId</a>         | Returns the message identifier.                                                                             |
| <a href="#">OriginalMessageId</a> | Specifies the identifier of the message in the last queue that generated this message.                      |
| <a href="#">Payload</a>           | Specifies the payload of the message.                                                                       |
| <a href="#">Priority</a>          | Specifies the priority of the message.                                                                      |
| <a href="#">Recipients</a>        | Specifies the list of recipients that overrides the default queue subscribers.                              |
| <a href="#">SenderId</a>          | Identifies the original sender of the message.                                                              |
| <a href="#">State</a>             | Specifies the state of the message at the time of dequeue.                                                  |
| <a href="#">TransactionGroup</a>  | Specifies the transaction group for the dequeued message.                                                   |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)

## OracleAQMessage Constructors

OracleAQMessage constructors create new instances of the OracleAQMessage class.

**Overload List:**

- [OracleAQMessage\(\)](#)

This constructor instantiates the OracleAQMessage class.

- [OracleAQMessage\(Object\)](#)

This constructor instantiates the OracleAQMessage class using the object provided as the payload.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

### OracleAQMessage()

This constructor instantiates the OracleAQMessage class.

**Declaration**

```
// C#  
public OracleAQMessage();
```

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

### OracleAQMessage(Object)

This constructor instantiates the OracleAQMessage class using the object provided as the *payload*.

### Declaration

```
// C#  
public OracleAQMessage(Object payload);
```

### Parameters

- *payload*

An Object specifying *payload*. It can be one of the following types:

- byte[]
- IOracleCustomType
- OracleBinary
- OracleString
- OracleXmlType
- String
- XmlReader

### Exceptions

ArgumentException - The specified *payload* value is of invalid type.

### Remarks

The ODP.NET AQ implementation currently does not support user defined types with LOB attributes. It also does not support other variants of user defined types such as VARRAY and nested tables, as Oracle Database AQ does not support them inherently.

## OracleAQMessage Properties

OracleAQMessage properties are listed in [Table 12-16](#).

**Table 12-16 OracleAQMessage Properties**

| Property                        | Description                                                                                     |
|---------------------------------|-------------------------------------------------------------------------------------------------|
| <a href="#">Correlation</a>     | Specifies an identification for the message.                                                    |
| <a href="#">Delay</a>           | Specifies the duration, in seconds, after which an enqueued message is available for dequeuing. |
| <a href="#">DeliveryMode</a>    | Specifies the delivery mode of the dequeued message.                                            |
| <a href="#">DequeueAttempts</a> | Returns the number of attempts that have been made to dequeue the message.                      |

Table 12-16 (Cont.) OracleAQMessage Properties

| Property                          | Description                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">EnqueueTime</a>       | Specifies the time when the message was enqueued.                                                           |
| <a href="#">ExceptionQueue</a>    | Specifies the name of the queue that the message should be moved to if it cannot be processed successfully. |
| <a href="#">Expiration</a>        | Specifies the duration, in seconds, for which an enqueued message is available for dequeuing.               |
| <a href="#">MessageId</a>         | Returns the message identifier.                                                                             |
| <a href="#">OriginalMessageId</a> | Specifies the identifier of the message in the last queue that generated this message.                      |
| <a href="#">Payload</a>           | Specifies the payload of the message.                                                                       |
| <a href="#">Priority</a>          | Specifies the priority of the message.                                                                      |
| <a href="#">Recipients</a>        | Specifies the list of recipients that overrides the default queue subscribers.                              |
| <a href="#">SenderId</a>          | Identifies the original sender of the message.                                                              |
| <a href="#">State</a>             | Specifies the state of the message at the time of dequeue.                                                  |
| <a href="#">TransactionGroup</a>  | Specifies the transaction group for the dequeued message.                                                   |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## Correlation

This instance property specifies an identification for the message.

**Declaration**

```
// C#  
public string Correlation {get;set;}
```

**Property Value**

A string that specifies the identification for the message.

**Remarks**

The producer of a message can set this property at the time of enqueueing. The consumer can then use this identification to dequeue specific messages by setting the Correlation property of an OracleAQDequeueOptions object. For more information regarding dequeuing messages based on Correlation, refer to ["Correlation"](#) under the OracleAQDequeueOptions class.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)
- ["Correlation"](#)

## Delay

This instance property specifies the duration, in seconds, after which an enqueued message is available for dequeuing.

**Declaration**

```
// C#  
public int Delay {get;set;}
```

**Property Value**

An integer that indicates the number of seconds after which an enqueued message is available for dequeuing.

**Exceptions**

ArgumentException - The value specified is less than 0.

**Remarks**

This property delays the immediate consumption of an enqueued message. The following are valid values for this property:

- Positive integer - Indicates the delay in seconds.
- 0 - indicates that the message is immediately available for dequeuing.

The default value is 0. The Delay property is not supported with buffered messaging.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## DeliveryMode

This instance property specifies the delivery mode of the dequeued message.

**Declaration**

```
// C#  
public OracleAQMessageDeliveryMode DeliveryMode {get;}
```

**Property Value**

An OracleAQMessageDeliveryMode enumerated value (OracleAQMessageDeliveryMode.Persistent or OracleAQMessageDeliveryMode.Buffered).

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## DequeueAttempts

This instance property returns the number of attempts that have been made to dequeue the message.

**Declaration**

```
// C#  
public int DequeueAttempts {get;}
```

**Property Value**

An integer that indicates the number of dequeue attempts.

**Remarks**

This property is available in an OracleAQMessage after the message has been dequeued from a queue.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## EnqueueTime

This instance property specifies the time when the message was enqueued.

**Declaration**

```
// C#  
public DateTime EnqueueTime {get;}
```

**Property Value**

A DateTime object.

### Remarks

This property is available after the message is dequeued. It provides the enqueue time of a dequeued message. The time granularity is in seconds as that is the granularity the database provides.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## ExceptionQueue

This instance property specifies the name of the queue that the message should be moved to if it cannot be processed successfully.

### Declaration

```
// C#  
public string ExceptionQueue {get;set;}
```

### Property Value

The name of the queue that a message should be moved to if it cannot be processed successfully. The default value is null.

### Remarks

This property specifies the queue that a message should be moved to if the message has expired or if the number of unsuccessful dequeue attempts have exceeded the `max_retries` value for the queue.

If this property is not set or the specified exception queue name does not exist, then the default exception queue associated with the queue table is used.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## Expiration

This instance property specifies the duration, in seconds, for which an enqueued message is available for dequeuing.

**Declaration**

```
// C#  
public int Expiration {get;set;}
```

**Property Value**

An integer that specifies the number of seconds an enqueued message is available for dequeuing.

**Exceptions**

ArgumentException - The value specified is less than -1.

**Remarks**

The value specified is an offset from the value specified in the Delay property.

The following are valid values for the property:

- Positive integer - Indicates the expiration in seconds.
- -1 - Indicates that the message never expires.

The default value is -1. When a message expires, the message moves from the READY state to the EXPIRED state.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## MessageId

This instance property returns the message identifier.

**Declaration**

```
// C#  
public byte[] MessageId {get;}
```

**Property Value**

A byte[] that specifies the message identifier.

**Remarks**

This property is available after an enqueue or dequeue operation. Dequeued buffered messages have a null value for MessageId.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## OriginalMessageId

This instance property specifies the identifier of the message in the last queue that generated this message.

**Declaration**

```
// C#  
public byte[] OriginalMessageId {get;}
```

**Property Value**

A byte[] that specifies the original message identifier.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## Payload

This instance property specifies the payload of the message.

**Declaration**

```
// C#  
public Object Payload {get;set;}
```

**Property Value**

An Object that specifies the payload of the message.

**Exceptions**

ArgumentException - The specified object is not one of the allowed types.

**Remarks**

For a complete discussion of various payload types, refer to "[MessageType](#)" under the OracleAQQueue class.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)
- ["MessageType"](#)

## Priority

This instance property specifies the priority of the message.

**Declaration**

```
// C#  
public int Priority {get;set;}
```

**Property Value**

An integer that specifies the priority of the message.

**Remarks**

The default value is 0. In order to take effect, this property must be set prior to enqueueing the message.

Smaller values indicate higher priority for the message. Negative values may also be used.

The priority of an enqueued message is useful for priority-based dequeuing.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## Recipients

This instance property specifies the list of recipients that overrides the default queue subscribers.

**Declaration**

```
// C#  
public OracleAQAgent[] Recipients {get; set;}
```

**Property Value**

An `OracleAQAgent[]`.

### Remarks

This recipient list is valid only for messages being enqueued to multiconsumer queues. The list of recipients is not returned with the message at the time of dequeuing.

TxEvtQ does not support recipient list.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## SenderId

This instance property identifies the original sender of the message.

### Declaration

```
// C#  
public OracleAQAgent SenderId {get; set;}
```

### Property Value

An `OracleAQAgent` object.

### Remarks

Sender identification is supported in all queue tables.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## State

This instance property specifies the state of the message at the time of dequeue.

### Declaration

```
// C#  
public OracleAQMessageState State {get;}
```

### Property Value

An `OracleAQMessageState` enumerated value.

**Remarks**

This property is available after the message is dequeued.

The state of buffered messages dequeued by specifying Correlation under dequeue options is always `OracleAQMessageState.Ready`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## TransactionGroup

This instance property specifies the transaction group for the dequeued message.

**Declaration**

```
// C#  
public string TransactionGroup {get;}
```

**Property Value**

A string that specifies the transaction group.

**Remarks**

Messages belonging to one queue can be grouped to form a set that can only be consumed by one user at a time. This requires that the queue be created in a queue table that is enabled for message grouping. All messages belonging to a group must be created in the same transaction. Also, all messages created in one transaction belong to the same group.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessage Class](#)
- [OracleAQMessage Members](#)

## OracleAQMessageAvailableEventArgs Class

The `OracleAQMessageAvailableEventArgs` class provides event data for the `OracleAQQueue.MessageAvailable` event.

**Class Inheritance**

`System.Object`

`System.EventArgs`

Oracle.DataAccess.Client.OracleAQMessageAvailableEventArgs

Declaration

```
// C#
public sealed class OracleAQMessageAvailableEventArgs
```

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

This class cannot be inherited.

For detailed information on all the inherited properties and methods, please read the documentation provided by Microsoft's .NET Documentation.

OracleAQMessageAvailableEventArgs Members

OracleAQMessageAvailableEventArgs members are listed in the following tables.

OracleAQMessageAvailableEventArgs Constructor

OracleAQMessageAvailableEventArgs constructor is listed in [Table 12-17](#)

**Table 12-17 OracleAQMessageAvailableEventArgs Constructor**

| Property                                                      | Description                                                                 |
|---------------------------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">OracleAQMessageAvailableEventArgs Constructor</a> | Instantiates a new instance of the OracleAQMessageAvailableEventArgs class. |

**OracleAQMessageAvailableEventArgs Properties**

OracleAQMessageAvailableEventArgs properties are listed in [Table 12-18](#).

**Table 12-18 OracleAQMessageAvailableEventArgs Properties**

| Property                          | Description                                                                                                   |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------|
| <a href="#">AvailableMessages</a> | Specifies the number of messages that raised this notification.                                               |
| <a href="#">ConsumerName</a>      | Provides the name of the consumer for which the message is available for dequeuing.                           |
| <a href="#">Correlation</a>       | Provides the user-defined identifier of the message.                                                          |
| <a href="#">Delay</a>             | Specifies the duration, in seconds, after which an enqueued message is available for dequeuing.               |
| <a href="#">DeliveryMode</a>      | Specifies the delivery mode of the message.                                                                   |
| <a href="#">EnqueueTime</a>       | Specifies the time when the message was enqueued.                                                             |
| <a href="#">ExceptionQueue</a>    | Specifies the name of the queue that the message is moved to if it cannot be processed successfully.          |
| <a href="#">Expiration</a>        | Specifies the duration, in seconds, for which an enqueued message is available for dequeuing before expiring. |
| <a href="#">MessageId</a>         | Returns an array of message identifiers.                                                                      |
| <a href="#">NotificationType</a>  | Indicates the type of notification such as regular, grouping, or timeout.                                     |
| <a href="#">OriginalMessageId</a> | Specifies the ID of the message, in the last queue, that generated this message.                              |
| <a href="#">Payload</a>           | Provides payload associated with the notification.                                                            |
| <a href="#">Priority</a>          | Specifies the priority of the message.                                                                        |
| <a href="#">Queue</a>             | Indicates OracleAQQueue instance corresponding to which the notification is received.                         |
| <a href="#">QueueName</a>         | Indicates the name of the queue that contains the message to be dequeued.                                     |
| <a href="#">SenderId</a>          | Identifies the original sender of the message.                                                                |
| <a href="#">State</a>             | Specifies the state of the message.                                                                           |

## OracleAQMessageAvailableEventArgs Constructor

This constructor creates an instance of the `OracleAQMessageAvailableEventArgs` class with default property values.

### Declaration

```
// C#  
public OracleAQMessageAvailableEventArgs();
```

## OracleAQMessageAvailableEventArgs Properties

`OracleAQMessageAvailableEventArgs` properties are listed in [Table 12-19](#).

**Table 12-19 OracleAQMessageAvailableEventArgs Properties**

| Property                          | Description                                                                                                   |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------|
| <a href="#">AvailableMessages</a> | Specifies the number of messages that raised this notification.                                               |
| <a href="#">ConsumerName</a>      | Provides the name of the consumer for which the message is available for dequeuing.                           |
| <a href="#">Correlation</a>       | Provides the user-defined identifier of the message.                                                          |
| <a href="#">Delay</a>             | Specifies the duration, in seconds, after which an enqueued message is available for dequeuing.               |
| <a href="#">DeliveryMode</a>      | Specifies the delivery mode of the message.                                                                   |
| <a href="#">EnqueueTime</a>       | Specifies the time when the message was enqueued.                                                             |
| <a href="#">ExceptionQueue</a>    | Specifies the name of the queue that the message is moved to if it cannot be processed successfully.          |
| <a href="#">Expiration</a>        | Specifies the duration, in seconds, for which an enqueued message is available for dequeuing before expiring. |
| <a href="#">MessageId</a>         | Returns an array of message identifiers.                                                                      |
| <a href="#">NotificationType</a>  | Indicates the type of notification such as regular, grouping, or timeout.                                     |
| <a href="#">OriginalMessageId</a> | Specifies the ID of the message, in the last queue, that generated this message.                              |
| <a href="#">Payload</a>           | Provides payload associated with the notification.                                                            |
| <a href="#">Priority</a>          | Specifies the priority of the message.                                                                        |
| <a href="#">Queue</a>             | Indicates <code>OracleAQQueue</code> instance corresponding to which the notification is received.            |

**Table 12-19 (Cont.) OracleAQMessageAvailableEventArgs Properties**

| Property                  | Description                                                               |
|---------------------------|---------------------------------------------------------------------------|
| <a href="#">QueueName</a> | Indicates the name of the queue that contains the message to be dequeued. |
| <a href="#">SenderId</a>  | Identifies the original sender of the message.                            |
| <a href="#">State</a>     | Specifies the state of the message.                                       |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## AvailableMessages

This instance property specifies the number of messages that raised this notification.

**Declaration**

```
// C#  
public int AvailableMessages{get;}
```

**Property Value**

An integer indicating the number of messages that raised this notification.

**Remarks**

The property value is 1 for a regular notification type. The notification type can be specified using the `OracleAQQueue.Notification` property.

This property is not relevant if the `NotificationType` is `OracleAQNotificationType.Timeout`.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## ConsumerName

This property provides the name of the consumer for which the message is available for dequeuing.

**Declaration**

```
// C#  
public string ConsumerName {get;}
```

**Property Value**

A string that identifies the name of the consumer.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## Correlation

This instance property specifies the identification for the message.

**Declaration**

```
// C#  
public string Correlation {get;}
```

**Property Value**

A string that specifies the identification for the message.

**Remarks**

This property specifies the correlation of the message for which the notification is raised. The consumer can then use this identification to dequeue specific messages by setting the "[Correlation](#)" property of the `OracleAQDequeueOptions` object.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)
- ["Correlation"](#)

## Delay

This instance property specifies the duration, in seconds, after which an enqueued message is available for dequeuing.

**Declaration**

```
// C#  
public int Delay {get;}
```

**Property Value**

An integer that indicates the duration, in seconds, after which an enqueued message is available for dequeuing.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## DeliveryMode

This instance property specifies the delivery mode of the message.

**Declaration**

```
// C#  
public OracleAQMessageDeliveryMode DeliveryMode {get;}
```

**Property Value**

An OracleAQMessageDeliveryMode enumerated value.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## EnqueueTime

This instance property specifies the time when the message was enqueued.

**Declaration**

```
// C#  
public DateTime EnqueueTime {get;}
```

**Property Value**

A DateTime object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## ExceptionQueue

This instance property specifies the name of the queue that the message is moved to if it cannot be processed successfully.

**Declaration**

```
// C#  
public string ExceptionQueue {get;}
```

**Property Value**

The name of the queue that a message to is moved if it cannot be processed successfully.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## Expiration

This instance property specifies the duration, in seconds, for which an enqueued message is available for dequeuing before expiring.

**Declaration**

```
// C#  
public int Expiration {get;}
```

**Property Value**

An integer that specifies the duration, in seconds, for which an enqueued message is available for dequeuing.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## MessageId

This instance property returns an array of message identifiers.

### Declaration

```
// C#  
public byte[][] MessageId{get;}
```

### Property Value

A byte[][] that specifies the message identifiers received as part of the notification.

### Remarks

This property specifies the message identifiers of the messages that raise the notification.

The size of the MessageId array is 1 for regular notifications. The size of the MessageId array is 1 for grouping notifications if the notification grouping type is OracleAQNotificationGroupingType.Last. This property is not relevant if the NotificationType is OracleAQNotificationType.Timeout.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## NotificationType

This property indicates the type of notification such as regular, grouping, or timeout.

### Declaration

```
// C#  
public OracleAQNotificationType NotificationType {get;}
```

### Property Value

An OracleAQNotificationType enum value.

### Remarks

Regular, grouping, and timeout notifications are supported for AQ but only regular notification is supported for TxEventQ.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## OriginalMessageId

This property specifies the ID of the message, in the last queue, that generated this message.

**Declaration**

```
// C#  
public byte[] OriginalMessageId {get;}
```

**Property Value**

A byte[] that specifies the original message ID.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## Payload

This instance property provides payload associated with the notification.

**Declaration**

```
// C#  
public object Payload {get;}
```

**Property Value**

An object that represents payload associated with the notification.

**Remarks**

We receive payload only with TxEventQ notifications. In case of classic queue, we don't receive Payload as part of notification hence the Payload property will be Null for such scenario.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## Priority

This instance property specifies the priority of the message.

**Declaration**

```
// C#  
public int Priority {get;}
```

**Property Value**

An integer that specifies the priority of the message.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## Queue

This property indicates OracleAQQueue instance corresponding to which the notification is received.

**Declaration**

```
// C#  
public OracleAQQueue Queue { get;}
```

**Property Value**

An OracleAQQueue instance corresponding to which the notification is received

**Remarks**

This property is introduced from 23.4 release onwards. Till 23.3 release, OracleAQMessageAvailableEventArgs class had a property named QueueName, value of which was queue name corresponding to which the notification is received but this property is removed from 23.4 release onwards because OracleAQQueue class itself contains property Name which solves the purpose for former property.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## QueueName

This property indicates the name of the queue that contains the message to be dequeued.

### Declaration

```
// C#  
public string QueueName {get;}
```

### Property Value

A string.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

## SenderId

This property identifies the original sender of the message.

### Declaration

```
// C#  
public OracleAQAgent SenderId {get;}
```

### Property Value

An OracleAQAgent object.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

State

This instance property specifies the state of the message.

Declaration

```
// C#
public OracleAQMessageState State {get;}
```

Property Value

An OracleAQMessageState enumerated value.

See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQMessageAvailableEventArgs Class](#)
- [OracleAQMessageAvailableEventArgs Members](#)

OracleAQMessageAvailableEventHandler Delegate

The OracleAQMessageAvailableEventHandler delegate represents the signature of the method that handles the OracleAQQueue.MessageAvailable event.

Declaration

```
// C#
public delegate void OracleAQMessageAvailableEventHandler (object
    sender, OracleAQMessageAvailableEventArgs eventArgs);
```

Parameters

- *sender*  
The source of the event.
- *eventArgs*  
The OracleAQMessageAvailableEventArgs object that contains the event data.

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

# OracleAQQueue Class

An OracleAQQueue object represents a queue.

**Class Inheritance**

System.Object  
    OracleAQQueue

**Declaration**

```
// C#  
public class OracleAQQueue : IDisposable
```

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

**Remarks**

A queue is a repository of messages and may either be a user queue, or an exception queue. A user queue is for normal message processing. A message is moved from a user queue to an exception queue if it cannot be retrieved and processed for some reason.

## OracleAQQueue Members

OracleAQQueue members are listed in the following tables.

### OracleAQQueue Constructors

OracleAQQueue constructors are listed in [Table 12-20](#).

**Table 12-20 OracleAQQueue Constructors**

| Constructor                                | Description                                                         |
|--------------------------------------------|---------------------------------------------------------------------|
| <a href="#">OracleAQQueue Constructors</a> | Instantiate a new instance of the OracleAQQueue class (Overloaded). |

### OracleAQQueue Static Methods

The OracleAQQueue static method is listed in [Table 12-21](#).

**Table 12-21 OracleAQQueue Static Methods**

| Static Method          | Description                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Listen</a> | Listens for messages on one or more queues for one or more consumers, as specified in the array of OracleAQAgent objects (Overloaded). |

### OracleAQQueue Properties

OracleAQQueue properties are listed in [Table 12-22](#).

**Table 12-22 OracleAQQueue Properties**

| Property                                  | Description                                                                                           |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">AutoCommitTEQNotification</a> | Used to automatically send a Commit acknowledgement after receiving a TxEventQ message's notification |
| <a href="#">Connection</a>                | Specifies the OracleConnection object associated with the queue.                                      |

**Table 12-22 (Cont.) OracleAQQueue Properties**

| Property                              | Description                                                                                                                                                     |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DequeueOptions</a>        | Specifies the dequeuing options to use when dequeuing a message from a queue.                                                                                   |
| <a href="#">EnqueueOptions</a>        | Specifies the enqueueing options used to enqueue a message to a queue.                                                                                          |
| <a href="#">MessageType</a>           | Specifies the type of queue table associated with this queue.                                                                                                   |
| <a href="#">Name</a>                  | Returns the name of the queue.                                                                                                                                  |
| <a href="#">Notification</a>          | Specifies the various notification options for notifications that are registered using the <code>MessageAvailable</code> event.                                 |
| <a href="#">NotificationConsumers</a> | Specifies the array of consumers, for a multiconsumer queue, that are to be notified asynchronously for any incoming messages on the queue.                     |
| <a href="#">UdtTypeName</a>           | Specifies the type name on which the queue and the corresponding queue table is based if the <code>MessageType</code> is <code>OracleAQMessageType.UDT</code> . |

**OracleAQQueue Public Methods**

The `OracleAQQueue` public methods are listed in [Table 12-23](#).

**Table 12-23 OracleAQQueue Public Methods**

| Public Method                                   | Description                                                                               |
|-------------------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">AcknowledgeTxEventQNotification</a> | Sends an acknowledgement for a <code>TxEventQ</code> notification                         |
| <a href="#">Dequeue</a>                         | Dequeues messages from queues (Overloaded).                                               |
| <a href="#">DequeueArray</a>                    | Dequeues multiple messages from queues (Overloaded).                                      |
| <a href="#">Dispose</a>                         | Releases any resources or memory allocated by the object                                  |
| <a href="#">Enqueue</a>                         | Enqueues messages to queues (Overloaded).                                                 |
| <a href="#">EnqueueArray</a>                    | Enqueues multiple messages to a queue (Overloaded).                                       |
| <a href="#">Listen</a>                          | Listens for messages on the queue on behalf of <code>ListenConsumers</code> (Overloaded). |

**OracleAQQueue Events**

The `OracleAQQueue` event is listed in [Table 12-24](#).

**Table 12-24 OracleAQQueue Events**

| Event Name                             | Description                                                                                |
|----------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">MessageAvailable Event</a> | Notifies when a message is available in the queue for <code>NotificationConsumers</code> . |

**① See Also**

## OracleAQQueue Properties

OracleAQQueue properties are listed in [Table 12-25](#).

**Table 12-25 OracleAQQueue Properties**

| Property                                  | Description                                                                                                                                 |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AutoCommitTEQNotification</a> | Used to automatically send a Commit acknowledgement after receiving a TxEventQ message's notification                                       |
| <a href="#">Connection</a>                | Specifies the OracleConnection object associated with the queue.                                                                            |
| <a href="#">DequeueOptions</a>            | Specifies the dequeuing options to use when dequeuing a message from a queue.                                                               |
| <a href="#">EnqueueOptions</a>            | Specifies the enqueueing options used to enqueue a message to a queue.                                                                      |
| <a href="#">MessageType</a>               | Specifies the type of queue table associated with this queue.                                                                               |
| <a href="#">Name</a>                      | Returns the name of the queue.                                                                                                              |
| <a href="#">Notification</a>              | Specifies the various notification options for notifications that are registered using the MessageAvailable event.                          |
| <a href="#">NotificationConsumers</a>     | Specifies the array of consumers, for a multiconsumer queue, that are to be notified asynchronously for any incoming messages on the queue. |
| <a href="#">UdtTypeName</a>               | Specifies the type name on which the queue and the corresponding queue table is based if the MessageType is OracleAQMessageType.UDT.        |

**① See Also**

- [OracleAQQueue Members](#)

## AutoCommitTEQNotification

This property is used to automatically send a Commit acknowledgement after receiving a TxEventQ message's notification.

**Declaration**

```
// C#  
public bool AutoCommitTEQNotification {get; set;}
```

**Property Value**

A Boolean value

**Remarks**

The default value is false.

If this instance property is set to true, then a Commit acknowledgement is sent to the server for every TxEventQ message notification received automatically. Once set to true, an OracleAQMessageAvailableEventArgs AcknowledgeTEQNotification call does not result in a change as all the messages will be in the Processed state now.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Connection

This property specifies the OracleConnection object associated with the queue.

**Declaration**

```
// C#  
public OracleConnection Connection {get; set;}
```

**Property Value**

An OracleConnection object that indicates the connection associated with the queue.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

This connection must be opened before calling methods like Enqueue and Dequeue.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## DequeueOptions

This instance property specifies the dequeuing options to use when dequeuing a message from a queue.

### Declaration

```
// C#  
public OracleAQDequeueOptions DequeueOptions {get; set}
```

### Property Value

An OracleAQDequeueOptions object.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

The default value is an OracleAQDequeueOptions object with default property values. Setting this property to null resets all dequeue options to their default values.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## EnqueueOptions

This instance property specifies the enqueueing options used to enqueue a message to a queue.

### Declaration

```
// C#  
public OracleAQEnqueueOptions EnqueueOptions {get; set}
```

### Property Value

An OracleAQEnqueueOptions object.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

The default value is an OracleAQEnqueueOptions object with default property values. Setting this property to null resets all enqueue options to their default values.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## MessageType

This instance property specifies the type of queue table associated with this queue.

**Declaration**

```
// C#  
public OracleAQMessageType MessageType {get; set;}
```

**Property Value**

An `OracleAQMessageType` enumerated value.

**Exceptions**

`ArgumentOutOfRangeException` - The type value specified is invalid.

`ObjectDisposedException` - The object is already disposed.

**Remarks**

The `MessageType` property also dictates the type of message payloads that are enqueued or dequeued from the queue. It is possible to enqueue a variety of payloads depending on the `MessageType`. All ODP.NET provider types support RAW, user-defined type, and XML data type payloads. Managed ODP.NET and ODP.NET Core also support JSON data type payloads. ODP.NET does not support other data types, such as Java Message Service data types.

[Table 12-26](#) lists the allowed payload types for various message types.

**Table 12-26 Message Types and Payloads**

| OracleAQQueue.MessageType                      | Allowed OracleAQMessage.Payload type to Enqueue                                                                       |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>OracleAQMessageType.JSON</code>          | Either <code>OracleString</code> or <code>string</code>                                                               |
| <code>OracleAQMessageType.Raw (default)</code> | <code>OracleBinary</code> , <code>byte[]</code>                                                                       |
| <code>OracleAQMessageType.Xml</code>           | <code>OracleXmlType</code> , <code>XmlReader</code> , <code>String</code> (well-formed XML, else exception is raised) |
| <code>OracleAQMessageType.UDT</code>           | UDT Custom Object                                                                                                     |

[Table 12-27](#) lists the payload types for dequeued messages.

**Table 12-27 Payload Types for Dequeued Messages**

| OracleAQQueue.MessageType             | DequeueOptions.ProviderSpecificType | OracleAQMessage.Payload of dequeued message |
|---------------------------------------|-------------------------------------|---------------------------------------------|
| <code>OracleAQMessageType.JSON</code> | <code>true</code>                   | <code>OracleString</code>                   |

**Table 12-27 (Cont.) Payload Types for Dequeued Messages**

| OracleAQQueue.MessageType | DequeueOptions.ProviderSpecificType | OracleAQMessage.Payload of dequeued message |
|---------------------------|-------------------------------------|---------------------------------------------|
| OracleAQMessageType.JSON  | false                               | string                                      |
| OracleAQMessageType.Xml   | true                                | OracleXmlType                               |
| OracleAQMessageType.Xml   | false                               | XmlReader                                   |
| OracleAQMessageType.Raw   | true                                | OracleBinary                                |
| OracleAQMessageType.Raw   | false                               | Byte[]                                      |
| OracleAQMessageType.UDT   | N.A.                                | UDT Custom Object                           |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Name

This instance property returns the name of the queue.

**Declaration**

```
// C#  
public string Name {get;}
```

**Property Value**

A string that indicates the name of the queue.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Notification

This instance property specifies the various notification options for notifications that are registered using the MessageAvailable event.

**Declaration**

```
// C#  
public OracleNotificationRequest Notification {get;}
```

**Property Value**

Specifies an `OracleNotificationRequest` object whose properties can be changed to alter the notification behavior.

**Remarks**

This property can be used to change various notification options. The notification options must be changed before registering with the `MessageAvailable` event. This property can be modified again only after unregistering from the `MessageAvailable` event.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## NotificationConsumers

This instance property specifies the array of consumers, for a multiconsumer queue, that are to be notified asynchronously for any incoming messages on the queue.

**Declaration**

```
// C#  
public string[] NotificationConsumers {get; set;}
```

**Property Value**

Specifies an array of consumer name strings for which the notifications are delivered.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - `MessageAvailable` registration is active.

**Remarks**

The consumer names must be in uppercase. This functionality only supports queues with uppercase names.

The list of consumers is used in the `MessageAvailable` event. The list must be set before registering for the event. This property cannot be modified after registering for the `MessageAvailable` event. This property can be modified again only after unregistering from `MessageAvailable` event.

- [OracleAQQueue Members](#)

## UdtTypeName

This instance property specifies the type name on which the queue and the corresponding queue table is based if the `MessageType` is `OracleAQMessageType.UDT`.

### Declaration

```
// C#  
public string UdtTypeName {get; set;}
```

### Property Value

Specifies the Oracle user-defined type name if the `MessageType` is `OracleAQMessageType.UDT`.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

### Remarks

The `UdtTypeName` property corresponds to the user-defined type name of the payload. This property must always be specified if the payload is a user-defined type. This property need not be set for other payload types.

## OracleAQQueue Constructors

`OracleAQQueue` constructors create new instances of the `OracleAQQueue` class.

### Overload List:

- [OracleAQQueue\(string\)](#)  
This constructor takes a queue name to initialize a queue object.
- [OracleAQQueue\(string, OracleConnection\)](#)  
This constructor takes a queue name and connection to initialize a queue object. The connection does not need be open during the queue object construction.
- [OracleAQQueue\(string, OracleConnection, OracleAQMessageType\)](#)

This constructor takes a queue name, connection, and message type enumeration to initialize a queue object.

- [OracleAQQueue\(string, OracleConnection, OracleAQMessageType, string\)](#)

This constructor takes a queue name, connection, message type enumeration, and UDT type name to initialize a queue object.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## OracleAQQueue(string)

This constructor takes a queue name to initialize a queue object.

### Declaration

```
// C#  
public OracleAQQueue(string name);
```

### Parameters

- *name*

The name of the queue as specified in the database.

### Exceptions

*ArgumentNullException* - The queue name is null.

*ArgumentException* - The queue name is empty.

### Remarks

The operation of creating an *OracleAQQueue* object does not involve checking for the existence of the queue in the database.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## OracleAQQueue(string, OracleConnection)

This constructor takes a queue name and connection to initialize a queue object. The connection does not need to be open during the queue object construction.

### Declaration

```
// C#  
public OracleAQQueue(string name, OracleConnection con);
```

### Parameters

- *name*  
Name of the queue as specified in the database.
- *con*  
An OracleConnection object that connects to the queue.

### Exceptions

ArgumentNullException - Either the connection is null or queue name is null.

ArgumentException - Queue name is empty.

### Remarks

The connection can be accessed using the Connection property, and it must be opened before calling any operational APIs such as Enqueue and Dequeue.

Creating an OracleAQQueue object does not check for the existence of the queue in the database.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## OracleAQQueue(string, OracleConnection, OracleAQMessageType)

This constructor takes a queue name, connection and message type enumeration to initialize a queue object. The connection does not need to be open during the queue object construction.

### Declaration

```
// C#  
public OracleAQQueue(string name, OracleConnection con, OracleAQMessageType  
    messageType);
```

### Parameters

- *name*  
The name of the queue as specified in the database.
- *con*  
An OracleConnection object that is used to connect to the queue.
- *messageType*

An *OracleAQMessageType* enumeration specifying the type of the message that is enqueued or dequeued from this queue.

### Exceptions

*ArgumentNullException* - Either the connection is null or queue name is null.

*ArgumentException* - Queue name is empty or the specified message type is not valid.

### Remarks

Creating an *OracleAQQueue* object does not check for the existence of the queue in the database.

You need to set the *UdtTypeName* property before using the queue object if the *messageType* is a UDT. Another approach is to create a queue using the other constructor overload by supplying the *udtTypeName*.

- [OracleAQQueue Members](#)

## OracleAQQueue(string, OracleConnection, OracleAQMessageType, string)

This constructor takes a queue name, connection, message type enumeration, and UDT type name to initialize a queue object. The connection does not need to be open during the queue object construction.

### Declaration

```
// C#
public OracleAQQueue(string name, OracleConnection con, OracleAQMessageType
    messageType, string udtTypeName);
```

### Parameters

- *name*  
The name of the queue as specified in the database.
- *con*  
An *OracleConnection* object that is used to connect to the queue.
- *messageType*  
An *OracleAQMessageType* enumeration specifying the type of the message that is enqueued or dequeued from this queue.
- *udtTypeName*  
The name of the database object type used if the *messageType* is UDT. The *udtTypeName* parameter represents the type on which the queue is based.

Exceptions

ArgumentNullException - The connection is null or the queue name is null.  
ArgumentException - The queue name is empty or the specified messageType is not valid.

Remarks

Creating an OracleAQQueue object does not check for the existence of the queue in the database.

OracleAQQueue Static Methods

OracleAQQueue static methods are listed in [Table 12-28](#).

Table 12-28 OracleAQQueue Static Methods

| Static Method          | Description                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Listen</a> | Listens for messages on one or more queues for one or more consumers, as specified in the array of OracleAQAgent objects (Overloaded). |

 See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

Listen

Listen methods listen for messages on one or more queues for one or more consumers as specified in the array of OracleAQAgent objects.

Listen methods are supported only for AQ, but not for TxEventQ

Overload list

- [Listen\(OracleConnection, OracleAQAgent\[\]\)](#)  
This static method listens for messages on one or more queues for one or more consumers as specified in the array of OracleAQAgent objects.

- [Listen\(OracleConnection, OracleAQAgent\[\], int\)](#)

This static method listens for messages on one or more queues for one or more consumers as specified in the array of `OracleAQAgent` objects. It also specifies a wait time.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Listen(OracleConnection, OracleAQAgent[])

This static method listens for messages on one or more queues for one or more consumers as specified in the array of `OracleAQAgent` objects.

### Declaration

```
// C#  
public static OracleAQAgent Listen(OracleConnection con, OracleAQAgent[]  
    listenConsumers);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *listenConsumers*  
The array of consumers being listened for. The name of the `OracleAQAgent` object must be null or empty for single consumer queues.

### Return Value

An `OracleAQAgent` object.

### Exceptions

`ArgumentNullException` - The *con* or *listenConsumers* parameter is null.

`InvalidOperationException` - The connection is not open.

### Remarks

`Listen` is useful in situations where one needs to monitor multiple queues until a message is available for a consumer in one of the queues. The `Name` property of the `OracleAQAgent` object represents the name of the consumer and the `Address` property represents the name of the queue.

This call blocks the calling thread until there is a message ready for consumption for a consumer in the list. It returns an `OracleAQAgent` object which specifies the consumer and queue for which a message is ready to be dequeued.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Listen(OracleConnection, OracleAQAgent[ ], int)

This static method listens for messages on one or more queues for one or more consumers as specified in the array of `OracleAQAgent` objects. The `Name` property of the `OracleAQAgent` object represents the name of the consumer and the `Address` property of the `OracleAQAgent` object represents the name of the queue.

### Declaration

```
// C#  
public static OracleAQAgent Listen(OracleConnection con, OracleAQAgent[]  
    listenConsumers, int waitTime);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *listenConsumers*  
The array of consumers being listened for. The name of the `OracleAQAgent` object must be null or empty for single consumer queues.
- *waitTime*  
Wait time in seconds.

### Return Value

An `OracleAQAgent` object.

### Exceptions

`ArgumentNullException` - The *con* or *listenConsumers* parameter is null.

`InvalidOperationException` - The connection is not open.

`ArgumentException` - *waitTime* is less than -1.

### Remarks

In case of timeout, this method returns null.

`Listen` is useful in situations where one needs to monitor multiple queues until a message is available for a consumer in one of the queues. The `Name` property of the `OracleAQAgent` object represents the name of the consumer and the `Address` property of the `OracleAQAgent` object represents the name of the queue.

A *waitTime* of -1 implies an infinite wait time.

This call blocks the calling thread until there is a message ready for consumption for a consumer in the list. It returns an `OracleAQAgent` object which specifies the consumer and queue for which a message is ready to be dequeued.

## OracleAQQueue Public Methods

OracleAQQueue public methods are listed in [Table 12-29](#).

**Table 12-29 OracleAQQueue Public Methods**

| Public Method                                   | Description                                                                               |
|-------------------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">AcknowledgeTxEventQNotification</a> | Sends an acknowledgement for a TxEventQ notification                                      |
| <a href="#">Dequeue</a>                         | Dequeues messages from queues (Overloaded).                                               |
| <a href="#">DequeueArray</a>                    | Dequeues multiple messages from queues (Overloaded).                                      |
| <a href="#">Dispose</a>                         | Releases any resources or memory allocated by the object                                  |
| <a href="#">Enqueue</a>                         | Enqueues messages to queues (Overloaded).                                                 |
| <a href="#">EnqueueArray</a>                    | Enqueues multiple messages to a queue (Overloaded).                                       |
| <a href="#">Listen</a>                          | Listens for messages on the queue on behalf of <code>ListenConsumers</code> (Overloaded). |

#### ① See Also

- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## AcknowledgeTxEventQNotification

This instance method sends an acknowledgement for a TxEventQ notification.

### Declaration

```
// C#
public void AcknowledgeTxEventQNotification( OracleTxEventQNotificationDirective
directive);
```

### Parameters

directive - Specifies the OracleTxEventQNotificationDirective enumeration value.

### Exceptions

InvalidOperationException is thrown when:

- the CIC connection is closed,
- registration is not found, or
- acknowledgement is being sent to an AQ.

### Remarks

This method should be called from a callback function after receiving a notification. There are two possible values for OracleTxEventQNotificationDirective enumeration, OracleTxEventQNotificationDirective.Commit or OracleTxEventQNotificationDirective.Rollback.

Acknowledgements are meant to be sent to TxEventQ only but not to an AQ queue. The callback method is invoked using a separate thread so its a good practice to catch exceptions otherwise the issues may go unnoticed.

In TxEventQ notifications, we get payload as part of the notification. In TxEventQ, each payload is associated with one of the three states below:

- Ready: This means message is available to be dequeued. As soon as a notification is sent for this message, the state gets changed to Acknowledgement\_waiting.
- Acknowledgement\_waiting: Notification for this message is sent and currently the TxEventQ is waiting for an acknowledgement from client application.
- Processed - This message is dequeued and it is not available for further dequeue.

When we send a Commit acknowledgement, all messages in the Acknowledgement\_waiting state are marked as Processed.

When we send a Rollback acknowledgement, all messages in the Acknowledgement\_waiting state are marked as Ready.

If message's state is Acknowledgement\_waiting and the connection between application-server is terminated or crashed, then the state of these messages will automatically be reset as Ready.

### Example

```

/*****Oracle DB Setup*****/

declare
    qprops          sys.dbms_aqadm.QUEUE_PROPS_T;
begin
    qprops.sort_list := 'enq_time';
    sys.dbms_aqadm.create_transactional_event_queue (queue_name =>
'raw_txeventq',
                                                    queue_payload_type => 'RAW',
                                                    queue_properties => qprops);

    END;
/

BEGIN

```

```

        dbms_aqadm.start_queue(
            queue_name => 'raw_txeventq');
    END;
    /
    *****/

// C#
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;

namespace TxEventQ_notification_test
{
    class Program
    {
        bool IsNotified = false;
        static Random rnd = new Random();

## Dequeue

Dequeue methods dequeue messages from queues.

### Overload List

- [Dequeue\(\)](#)  
This instance method dequeues messages from a queue using the DequeueOptions for the instance.
- [Dequeue\(OracleAQDequeueOptions\)](#)  
This instance method dequeues messages from a queue using the supplied dequeue options.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Dequeue()

This instance method is used to dequeue a message from a queue using the DequeueOptions for the instance.

**Declaration**

```
// C#  
public OracleAQMessage Dequeue();
```

**Return Value**

An OracleAQMessage instance representing the dequeued message.

**Exceptions**

InvalidOperationException - The connection is not open.

ObjectDisposedException - The object is already disposed.

OracleException - In case of timeout, an exception is thrown with the message, ORA-25228: timeout or end-of-fetch during message dequeue from queue\_name. Timeout may happen if DequeueOptions.Wait is set to a value other than -1.

**Remarks**

The MessageType property must be set appropriately before calling this function. If the MessageType is OracleAQMessageType.UDT, then the UdtTypeName property must also be set.

Dequeued buffered messages always have null MessageId values.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Dequeue(OracleAQDequeueOptions)

This instance method dequeues messages from a queue using the supplied dequeue options.

**Declaration**

```
// C#  
public OracleAQMessage Dequeue(OracleAQDequeueOptions dequeueOptions);
```

### Parameters

- *dequeueOptions*  
An OracleAQDequeueOptions object.

### Return Value

An OracleAQMessage instance representing the dequeued message.

### Exceptions

InvalidOperationException - The connection is not open.

ObjectDisposedException - The object is already disposed.

OracleException - In case of timeout, an exception is thrown with the message, ORA-25228: timeout or end-of-fetch during message dequeue from queue\_name. Timeout may happen if DequeueOptions.Wait is set to a value other than -1.

### Remarks

If the supplied dequeueOptions object is null, then the dequeue options default values are used. The queue object's DequeueOptions property is ignored for this operation.

Calling this method does not change the DequeueOptions property of the queue.

The MessageType property must be set appropriately before calling this function. If the MessageType is OracleAQMessageType.UDT, then the UdtTypeName property must also be set.

Dequeued buffered messages always have null MessageId values.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## DequeueArray

DequeueArray methods dequeue multiple messages from queues.

### Overload List

- [DequeueArray\(int\)](#)  
This instance method dequeues multiple messages from a queue using the DequeueOptions of the instance.
- [DequeueArray\(int, OracleAQDequeueOptions\)](#)  
This instance method dequeues multiple messages from a queue using the supplied dequeue options.

**Note**

DequeueArray methods are not supported for JSON Data type for both AQ and TxEventQ, the workaround is to use non-array APIs with JSON type payloads.

DequeueMode = RemoveNoData is not supported for TxEventQ. For AQ, it is not supported only for JSON data type.

DequeueMode = Locked is not supported with Visibility = Immediate for AQ and TxEventQ, the workaround is to use DequeueMode = Locked with Visibility = OnCommit.

DeliveryMode = Buffered is not supported for AQ and TxEventQ operations, workaround is to use DeliveryMode = Persistent.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## DequeueArray(int)

This instance method dequeues multiple messages from a queue using the DequeueOptions of the instance.

**Note**

JSON payloads are not supported.

**Declaration**

```
// C#  
public OracleAQMessage[] DequeueArray(int dequeueCount);
```

**Parameters**

- *dequeueCount*  
An integer specifying the numbers of messages to dequeue.

**Return Value**

An array of OracleAQMessage instances representing the dequeued messages.

**Exceptions**

ArgumentOutOfRangeException - dequeueCount is less than or equal to 0.

InvalidOperationException - The connection is not open.

ObjectDisposedException - The object is already disposed.

OracleException - In case of timeout, an exception is thrown with the message, ORA-25228: timeout or end-of-fetch during message dequeue from queue\_name. Timeout may happen if DequeueOptions.Wait is set to a value other than -1.

### Remarks

The MessageType property must be set appropriately before calling this function. If the MessageType is OracleAQMessageType.UDT, then the UdtTypeName property must be set as well.

The size of the returned array may be less than the dequeueCount. It depends on the actual number of messages present in the queue.

Dequeued buffered messages always have null MessageId values irrespective of the database version.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## DequeueArray(int, OracleAQDequeueOptions)

This instance method dequeues multiple messages from a queue using the supplied dequeue options.

#### ① Note

JSON payloads are not supported.

### Declaration

```
// C#  
public OracleAQMessage[] DequeueArray(int dequeueCount, OracleAQDequeueOptions  
dequeueOptions);
```

### Parameters

- *dequeueCount*  
An integer specifying the numbers of messages to dequeue.
- *dequeueOptions*  
An OracleAQDequeueOptions object.

### Return Value

An array of OracleAQMessage instances representing the dequeued messages.

## Exceptions

`ArgumentOutOfRangeException` - `dequeueCount` is less than or equal to 0.

`InvalidOperationException` - The connection is not open.

`ObjectDisposedException` - The object is already disposed.

`OracleException` - In case of timeout, an exception is thrown with the message, ORA-25228: timeout or end-of-fetch during message dequeue from `queue_name`. Timeout may happen if `DequeueOptions.Wait` is set to a value other than -1.

## Remarks

Calling this method does not change the `DequeueOptions` property of the queue.

If the supplied `dequeueOptions` object is null, then the dequeue options default values are used. The `DequeueOptions` property of the queue object is ignored in this operation.

The `MessageType` property must be set appropriately before calling this function. If the `MessageType` is `OracleAQMessageType.UDT`, then the `UdtTypeName` property must be set as well.

The size of the returned array may be less than the `dequeueCount`. It depends on the actual number of messages present in the queue.

Dequeued buffered messages always have null `MessageId` values irrespective of the database version.

## Dispose

This method releases any resources or memory allocated by the object.

## Declaration

```
// C#  
public void Dispose();
```

## Implements

`IDisposable`.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Enqueue

Enqueue instance methods enqueue messages to queues.

### Overload List

- [Enqueue\(OracleAQMessage\)](#)  
This instance method enqueues messages to a queue using the EnqueueOptions of the instance.
- [Enqueue\(OracleAQMessage, OracleAQEnqueueOptions\)](#)  
This instance method enqueues messages to a queue using the supplied enqueue options.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Enqueue(OracleAQMessage)

This instance method enqueues messages to a queue using the EnqueueOptions of the instance.

### Declaration

```
// C#  
public void Enqueue(OracleAQMessage message);
```

### Parameters

- *message*  
An OracleAQMessage object.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The connection is not open.

ArgumentNullException - The message parameter is null.

**ArgumentException** - The message payload is `OracleXmlType` and the connection used to create `OracleXmlType` is different from the queue's connection.

### Remarks

`MessageId` of the enqueued message is populated after the call to `Enqueue` completes. Enqueued buffered messages always have null `MessageId` values.

The `MessageType` property needs to be set appropriately before calling this function. If the `MessageType` is `OracleAQMessageType.UDT`, then the `UdtTypeName` property must be set as well.

## Enqueue(OracleAQMessage, OracleAQEnqueueOptions)

This instance method enqueues messages to a queue using the supplied enqueue options.

### Declaration

```
// C#  
public void Enqueue(OracleAQMessage message, OracleAQEnqueueOptions enqueueOptions);
```

### Parameters

- *message*  
An `OracleAQMessage` object.
- *enqueueOptions*  
An `OracleAQEnqueueOptions` object.

### Exceptions

**ObjectDisposedException** - The object is already disposed.

**InvalidOperationException** - The connection is not open.

**ArgumentNullException** - The message parameter is null.

**ArgumentException** - The message payload is `OracleXmlType` and the connection used to create `OracleXmlType` is different from the queue's connection.

### Remarks

If the supplied `enqueueOptions` object is null, then the enqueue options default values are used. The `EnqueueOptions` property of the queue object is ignored in this operation.

The `MessageId` of the enqueued message is populated after the call to `Enqueue` completes. Enqueued buffered messages always have null `MessageId` values. Calling this method does not change the `EnqueueOptions` property of the queue.

The `MessageType` property must be set appropriately before calling this function. If the `MessageType` is `OracleAQMessageType.UDT`, then the `UdtTypeName` property must also be set.

## EnqueueArray

`EnqueueArray` instance methods enqueue multiple messages to a queue.

### Overload List

- [EnqueueArray\(OracleAQMessage\[\] \)](#)  
This instance method enqueues multiple messages to a queue using the `EnqueueOptions` of the instance.
- [EnqueueArray\(OracleAQMessage\[\] , OracleAQEnqueueOptions\)](#)  
This instance method enqueues multiple messages to a queue using the supplied enqueue options.

#### Note

The enqueue array functionality is not supported for JSON data type for both AQ and TxEventQ, the workaround is to use non-array APIs for JSON payloads.

Enqueue Array with `Visibility = Immediate` is not supported for TxEventQ, the workaround is to use `Visibility = OnCommit`.

Buffered delivery mode is not supported for AQ and TxEventQ operations, the workaround is to use `DeliveryMode = Persistent`.

## EnqueueArray(OracleAQMessage[] )

This instance method enqueues multiple messages to a queue using the `EnqueueOptions` of the instance.

**Note**

JSON payloads are not supported.

**Declaration**

```
// C#  
public int EnqueueArray(OracleAQMessage[] messages);
```

**Parameters**

- *messages*  
An array of OracleAQMessage objects.

**Return Value**

An integer representing the number of messages actually enqueued.

**Exceptions**

ArgumentNullException - The message parameter is null.

ArgumentException - At least one of the OracleAQMessage[] elements is null, or at least one of the OracleAQMessage[] elements has a payload of OracleXmlType, which is created using a connection that is different from the queue's connection.

InvalidOperationException - The OracleAQMessage array is empty or the connection is not open.

ObjectDisposedException - The object is already disposed.

**Remarks**

The MessageId properties of the enqueued messages are populated after the call to Enqueue completes. Enqueued buffered messages always have null MessageId values.

The MessageType property must be set appropriately before calling this function. If the MessageType is OracleAQMessageType.UDT, then the UdtTypeName property must also be set.

**See Also**

## EnqueueArray(OracleAQMessage[], OracleAQEnqueueOptions)

This instance method enqueues multiple messages to a queue using the supplied enqueue options.

**Note**

JSON payloads are not supported.

**Declaration**

```
// C#  
public int EnqueueArray(OracleAQMessage[] messages, OracleAQEnqueueOptions  
    enqueueOptions);
```

**Parameters**

- *messages*  
An array of OracleAQMessage objects.
- *enqueueOptions*  
An OracleAQEnqueueOptions object.

**Return Value**

An integer representing the number of messages actually enqueued.

**Exceptions**

ArgumentNullException - The message parameter is null.

ArgumentException - At least one of the OracleAQMessage[] elements is null, or at least one of the OracleAQMessage[] elements has a payload of OracleXmlType, which is created using a connection that is different from the queue's connection.

InvalidOperationException - The OracleAQMessage array is empty or the connection is not open.

ObjectDisposedException - The object is already disposed.

**Remarks**

MessageId properties of the enqueued messages are populated after the call to Enqueue completes. Enqueued buffered messages always have null MessageId values. Calling this method does not change the EnqueueOptions property of the queue.

If the supplied enqueueOptions object is null, then the enqueue options default values are used. The EnqueueOptions property of the queue object is ignored in this operation.

The MessageType property must be set appropriately before calling this function. If the MessageType is OracleAQMessageType.UDT, then the UdtTypeName property must also be set.

## Listen

Listen methods listen for messages on the queue on behalf of `listenConsumers`.

Listen methods are supported for AQ, but not for `TxEvtQ`.

### Overload List

- [Listen\(string\[\]\)](#)  
This method listens for messages on the queue on behalf of `listenConsumers`.
- [Listen \(string\[\], int\)](#)  
This method listens for messages on behalf of `listenConsumers` for a specified time.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## Listen(string[])

This method listens for messages on the queue on behalf of `listenConsumers`.

### Declaration

```
// C#  
public string Listen(string[] listenConsumers);
```

### Parameters

- *listenConsumers*  
An array of consumers to listen for on this queue. This parameter should be null in case of single consumer queues.

### Return Value

A string.

### Exceptions

`InvalidOperationException` - The connection is not open.

`ObjectDisposedException` - The object is already disposed.

### Remarks

This call blocks the calling thread until there is a message ready for consumption for a consumer in the `listenConsumers` array. It returns a string representing the consumer name for which the message is ready.

`Listen` is useful in situations that require waiting until a message is available in the queue for consumers whose names are specified in `listenConsumers`.

## Example

The following example demonstrates using the Listen method. The first part of the example performs the requisite database setup for the database user, SCOTT. The second part of the example demonstrates how a thread can listen and wait until a message is enqueued.

```
-- Part I: Database setup required for this demo

-----
-- SQL to grant appropriate privilege to database user, SCOTT
-----
SQL> ALTER USER SCOTT ACCOUNT UNLOCK IDENTIFIED BY Pwd4Sct;
User altered.
GRANT ALL ON DBMS_AQADM TO scott;

-----
-- PLSQL to create queue-table and queue and start queue for SCOTT
-----
BEGIN
  DBMS_AQADM.CREATE_QUEUE_TABLE(
    queue_table=>'scott.test_q_tab',
    queue_payload_type=>'RAW',
    multiple_consumers=>FALSE);

  DBMS_AQADM.CREATE_QUEUE(
    queue_name=>'scott.test_q',
    queue_table=>'scott.test_q_tab');

  DBMS_AQADM.START_QUEUE(queue_name=>'scott.test_q');
END;
/

-----
-- PLSQL to stop queue and drop queue & queue-table from SCOTT
-----
BEGIN
  DBMS_AQADM.STOP_QUEUE('scott.test_q');

  DBMS_AQADM.DROP_QUEUE(
    queue_name => 'scott.test_q',
    auto_commit => TRUE);

  DBMS_AQADM.DROP_QUEUE_TABLE(
    queue_table => 'scott.test_q_tab',
    force => FALSE,
    auto_commit => TRUE);
END;
/
-- End of Part I, database setup.

//Part II: Demonstrates using the Listen method
//C#
using System;
using System.Text;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;
using System.Threading;

namespace ODPSample
{
  /// <summary>

## Listen (string[], int)

This method listens for messages on behalf of `listenConsumers` for a specified time.

### Declaration

```
// C#
public string Listen(string[] listenConsumers, int waitTime);
```

### Parameters

- *listenConsumers*  
Array of consumers for which to listen on this queue.
- *waitTime*  
Wait time in seconds.

### Return Value

A string

### Exceptions

`InvalidOperationException` - The connection is not open.

`ArgumentException` - *waitTime* is less than -1.

`ObjectDisposedException` - The object is already disposed.

### Remarks

`Listen` is useful in situations that require waiting until a message is available in the queue for consumers whose names are specified in `listenConsumers`.

This call blocks the calling thread until there is a message ready for consumption for a consumer in the `listenConsumers` array. It returns a string representing the consumer name for which the message is ready. The method returns `null` if a timeout occurs.

The `listenConsumers` parameter should be `null` for single consumer queues. An empty string is returned in such cases.

A `waitTime` of `-1` implies infinite wait time.

## OracleAQQueue Events

The `OracleAQQueue` event is listed in [Table 12-30](#).

**Table 12-30 OracleAQQueue Events**

| Event Name                             | Description                                                                                |
|----------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">MessageAvailable Event</a> | Notifies when a message is available in the queue for <code>NotificationConsumers</code> . |

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleAQQueue Class](#)
- [OracleAQQueue Members](#)

## MessageAvailable Event

This event is notified when a message is available in the queue for `NotificationConsumers`.

`TxEvtQ` notifications are not supported with ODP.NET Unmanaged Driver.

### Declaration

```
// C#
public event OracleAQMessageAvailableEventHandler MessageAvailable;
```

### Event Data

The event handler receives an `OracleAQMessageAvailableEventArgs` object.

## Exceptions

InvalidOperationException - The connection is not open.

## Remarks

Asynchronous notification is supported in all queue tables.

In order to receive the notification about message availability, the client must create an `OracleAQMessageAvailableEventHandler` delegate to listen to this event. The delegate should be added to this event only after setting the [NotificationConsumers](#) and [Notification](#) properties.

The notification registration takes place after the first delegate is added to the event. The notification is unregistered when the last delegate is removed from the event. Notifications set on an `OracleAQQueue` object get cancelled automatically when the object gets disposed.

When registering for notifications with classic queue, commonly referred to as AQ, Oracle Data Provider for .NET opens a port to listen for notifications. HA events, load balancing, and continuous query notification features also share the same port. This port can be configured centrally by setting the database notification port in an application or Web configuration file. The following example code specifies a port number of 1200:

```
<configuration>
  <oracle.dataaccess.client>
    <settings>
      <add name="DbNotificationPort" value="1200"/>
    </settings>
  </oracle.dataaccess.client>
</configuration>
```

If the configuration file does not exist or the db notification port is not specified, then ODP.NET uses a valid and random port number. The configuration file may also request for a random port number by specifying a db notification port value of -1.

The notification listener, which runs in the same application domain as ODP.NET, uses the specified port number to listen to notifications from the database. A notification listener gets created when the application registers with `OracleAQQueue.MessageAvailable` event. One notification listener can listen to all notification types. Only one notification listener is created for each application domain.

When connecting to Transactional Event Queue (TxEventQ), ODP.NET will not use a listener nor open a port to receive notification. Instead, it will use a Client Initiated Connection(CIC). CIC uses a dedicated connection instead of the listening end point. It does not count toward Min Pool Size and Max Pool Size limits.

When notifications are registered with Classic Queues(AQ), all registrations get notification when a message is available but in case of TxEventQ, only one of the registrations get notification because it contains Payload also which can be dequeued from the notification itself upon sending a "Commit" Acknowledgement.

## Example

The following example demonstrates application notification. The first part of the example performs the requisite database setup for the database user, SCOTT. The second part of the example demonstrates how an application is notified when a message is available in the queue.

-- Part I: Database setup required for this demo

-----

```

-- SQL to grant appropriate privilege to database user, SCOTT
-----
SQL> ALTER USER SCOTT ACCOUNT UNLOCK IDENTIFIED BY Pwd4Sct;
User altered.
SQL> GRANT ALL ON DBMS_AQADM TO scott;

-----
-- PLSQL to create queue-table and queue and start queue for SCOTT
-----
BEGIN
  DBMS_AQADM.CREATE_QUEUE_TABLE(
    queue_table=>'scott.test_q_tab',
    queue_payload_type=>'RAW',
    multiple_consumers=>FALSE);

  DBMS_AQADM.CREATE_QUEUE(
    queue_name=>'scott.test_q',
    queue_table=>'scott.test_q_tab');

  DBMS_AQADM.START_QUEUE(queue_name=>'scott.test_q');
END;
/

-----
-- PLSQL to stop queue and drop queue & queue-table from SCOTT
-----
BEGIN
  DBMS_AQADM.STOP_QUEUE('scott.test_q');

  DBMS_AQADM.DROP_QUEUE(
    queue_name => 'scott.test_q',
    auto_commit => TRUE);

  DBMS_AQADM.DROP_QUEUE_TABLE(
    queue_table => 'scott.test_q_tab',
    force => FALSE,
    auto_commit => TRUE);
END;
/
-- End of Part I, database setup.

//Part II: Demonstrates application notification

## OracleAQDequeueMode Enumeration

[Table 12-31](#) lists all the OracleAQDequeueMode enumeration values with a description of each enumerated value.

**Table 12-31 OracleAQDequeueMode Members**

| Member Name  | Description                                                                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Browse       | Reads the message without acquiring any lock on the message. This is equivalent to a SELECT statement.                                                  |
| Locked       | Reads and obtains a write lock on the message. The lock lasts for the duration of the transaction. This is equivalent to a SELECT FOR UPDATE statement. |
| Remove       | Reads the message and updates or deletes it. This is the default. The message can be retained in the queue table based on the retention properties      |
| RemoveNoData | Confirms receipt of the message but does not deliver the actual message content.                                                                        |

## OracleAQMessageDeliveryMode Enumeration

The OracleAQMessageDeliveryMode enumeration type specifies the delivery mode of the message.

[Table 12-32](#) lists all the OracleAQMessageDeliveryMode enumeration values with a description of each enumerated value.

**Table 12-32 OracleAQMessageDeliveryMode Members**

| Member Name          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Buffered             | <p>Indicates a buffered message.</p> <p>Both enqueue and dequeue buffered messaging operations must be in IMMEDIATE visibility mode. This means that these operations cannot be part of another transaction. You cannot specify delay when enqueueing buffered messages.</p> <p>Dequeueing applications can choose to dequeue persistent messages only, buffered messages only, or both types.</p> <p>Buffered messages can be queried using the AQ\$Queue_Table_Name view. These messages appear with states, IN-MEMORY or SPILLED.</p> <p>Transaction grouping queues and array enqueues are not supported for buffered messages in Oracle Database 11g release 1 (11.1) . One can still use the array enqueue procedure to enqueue buffered messages, but the array size must be set to 1. Array dequeue is not supported for buffered messaging, but one can still use the array dequeue procedure by setting array size to 1.</p> <p>Buffered messaging is faster than persistent messaging. Use buffered messaging for applications that do not require the reliability and transaction support of Oracle Database AQ persistent messaging.</p> |
| Persistent           | <p>Indicates a persistent message.</p> <p>Persistent messaging ensures reliability and support transactions. It is slower than buffered messaging.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PersistentOrBuffered | <p>Indicates a persistent or buffered message.</p> <p>This is used with Dequeue( ) when a consumer wants to dequeue a message irrespective of whether it is Persistent or Buffered.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |

# OracleAQMessageState Enumeration

The OracleAQMessageState enumeration type identifies the state of the message at the time of dequeue.

[Table 12-33](#) lists all the OracleAQMessageState enumeration values with a description of each enumerated value.

**Table 12-33 OracleAQMessageState Members**

| Member Name | Description                                                       |
|-------------|-------------------------------------------------------------------|
| Expired     | Indicates that the message has been moved to the exception queue. |
| Processed   | Indicates that the message has been processed and retained.       |
| Ready       | Indicates that the message is ready to be processed.              |
| Waiting     | Indicates that the message delay has not been reached.            |

## Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |

# OracleAQMessageType Enumeration

The OracleAQMessageType enumeration type specifies the message payload type.

[Table 12-34](#) lists all the OracleAQMessageType enumeration values with a description of each enumerated value.

**Table 12-34 OracleAQMessageType Members**

| Member Name | Description                                                                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Json        | Indicates the Json message type.<br>The data type of the payload must be either <code>OracleString</code> or <code>string</code> .                                                                                                                                                                                   |
| Raw         | Indicates the Raw message type (default).<br>The data type of the payload must be either <code>OracleBinary</code> or <code>byte[]</code> to enqueue the message.                                                                                                                                                    |
| Udt         | Indicates the Oracle UDT message type.<br>The ODP.NET AQ implementation currently does not support user defined types with LOB attributes. It also does not support other variants of user defined types such as VARRAY and nested tables, as Oracle Database AQ does not support them inherently.                   |
| Xml         | Indicates the XML message type.<br>The data type of the payload must be <code>OracleXmlType</code> , <code>XmlReader</code> , or <code>String</code> in order to enqueue the message. If the data type is <code>String</code> , it must be well-formed XML, else an exception is raised when enqueueing the message. |

## OracleAQNavigationMode Enumeration

[Table 12-35](#) lists all the `OracleAQNavigationMode` enumeration values with a description of each enumerated value.

**Table 12-35 OracleAQNavigationMode Members**

| Member Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FirstMessage           | Retrieves the first message that is available and matches the search criteria. This resets the position to the beginning of the queue.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FirstMessageMultiGroup | <p>Indicates that a call to DequeueArray resets the position to the beginning of the queue, and dequeues messages that are available and match the search criteria. Messages are dequeued till the dequeueCount limit is reached. The dequeued messages can belong to different transaction groups.</p> <p>You can use the OracleAQMessage.TransactionGroup property to distinguish between messages from different transaction groups. All messages from the same transaction group have the same value for the OracleAQMessage.TransactionGroup property.</p> |
| NextMessage            | Retrieves the next message that is available and matches the search criteria. If the previous message belongs to a message group, AQ retrieves the next available message that matches the search criteria and belongs to the message group.                                                                                                                                                                                                                                                                                                                    |
| NextMessageMultiGroup  | <p>Indicates that a call to DequeueArray dequeues the next set of messages that are available and match the search criteria. Messages are dequeued till the dequeueCount limit is reached. The dequeued messages can belong to different transaction groups.</p> <p>You can use the OracleAQMessage.TransactionGroup property to distinguish between messages from different transaction groups. All messages from the same transaction group have the same value for the OracleAQMessage.TransactionGroup property.</p>                                        |
| NextTransaction        | Skips the remainder of the current transaction group (if any) and retrieves the first message of the next transaction group.                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |

## OracleAQNotificationGroupingType Enumeration

The OracleAQNotificationGroupingType enumeration type specifies the notification grouping type.

[Table 12-36](#) lists all the OracleAQNotificationGroupingType enumeration values with a description of each enumerated value.

**Table 12-36 OracleAQNotificationGroupingType Members**

| Member Name | Description                                                                             |
|-------------|-----------------------------------------------------------------------------------------|
| Last        | Indicates that only details of the last message in the notification group are provided. |
| Summary     | Indicates that the Summary of all messages in the notification group is provided.       |

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## OracleAQNotificationType Enumeration

The OracleAQNotificationType enumeration type specifies the notification type of the received notification.

[Table 12-37](#) lists all the OracleAQNotificationType enumeration values with a description of each enumerated value.

**Table 12-37 OracleAQNotificationType Members**

| Member Name | Description                                                          |
|-------------|----------------------------------------------------------------------|
| Group       | Indicates that the received notification is a grouping notification. |

Table 12-37 (Cont.) OracleAQNotificationType Members

| Member Name | Description                                                          |
|-------------|----------------------------------------------------------------------|
| Regular     | Indicates that the received notification is a regular notification.  |
| Timeout     | Indicates that the received notification is raised due to a timeout. |

**Requirements**

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## OracleAQVisibilityMode Enumeration

[Table 12-38](#) lists all the OracleAQVisibilityMode enumeration values with a description of each enumerated value.

Table 12-38 OracleAQVisibilityMode Members

| Member Name | Description                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Immediate   | Indicates that the enqueue or dequeue operation is not part of the current transaction. The operation constitutes a transaction of its own. |
| OnCommit    | Indicates that the enqueue or dequeue operation is part of the current transaction. This is the default case.                               |

**Requirements**

| Provider         | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver         | ODP.NET Core                    |
|------------------|---------------------------|---------------------------------|---------------------------------|
| <b>Assembly</b>  | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| <b>Namespace</b> | Oracle.DataAccess.Client  | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## OracleTxEventQNotificationDirective Enumeration

The OracleTxEventQNotificationDirective enumeration type specifies the TxEventQ notification's acknowledgement directive value.

[Table 12-39](#) lists all the OracleTxEventQNotificationDirective enumeration values with a description of each enumerated value.

**Table 12-39 OracleTxEventQNotificationDirective Members**

| Member Name | Description                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Commit      | A Commit acknowledgement indicates this message and all prior enqueued messages that are associated with the Acknowledgement_waiting state will have their state value set to Processed. |
| Rollback    | A Rollback acknowledgement indicates this message and all prior enqueued messages that are associated with the Acknowledgement_waiting state will have their state value reset to Ready. |

#### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

# Oracle Data Provider for .NET Types Classes

This chapter describes the large object and REF CURSOR objects provided by Oracle Data Provider for .NET.

This chapter contains these topics:

- ODP.NET Types (ODP.NET LOB objects) consisting of these object classes:
  - [OracleBFile Class](#)
  - [OracleBlob Class](#)
  - [OracleClob Class](#)
- [OracleRefCursor Class](#)

All offsets are 0-based for all ODP.NET LOB object parameters.

## OracleBFile Class

An OracleBFile is an object that has a reference to BFILE data. It provides methods for performing operations on BFILES.

 **Note**

OracleBFile is supported for applications running against Oracle8.x and later.

### Class Inheritance

System.Object  
System.MarshalByRefObject  
System.IO.Stream  
Oracle.DataAccess.Types.OracleBFile

### Declaration

```
// C#  
public sealed class OracleBFile : Stream, ICloneable, INullable
```

### Requirements

| Provider  | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------|---------------------------------|---------------------------------|
| Assembly  | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.DataAccess.Client  | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

OracleBFile is supported for applications running against Oracle8.x and later.

### Example

```
// Database Setup, if you have not done so yet.
/* Log on as DBA (SYS or SYSTEM) that has CREATE ANY DIRECTORY privilege.

CREATE OR REPLACE DIRECTORY MYDIR AS 'C:\TEMP';

*/

// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class OracleBFileSample
{
    static void Main()
    {
        // Create MYDIR directory object as indicated previously and create a file
        // MyFile.txt with the text ABCDABC under C:\TEMP directory.
        // Note that the byte representation of the ABCDABC is 65666768656667

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBFile bFile = new OracleBFile(con, "MYDIR", "MyFile.txt");

        // Open the OracleBFile
        bFile.OpenFile();

        // Read 7 bytes into readBuffer, starting at buffer offset 0
        byte[] readBuffer = new byte[7];
        int bytesRead = bFile.Read(readBuffer, 0, 7);

        // Prints "bytesRead = 7"
        Console.WriteLine("bytesRead = " + bytesRead);

        // Prints "readBuffer = 65666768656667"
        Console.Write("readBuffer = ");
        for(int index = 0; index < readBuffer.Length; index++)
        {
```

```
        Console.Write(readBuffer[index]);
    }
    Console.WriteLine();

    // Search for the 2nd occurrence of a byte pattern {66,67}
    // starting from byte offset 1 in the OracleBFile
    byte[] pattern = new byte[2] {66, 67};
    long posFound = bFile.Search(pattern, 1, 2);

    // Prints "posFound    = 6"
    Console.WriteLine("posFound    = " + posFound);

    // Close the OracleBFile
    bFile.CloseFile();

    bFile.Close();
    bFile.Dispose();

    con.Close();
    con.Dispose();
}
}
```

## OracleBFile Members

OracleBFile members are listed in the following tables.

### OracleBFile Constructors

OracleBFile constructors are listed in [Table 13-1](#).

**Table 13-1 OracleBFile Constructors**

| Constructor                              | Description                                               |
|------------------------------------------|-----------------------------------------------------------|
| <a href="#">OracleBFile Constructors</a> | Creates an instance of the OracleBFile class (Overloaded) |

### OracleBFile Static Fields

OracleBFile static fields are listed in [Table 13-2](#).

**Table 13-2 OracleBFile Static Fields**

| Field                   | Description                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxSize</a> | The static field holds the maximum number of bytes a BFILE can hold, which is 4,294,967,295 ( $2^{32} - 1$ ) bytes |
| <a href="#">Null</a>    | Represents a null value that can be assigned to the value of an OracleBFile instance                               |

**OracleBFile Static Methods**

OracleBFile static methods are listed in [Table 13-3](#).

**Table 13-3 OracleBFile Static Methods**

| Methods                | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

**OracleBFile Instance Properties**

OracleBFile instance properties are listed in [Table 13-4](#).

**Table 13-4 OracleBFile Instance Properties**

| Properties                    | Description                                                                    |
|-------------------------------|--------------------------------------------------------------------------------|
| <a href="#">CanRead</a>       | Indicates whether or not the LOB stream can be read                            |
| <a href="#">CanSeek</a>       | Indicates whether or not forward and backward seek operations can be performed |
| <a href="#">CanWrite</a>      | Indicates whether or not the LOB object supports writing                       |
| <a href="#">Connection</a>    | Indicates the connection used to read from a BFILE                             |
| <a href="#">DirectoryName</a> | Indicates the directory alias of the BFILE                                     |
| <a href="#">FileExists</a>    | Indicates whether or not the specified BFILE exists                            |
| <a href="#">FileName</a>      | Indicates the name of the BFILE                                                |
| <a href="#">IsEmpty</a>       | Indicates whether the BFILE is empty or not                                    |
| <a href="#">IsNull</a>        | Indicates whether or not the current instance has a null value                 |
| <a href="#">IsOpen</a>        | Indicates whether the BFILE has been opened by this instance or not            |
| <a href="#">Length</a>        | Indicates the size of the BFILE data in bytes                                  |
| <a href="#">Position</a>      | Indicates the current read position in the LOB stream                          |
| <a href="#">Value</a>         | Returns the data, starting from the first byte in BFILE, as a byte array       |

**OracleBFile Instance Methods**

OracleBFile instance methods are listed in [Table 13-5](#).

Table 13-5 OracleBFile Instance Methods

| Methods                     | Description                                                                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BeginRead                   | Inherited from System.IO.Stream                                                                                                                                              |
| BeginWrite                  | <i>Not Supported</i>                                                                                                                                                         |
| <a href="#">Clone</a>       | Creates a copy of an OracleBFile object                                                                                                                                      |
| <a href="#">Close</a>       | Closes the current stream and releases any resources associated with the stream                                                                                              |
| <a href="#">CloseFile</a>   | Closes the BFILE referenced by the current BFILE instance                                                                                                                    |
| <a href="#">Compare</a>     | Compares data referenced by the two OracleBFiles                                                                                                                             |
| CreateObjRef                | Inherited from System.MarshalByRefObject                                                                                                                                     |
| <a href="#">CopyTo</a>      | Copies data as specified (Overloaded)                                                                                                                                        |
| <a href="#">CopyToAsync</a> | Returns a Task-based asynchronous version of OracleBFile.CopyTo(), which copies data from the current instance to the provided object. (Overloaded)                          |
| <a href="#">Dispose</a>     | Releases resources allocated by this object                                                                                                                                  |
| EndRead                     | Inherited from System.IO.Stream                                                                                                                                              |
| EndWrite                    | <i>Not Supported</i>                                                                                                                                                         |
| Equals                      | Inherited from System.Object (Overloaded)                                                                                                                                    |
| <a href="#">Flush</a>       | <i>Not Supported</i>                                                                                                                                                         |
| <a href="#">FlushAsync</a>  | <i>Not Supported</i>                                                                                                                                                         |
| GetHashCode                 | Inherited from System.Object                                                                                                                                                 |
| GetLifetimeService          | Inherited from System.MarshalByRefObject                                                                                                                                     |
| GetType                     | Inherited from System.Object                                                                                                                                                 |
| InitializeLifetimeService   | Inherited from System.MarshalByRefObject                                                                                                                                     |
| <a href="#">IsEqual</a>     | Compares the LOB references                                                                                                                                                  |
| <a href="#">OpenFile</a>    | Opens the BFILE specified by the FileName and DirectoryName                                                                                                                  |
| <a href="#">Read</a>        | Reads a specified amount of bytes from the OracleBFile instance and populates the buffer                                                                                     |
| <a href="#">ReadAsync</a>   | Returns a Task-based asynchronous version of OracleBFile.Read(), which reads a specified number of bytes from the OracleBFile instance and populates the buffer (Overloaded) |
| ReadByte                    | Inherited from System.IO.Stream                                                                                                                                              |
| <a href="#">Search</a>      | Searches for a binary pattern in the current instance of an OracleBFile                                                                                                      |
| <a href="#">Seek</a>        | Sets the position on the current LOB stream                                                                                                                                  |
| <a href="#">SetLength</a>   | <i>Not Supported</i>                                                                                                                                                         |
| ToString                    | Inherited from System.Object                                                                                                                                                 |
| <a href="#">Write</a>       | <i>Not Supported</i>                                                                                                                                                         |
| WriteByte                   | <i>Not Supported</i>                                                                                                                                                         |

## OracleBFile Constructors

OracleBFile constructors create new instances of the OracleBFile class.

### Overload List:

- [OracleBFile\(OracleConnection\)](#)

This constructor creates an instance of the OracleBFile class with an OracleConnection object.

- [OracleBFile\(OracleConnection, string, string\)](#)

This constructor creates an instance of the OracleBFile class with an OracleConnection object, the location of the BFILE, and the name of the BFILE.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## OracleBFile(OracleConnection)

This constructor creates an instance of the OracleBFile class with an OracleConnection object.

### Declaration

```
// C#  
public OracleBFile(OracleConnection con);
```

### Parameters

- *con*

The OracleConnection object.

### Exceptions

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

The connection must be opened explicitly by the application. OracleBFile does not open the connection implicitly.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## OracleBFile(OracleConnection, string, string)

This constructor creates an instance of the `OracleBFile` class with an `OracleConnection` object, the location of the BFILE, and the name of the BFILE.

### Declaration

```
// C#  
public OracleBFile(OracleConnection con, string directoryName, string  
    fileName);
```

### Parameters

- *con*  
The `OracleConnection` object.
- *directoryName*  
The directory alias created by the `CREATE DIRECTORY` SQL statement.
- *fileName*  
The name of the external LOB.

### Exceptions

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

### Remarks

The `OracleConnection` must be opened explicitly by the application. `OracleBFile` does not open the connection implicitly.

To initialize a BFILE column using an `OracleBFile` instance as an input parameter of a SQL INSERT statement, *directoryName* and *fileName* must be properly set.

## OracleBFile Static Fields

OracleBFile static fields are listed in [Table 13-6](#).

**Table 13-6 OracleBFile Static Fields**

| Field                   | Description                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxSize</a> | The static field holds the maximum number of bytes a BFILE can hold, which is 4,294,967,295 ( $2^{32} - 1$ ) bytes |
| <a href="#">Null</a>    | Represents a null value that can be assigned to the value of an OracleBFile instance                               |

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## MaxSize

This static field holds the maximum number of bytes a BFILE can hold, which is 4,294,967,295 ( $2^{32} - 1$ ) bytes.

### Declaration

```
// C#  
public static readonly Int64 MaxSize = 4294967295;
```

### Remarks

This field is useful in code that checks whether or not the operation exceeds the maximum length allowed.

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Null

This static field represents a null value that can be assigned to the value of an OracleBFile instance.

## Declaration

```
// C#  
public static readonly OracleBFile Null;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## OracleBFile Static Methods

OracleBFile static methods are listed in [Table 13-7](#).

**Table 13-7 OracleBFile Static Methods**

| Methods                | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## OracleBFile Instance Properties

OracleBFile instance properties are listed in [Table 13-8](#).

**Table 13-8 OracleBFile Instance Properties**

| Properties                    | Description                                                                    |
|-------------------------------|--------------------------------------------------------------------------------|
| <a href="#">CanRead</a>       | Indicates whether or not the LOB stream can be read                            |
| <a href="#">CanSeek</a>       | Indicates whether or not forward and backward seek operations can be performed |
| <a href="#">CanWrite</a>      | Indicates whether or not the LOB object supports writing                       |
| <a href="#">Connection</a>    | Indicates the connection used to read from a BFILE                             |
| <a href="#">DirectoryName</a> | Indicates the directory alias of the BFILE                                     |
| <a href="#">FileExists</a>    | Indicates whether or not the specified BFILE exists                            |
| <a href="#">FileName</a>      | Indicates the name of the BFILE                                                |
| <a href="#">IsEmpty</a>       | Indicates whether the BFILE is empty or not                                    |

**Table 13-8 (Cont.) OracleBFile Instance Properties**

| Properties               | Description                                                              |
|--------------------------|--------------------------------------------------------------------------|
| <a href="#">IsNull</a>   | Indicates whether or not the current instance has a null value           |
| <a href="#">IsOpen</a>   | Indicates whether the BFILE has been opened by this instance or not      |
| <a href="#">Length</a>   | Indicates the size of the BFILE data in bytes                            |
| <a href="#">Position</a> | Indicates the current read position in the LOB stream                    |
| <a href="#">Value</a>    | Returns the data, starting from the first byte in BFILE, as a byte array |

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## CanRead

Overrides Stream

This instance property indicates whether or not the LOB stream can be read.

**Declaration**

```
// C#  
public override bool CanRead{get;}
```

**Property Value**

If the LOB stream can be read, returns true; otherwise, returns false.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## CanSeek

Overrides Stream

This instance property indicates whether or not forward and backward seek operations can be performed.

**Declaration**

```
// C#  
public override bool CanSeek{get;}
```

**Property Value**

If forward and backward seek operations can be performed, returns true; otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## CanWrite

Overrides Stream

This instance property indicates whether or not the LOB object supports writing.

**Declaration**

```
// C#  
public override bool CanWrite{get;}
```

**Property Value**

BFILE is read only.

**Remarks**

BFILE is read-only, therefore, the boolean value is always false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Connection

This instance property indicates the connection used to read from a BFILE.

**Declaration**

```
// C#  
public OracleConnection Connection {get;}
```

**Property Value**

An object of `OracleConnection`.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## DirectoryName

This instance property indicates the directory alias of the BFILE.

**Declaration**

```
// C#  
public string DirectoryName {get;set;}
```

**Property Value**

A string.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The value of the `DirectoryName` changed while the BFILE is open.

**Remarks**

The maximum length of a `DirectoryName` is 30 bytes.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## FileExists

This instance property indicates whether or not the BFILE specified by the `DirectoryName` and `FileName` exists.

**Declaration**

```
// C#  
public bool FileExists {get;}
```

**Property Value**

bool

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

Unless a connection, file name, and directory name are provided, this property is set to false by default.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## FileName

This instance property indicates the name of the BFILE.

**Declaration**

```
// C#  
public string FileName {get;set}
```

**Property Value**

A string that contains the BFILE name.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The value of the DirectoryName changed while the BFILE is open.

**Remarks**

The maximum length of a FileName is 255 bytes.

Changing the FileName property while the BFILE object is opened causes an exception.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## IsEmpty

This instance property indicates whether the BFILE is empty or not.

### Declaration

```
// C#  
public bool IsEmpty {get;}
```

### Property Value

bool

### Exceptions

ObjectDisposedException - The object is already disposed.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

### Declaration

```
// C#  
public bool IsNull{get;}
```

### Property Value

Returns true if the current instance has a null value; otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## IsOpen

This instance property indicates whether the BFILE has been opened by this instance or not.

**Declaration**

```
// C#  
public bool IsOpen {get;}
```

**Property Value**

A bool.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Length

Overrides Stream

This instance property indicates the size of the BFILE data in bytes.

**Declaration**

```
// C#  
public override Int64 Length {get;}
```

**Property Value**

Int64

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Position

Overrides Stream

This instance property indicates the current read position in the LOB stream.

### Declaration

```
// C#  
public override Int64 Position{get; set;}
```

### Property Value

An Int64 value that indicates the read position.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The value is less than 0.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Value

This instance property returns the data, starting from the first byte in BFILE, as a byte array.

### Declaration

```
// C#  
public byte[] Value{get;}
```

### Property Value

A byte array.

## Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

## Remarks

The length of data is bound by the maximum length of the byte array. The current value of the Position property is not used or changed.

For very large values, .NET may not be able to allocate enough contiguous memory to store all the data. Typically, you will see a System.OverflowException or System.OutOfMemoryException error then. To retrieve the large value, you can retrieve the data in chunks by calling GetChars() or GetBytes() method on the OracleDataReader. You can also call Read() method on the class.

## OracleBFile Instance Methods

OracleBFile instance methods are listed in [Table 13-9](#).

**Table 13-9 OracleBFile Instance Methods**

| Methods                     | Description                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| BeginRead                   | Inherited from System.IO.Stream                                                                                                                     |
| BeginWrite                  | <i>Not Supported</i>                                                                                                                                |
| <a href="#">Clone</a>       | Creates a copy of an OracleBFile object                                                                                                             |
| <a href="#">Close</a>       | Closes the current stream and releases any resources associated with the stream                                                                     |
| <a href="#">CloseFile</a>   | Closes the BFILE referenced by the current BFILE instance                                                                                           |
| <a href="#">Compare</a>     | Compares data referenced by the two OracleBFiles                                                                                                    |
| CreateObjRef                | Inherited from System.MarshalByRefObject                                                                                                            |
| <a href="#">CopyTo</a>      | Copies data as specified (Overloaded)                                                                                                               |
| <a href="#">CopyToAsync</a> | Returns a Task-based asynchronous version of OracleBFile.CopyTo(), which copies data from the current instance to the provided object. (Overloaded) |
| <a href="#">Dispose</a>     | Releases resources allocated by this object                                                                                                         |
| EndRead                     | Inherited from System.IO.Stream                                                                                                                     |
| EndWrite                    | <i>Not Supported</i>                                                                                                                                |

Table 13-9 (Cont.) OracleBFile Instance Methods

| Methods                    | Description                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Equals                     | Inherited from System.Object (Overloaded)                                                                                                                                    |
| <a href="#">Flush</a>      | <i>Not Supported</i>                                                                                                                                                         |
| <a href="#">FlushAsync</a> | <i>Not Supported</i>                                                                                                                                                         |
| GetHashCode                | Inherited from System.Object                                                                                                                                                 |
| GetLifetimeService         | Inherited from System.MarshalByRefObject                                                                                                                                     |
| GetType                    | Inherited from System.Object                                                                                                                                                 |
| InitializeLifetimeService  | Inherited from System.MarshalByRefObject                                                                                                                                     |
| <a href="#">IsEqual</a>    | Compares the LOB references                                                                                                                                                  |
| <a href="#">OpenFile</a>   | Opens the BFILE specified by the FileName and DirectoryName                                                                                                                  |
| <a href="#">Read</a>       | Reads a specified amount of bytes from the OracleBFile instance and populates the buffer                                                                                     |
| <a href="#">ReadAsync</a>  | Returns a Task-based asynchronous version of OracleBFile.Read(), which reads a specified number of bytes from the OracleBFile instance and populates the buffer (Overloaded) |
| ReadByte                   | Inherited from System.IO.Stream                                                                                                                                              |
| <a href="#">Search</a>     | Searches for a binary pattern in the current instance of an OracleBFile                                                                                                      |
| <a href="#">Seek</a>       | Sets the position on the current LOB stream                                                                                                                                  |
| <a href="#">SetLength</a>  | <i>Not Supported</i>                                                                                                                                                         |
| ToString                   | Inherited from System.Object                                                                                                                                                 |
| <a href="#">Write</a>      | <i>Not Supported</i>                                                                                                                                                         |
| WriteByte                  | <i>Not Supported</i>                                                                                                                                                         |

## Clone

This instance method creates a copy of an OracleBFile object.

#### Declaration

```
// C#
public object Clone();
```

### Return Value

An OracleBFile object.

### Implements

ICloneable

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

The cloned object has the same property values as that of the object being cloned.

### Example

```
// Database Setup, if you have not done so yet.
/* Log on as DBA (SYS or SYSTEM) that has CREATE ANY DIRECTORY privilege.

CREATE OR REPLACE DIRECTORY MYDIR AS 'C:\TEMP';

*/

// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class CloneSample
{
    static void Main()
    {
        // Create MYDIR directory object as indicated above and create a file
        // MyFile.txt with the text ABCDABC under C:\TEMP directory.
        // Note that the byte representation of the ABCDABC is 65666768656667

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBFile bFile1 = new OracleBFile(con, "MYDIR", "MyFile.txt");

        // Open the OracleBFile
        bFile1.OpenFile();

        // Prints "bFile1.Position = 0"
        Console.WriteLine("bFile1.Position = " + bFile1.Position);

        // Set the Position before calling Clone()
        bFile1.Position = 1;

        // Clone the OracleBFile
        OracleBFile bFile2 = (OracleBFile) bFile1.Clone();

        // Open the OracleBFile
```

```
bFile2.OpenFile();

// Prints "bFile2.Position = 1"
Console.WriteLine("bFile2.Position = " + bFile2.Position);

// Close the OracleBFile
bFile1.CloseFile();

bFile1.Close();
bFile1.Dispose();

// Close the Cloned OracleBFile
bFile2.CloseFile();

bFile2.Close();
bFile2.Dispose();

con.Close();
con.Dispose();
}
}
```

- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Close

Overrides Stream

This instance method closes the current stream and releases any resources associated with it.

#### Declaration

```
// C#
public override void Close();
```

#### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## CloseFile

This instance method closes the BFILE referenced by the current BFILE instance.

### Declaration

```
// C#  
public void CloseFile();
```

### Remarks

No error is returned if the BFILE exists, but is not opened.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Compare

This instance method compares data referenced by the two OracleBFiles.

### Declaration

```
// C#  
public int Compare(Int64 src_offset, OracleBFile obj, Int64 dst_offset,  
    Int64 amount);
```

### Parameters

- *src\_offset*  
The offset of the current instance.
- *obj*  
The provided OracleBFile object.
- *dst\_offset*  
The offset of the OracleBFile object.
- *amount*  
The number of bytes to compare.

### Return Value

Returns a number that is:

- Less than zero: if the BFILE data of the current instance is less than that of the provided BFILE data.
- Zero: if both the BFILES store the same data.

- Greater than zero: if the BFILE data of the current instance is greater than that of the provided BFILE data.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - The `src_offset`, the `dst_offset`, or the `amount` is less than 0.

### Remarks

The provided object and the current instance must be using the same connection, that is, the same `OracleConnection` object.

The BFILE needs to be opened using `OpenFile` before the operation.

### Example

```
// Database Setup, if you have not done so yet.
/* Log on as DBA (SYS or SYSTEM) that has CREATE ANY DIRECTORY privilege.

CREATE OR REPLACE DIRECTORY MYDIR AS 'C:\TEMP';

*/

// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class CompareSample
{
    static void Main()
    {
        // Create MYDIR directory object as indicated previously and create a file
        // MyFile.txt with the text ABCDABC under C:\TEMP directory.
        // Note that the byte representation of the ABCDABC is 65666768656667

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBFile bFile1 = new OracleBFile(con, "MYDIR", "MyFile.txt");
        OracleBFile bFile2 = new OracleBFile(con, "MYDIR", "MyFile.txt");

        // Open the OracleBFiles
        bFile1.OpenFile();
        bFile2.OpenFile();

        // Compare 2 bytes from the 1st byte of bFile1 and
        // the 5th byte of bFile2 onwards
        int result = bFile1.Compare(1, bFile2, 5, 2);

        // Prints "result = 0" (Indicates the data is identical)
        Console.WriteLine("result = " + result);

        // Close the OracleBFiles
```

```
bFile1.CloseFile();  
bFile2.CloseFile();  
  
bFile1.Close();  
bFile1.Dispose();  
  
bFile2.Close();  
bFile2.Dispose();  
  
con.Close();  
con.Dispose();  
}  
}
```

## CopyTo

CopyTo copies data from the current instance to the provided object.

#### Overload List:

- [CopyTo\(OracleBlob\)](#)  
This instance method copies data from the current instance to the provided OracleBlob object.
- [CopyTo\(OracleBlob, Int64\)](#)  
This instance method copies data from the current OracleBFile instance to the provided OracleBlob object with the specified destination offset.
- [CopyTo\(Int64, OracleBlob, Int64, Int64\)](#)  
This instance method copies data from the current OracleBFile instance to the provided OracleBlob object with the specified source offset, destination offset, and character amounts.
- [CopyTo\(OracleClob\)](#)  
This instance method copies data from the current OracleBFile instance to the provided OracleClob object.
- [CopyTo\(OracleClob, Int64\)](#)  
This instance method copies data from the current OracleBFile instance to the provided OracleClob object with the specified destination offset.
- [CopyTo\(Int64, OracleClob, Int64, Int64\)](#)  
This instance method copies data from the current OracleBFile instance to the provided OracleClob object with the specified source offset, destination offset, and amount of characters.

**① See Also**

- [OracleBFile Members](#)

## CopyTo(OracleBlob)

This instance method copies data from the current instance to the provided `OracleBlob` object.

**Declaration**

```
// C#  
public Int64 CopyTo(OracleBlob obj);
```

**Parameters**

- *obj*

The `OracleBlob` object to which the data is copied.

**Return Value**

The return value is the amount copied.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - This exception is thrown if any of the following conditions exist:

- The `OracleConnection` is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

**Remarks**

The provided object and the current instance must be using the same connection; that is, the same `OracleConnection` object.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## CopyTo(OracleBlob, Int64)

This instance method copies data from the current `OracleBFile` instance to the provided `OracleBlob` object with the specified destination offset.

**Declaration**

```
// C#  
public Int64 CopyTo(OracleBlob obj, Int64 dst_offset);
```

**Parameters**

- *obj*  
The OracleBlob object to which the data is copied.
- *dst\_offset*  
The offset (in bytes) at which the OracleBlob object is copied.

**Return Value**

The return value is the amount copied.

**Exceptions**

ObjectDisposedException - The object is already disposed.

ArgumentOutOfRangeException - The *dst\_offset* is less than 0.

InvalidOperationException - This exception is thrown if any of the following conditions exist:

- The OracleConnection is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

**Remarks**

If the *dst\_offset* is beyond the end of the OracleBlob data, spaces are written into the OracleBlob until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection; that is, the same OracleConnection object.

## CopyTo(Int64, OracleBlob, Int64, Int64)

This instance method copies data from the current OracleBFile instance to the provided OracleBlob object with the specified source offset, destination offset, and character amounts.

**Declaration**

```
// C#  
public Int64 CopyTo(Int64 src_offset, OracleBlob obj, Int64 dst_offset,  
    Int64 amount);
```

### Parameters

- *src\_offset*  
The offset (in bytes) in the current instance, from which the data is read.
- *obj*  
An OracleBlob object to which the data is copied.
- *dst\_offset*  
The offset (in bytes) to which the OracleBlob object is copied.
- *amount*  
The amount of data to be copied.

### Return Value

The return value is the amount copied.

### Exceptions

ObjectDisposedException - The object is already disposed.

ArgumentOutOfRangeException - The *src\_offset*, the *dst\_offset*, or the *amount* is less than 0.

InvalidOperationException - This exception is thrown if any of the following conditions exist:

- The OracleConnection is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

### Remarks

If the *dst\_offset* is beyond the end of the OracleBlob data, spaces are written into the OracleBlob until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection; that is, the same OracleConnection object.

## CopyTo(OracleClob)

This instance method copies data from the current OracleBFile instance to the provided OracleClob object.

**Declaration**

```
// C#  
public Int64 CopyTo(OracleClob obj);
```

**Parameters**

- *obj*

The OracleClob object to which the data is copied.

**Return Value**

The return value is the amount copied.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - This exception is thrown if any of the following conditions exist:

- The OracleConnection is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

**Remarks**

The provided object and the current instance must be using the same connection, that is, the same OracleConnection object.

## CopyTo(OracleClob, Int64)

This instance method copies data from the current OracleBFile instance to the provided OracleClob object with the specified destination offset.

**Declaration**

```
// C#  
public Int64 CopyTo(OracleClob obj, Int64 dst_offset);
```

**Parameters**

- *obj*

The OracleClob object that the data is copied to.

- *dst\_offset*

The offset (in characters) at which the OracleClob object is copied to.

**Return Value**

The amount copied.

**Exceptions****Exceptions**

ObjectDisposedException - The object is already disposed.

ArgumentOutOfRangeException - The *dst\_offset* is less than 0.

InvalidOperationException - This exception is thrown if any of the following conditions exist:

- The OracleConnection is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

**Remarks**

If the *dst\_offset* is beyond the end of the OracleClob data, spaces are written into the OracleClob until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection, that is, the same OracleConnection object.

## CopyTo(Int64, OracleClob, Int64, Int64)

This instance method copies data from the current OracleBFile instance to the provided OracleClob object with the specified source offset, destination offset, and amount of characters.

**Declaration**

```
// C#  
public Int64 CopyTo(Int64 src_offset, OracleClob obj, Int64 dst_offset,  
    Int64 amount);
```

**Parameters**

- *src\_offset*  
The offset (in characters) in the current instance, from which the data is read.
- *obj*  
An OracleClob object that the data is copied to.
- *dst\_offset*

The offset (in characters) at which the `OracleClob` object is copied to.

- *amount*

The amount of data to be copied.

### Return Value

The return value is the amount copied.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* is less than 0.

`InvalidOperationException` - This exception is thrown if any of the following conditions exist:

- The `OracleConnection` is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

### Remarks

If the *dst\_offset* is beyond the end of the current `OracleClob` data, spaces are written into the `OracleClob` until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection, that is, the same `OracleConnection` object.

## CopyToAsync

`CopyToAsync` returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Overload List:

- [CopyToAsync\(Int64, OracleBlob, Int64, Int64\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(Int64, OracleBlob, Int64, Int64, CancellationToken\)](#)

`CopyToAsync` returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleBlob, Int64\)](#)

CopyToAsync returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleBlob, Int64, CancellationToken\)](#)

CopyToAsync returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleBlob\)](#)

CopyToAsync returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleBlob, CancellationToken\)](#)

CopyToAsync returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(Int64, OracleClob, Int64, Int64\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(Int64, OracleClob, Int64, Int64, CancellationToken\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleClob, Int64\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleClob, Int64, CancellationToken\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleClob\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

- [CopyToAsync\(OracleClob, CancellationToken\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Example (includes all overloads)

```
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";

            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(Cancellation_token.None);
        }
    }
}
```

```
OracleCommand cmd = oc.CreateCommand();
cmd.CommandText = " select bfile_column from tab1";

OracleBlob blob1 = new OracleBlob(oc);
OracleBlob blob2 = new OracleBlob(oc);
OracleBlob blob3 = new OracleBlob(oc);
OracleBlob blob4 = new OracleBlob(oc);
OracleBlob blob5 = new OracleBlob(oc);
OracleBlob blob6 = new OracleBlob(oc);

OracleClob clob1 = new OracleClob(oc);
OracleClob clob2 = new OracleClob(oc);
OracleClob clob3 = new OracleClob(oc);
OracleClob clob4 = new OracleClob(oc);
OracleClob clob5 = new OracleClob(oc);
OracleClob clob6 = new OracleClob(oc);

OracleDataReader reader = await cmd.ExecuteReaderAsync();

await reader.ReadAsync(CancellationToken.None);
using (OracleBFile bfile = reader.GetOracleBFile(0))
{
    //asynchronously copy bfile data
    Int64 bytesCopied1 = await bfile.CopyToAsync(0, blob1, 0, bfile.Length);
    Console.WriteLine("bytes copied to blob1 = " + bytesCopied1);

    //asynchronously copy bfile data
    Int64 bytesCopied2 = await bfile.CopyToAsync(0, blob2, 0, bfile.Length,
CancellationTokentoken.None);
    Console.WriteLine("bytes copied to blob2 = " + bytesCopied2);

    //asynchronously copy bfile data
    Int64 bytesCopied3 = await bfile.CopyToAsync(blob3, 0);
    Console.WriteLine("bytes copied to blob3 = " + bytesCopied3);

    //asynchronously copy bfile data
    Int64 bytesCopied4 = await bfile.CopyToAsync(blob4, 0, CancellationToken.None);
    Console.WriteLine("bytes copied to blob4 = " + bytesCopied4);

    //asynchronously copy bfile data
    Int64 bytesCopied5 = await bfile.CopyToAsync(blob5);
    Console.WriteLine("bytes copied to blob5 = " + bytesCopied5);

    //asynchronously copy bfile data
    Int64 bytesCopied6 = await bfile.CopyToAsync(blob6, CancellationToken.None);
    Console.WriteLine("bytes copied to blob6 = " + bytesCopied6);

    //asynchronously copy bfile data
    bytesCopied1 = await bfile.CopyToAsync(0, clob1, 0, bfile.Length);
    Console.WriteLine("bytes copied to clob1 = " + bytesCopied1);

    //asynchronously copy bfile data
    bytesCopied2 = await bfile.CopyToAsync(0, clob2, 0, bfile.Length,
CancellationTokentoken.None);
    Console.WriteLine("bytes copied to clob2 = " + bytesCopied2);

    //asynchronously copy bfile data
    bytesCopied3 = await bfile.CopyToAsync(clob3, 0);
    Console.WriteLine("bytes copied to clob3 = " + bytesCopied3);

    //asynchronously copy bfile data
```

```
bytesCopied4 = await bfile.CopyToAsync(clob4, 0, CancellationToken.None);

## CopyToAsync(Int64, OracleBlob, Int64, Int64)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Declaration

```
// C#
public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64 dst_offset, Int64
amount)
```

### Parameters

- `src_offset` - The offset (in bytes) in the current instance, from which the data is read.
- `obj` - The `OracleBlob` object to which the data is copied.
- `dst_offset` - The offset (in bytes) at which the `OracleBlob` object is copied.
- `amount` - The amount of data to be copied.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The parameter has a different connection than the object, `OracleConnection` is not opened, or `OracleConnection` has been reopened.
- `ArgumentOutOfRangeException` - The `src_offset`, the `dst_offset`, or the amount parameter is less than 0.

## CopyToAsync(Int64, OracleBlob, Int64, Int64, CancellationToken)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

**Declaration**

```
// C#
public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64 dst_offset, Int64
amount, CancellationToken cancellationToken)
```

**Parameters**

- `src_offset` - The offset (in bytes) in the current instance, from which the data is read.
- `obj` - The `OracleBlob` object to which the data is copied.
- `dst_offset` - The offset (in bytes) at which the `OracleBlob` object is copied.
- `amount` - The amount of data to be copied.
- `cancellationToken` - The input cancellation token which can be used by the application to cancel the task.

**Return Value**

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Exceptions**

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `src_offset`, the `dst_offset`, or the amount parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleBlob, Int64)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Declaration

```
// C#  
public async Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset)
```

### Parameters

- `obj` - The `OracleBlob` object to which the data is copied.
- `dst_offset` - The offset (in bytes) at which the `OracleBlob` object is copied.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `dst_offset` parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleBlob, Int64, CancellationToken)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Declaration

```
// C#  
public async Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset, CancellationToken  
cancellation_token)
```

### Parameters

- `obj` - The `OracleBlob` object to which the data is copied.
- `dst_offset` - The offset (in bytes) at which the `OracleBlob` object is copied.

- `cancellationToken` - The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `dst_offset` is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(Int64, OracleClob, Int64, Int64)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Declaration

```
// C#  
public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64 dst_offset, Int64  
amount)
```

### Parameters

- `src_offset` - The offset (in characters) in the current instance, from which the data is read.
- `obj` - The `OracleClob` object to which the data is copied.
- `dst_offset` - The offset (in characters) at which the `OracleClob` object is copied.
- `amount` - The amount of data to be copied.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `src_offset`, the `dst_offset`, or the `amount` parameter is less than 0.
- `InvalidOperationException` - The parameter has a different connection than the object, `OracleConnection` is not opened, or `OracleConnection` has been reopened.

## CopyToAsync(Int64, OracleClob, Int64, Int64, CancellationToken)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Declaration

```
// C#  
public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64 dst_offset, Int64  
amount, CancellationToken cancellationToken)
```

### Parameters

- `src_offset` - The offset (in characters) in the current instance, from which the data is read.
- `obj` - The `OracleClob` object to which the data is copied.
- `dst_offset` - The offset (in characters) at which the `OracleClob` object is copied.

- `amount` - The amount of data to be copied.
- `cancellationToken` - The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `src_offset`, the `dst_offset`, or the `amount` parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The `LOB` object parameter has a different connection than the object.

## CopyToAsync(OracleClob, Int64, CancellationToken)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

### Declaration

```
// C#
public async Task<Int64> CopyToAsync(OracleClob obj, Int64 dst_offset, CancellationToken
cancellation_token)
```

### Parameters

- `obj` - The `OracleClob` object to which the data is copied.
- `dst_offset` - The offset (in characters) at which the `OracleClob` object is copied.
- `cancellation_token` - The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `dst_offset` is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleClob)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

**Declaration**

```
// C#  
public async Task<Int64> CopyToAsync(OracleClob obj)
```

**Parameters**

- `obj` - The `OracleClob` object to which the data is copied.

**Return Value**

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Exceptions**

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleClob, CancellationToken)

This method returns a Task-based asynchronous version of `OracleBFile.CopyTo()`, which copies data from the current instance to the provided object.

**Declaration**

```
// C#  
public async Task<Int64> CopyToAsync(OracleClob obj, CancellationToken cancellationToken)
```

### Parameters

- `obj` - The `OracleClob` object to which the data is copied.
- `cancellationToken` - The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBFile Class](#)
- [OracleBFile Members](#)

## Dispose

This instance method releases resources allocated by this object.

### Declaration

```
// C#  
public void Dispose();
```

### Implements

`IDisposable`

### Remarks

Although some properties can still be accessed, their values may not be accountable. Since resources are freed, method calls may lead to exceptions. The object cannot be reused after being disposed.

### ① See Also

- [OracleBFile Class](#)
- [OracleBFile Members](#)

## IsEqual

This instance method compares the LOB references.

### Declaration

```
// C#  
public bool IsEqual(OracleBFile obj);
```

### Parameters

- *obj*  
The provided OracleBFile object.

### Return Value

Returns true if the current OracleBFile and the provided OracleBFile object refer to the same external LOB. Returns false otherwise.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

Note that this method can return true even if the two OracleBFile objects return false for `==` or `Equals()` since two different OracleBFile instances can refer to the same external LOB.

The provided object and the current instance must be using the same connection; that is, the same OracleConnection object.

## OpenFile

This instance method opens the BFILE specified by the FileName and DirectoryName.

### Declaration

```
// C#  
public void OpenFile();
```

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

Many operations, such as `Compare()`, `CopyTo()`, `Read()`, and `Search()` require that the BFILE be opened using `OpenFile` before the operation.

Calling `OpenFile` on an opened BFILE is not operational.

## Read

Overrides Stream

This instance method reads a specified amount of bytes from the `OracleBFile` instance and populates the buffer.

### Declaration

```
// C#  
public override int Read(byte[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The byte array buffer to be populated.
- *offset*  
The offset of the byte array buffer to be populated.
- *count*  
The amount of bytes to read.

### Return Value

The return value indicates the number of bytes read from the BFILE, that is, the external LOB.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - Either the *offset* or the *count* parameter is less than 0 or the *offset* is greater than or equal to the *buffer.Length* or the *offset* and the *count* together are greater than *buffer.Length*.

### Remarks

The LOB data is read starting from the position specified by the `Position` property.

### Example

```
// Database Setup, if you have not done so yet.  
/* Log on as DBA (SYS or SYSTEM) that has CREATE ANY DIRECTORY privilege.  
  
CREATE OR REPLACE DIRECTORY MYDIR AS 'C:\TEMP';  
  
*/  
  
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class ReadSample  
{
```

```
static void Main()
{
    // Create MYDIR directory object as indicated previously and create a file
    // MyFile.txt with the text ABCDABC under C:\TEMP directory.
    // Note that the byte representation of the ABCDABC is 65666768656667

    string constr = "User Id=scott;Password=tiger;Data Source=oracle";
    OracleConnection con = new OracleConnection(constr);
    con.Open();

    OracleBFile bFile = new OracleBFile(con, "MYDIR", "MyFile.txt");

    // Open the OracleBFile
    bFile.OpenFile();

    // Read 7 bytes into readBuffer, starting at buffer offset 0
    byte[] readBuffer = new byte[7];
    int bytesRead = bFile.Read(readBuffer, 0, 7);

    // Prints "bytesRead = 7"
    Console.WriteLine("bytesRead = " + bytesRead);

    // Prints "readBuffer = 65666768656667"
    Console.Write("readBuffer = ");
    for(int index = 0; index < readBuffer.Length; index++)
    {
        Console.Write(readBuffer[index]);
    }
    Console.WriteLine();

    // Close the OracleBFile
    bFile.CloseFile();

    bFile.Close();
    bFile.Dispose();

    con.Close();
    con.Dispose();
}
```

## ReadAsync

ReadAsync returns a Task-based asynchronous version of `OracleBFile.Read()`, which reads a specified number of bytes from the `OracleBFile` instance and populates the buffer.

#### Overload List:

- [ReadAsync\(byte\[\], int, int\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.Read()`, which reads a specified number of bytes from the `OracleBFile` instance and populates the buffer.

- [ReadAsync\(byte\[\], int, int, CancellationToken\)](#)

This method returns a Task-based asynchronous version of `OracleBFile.Read()`, which reads a specified number of bytes from the `OracleBFile` instance and populates the buffer.

#### See Also

## ReadAsync(byte[], int, int)

This method returns a Task-based asynchronous version of `OracleBFile.Read()`, which reads a specified number of bytes from the `OracleBFile` instance and populates the buffer.

### Declaration

```
// C#  
public Task<int> ReadAsync(byte[] buffer, int offset, int count)
```

### Parameters

- `buffer` - The byte array buffer to be populated.
- `offset` - The starting offset (in bytes) at which the buffer is populated.
- `count` - The number of bytes to read.

### Return Value

`Task<Int>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

Stream

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The `offset` or the `count` parameter is less than 0.
  - The `offset` is greater than or equal to the `buffer.Length`.
  - The `offset` and the `count` together are greater than the `buffer.Length`.

## ReadAsync(byte[], int, int, CancellationToken)

This method returns a Task-based asynchronous version of `OracleBFile.Read()`, which reads a specified number of bytes from the `OracleBFile` instance and populates the buffer.

### Declaration

```
// C#  
public override Task<int> ReadAsync(byte[] buffer, int offset, int count,  
CancellationToken cancellationToken)
```

### Parameters

- `buffer` - The byte array buffer to be populated.
- `offset` - The starting offset (in bytes) at which the buffer is populated.
- `count` - The number of bytes to read.
- `cancellationToken` - The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<Int>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

Stream

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

### Example

```
using Oracle.ManagedDataAccess.Client;  
using Oracle.ManagedDataAccess.Types;  
using System;
```

```

using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";

            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationTokens.None);

            OracleCommand cmd = oc.CreateCommand();
            cmd.CommandText = " select bfile_column from tab1";

            OracleDataReader reader = await cmd.ExecuteReaderAsync();

            await reader.ReadAsync(CancellationTokens.None);
            using (var bfile = reader.GetOracleBFile(0))
            {
                bfile.OpenFile();
                byte[] buffer = new byte[100];

                //asynchronously read bfile data
                Task<int> task = bfile.ReadAsync(buffer, 0, 64, CancellationTokens.None);

                //other operations
                Console.WriteLine("Hello World");

                //await for asynchronous ReadAsync
                int bytesRead = await task;
                Console.WriteLine("Bytes Read: " + bytesRead);
            }
        }
    }
}

```

## Search

This instance method searches for a binary pattern in the current instance of an OracleBFile.

### Declaration

```

// C#
public int Search(byte[] val, Int64 offset, Int64 nth);

```

### Parameters

- *val*

The binary pattern being searched for.

- *offset*

The 0-based offset (in bytes) starting from which the OracleBFile is searched.

- *nth*

The specific occurrence (1-based) of the match for which the offset is returned.

### Return Value

Returns the absolute *offset* of the start of the matched pattern (in bytes) for the *nth* occurrence of the match. Otherwise, 0 is returned.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - Either the *offset* is less than 0 or *nth* is less than or equal to 0 or *val.Length* is greater than 16383 or *nth* is greater than or equal to OracleBFile.MaxSize or *offset* is greater than or equal to OracleBFile.MaxSize.

### Remarks

The limit of the search pattern is 16383 bytes.

### Example

```
// Database Setup, if you have not done so yet.
/* Log on as DBA (SYS or SYSTEM) that has CREATE ANY DIRECTORY privilege.

CREATE OR REPLACE DIRECTORY MYDIR AS 'C:\TEMP';

*/

// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class SearchSample
{
    static void Main()
    {
        // Create MYDIR directory object as indicated previously and create a file
        // MyFile.txt with the text ABCDABC under C:\TEMP directory.
        // Note that the byte representation of the ABCDABC is 65666768656667

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBFile bFile = new OracleBFile(con, "MYDIR", "MyFile.txt");

        // Open the OracleBFile
        bFile.OpenFile();

        // Search for the 2nd occurrence of a byte pattern {66,67}
```

```
// starting from byte offset 1 in the OracleBFile
byte[] pattern = new byte[2] {66, 67};
long posFound = bFile.Search(pattern, 1, 2);

// Prints "posFound = 6"
Console.WriteLine("posFound = " + posFound);

// Close the OracleBFile
bFile.CloseFile();

bFile.Close();
bFile.Dispose();

con.Close();
con.Dispose();
}
}
```

## Seek

Overrides Stream

This instance method sets the position on the current LOB stream.

### Declaration

```
// C#
public override Int64 Seek(Int64 offset, SeekOrigin origin);
```

### Parameters

- *offset*  
A byte offset relative to origin.
- *origin*  
A value of type `System.IO.SeekOrigin` indicating the reference point used to obtain the new position.

### Return Value

Returns an `Int64` that indicates the position.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

## Remarks

If *offset* is negative, the new position precedes the position specified by *origin* by the number of bytes specified by *offset*.

If *offset* is zero, the new position is the position specified by *origin*.

If *offset* is positive, the new position follows the position specified by *origin* by the number of bytes specified by *offset*.

SeekOrigin.Begin specifies the beginning of a stream.

SeekOrigin.Current specifies the current position within a stream.

SeekOrigin.End specifies the end of a stream.

## Example

```
// Database Setup, if you have not done so yet.
/* Log on as DBA (SYS or SYSTEM) that has CREATE ANY DIRECTORY privilege.

CREATE OR REPLACE DIRECTORY MYDIR AS 'C:\TEMP';

*/

// C#

using System;
using System.IO;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class SeekSample
{
    static void Main()
    {
        // Create MYDIR directory object as indicated previously and create a file
        // MyFile.txt with the text ABCDABC under C:\TEMP directory.
        // Note that the byte representation of the ABCDABC is 65666768656667

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBFile bFile = new OracleBFile(con, "MYDIR", "MyFile.txt");

        // Open the OracleBFile
        bFile.OpenFile();

        // Set the Position to 2 with respect to SeekOrigin.Begin
        long newPosition = bFile.Seek(2, SeekOrigin.Begin);

        // Prints "newPosition      = 2"
        Console.WriteLine("newPosition      = " + newPosition);

        // Prints "bFile.Position  = 2"
        Console.WriteLine("bFile.Position  = " + bFile.Position);

        // Read 2 bytes into readBuffer, starting at buffer offset 1
        byte[] readBuffer = new byte[4];
        int bytesRead = bFile.Read(readBuffer, 1, 2);
    }
}
```

```
// Prints "bytesRead      = 2"
Console.WriteLine("bytesRead      = " + bytesRead);

// Prints "readBuffer      = 067680"
Console.Write("readBuffer      = ");
for(int index = 0; index < readBuffer.Length; index++)
{
    Console.Write(readBuffer[index]);
}
Console.WriteLine();

// Close the OracleBFile
bFile.CloseFile();

bFile.Close();
bFile.Dispose();

con.Close();
con.Dispose();
}
}
```

# OracleBlob Class

An OracleBlob object is an object that has a reference to BLOB data. It provides methods for performing operations on BLOBs.

### Class Inheritance

System.Object  
System.MarshalByRefObject  
System.IO.Stream  
Oracle.DataAccess.Types.OracleBlob

### Declaration

```
// C#  
public sealed class OracleBlob : Stream, ICloneable, INullable
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class OracleBlobSample
```

```
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBlob blob = new OracleBlob(con);

        // Write 4 bytes from writeBuffer, starting at buffer offset 0
        byte[] writeBuffer = new byte[4] {1, 2, 3, 4};
        blob.Write(writeBuffer, 0, 4);

        // Append first 2 bytes from writeBuffer {1, 2} to the oracleBlob
        blob.Append(writeBuffer, 0, 2);

        // Prints "blob.Length = 6"
        Console.WriteLine("blob.Length = " + blob.Length);

        // Reset the Position for the Read
        blob.Position = 0;

        // Read 6 bytes into readBuffer, starting at buffer offset 0
        byte[] readBuffer = new byte[6];
        int bytesRead = blob.Read(readBuffer, 0, 6);

        // Prints "bytesRead = 6"
        Console.WriteLine("bytesRead = " + bytesRead);

        // Prints "readBuffer = 123412"
        Console.Write("readBuffer = ");
        for(int index = 0; index < readBuffer.Length; index++)
        {
            Console.Write(readBuffer[index]);
        }
        Console.WriteLine();

        // Search for the 2nd occurrence of a byte pattern '12'
        // starting from byte offset 0 in the OracleBlob
        byte[] pattern = new byte[2] {1, 2};
        long posFound = blob.Search(pattern, 0, 2);

        // Prints "posFound = 5"
        Console.WriteLine("posFound = " + posFound);

        // Erase 4 bytes of data starting at byte offset 1
        // Sets bytes to zero
        blob.Erase(1, 4);

        byte[] erasedBuffer = blob.Value;

        //Prints "erasedBuffer = 100002"
        Console.Write("erasedBuffer = ");
        for(int index = 0; index < erasedBuffer.Length; index++)
        {
            Console.Write(erasedBuffer[index]);
        }
        Console.WriteLine();

        blob.Close();
        blob.Dispose();
    }
}
```

```
        con.Close();  
        con.Dispose();  
    }  
}
```

## OracleBlob Members

OracleBlob members are listed in the following tables.

### OracleBlob Constructors

OracleBlob constructors are listed in [Table 13-10](#).

**Table 13-10 OracleBlob Constructors**

| Constructor                             | Description                                              |
|-----------------------------------------|----------------------------------------------------------|
| <a href="#">OracleBlob Constructors</a> | Creates an instance of the OracleBlob class (Overloaded) |

### OracleBlob Static Fields

OracleBlob static fields are listed in [Table 13-11](#).

**Table 13-11 OracleBlob Static Fields**

| Field                   | Description                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">MaxSize</a> | Holds the maximum number of bytes a BLOB can hold, which is 4,294,967,295 (2 <sup>32</sup> - 1) bytes |
| <a href="#">Null</a>    | Represents a null value that can be assigned to the value of an OracleBlob instance                   |

### OracleBlob Static Methods

OracleBlob static methods are listed in [Table 13-12](#).

**Table 13-12 OracleBlob Static Methods**

| Methods             | Description                                            |
|---------------------|--------------------------------------------------------|
| <code>Equals</code> | Inherited from <code>System.Object</code> (Overloaded) |

**OracleBlob Instance Properties**

OracleBlob instance properties are listed in [Table 13-13](#).

**Table 13-13 OracleBlob Instance Properties**

| Properties                         | Description                                                                                                                      |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CanRead</a>            | Indicates whether or not the LOB stream can be read                                                                              |
| <a href="#">CanSeek</a>            | Indicates whether or not forward and backward seek operations be performed                                                       |
| <a href="#">CanWrite</a>           | Indicates whether or not the LOB object supports writing                                                                         |
| <a href="#">Connection</a>         | Indicates the <code>OracleConnection</code> that is used to retrieve and write BLOB data                                         |
| <a href="#">IsEmpty</a>            | Indicates whether the BLOB is empty or not                                                                                       |
| <a href="#">IsInChunkWriteMode</a> | Indicates whether or not the BLOB has been opened to defer index updates                                                         |
| <a href="#">IsNull</a>             | Indicates whether or not the current instance has a null value                                                                   |
| <a href="#">IsTemporary</a>        | Indicates whether or not the current instance is bound to a temporary BLOB                                                       |
| <a href="#">Length</a>             | Indicates the size of the BLOB data                                                                                              |
| <a href="#">OptimumChunkSize</a>   | Indicates the optimal data buffer length (or multiples thereof) that read and write operations should use to improve performance |
| <a href="#">Position</a>           | Indicates the current read or write position in the LOB stream                                                                   |
| <a href="#">Value</a>              | Returns the data, starting from the first byte in BLOB, as a byte array                                                          |

**OracleBlob Instance Methods**

OracleBlob instance methods are listed in [Table 13-14](#).

**Table 13-14 OracleBlob Instance Methods**

| Methods                         | Description                                                                            |
|---------------------------------|----------------------------------------------------------------------------------------|
| <a href="#">Append</a>          | Appends the supplied data to the current <code>OracleBlob</code> instance (Overloaded) |
| <a href="#">BeginChunkWrite</a> | Opens the BLOB                                                                         |
| <code>BeginRead</code>          | Inherited from <code>System.IO.Stream</code>                                           |
| <code>BeginWrite</code>         | Inherited from <code>System.IO.Stream</code>                                           |
| <a href="#">Clone</a>           | Creates a copy of an <code>OracleBlob</code> object                                    |

Table 13-14 (Cont.) OracleBlob Instance Methods

| Methods                       | Description                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Close</a>         | Closes the current stream and releases any resources associated with it                                                                                                            |
| <a href="#">Compare</a>       | Compares data referenced by the current instance and that of the supplied object                                                                                                   |
| <a href="#">CopyTo</a>        | Copies from the current OracleBlob instance to an OracleBlob object (Overloaded)                                                                                                   |
| <a href="#">CopyToAsync</a>   | Returns a Task-based asynchronous version of OracleBlob.CopyTo() (Overloaded)                                                                                                      |
| CreateObjRef                  | Inherited from System.MarshalByRefObject                                                                                                                                           |
| <a href="#">Dispose</a>       | Releases resources allocated by this object                                                                                                                                        |
| <a href="#">EndChunkWrite</a> | Closes the BLOB referenced by the current OracleBlob instance                                                                                                                      |
| EndRead                       | Inherited from System.IO.Stream                                                                                                                                                    |
| EndWrite                      | Inherited from System.IO.Stream                                                                                                                                                    |
| Equals                        | Inherited from System.Object (Overloaded)                                                                                                                                          |
| <a href="#">Erase</a>         | Erases data (Overloaded)                                                                                                                                                           |
| <a href="#">Flush</a>         | <i>Not supported</i>                                                                                                                                                               |
| GetHashCode                   | Inherited from System.Object                                                                                                                                                       |
| GetLifetimeService            | Inherited from System.MarshalByRefObject                                                                                                                                           |
| GetType                       | Inherited from System.Object                                                                                                                                                       |
| InitializedLifetimeService    | Inherited from System.MarshalByRefObject                                                                                                                                           |
| <a href="#">IsEqual</a>       | Compares the LOB data referenced by the two OracleBlobs                                                                                                                            |
| <a href="#">Read</a>          | Reads a specified amount of bytes from the ODP.NET LOB Type instance and populates the buffer                                                                                      |
| <a href="#">ReadAsync</a>     | Returns a Task-based asynchronous version of OracleBlob.Read(), which reads a specified number of bytes from the ODP.NET LOB instance and populates the <i>buffer</i> (Overloaded) |
| ReadByte                      | Inherited from System.IO.Stream                                                                                                                                                    |
| <a href="#">Search</a>        | Searches for a binary pattern in the current instance of an OracleBlob                                                                                                             |
| <a href="#">Seek</a>          | Sets the position in the current LOB stream                                                                                                                                        |
| <a href="#">SetLength</a>     | Trims or truncates the BLOB value to the specified length                                                                                                                          |
| ToString                      | Inherited from System.Object                                                                                                                                                       |
| <a href="#">Write</a>         | Writes the supplied buffer into the OracleBlob                                                                                                                                     |
| <a href="#">WriteAsync</a>    | Returns a Task-based asynchronous version of OracleBlob.Write().                                                                                                                   |
| WriteByte                     | Inherited from System.IO.Stream                                                                                                                                                    |

## OracleBlob Constructors

OracleBlob constructors are listed in [Table 13-10](#).

### Overload List:

- [OracleBlob\(OracleConnection\)](#)

This constructor creates an instance of the OracleBlob class bound to a temporary BLOB with an OracleConnection object.

- [OracleBlob\(OracleConnection, bool\)](#)

This constructor creates an instance of the OracleBlob class bound to a temporary BLOB with an OracleConnection object and a boolean value for caching.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## OracleBlob(OracleConnection)

This constructor creates an instance of the OracleBlob class bound to a temporary BLOB with an OracleConnection object.

### Declaration

```
// C#  
public OracleBlob(OracleConnection con);
```

### Parameters

- *con*

The OracleConnection object.

### Exceptions

InvalidOperationException - The OracleConnection is not opened.

### Remarks

The connection must be opened explicitly by the application. OracleBlob does not open the connection implicitly.

The temporary BLOB utilizes the provided connection to store BLOB data. Caching is not turned on by this constructor.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## OracleBlob(OracleConnection, bool)

This constructor creates an instance of the `OracleBlob` class bound to a temporary BLOB with an `OracleConnection` object and a boolean value for caching.

### Declaration

```
// C#  
public OracleBlob(OracleConnection con, bool bCaching);
```

### Parameters

- *con*  
The `OracleConnection` object.
- *bCaching*  
A flag for enabling or disabling server-side caching.

### Exceptions

`InvalidOperationException` - The `OracleConnection` is not opened.

### Remarks

The connection must be opened explicitly by the application. `OracleBlob` does not open the connection implicitly.

The temporary BLOB uses the provided connection to store BLOB data. The *bCaching* input parameter determines whether or not server-side caching is used.

## OracleBlob Static Fields

`OracleBlob` static fields are listed in [Table 13-15](#).

**Table 13-15 OracleBlob Static Fields**

| Field                   | Description                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------|
| <a href="#">MaxSize</a> | Holds the maximum number of bytes a BLOB can hold, which is 4,294,967,295 ( $2^{32} - 1$ ) bytes |
| <a href="#">Null</a>    | Represents a null value that can be assigned to the value of an OracleBlob instance              |

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## MaxSize

The MaxSize field holds the maximum number of bytes a BLOB can hold, which is 4,294,967,295 ( $2^{32} - 1$ ) bytes.

**Declaration**

```
// C#  
public static readonly Int64 MaxSize = 4294967295;
```

**Remarks**

This field can be useful in code that checks whether or not the operation exceeds the maximum length allowed.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Null

This static field represents a null value that can be assigned to the value of an OracleBlob instance.

**Declaration**

```
// C#  
public static readonly OracleBlob Null;
```

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## OracleBlob Static Methods

OracleBlob static methods are listed in [Table 13-16](#).

**Table 13-16 OracleBlob Static Methods**

| Methods                | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)

## OracleBlob Instance Properties

OracleBlob instance properties are listed in [Table 13-17](#).

**Table 13-17 OracleBlob Instance Properties**

| Properties                         | Description                                                                 |
|------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">CanRead</a>            | Indicates whether or not the LOB stream can be read                         |
| <a href="#">CanSeek</a>            | Indicates whether or not forward and backward seek operations be performed  |
| <a href="#">CanWrite</a>           | Indicates whether or not the LOB object supports writing                    |
| <a href="#">Connection</a>         | Indicates the OracleConnection that is used to retrieve and write BLOB data |
| <a href="#">IsEmpty</a>            | Indicates whether the BLOB is empty or not                                  |
| <a href="#">IsInChunkWriteMode</a> | Indicates whether or not the BLOB has been opened to defer index updates    |
| <a href="#">IsNull</a>             | Indicates whether or not the current instance has a null value              |
| <a href="#">IsTemporary</a>        | Indicates whether or not the current instance is bound to a temporary BLOB  |
| <a href="#">Length</a>             | Indicates the size of the BLOB data                                         |

**Table 13-17 (Cont.) OracleBlob Instance Properties**

| Properties                       | Description                                                                                                                      |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OptimumChunkSize</a> | Indicates the optimal data buffer length (or multiples thereof) that read and write operations should use to improve performance |
| <a href="#">Position</a>         | Indicates the current read or write position in the LOB stream                                                                   |
| <a href="#">Value</a>            | Returns the data, starting from the first byte in BLOB, as a byte array                                                          |

**① See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"

## CanRead

Overrides Stream

This instance property indicates whether or not the LOB stream can be read.

**Declaration**

```
// C#  
public override bool CanRead{get;}
```

**Property Value**

If the LOB stream can be read, returns true; otherwise, returns false.

**① See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## CanSeek

Overrides Stream

This instance property indicates whether or not forward and backward seek operations can be performed.

**Declaration**

```
// C#  
public override bool CanSeek{get;}
```

**Property Value**

If forward and backward seek operations can be performed, returns true; otherwise, returns false.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## CanWrite

Overrides Stream

This instance property indicates whether or not the LOB object supports writing.

**Declaration**

```
// C#  
public override bool CanWrite{get;}
```

**Property Value**

If the LOB stream can be written, returns true; otherwise, returns false.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Connection

This instance property indicates the OracleConnection that is used to retrieve and write BLOB data.

**Declaration**

```
// C#  
public OracleConnection Connection {get;}
```

**Property Value**

An object of OracleConnection.

**Exceptions**

ObjectDisposedException - The object is already disposed.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## IsEmpty

This instance property indicates whether the BLOB is empty or not.

### Declaration

```
// C#  
public bool IsEmpty {get;}
```

### Property Value

A bool that indicates whether or not the BLOB is empty.

### Exceptions

ObjectDisposedException - The object is already disposed.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## IsInChunkWriteMode

This instance property indicates whether or not the BLOB has been opened to defer index updates.

### Declaration

```
// C#  
public bool IsInChunkWriteMode{get;}
```

### Property Value

If the BLOB has been opened, returns true; otherwise, returns false.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

### Declaration

```
// C#  
public bool IsNull{get;}
```

### Property Value

Returns true if the current instance has a null value; otherwise, returns false.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## IsTemporary

This instance property indicates whether or not the current instance is bound to a temporary BLOB.

### Declaration

```
// C#  
public bool IsTemporary {get;}
```

### Property Value

bool

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Length

Overrides Stream

This instance property indicates the size of the BLOB data in bytes.

### Declaration

```
// C#  
public override Int64 Length {get;}
```

### Property Value

A number indicating the size of the BLOB data in bytes.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## OptimumChunkSize

This instance property indicates the optimal data buffer length (or multiples thereof) that read and write operations should use to improve performance.

### Declaration

```
// C#  
public int OptimumChunkSize{get;}
```

### Property Value

A number representing the minimum bytes to retrieve or send.

### Exceptions

ObjectDisposedException - The object is already disposed.

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Position

Overrides Stream

This instance property indicates the current read or write position in the LOB stream.

### Declaration

```
// C#  
public override Int64 Position{get; set;}
```

### Property Value

An Int64 that indicates the read or write position.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The Position is less than 0.

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Value

This instance property returns the data, starting from the first byte in the BLOB, as a byte array.

### Declaration

```
// C#  
public Byte[] Value{get;}
```

### Property Value

A byte array.

## Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - The Value is less than 0.

## Remarks

The value of `Position` is not used or changed by using this property. 2 GB is the maximum byte array length that can be returned by this property.

For very large values, .NET may not be able to allocate enough contiguous memory to store all the data. Typically, you will see a `System.OverflowException` or `System.OutOfMemoryException` error then. To retrieve the large value, you can retrieve the data in chunks by calling `GetChars()` or `GetBytes()` method on the `OracleDataReader`. You can also call `Read()` method on the class.

## OracleBlob Instance Methods

OracleBlob instance methods are listed in [Table 13-18](#).

**Table 13-18 OracleBlob Instance Methods**

| Methods                         | Description                                                                                                |
|---------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">Append</a>          | Appends the supplied data to the current <code>OracleBlob</code> instance (Overloaded)                     |
| <a href="#">BeginChunkWrite</a> | Opens the BLOB                                                                                             |
| <code>BeginRead</code>          | Inherited from <code>System.IO.Stream</code>                                                               |
| <code>BeginWrite</code>         | Inherited from <code>System.IO.Stream</code>                                                               |
| <a href="#">Clone</a>           | Creates a copy of an <code>OracleBlob</code> object                                                        |
| <a href="#">Close</a>           | Closes the current stream and releases any resources associated with it                                    |
| <a href="#">Compare</a>         | Compares data referenced by the current instance and that of the supplied object                           |
| <a href="#">CopyTo</a>          | Copies from the current <code>OracleBlob</code> instance to an <code>OracleBlob</code> object (Overloaded) |
| <a href="#">CopyToAsync</a>     | Returns a Task-based asynchronous version of <code>OracleBlob.CopyTo()</code> (Overloaded)                 |
| <code>CreateObjRef</code>       | Inherited from <code>System.MarshalByRefObject</code>                                                      |

Table 13-18 (Cont.) OracleBlob Instance Methods

| Methods                       | Description                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Dispose</a>       | Releases resources allocated by this object                                                                                                                                        |
| <a href="#">EndChunkWrite</a> | Closes the BLOB referenced by the current OracleBlob instance                                                                                                                      |
| EndRead                       | Inherited from System.IO.Stream                                                                                                                                                    |
| EndWrite                      | Inherited from System.IO.Stream                                                                                                                                                    |
| Equals                        | Inherited from System.Object (Overloaded)                                                                                                                                          |
| <a href="#">Erase</a>         | Erases data (Overloaded)                                                                                                                                                           |
| <a href="#">Flush</a>         | <i>Not supported</i>                                                                                                                                                               |
| GetHashCode                   | Inherited from System.Object                                                                                                                                                       |
| GetLifetimeService            | Inherited from System.MarshalByRefObject                                                                                                                                           |
| GetType                       | Inherited from System.Object                                                                                                                                                       |
| InitializedLifetimeService    | Inherited from System.MarshalByRefObject                                                                                                                                           |
| <a href="#">IsEqual</a>       | Compares the LOB data referenced by the two OracleBlobs                                                                                                                            |
| <a href="#">Read</a>          | Reads a specified amount of bytes from the ODP.NET LOB Type instance and populates the buffer                                                                                      |
| <a href="#">ReadAsync</a>     | Returns a Task-based asynchronous version of OracleBlob.Read(), which reads a specified number of bytes from the ODP.NET LOB instance and populates the <i>buffer</i> (Overloaded) |
| ReadByte                      | Inherited from System.IO.Stream                                                                                                                                                    |
| <a href="#">Search</a>        | Searches for a binary pattern in the current instance of an OracleBlob                                                                                                             |
| <a href="#">Seek</a>          | Sets the position in the current LOB stream                                                                                                                                        |
| <a href="#">SetLength</a>     | Trims or truncates the BLOB value to the specified length                                                                                                                          |
| ToString                      | Inherited from System.Object                                                                                                                                                       |
| <a href="#">Write</a>         | Writes the supplied buffer into the OracleBlob                                                                                                                                     |
| <a href="#">WriteAsync</a>    | Returns a Task-based asynchronous version of OracleBlob.Write().                                                                                                                   |
| WriteByte                     | Inherited from System.IO.Stream                                                                                                                                                    |

## Append

Append appends the supplied data to the end of the current OracleBlob instance.

**Overload List:**

- [Append\(OracleBlob\)](#)  
This instance method appends the BLOB data referenced by the provided `OracleBlob` object to the current `OracleBlob` instance.
- [Append\(byte\[\], int, int\)](#)  
This instance method appends data from the supplied byte array buffer to the end of the current `OracleBlob` instance.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Append(OracleBlob)

This instance method appends the BLOB data referenced by the provided `OracleBlob` object to the current `OracleBlob` instance.

**Declaration**

```
// C#  
public void Append(OracleBlob obj);
```

**Parameters**

- *obj*  
An object of `OracleBlob`.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The parameter has a different connection than the object, `OracleConnection` is not opened, or `OracleConnection` has been reopened.

**Remarks**

No character set conversions are made.

The provided object and the current instance must be using the same connection; that is, the same `OracleConnection` object.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Append(byte[ ], int, int)

This instance method appends data from the supplied byte array buffer to the end of the current OracleBlob instance.

### Declaration

```
// C#  
public void Append(byte[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
An array of bytes.
- *offset*  
The zero-based byte offset in the buffer from which data is read.
- *count*  
The number of bytes to be appended.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class AppendSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        OracleBlob blob = new OracleBlob(con);  
  
        // Append 2 bytes {4, 5} to the OracleBlob  
        byte[] buffer = new byte[3] {4, 5, 6};  
        blob.Append(buffer, 0, 2);  
    }  
}
```

```
byte[] appendBuffer = blob.Value;

// Prints "appendBuffer = 45"
Console.Write("appendBuffer = ");
for(int index = 0; index < appendBuffer.Length; index++)
{
    Console.Write(appendBuffer[index]);
}
Console.WriteLine();

blob.Close();
blob.Dispose();

con.Close();
con.Dispose();
}
}
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## BeginChunkWrite

This instance method opens the BLOB.

### Declaration

```
// C#
public void BeginChunkWrite();
```

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

BeginChunkWrite does not need to be called before manipulating the BLOB data. This is provided for performance reasons.

After this method is called, write operations do not cause the domain or function-based index on the column to be updated. Index updates occur only once after EndChunkWrite is called.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Clone

This instance method creates a copy of an OracleBlob object.

**Declaration**

```
// C#  
public object Clone();
```

**Return Value**

An OracleBlob object.

**Implements**

ICloneable

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

The cloned object has the same property values as that of the object being cloned.

**Example**

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class CloneSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";  
        OracleConnection con = new OracleConnection(constr);  
        con.Open();  
  
        OracleBlob blob1 = new OracleBlob(con);  
  
        // Prints "blob1.Position = 0"  
        Console.WriteLine("blob1.Position = " + blob1.Position);  
  
        // Set the Position before calling Clone()  
        blob1.Position = 1;
```

```
// Clone the OracleBlob
OracleBlob blob2 = (OracleBlob)blob1.Clone();

// Prints "blob2.Position = 1"
Console.WriteLine("blob2.Position = " + blob2.Position);

blob1.Close();
blob1.Dispose();

blob2.Close();
blob2.Dispose();

con.Close();
con.Dispose();
}
}
```

## Close

Overrides Stream

This instance method closes the current stream and releases any resources associated with it.

#### Declaration

```
// C#
public override void Close();
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Compare

This instance method compares data referenced by the current instance and that of the supplied object.

#### Declaration

```
// C#
public int Compare(Int64 src_offset, OracleBlob obj, Int64 dst_offset,
    Int64 amount);
```

### Parameters

- *src\_offset*  
The comparison starting point (in bytes) for the current instance.
- *obj*  
The provided `OracleBlob` object.
- *dst\_offset*  
The comparison starting point (in bytes) for the provided `OracleBlob`.
- *amount*  
The number of bytes to compare.

### Return Value

Returns a value that is:

- Less than zero: if the data referenced by the current instance is less than that of the supplied instance
- Zero: if both objects reference the same data
- Greater than zero: if the data referenced by the current instance is greater than that of the supplied instance

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The parameter has a different connection than the object, `OracleConnection` is not opened, or `OracleConnection` has been reopened.

`ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* parameter is less than 0.

### Remarks

The provided object and the current instance must be using the same connection, that is, the same `OracleConnection` object.

#### ① See Also

## CopyTo

`CopyTo` copies data from the current instance to the provided `OracleBlob` object.

### Overload List:

- [CopyTo\(OracleBlob\)](#)

This instance method copies data from the current instance to the provided `OracleBlob` object.

- [CopyTo\(OracleBlob, Int64\)](#)

This instance method copies data from the current `OracleBlob` instance to the provided `OracleBlob` object with the specified destination offset.

- [CopyTo\(Int64, OracleBlob, Int64, Int64\)](#)

This instance method copies data from the current `OracleBlob` instance to the provided `OracleBlob` object with the specified source offset, destination offset, and character amounts.

#### See Also

## CopyTo(OracleBlob)

This instance method copies data from the current instance to the provided `OracleBlob` object.

### Declaration

```
// C#  
public Int64 CopyTo(OracleBlob obj);
```

### Parameters

- *obj*  
The `OracleBlob` object to which the data is copied.

### Return Value

The return value is the amount copied.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - This exception is thrown if any of the following conditions exist:

- The `OracleConnection` is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

### Remarks

The provided object and the current instance must be using the same connection; that is, the same `OracleConnection` object.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## CopyTo(OracleBlob, Int64)

This instance method copies data from the current `OracleBlob` instance to the provided `OracleBlob` object with the specified destination offset.

### Declaration

```
// C#  
public Int64 CopyTo(OracleBlob obj, Int64 dst_offset);
```

### Parameters

- *obj*  
The `OracleBlob` object to which the data is copied.
- *dst\_offset*  
The offset (in bytes) at which the `OracleBlob` object is copied.

### Return Value

The return value is the amount copied.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`ArgumentOutOfRangeException` - The *dst\_offset* is less than 0.

`InvalidOperationException` - This exception is thrown if any of the following conditions exist:

- The `OracleConnection` is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

### Remarks

If the *dst\_offset* is beyond the end of the `OracleBlob` data, spaces are written into the `OracleBlob` until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection; that is, the same `OracleConnection` object.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## CopyTo(Int64, OracleBlob, Int64, Int64)

This instance method copies data from the current `OracleBlob` instance to the provided `OracleBlob` object with the specified source offset, destination offset, and character amounts.

### Declaration

```
// C#  
public Int64 CopyTo(Int64 src_offset, OracleBlob obj, Int64 dst_offset,  
    Int64 amount);
```

### Parameters

- *src\_offset*  
The offset (in bytes) in the current instance, from which the data is read.
- *obj*  
The `OracleBlob` object to which the data is copied.
- *dst\_offset*  
The offset (in bytes) at which the `OracleBlob` object is copied.
- *amount*  
The amount of data to be copied.

### Return Value

The return value is the amount copied.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The parameter has a different connection than the object, `OracleConnection` is not opened, or `OracleConnection` has been reopened.

`ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* parameter is less than 0.

### Remarks

If the *dst\_offset* is beyond the end of the `OracleBlob` data, spaces are written into the `OracleBlob` until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection; that is, the same `OracleConnection` object.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class CopyToSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBlob blob1 = new OracleBlob(con);
        OracleBlob blob2 = new OracleBlob(con);

        // Write 4 bytes, starting at buffer offset 0
        byte[] buffer = new byte[4] {1, 2, 3, 4};
        blob1.Write(buffer, 0, 4);

        // Copy 2 bytes from byte 0 of blob1 to byte 1 of blob2
        blob1.CopyTo(0, blob2, 1, 2);

        byte[] copyBuffer = blob2.Value;

        //Prints "Value = 012"
        Console.Write("Value = ");
        for(int index = 0; index < copyBuffer.Length; index++)
        {
            Console.Write(copyBuffer[index]);
        }
        Console.WriteLine();

        blob1.Close();
        blob1.Dispose();

        blob2.Close();
        blob2.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

This instance method returns a Task-based asynchronous version of `OracleBlob.CopyTo()`.
- [CopyToAsync\(OracleBlob, CancellationToken\)](#)  
This instance method returns a Task-based asynchronous version of `OracleBlob.CopyTo()`.

**Example (includes all Overloads)**

```
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";

            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationToken.None);

            OracleCommand cmd = oc.CreateCommand();
            cmd.CommandText = " select blob_column from tab1";

            OracleBlob blob1 = new OracleBlob(oc);
            OracleBlob blob2 = new OracleBlob(oc);
            OracleBlob blob3 = new OracleBlob(oc);
            OracleBlob blob4 = new OracleBlob(oc);
            OracleBlob blob5 = new OracleBlob(oc);
            OracleBlob blob6 = new OracleBlob(oc);

            OracleDataReader reader = await cmd.ExecuteReaderAsync();
```

```

        await reader.ReadAsync(CancellationTokens.None) ;
        using (OracleBlob blob = reader.GetOracleBlob(0))
        {
            //asynchronously copy blob data
            Int64 bytesCopied1 = await blob.CopyToAsync(0, blob1, 0, blob.Length);
            Console.WriteLine("bytes copied to blob1 = " + bytesCopied1);

            //asynchronously copy blob data
            Int64 bytesCopied2 = await blob.CopyToAsync(0, blob2, 0, blob.Length,
CancellationTokens.None);
            Console.WriteLine("bytes copied to blob2 = " + bytesCopied2);

            //asynchronously copy blob data
            Int64 bytesCopied3 = await blob.CopyToAsync(blob3, 0);
            Console.WriteLine("bytes copied to blob3 = " + bytesCopied3);

            //asynchronously copy blob data
            Int64 bytesCopied4 = await blob.CopyToAsync(blob4, 0, CancellationTokens.None);
            Console.WriteLine("bytes copied to blob4 = " + bytesCopied4);

            //asynchronously copy blob data
            Int64 bytesCopied5 = await blob.CopyToAsync(blob5);
            Console.WriteLine("bytes copied to blob5 = " + bytesCopied5);

            //asynchronously copy blob data
            Int64 bytesCopied6 = await blob.CopyToAsync(blob6, CancellationTokens.None);
            Console.WriteLine("bytes copied to blob6 = " + bytesCopied6);
        }
    }
}
}
}

```

## CopyToAsync(Int64, OracleBlob, Int64, Int64)

The CopyToAsync method returns a Task-based asynchronous version of OracleBlob.CopyTo().

### Declaration

```
// C#
public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64 dst_offset, Int64 amount);
```

### Parameters

- *src\_offset*

The offset (in bytes) in the current instance, from which the data is read.

- *obj*

The `OracleBlob` object to which the data is copied.

- *dst\_offset*

The offset (in bytes) at which the `OracleBlob` object is copied.

- *amount*

The amount of data to be copied.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(Int64, OracleBlob, Int64, Int64, CancellationToken)

The `CopyToAsync` method returns a Task-based asynchronous version of `OracleBlob.CopyTo()`.

### Declaration

```
// C#
public Task<Int64> CopyToAsync(Int64 src_offset, OracleBlob obj, Int64 dst_offset, Int64 amount, CancellationToken cancellationToken);
```

### Parameters

- *src\_offset*

The offset (in bytes) in the current instance, from which the data is read.

- *obj*

The `OracleBlob` object to which the data is copied.

- *dst\_offset*

The offset (in bytes) at which the `OracleBlob` object is copied.

- *amount*  
The amount of data to be copied.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task

### Return Value

Task<Int64> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleBlob, Int64)

The `CopyToAsync` method returns a Task-based asynchronous version of `OracleBlob.CopyTo()`.

### Declaration

```
// C#  
public async Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset);
```

### Parameters

- *obj*  
The `OracleBlob` object to which the data is copied.
- *dst\_offset*  
The offset (in bytes) at which the `OracleBlob` object is copied.

### Return Value

Task<Int64> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The *dst\_offset* parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleBlob, Int64, CancellationToken)

The `CopyToAsync` method returns a Task-based asynchronous version of `OracleBlob.CopyTo()`.

### Declaration

```
// C#
public async Task<Int64> CopyToAsync(OracleBlob obj, Int64 dst_offset, CancellationToken
cancellation_token);
```

### Parameters

- *obj*  
The `OracleBlob` object to which the data is copied.
- *dst\_offset*  
The offset (in bytes) at which the `OracleBlob` object is copied.
- *cancellation\_token*  
The input cancellation token which can be used by the application to cancel the task

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The *dst\_offset* is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.

- The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleBlob)

The CopyToAsync method returns a Task-based asynchronous version of OracleBlob.CopyTo().

### Declaration

```
// C#  
public async Task<Int64> CopyToAsync(OracleBlob obj);
```

### Parameters

- *obj*  
The OracleBlob object to which the data is copied.

### Return Value

Task<Int64> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## CopyToAsync(OracleBlob, Cancellation\_token)

The CopyToAsync method returns a Task-based asynchronous version of OracleBlob.CopyTo().

### Declaration

```
// C#  
public async Task<Int64> CopyToAsync(OracleBlob obj, CancellationToken  
cancellation_token);
```

### Parameters

- *obj*  
The OracleBlob object to which the data is copied.
- *cancellation\_token*  
The input cancellation token which can be used by the application to cancel the task

### Return Value

Task<Int64> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- *ObjectDisposedException* - The object is already disposed.
- *InvalidOperationException* - This exception is thrown if any of the following conditions exist:
  - The *OracleConnection* is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Dispose

This instance method releases resources allocated by this object.

### Declaration

```
// C#  
public void Dispose();
```

### Implements

IDisposable

### Remarks

Once *Dispose()* is called, the object of *OracleBlob* is in an uninitialized state.

Although some properties can still be accessed, their values may not be accountable. Since resources are freed, method calls may lead to exceptions. The object cannot be reused after being disposed.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## EndChunkWrite

This instance method closes the BLOB referenced by the current OracleBlob instance.

### Declaration

```
// C#  
public void EndChunkWrite();
```

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

Index updates occur immediately if there is write operation(s) deferred by the BeginChunkWrite method.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Erase

Erase erases a portion or all data.

### Overload List:

- [Erase\(\)](#)

This instance method erases all data.

- [Erase\(Int64, Int64\)](#)

This instance method erases a specified portion of data.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Erase()

This instance method erases all data.

**Declaration**

```
// C#  
public Int64 Erase();
```

**Return Value**

The number of bytes erased.

**Remarks**

Erase() replaces all data with zero-byte fillers.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Erase(Int64, Int64)

This instance method erases a specified portion of data.

**Declaration**

```
// C#  
public Int64 Erase(Int64 offset, Int64 amount);
```

**Parameters**

- *offset*  
The offset from which to erase.
- *amount*  
The quantity (in bytes) to erase.

**Return Value**

The number of bytes erased.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The *offset* or *amount* parameter is less than 0.

### Remarks

Replaces the specified *amount* of data with zero-byte fillers.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Flush

This method is not supported.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## IsEqual

This instance method compares the LOB data referenced by the two OracleBlobs.

### Declaration

```
// C#  
public bool IsEqual(OracleBlob obj);
```

### Parameters

- *obj*  
An OracleBlob object.

### Return Value

If the current OracleBlob and the provided OracleBlob refer to the same LOB, returns true. Returns false otherwise.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

Note that this method can return true even if the two OracleBlob objects return false for == or Equals() because two different OracleBlob instances can refer to the same LOB.

The provided object and the current instance must be using the same connection, that is, the same OracleConnection object.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Read

Overrides Stream

This instance method reads a specified amount of bytes from the ODP.NET LOB instance and populates the buffer.

### Declaration

```
// C#  
public override int Read(byte[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The byte array buffer to be populated.
- *offset*  
The starting offset (in bytes) at which the buffer is populated.
- *count*  
The amount of bytes to read.

### Return Value

The return value indicates the number of bytes read from the LOB.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**ArgumentOutOfRangeException** - This exception is thrown if any of the following conditions exist:

- The *offset* or the *count* parameter is less than 0.
- The *offset* is greater than or equal to the *buffer.Length*.
- The *offset* and the *count* together are greater than the *buffer.Length*.

### Remarks

The LOB data is read starting from the position specified by the *Position* property.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class ReadSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBlob blob = new OracleBlob(con);

        // Write 3 bytes, starting at buffer offset 1
        byte[] writeBuffer = new byte[4] {1, 2, 3, 4};
        blob.Write(writeBuffer, 1, 3);

        // Reset the Position for Read
        blob.Position = 1;

        // Read 2 bytes into buffer starting at buffer offset 1
        byte[] readBuffer = new byte[4];
        int bytesRead = blob.Read(readBuffer, 1, 2);

        // Prints "bytesRead = 2"
        Console.WriteLine("bytesRead = " + bytesRead);

        // Prints "readBuffer = 0340"
        Console.Write("readBuffer = ");
        for(int index = 0; index < readBuffer.Length; index++)
        {
            Console.Write(readBuffer[index]);
        }
        Console.WriteLine();

        blob.Close();
        blob.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## ReadAsync(byte[], int, int)

The ReadAsync method returns a Task-based asynchronous version of `OracleBlob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

### Declaration

```
// C#  
public Task<int> ReadAsync(byte[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The byte array buffer to be populated.
- *offset*  
The starting offset (in bytes) at which the buffer is populated.
- *count*  
The number of bytes to read.

### Return Value

Task<Int> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

### Remark

This will call into the `ReadAsync` implementation with argument `cancellationToken` passed as `CancellationToken.None`.

- [OracleBlob Class](#)
- [OracleBlob Members](#)

## ReadAsync(byte[], int, int, CancellationToken)

The `ReadAsync` method returns a Task-based asynchronous version of `OracleBlob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

### Declaration

```
// C#
public override Task<int> ReadAsync(byte[] buffer, int offset, int count,
CancellationToken cancellationToken);
```

### Parameters

- *buffer*  
The byte array buffer to be populated.
- *offset*  
The starting offset (in bytes) at which the buffer is populated.
- *count*  
The number of bytes to read.

- *cancellationToken*

The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<Int>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

### Example

```
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";

            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationToken.None);

            OracleCommand cmd = oc.CreateCommand();
            cmd.CommandText = " select blob_column from tab1";

            OracleDataReader reader = await cmd.ExecuteReaderAsync();

            while (await reader.ReadAsync(CancellationToken.None))
            {
                using (OracleBlob blob = reader.GetOracleBlob(0))
                {
                    byte[] buffer = new byte[100];
                    //asynchronously read blob data
                    Task<int> task = blob.ReadAsync(buffer, 0, 64, CancellationToken.None);

                    //other operations
                    Console.WriteLine("Hello World");

                    //await for asynchronous ReadAsync
                    int bytesRead = await task;
                }
            }
        }
    }
}
```

```
        Console.WriteLine("Bytes Read: " + bytesRead);  
    }  
    }  
}
```

## Search

This instance method searches for a binary pattern in the current instance of an `OracleBlob`.

### Declaration

```
// C#  
public Int64 Search(byte[] val, int64 offset, int64 nth);
```

### Parameters

- *val*  
The binary pattern being searched for.
- *offset*  
The 0-based offset (in bytes) starting from which the `OracleBlob` is searched.
- *nth*  
The specific occurrence (1-based) of the match for which the absolute offset (in bytes) is returned.

### Return Value

Returns the absolute *offset* of the start of the matched pattern (in bytes) for the *nth* occurrence of the match. Otherwise, 0 is returned.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:

- The *offset* is less than 0.
- The *nth* is less than or equal to 0.
- The *val.Length* is greater than 16383.
- The *nth* is greater than or equal to `OracleBlob.MaxSize`.

- The *offset* is greater than or equal to `OracleBlob.MaxValue`.

### Remarks

The limit of the search pattern is 16383 bytes.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class SearchSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBlob blob = new OracleBlob(con);

        // Write 7 bytes, starting at buffer offset 0
        byte[] buffer = new byte[7] {1, 2, 3, 4, 1, 2, 3};
        blob.Write(buffer, 0, 7);

        // Search for the 2nd occurrence of a byte pattern '23'
        // starting at offset 1 in the OracleBlob
        byte[] pattern = new byte[2] {2, 3};
        long posFound = blob.Search(pattern, 1, 2);

        // Prints "posFound = 6"
        Console.WriteLine("posFound = " + posFound);

        blob.Close();
        blob.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## Seek

### Overrides Stream

This instance method sets the position on the current LOB stream.

### Declaration

```
// C#  
public override Int64 Seek(Int64 offset, SeekOrigin origin);
```

### Parameters

- *offset*  
A byte offset relative to origin.
- *origin*  
A value of type `System.IO.SeekOrigin` indicating the reference point used to obtain the new position.

### Return Value

Returns `Int64` for the position.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

### Remarks

If *offset* is negative, the new position precedes the position specified by *origin* by the number of bytes specified by *offset*.

If *offset* is zero, the new position is the position specified by *origin*.

If *offset* is positive, the new position follows the position specified by *origin* by the number of bytes specified by *offset*.

`SeekOrigin.Begin` specifies the beginning of a stream.

`SeekOrigin.Current` specifies the current position within a stream.

`SeekOrigin.End` specifies the end of a stream.

## SetLength

Overrides `Stream`

This instance method trims or truncates the BLOB value to the specified length (in bytes).

**Declaration**

```
// C#  
public override void SetLength(Int64 newlen);
```

**Parameters**

- *newlen*

The desired length of the current stream in bytes.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The *newlen* parameter is less than 0.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBlob Class](#)
- [OracleBlob Members](#)

## Write

Overrides Stream

This instance method writes the supplied buffer into the OracleBlob.

**Declaration**

```
// C#  
public override void Write(byte[ ] buffer, int offset, int count);
```

**Parameters**

- *buffer*

The byte array buffer that provides the data.

- *offset*

The 0-based offset (in bytes) from which the buffer is read.

- *count*

The amount of data (in bytes) that is to be written into the OracleBlob.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**ArgumentOutOfRangeException** - This exception is thrown if any of the following conditions exist:

- The *offset* or the *count* is less than 0.
- The *offset* is greater than or equal to the *buffer.Length*.
- The *offset* and the *count* together are greater than *buffer.Length*.

### Remarks

Destination *offset* in the *OracleBlob* can be specified by the *Position* property.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class WriteSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleBlob blob = new OracleBlob(con);

        // Set the Position for the Write
        blob.Position = 0;

        // Begin ChunkWrite to improve performance
        // Index updates occur only once after EndChunkWrite
        blob.BeginChunkWrite();

        // Write to the OracleBlob in 5 chunks of 2 bytes each
        byte[] b = new byte[2] {1, 2};
        for(int index = 0; index < 5; index++)
        {
            blob.Write(b, 0, b.Length);
        }
        blob.EndChunkWrite();

        byte[] chunkBuffer = blob.Value;

        // Prints "chunkBuffer = 1212121212"
        Console.Write("chunkBuffer = ");
        for(int index = 0; index < chunkBuffer.Length; index++)
        {
            Console.Write(chunkBuffer[index]);
        }
        Console.WriteLine();

        blob.Close();
        blob.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## WriteAsync

WriteAsync returns a Task-based asynchronous version of `OracleBlob.Write()`.

### Overload List:

- [WriteAsync\(byte\[\], int, int\)](#)  
This instance method returns a Task-based asynchronous version of `OracleBlob.Write()`.
- [WriteAsync\(byte\[\], int, int, CancellationToken\)](#)  
This instance method returns a Task-based asynchronous version of `OracleBlob.Write()`.

### ① See Also

## WriteAsync(byte[], int, int)

The `WriteAsync` method returns a Task-based asynchronous version of `OracleBlob.Write()`.

### Declaration

```
// C#  
public Task WriteAsync(byte[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The byte array buffer that provides the data.
- *offset*  
The 0-based offset (in bytes) from which the buffer is read.
- *count*  
The amount of data (in bytes) that is to be written into the `OracleBlob`.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

### Remark

This will call into the `WriteAsync` implementation with argument `cancellationToken` passed as `CancellationToken.None`.

## WriteAsync(byte[], int, int, CancellationToken)

The `WriteAsync` method returns a Task-based asynchronous version of `OracleBlob.Write()`.

### Declaration

```
// C#  
public override Task WriteAsync(byte[] buffer, int offset, int count, CancellationToken  
cancellationToken);
```

### Parameters

- *buffer*  
The byte array buffer that provides the data.
- *offset*  
The 0-based offset (in bytes) from which the buffer is read.
- *count*  
The amount of data (in bytes) that is to be written into the `OracleBlob`.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

## Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

## Example

```
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";

            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationTokens.None);

            OracleBlob blob = new OracleBlob(oc);

            byte[] writeBuffer = new byte[4] { 1, 2, 3, 4 };

            //Write data to Binary Large Object, asynchronously
            Task task = blob.WriteAsync(writeBuffer, 0, 4, CancellationTokens.None);

            //other operations
            Console.WriteLine("Hello World");

            //await for asynchronous WriteAsync
            await task;
            Console.WriteLine("blob.Length = " + blob.Length);
        }
    }
}
```

# OracleClob Class

An OracleClob is an object that has a reference to CLOB data. It provides methods for performing operations on CLOBs.

**Note**

The OracleClob object uses the client side character set when retrieving or writing CLOB data using a .NET Framework byte array.

**Class Inheritance**

System.Object  
    System.MarshalByRefObject  
        System.IO.Stream  
            Oracle.DataAccess.Types.OracleClob

**Declaration**

```
// C#
public sealed class OracleClob : Stream, ICloneable, INullable
```

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

**Example**

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class OracleClobSample
{
    static void Main()
```

```
{
    string constr = "User Id=scott;Password=tiger;Data Source=oracle";
    OracleConnection con = new OracleConnection(constr);
    con.Open();

    OracleClob clob = new OracleClob(con);

    // Write 4 chars from writeBuffer, starting at buffer offset 0
    char[] writeBuffer = new char[4] {'a', 'b', 'c', 'd'};
    clob.Write(writeBuffer, 0, 4);

    // Append first 2 chars from writeBuffer {'a', 'b'} to the oracleClob
    clob.Append(writeBuffer, 0, 2);

    // Prints "clob.Length = 12"
    Console.WriteLine("clob.Length = " + clob.Length);

    // Reset the Position for the Read
    clob.Position = 0;

    // Read 6 chars into readBuffer, starting at buffer offset 0
    char[] readBuffer = new char[6];
    int charsRead = clob.Read(readBuffer, 0, 6);

    // Prints "charsRead = 6"
    Console.WriteLine("charsRead = " + charsRead);

    // Prints "readBuffer = abcdab"
    Console.Write("readBuffer = ");
    for(int index = 0; index < readBuffer.Length; index++)
    {
        Console.Write(readBuffer[index]);
    }
    Console.WriteLine();

    // Search for the 2nd occurrence of a char pattern 'ab'
    // starting from char offset 0 in the OracleClob
    char[] pattern = new char[2] {'a', 'b'};
    long posFound = clob.Search(pattern, 0, 2);

    // Prints "posFound = 5"
    Console.WriteLine("posFound = " + posFound);

    // Erase 4 chars of data starting at char offset 1
    // Sets chars to ''
    clob.Erase(1, 4);

    //Prints "clob.Value = a b"
    Console.WriteLine("clob.Value = " + clob.Value);

    clob.Close();
    clob.Dispose();

    con.Close();
    con.Dispose();
}
```

## OracleClob Members

OracleClob members are listed in the following tables.

### OracleClob Constructors

OracleClob constructors are listed in [Table 13-19](#).

**Table 13-19 OracleClob Constructors**

| Constructor                             | Description                                                                        |
|-----------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">OracleClob Constructors</a> | Creates an instance of the OracleClob class bound to a temporary CLOB (Overloaded) |

### OracleClob Static Fields

OracleClob static fields are listed in [Table 13-20](#).

**Table 13-20 OracleClob Static Fields**

| Field                   | Description                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">MaxSize</a> | Holds the maximum number of bytes a CLOB can hold, which is 4,294,967,295 (2 <sup>32</sup> - 1) bytes |
| <a href="#">Null</a>    | Represents a null value that can be assigned to the value of an OracleClob instance                   |

### OracleClob Static Methods

OracleClob static methods are listed in [Table 13-21](#).

**Table 13-21 OracleClob Static Methods**

| Methods                | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

## OracleClob Instance Properties

OracleClob instance properties are listed in [Table 13-22](#).

**Table 13-22 OracleClob Instance Properties**

| Properties                         | Description                                                                                                  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">CanRead</a>            | Indicates whether or not the LOB stream can be read                                                          |
| <a href="#">CanSeek</a>            | Indicates whether or not forward and backward seek operations can be performed                               |
| <a href="#">CanWrite</a>           | Indicates whether or not the LOB stream can be written                                                       |
| <a href="#">Connection</a>         | Indicates the <code>OracleConnection</code> that is used to retrieve and write CLOB data                     |
| <a href="#">IsEmpty</a>            | Indicates whether the CLOB is empty or not                                                                   |
| <a href="#">IsInChunkWriteMode</a> | Indicates whether or not the CLOB has been opened                                                            |
| <a href="#">IsNClob</a>            | Indicates whether or not the <code>OracleClob</code> object represents an NCLOB.                             |
| <a href="#">IsNull</a>             | Indicates whether or not the current instance has a null value                                               |
| <a href="#">IsTemporary</a>        | Indicates whether or not the current instance is bound to a temporary CLOB                                   |
| <a href="#">Length</a>             | Indicates the size of the CLOB data in bytes                                                                 |
| <a href="#">OptimumChunkSize</a>   | Indicates the minimum number of bytes to retrieve or send from the database during a read or write operation |
| <a href="#">Position</a>           | Indicates the current read or write position in the LOB stream in bytes                                      |
| <a href="#">Value</a>              | Returns the data, starting from the first character in the CLOB or NCLOB, as a string                        |

## OracleClob Instance Methods

The `OracleClob` instance methods are listed in [Table 13-23](#).

**Table 13-23 OracleClob Instance Methods**

| Methods                         | Description                                                                     |
|---------------------------------|---------------------------------------------------------------------------------|
| <a href="#">Append</a>          | Appends data to the current <code>OracleClob</code> instance (Overloaded)       |
| <a href="#">BeginChunkWrite</a> | Opens the CLOB                                                                  |
| <a href="#">BeginRead</a>       | Inherited from <code>System.IO.Stream</code>                                    |
| <a href="#">BeginWrite</a>      | Inherited from <code>System.IO.Stream</code>                                    |
| <a href="#">Clone</a>           | Creates a copy of an <code>OracleClob</code> object                             |
| <a href="#">Close</a>           | Closes the current stream and releases resources associated with it             |
| <a href="#">Compare</a>         | Compares data referenced by the current instance to that of the supplied object |
| <a href="#">CopyTo</a>          | Copies the data to an <code>OracleClob</code> (Overloaded)                      |

Table 13-23 (Cont.) OracleClob Instance Methods

| Methods                                | Description                                                                                                                                                                                |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CopyToAsync</a>            | Returns a Task-based asynchronous version of <code>OracleClob.CopyTo()</code> , which copies data from the current instance to the provided <code>OracleClob</code> object (Overloaded)    |
| <code>CreateObjRef</code>              | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                      |
| <a href="#">Dispose</a>                | Releases resources allocated by this object                                                                                                                                                |
| <a href="#">EndChunkWrite</a>          | Closes the CLOB referenced by the current <code>OracleClob</code> instance                                                                                                                 |
| <code>EndRead</code>                   | Inherited from <code>System.IO.Stream</code>                                                                                                                                               |
| <code>EndWrite</code>                  | Inherited from <code>System.IO.Stream</code>                                                                                                                                               |
| <code>Equals</code>                    | Inherited from <code>System.Object</code> (Overloaded)                                                                                                                                     |
| <a href="#">Erase</a>                  | Erases the specified amount of data (Overloaded)                                                                                                                                           |
| <a href="#">Flush</a>                  | <i>Not supported</i>                                                                                                                                                                       |
| <a href="#">GetHashCode</a>            | Returns a hash code for the current instance                                                                                                                                               |
| <code>GetLifetimeService</code>        | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                      |
| <code>GetType</code>                   | Inherited from <code>System.Object</code>                                                                                                                                                  |
| <code>InitializeLifetimeService</code> | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                      |
| <a href="#">IsEqual</a>                | Compares the LOB data referenced by two <code>OracleClob</code> s                                                                                                                          |
| <a href="#">Read</a>                   | Reads from the current instance (Overloaded)                                                                                                                                               |
| <a href="#">ReadAsync</a>              | Returns a Task-based asynchronous version of <code>OracleClob.Read()</code> , which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer (Overloaded)  |
| <code>ReadByte</code>                  | Inherited from <code>System.IO.Stream</code>                                                                                                                                               |
| <a href="#">Search</a>                 | Searches for a character pattern in the current instance of <code>OracleClob</code> (Overloaded)                                                                                           |
| <a href="#">Seek</a>                   | Sets the position in the current LOB stream                                                                                                                                                |
| <a href="#">SetLength</a>              | Trims or truncates the CLOB value                                                                                                                                                          |
| <code>ToString</code>                  | Inherited from <code>System.Object</code>                                                                                                                                                  |
| <a href="#">Write</a>                  | Writes the provided buffer into the <code>OracleClob</code> (Overloaded)                                                                                                                   |
| <a href="#">WriteAsync</a>             | Returns a Task-based asynchronous version of <code>OracleClob.Write()</code> , which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer (Overloaded) |
| <code>WriteByte</code>                 | Inherited from <code>System.IO.Stream</code>                                                                                                                                               |

## OracleClob Constructors

OracleClob constructors create instances of the OracleClob class bound to a temporary CLOB.

**Overload List:**

- [OracleClob\(OracleConnection\)](#)

This constructor creates an instance of the OracleClob class bound to a temporary CLOB with an OracleConnection object.

- [OracleClob\(OracleConnection, bool, bool\)](#)

This constructor creates an instance of the OracleClob class that is bound to a temporary CLOB, with an OracleConnection object, a boolean value for caching, and a boolean value for NCLOB.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## OracleClob(OracleConnection)

This constructor creates an instance of the OracleClob class bound to a temporary CLOB with an OracleConnection object.

**Declaration**

```
// C#  
public OracleClob(OracleConnection con);
```

**Parameters**

- *con*

The OracleConnection object.

**Exceptions**

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

The connection must be opened explicitly by the application. `OracleClob` does not open the connection implicitly. The temporary CLOB utilizes the provided connection to store CLOB data. Caching is not enabled by default.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## OracleClob(OracleConnection, bool, bool)

This constructor creates an instance of the `OracleClob` class that is bound to a temporary CLOB, with an `OracleConnection` object, a boolean value for caching, and a boolean value for NLOB.

### Declaration

```
// C#  
public OracleClob(OracleConnection con, bool bCaching, bool bNLOB);
```

### Parameters

- *con*  
The `OracleConnection` object connection.
- *bCaching*  
A flag that indicates whether or not server-side caching is enabled.
- *bNLOB*  
A flag that is set to true if the instance is a NLOB or false if it is a CLOB.

### Exceptions

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

### Remarks

The connection must be opened explicitly by the application. `OracleClob` does not open the connection implicitly. The temporary CLOB or NLOB uses the provided connection to store CLOB data.

# OracleClob Static Fields

OracleClob static fields are listed in [Table 13-24](#).

**Table 13-24 OracleClob Static Fields**

| Field                   | Description                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">MaxSize</a> | Holds the maximum number of bytes a CLOB can hold, which is 4,294,967,295 (2 <sup>32</sup> - 1) bytes |
| <a href="#">Null</a>    | Represents a null value that can be assigned to the value of an OracleClob instance                   |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

# MaxSize

The MaxSize field holds the maximum number of bytes a CLOB can hold, which is 4,294,967,295 (2<sup>32</sup> - 1) bytes.

**Declaration**

```
// C#  
public static readonly Int64 MaxSize = 4294967295;
```

**Remarks**

This field is useful in code that checks whether or not your operation exceeds the maximum length (in bytes) allowed.

- [OracleClob Class](#)
- [OracleClob Members](#)

## Null

This static field represents a null value that can be assigned to the value of an `OracleClob` instance.

### Declaration

```
// C#  
public static readonly OracleClob Null;
```

- [OracleClob Members](#)

## OracleClob Instance Properties

`OracleClob` instance properties are listed in [Table 13-26](#).

**Table 13-26 OracleClob Instance Properties**

| Properties               | Description                                                                    |
|--------------------------|--------------------------------------------------------------------------------|
| <a href="#">CanRead</a>  | Indicates whether or not the LOB stream can be read                            |
| <a href="#">CanSeek</a>  | Indicates whether or not forward and backward seek operations can be performed |
| <a href="#">CanWrite</a> | Indicates whether or not the LOB stream can be written                         |

**Table 13-26 (Cont.) OracleClob Instance Properties**

| Properties                         | Description                                                                                                  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">Connection</a>         | Indicates the <code>OracleConnection</code> that is used to retrieve and write CLOB data                     |
| <a href="#">IsEmpty</a>            | Indicates whether the CLOB is empty or not                                                                   |
| <a href="#">IsInChunkWriteMode</a> | Indicates whether or not the CLOB has been opened                                                            |
| <a href="#">IsNClob</a>            | Indicates whether or not the <code>OracleClob</code> object represents an NCLOB.                             |
| <a href="#">IsNull</a>             | Indicates whether or not the current instance has a null value                                               |
| <a href="#">IsTemporary</a>        | Indicates whether or not the current instance is bound to a temporary CLOB                                   |
| <a href="#">Length</a>             | Indicates the size of the CLOB data in bytes                                                                 |
| <a href="#">OptimumChunkSize</a>   | Indicates the minimum number of bytes to retrieve or send from the database during a read or write operation |
| <a href="#">Position</a>           | Indicates the current read or write position in the LOB stream in bytes                                      |
| <a href="#">Value</a>              | Returns the data, starting from the first character in the CLOB or NCLOB, as a string                        |

## CanRead

Overrides `Stream`

This instance property indicates whether or not the LOB stream can be read.

**Declaration**

```
// C#  
public override bool CanRead{get;}
```

**Property Value**

If the LOB stream can be read, returns `true`; otherwise, returns `false`.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## CanSeek

Overrides Stream

This instance property indicates whether or not forward and backward seek operations can be performed.

### Declaration

```
// C#  
public override bool CanSeek{get;}
```

### Property Value

If forward and backward seek operations can be performed, returns true; otherwise, returns false.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## CanWrite

Overrides Stream

This instance property indicates whether or not the LOB object supports writing.

### Declaration

```
// C#  
public override bool CanWrite{get;}
```

### Property Value

If the LOB stream can be written, returns true; otherwise, returns false.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Connection

This instance property indicates the OracleConnection that is used to retrieve and write CLOB data.

**Declaration**

```
// C#  
public OracleConnection Connection {get;}
```

**Property Value**

An OracleConnection.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## IsEmpty

This instance property indicates whether the CLOB is empty or not.

**Declaration**

```
// C#  
public bool IsEmpty {get;}
```

**Property Value**

A bool.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## IsInChunkWriteMode

This instance property indicates whether or not the CLOB has been opened to defer index updates.

**Declaration**

```
// C#  
public bool IsInChunkWriteMode{get;}
```

**Property Value**

If the CLOB has been opened, returns true; otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## IsNClob

This instance property indicates whether or not the OracleClob object represents an NClob.

**Declaration**

```
// C#  
public bool IsNClob {get;}
```

**Property Value**

A bool.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

**Declaration**

```
// C#  
public bool IsNull{get;}
```

**Property Value**

Returns true if the current instance has a null value; otherwise, returns false.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## IsTemporary

This instance property indicates whether or not the current instance is bound to a temporary CLOB.

### Declaration

```
// C#  
public bool IsTemporary {get;}
```

### Property Value

A bool.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Length

Overrides Stream

This instance property indicates the size of the CLOB data in bytes.

### Declaration

```
// C#  
public override Int64 Length {get;}
```

### Property Value

An Int64 that indicates the size of the CLOB in bytes.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## OptimumChunkSize

This instance property indicates the minimum number of bytes to retrieve or send from the database during a read or write operation.

**Declaration**

```
// C#  
public int OptimumChunkSize{get;}
```

**Property Value**

A number representing the minimum bytes to retrieve or send.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Position

Overrides Stream

This instance property indicates the current read or write position in the LOB stream in bytes.

**Declaration**

```
// C#  
public override Int64 Position{get; set;}
```

**Property Value**

An Int64 that indicates the read or write position.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The Position is less than 0.

- [OracleClob Members](#)

## Value

This instance property returns the data, starting from the first character in the CLOB or NCLOB, as a string.

### Declaration

```
// C#  
public string Value{get;}
```

### Property Value

A string.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The Value is less than 0.

### Remarks

The value of Position is neither used nor changed by using this property.

The maximum string length that can be returned by this property is 2 GB.

For very large values, .NET may not be able to allocate enough contiguous memory to store all the data. Typically, you will see a System.OverflowException or System.OutOfMemoryException error then. To retrieve the large value, you can retrieve the data in chunks by calling GetChars() or GetBytes() method on the OracleDataReader. You can also call Read() method on the class.

## OracleClob Instance Methods

The `OracleClob` instance methods are listed in [Table 13-27](#).

**Table 13-27 OracleClob Instance Methods**

| Methods                                | Description                                                                                                                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Append</a>                 | Appends data to the current <code>OracleClob</code> instance (Overloaded)                                                                                                                 |
| <a href="#">BeginChunkWrite</a>        | Opens the CLOB                                                                                                                                                                            |
| <code>BeginRead</code>                 | Inherited from <code>System.IO.Stream</code>                                                                                                                                              |
| <code>BeginWrite</code>                | Inherited from <code>System.IO.Stream</code>                                                                                                                                              |
| <a href="#">Clone</a>                  | Creates a copy of an <code>OracleClob</code> object                                                                                                                                       |
| <a href="#">Close</a>                  | Closes the current stream and releases resources associated with it                                                                                                                       |
| <a href="#">Compare</a>                | Compares data referenced by the current instance to that of the supplied object                                                                                                           |
| <a href="#">CopyTo</a>                 | Copies the data to an <code>OracleClob</code> (Overloaded)                                                                                                                                |
| <a href="#">CopyToAsync</a>            | Returns a Task-based asynchronous version of <code>OracleClob.CopyTo()</code> , which copies data from the current instance to the provided <code>OracleClob</code> object (Overloaded)   |
| <code>CreateObjRef</code>              | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                     |
| <a href="#">Dispose</a>                | Releases resources allocated by this object                                                                                                                                               |
| <a href="#">EndChunkWrite</a>          | Closes the CLOB referenced by the current <code>OracleClob</code> instance                                                                                                                |
| <code>EndRead</code>                   | Inherited from <code>System.IO.Stream</code>                                                                                                                                              |
| <code>EndWrite</code>                  | Inherited from <code>System.IO.Stream</code>                                                                                                                                              |
| <code>Equals</code>                    | Inherited from <code>System.Object</code> (Overloaded)                                                                                                                                    |
| <a href="#">Erase</a>                  | Erases the specified amount of data (Overloaded)                                                                                                                                          |
| <a href="#">Flush</a>                  | <i>Not supported</i>                                                                                                                                                                      |
| <a href="#">GetHashCode</a>            | Returns a hash code for the current instance                                                                                                                                              |
| <code>GetLifetimeService</code>        | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                     |
| <code>GetType</code>                   | Inherited from <code>System.Object</code>                                                                                                                                                 |
| <code>InitializeLifetimeService</code> | Inherited from <code>System.MarshalByRefObject</code>                                                                                                                                     |
| <a href="#">IsEqual</a>                | Compares the LOB data referenced by two <code>OracleClob</code> s                                                                                                                         |
| <a href="#">Read</a>                   | Reads from the current instance (Overloaded)                                                                                                                                              |
| <a href="#">ReadAsync</a>              | Returns a Task-based asynchronous version of <code>OracleClob.Read()</code> , which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer (Overloaded) |
| <code>ReadByte</code>                  | Inherited from <code>System.IO.Stream</code>                                                                                                                                              |
| <a href="#">Search</a>                 | Searches for a character pattern in the current instance of <code>OracleClob</code> (Overloaded)                                                                                          |
| <a href="#">Seek</a>                   | Sets the position in the current LOB stream                                                                                                                                               |

Table 13-27 (Cont.) OracleClob Instance Methods

| Methods                    | Description                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SetLength</a>  | Trims or truncates the CLOB value                                                                                                                                            |
| ToString                   | Inherited from System.Object                                                                                                                                                 |
| <a href="#">Write</a>      | Writes the provided buffer into the OracleClob (Overloaded)                                                                                                                  |
| <a href="#">WriteAsync</a> | Returns a Task-based asynchronous version of OracleClob.Write(), which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer (Overloaded) |
| WriteByte                  | Inherited from System.IO.Stream                                                                                                                                              |

## Append

This instance method appends data to the current OracleClob instance.

**Overload List:**

- [Append\(OracleClob\)](#)  
This instance method appends the CLOB data referenced by the provided OracleClob object to the current OracleClob instance.
- [Append\(byte \[\], int, int\)](#)  
This instance method appends data at the end of the CLOB, from the supplied byte array buffer, starting from offset (in bytes) of the supplied byte array buffer.
- [Append\(char \[\], int, int\)](#)  
This instance method appends data from the supplied character array buffer to the end of the current OracleClob instance, starting at the offset (in characters) of the supplied character buffer.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleClob Class](#)
- [OracleClob Members](#)

## Append(OracleClob)

This instance method appends the CLOB data referenced by the provided `OracleClob` object to the current `OracleClob` instance.

### Declaration

```
// C#  
public void Append(OracleClob obj);
```

### Parameters

- *obj*  
An `OracleClob` object.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The parameter has a different connection than the object, `OracleConnection` is not opened, or `OracleConnection` has been reopened.

### Remarks

No character set conversions are made.

The provided object and the current instance must be using the same connection; that is, the same `OracleConnection` object.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Append(byte [], int, int)

This instance method appends data at the end of the CLOB, from the supplied byte array buffer, starting from offset (in bytes) of the supplied byte array buffer.

### Declaration

```
// C#  
public int Append(byte[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
An array of bytes, representing a Unicode string.
- *offset*  
The zero-based byte offset in the buffer from which data is read.

- *count*

The number of bytes to be appended.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - Either the *offset* or the *count* parameter is not even.

### Remarks

Both *offset* and *count* must be even numbers for CLOB and NCLOB because every two bytes represent a Unicode character.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Append(char [], int, int)

This instance method appends data from the supplied character array buffer to the end of the current OracleClob instance, starting at the offset (in characters) of the supplied character buffer.

### Declaration

```
// C#  
public void Append(char[] buffer, int offset, int count);
```

### Parameters

- *buffer*  
An array of characters.
- *offset*  
The zero-based offset (in characters) in the buffer from which data is read.
- *count*  
The number of characters to be appended.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class AppendSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleClob clob = new OracleClob(con);

        // Append 2 chars {'d', 'e'} to the OracleClob
        char[] buffer = new char[3] {'d', 'e', 'f'};
        clob.Append(buffer, 0, 2);

        // Prints "clob.Value = de"
        Console.WriteLine("clob.Value = " + clob.Value);

        clob.Close();
        clob.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

#### See Also

## BeginChunkWrite

This instance method opens the CLOB.

### Declaration

```
// C#
public void BeginChunkWrite();
```

### Exceptions

**ObjectDisposedException** - The object is already disposed.

**InvalidOperationException** - The **OracleConnection** is not open or has been closed during the lifetime of the object.

## Remarks

BeginChunkWrite does not need to be called before manipulating the CLOB data. This is provided for performance reasons.

After this method is called, write operations do not cause the domain or function-based index on the column to be updated. Index updates occur only once after EndChunkWrite is called.

## Clone

This instance method creates a copy of an OracleClob object.

### Declaration

```
// C#  
public object Clone();
```

### Return Value

An OracleClob object.

### Implements

ICloneable

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

### Remarks

The cloned object has the same property values as that of the object being cloned.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class CloneSample  
{  
    static void Main()  
    {  
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
```

```
OracleConnection con = new OracleConnection(constr);
con.Open();

OracleClob clob1 = new OracleClob(con);

// Prints "clob1.Position = 0"
Console.WriteLine("clob1.Position = " + clob1.Position);

// Set the Position before calling Clone()
clob1.Position = 1;

// Clone the OracleClob
OracleClob clob2 = (OracleClob)clob1.Clone();

// Prints "clob2.Position = 1"
Console.WriteLine("clob2.Position = " + clob2.Position);

clob1.Close();
clob1.Dispose();

clob2.Close();
clob2.Dispose();

con.Close();
con.Dispose();
}
}
```

## Close

Overrides Stream

This instance method closes the current stream and releases resources associated with it.

#### Declaration

```
// C#
public override void Close();
```

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Compare

This instance method compares data referenced by the current instance to that of the supplied object.

### Declaration

```
// C#  
public int Compare(Int64 src_offset, OracleClob obj, Int64 dst_offset,  
    Int64 amount);
```

### Parameters

- *src\_offset*  
The comparison starting point (in characters) for the current instance.
- *obj*  
The provided OracleClob object.
- *dst\_offset*  
The comparison starting point (in characters) for the provided OracleClob.
- *amount*  
The number of characters to compare.

### Return Value

The method returns a value that is:

- Less than zero: if the data referenced by the current instance is less than that of the supplied instance.
- Zero: if both objects reference the same data.
- Greater than zero: if the data referenced by the current instance is greater than that of the supplied instance.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The parameter has a different connection than the object, OracleConnection is not opened, or OracleConnection has been reopened.

ArgumentOutOfRangeException - Either the *src\_offset*, *dst\_offset*, or *amount* parameter is less than 0.

### Remarks

The character set of the two OracleClob objects being compared should be the same for a meaningful comparison.

The provided object and the current instance must be using the same connection, that is, the same OracleConnection object.

## CopyTo

CopyTo copies data from the current instance to the provided OracleClob object.

**Overload List:**

- [CopyTo\(OracleClob\)](#)  
This instance method copies data from the current instance to the provided OracleClob object.
- [CopyTo\(OracleClob, Int64\)](#)  
This instance method copies data from the current OracleClob instance to the provided OracleClob object with the specified destination offset.
- [CopyTo\(Int64, OracleClob, Int64, Int64\)](#)  
This instance method copies data from the current OracleClob instance to the provided OracleClob object with the specified source offset, destination offset, and character amounts.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## CopyTo(OracleClob)

This instance method copies data from the current instance to the provided OracleClob object.

**Declaration**

```
// C#  
public Int64 CopyTo(OracleClob obj);
```

**Parameters**

- *obj*  
The OracleClob object to which the data is copied.

**Return Value**

The return value is the amount copied.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - This exception is thrown if any of the following conditions exist:

- The OracleConnection is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

### Remarks

The provided object and the current instance must be using the same connection, that is, the same OracleConnection object.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## CopyTo(OracleClob, Int64)

This instance method copies data from the current OracleClob instance to the provided OracleClob object with the specified destination offset.

### Declaration

```
// C#  
public Int64 CopyTo(OracleClob obj, Int64 dst_offset);
```

### Parameters

- *obj*  
The OracleClob object to which the data is copied.
- *dst\_offset*  
The offset (in characters) at which the OracleClob object is copied.

### Return Value

The return value is the amount copied.

### Exceptions

ObjectDisposedException - The object is already disposed.

ArgumentOutOfRangeException - The *dst\_offset* is less than 0.

InvalidOperationException - This exception is thrown if any of the following conditions exist:

- The OracleConnection is not open or has been closed during the lifetime of the object.
- The LOB object parameter has a different connection than the object.

## Remarks

If the *dst\_offset* is beyond the end of the `OracleClob` data, spaces are written into the `OracleClob` until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection; that is, the same `OracleConnection` object.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## CopyTo(Int64, OracleClob, Int64, Int64)

This instance method copies data from the current `OracleClob` instance to the provided `OracleClob` object with the specified source offset, destination offset, and character amounts.

## Declaration

```
// C#
public Int64 CopyTo(Int64 src_offset, OracleClob obj, Int64 dst_offset,
    Int64 amount);
```

## Parameters

- *src\_offset*  
The offset (in characters) in the current instance, from which the data is read.
- *obj*  
The `OracleClob` object to which the data is copied.
- *dst\_offset*  
The offset (in characters) at which the `OracleClob` object is copied.
- *amount*  
The amount of data to be copied.

## Return Value

The return value is the amount copied.

## Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The parameter has a different connection than the object, `OracleConnection` is not opened, or `OracleConnection` has been reopened.

`ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* parameter is less than 0.

### Remarks

If the *dst\_offset* is beyond the end of the `OracleClob` data, spaces are written into the `OracleClob` until the *dst\_offset* is met.

The offsets are 0-based. No character conversion is performed by this operation.

The provided object and the current instance must be using the same connection, that is, the same `OracleConnection` object.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class CopyToSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleClob clob1 = new OracleClob(con);
        OracleClob clob2 = new OracleClob(con);

        // Write 4 chars, starting at buffer offset 0
        char[] buffer = new char[4] { 'a', 'b', 'c', 'd' };
        clob1.Write(buffer, 0, 4);

        // Copy 2 chars from char 0 of clob1 to char 1 of clob2
        clob1.CopyTo(0, clob2, 1, 2);

        //Prints "clob2.Value = ab"
        Console.WriteLine("clob2.Value = " + clob2.Value);

        clob1.Close();
        clob1.Dispose();

        clob2.Close();
        clob2.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## CopyToAsync

CopyToAsync returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

**Overload List:**

- [CopyToAsync\(Int64, OracleClob, Int64, Int64\)](#)  
This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.
- [CopyToAsync\(Int64, OracleClob, Int64, Int64, CancellationToken\)](#)  
This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.
- [CopyToAsync\(OracleClob, Int64\)](#)  
This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.
- [CopyToAsync\(OracleClob, Int64, CancellationToken\)](#)  
This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.
- [CopyToAsync\(OracleClob\)](#)  
This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.
- [CopyToAsync\(OracleClob, CancellationToken\)](#)  
This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

**Example**

```
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;
using System;
using System.Threading;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";
```

```

OracleConnection oc = new OracleConnection(connectionString);
await oc.OpenAsync(CancellationToken.None);

OracleCommand cmd = oc.CreateCommand();
cmd.CommandText = " select clob_column from tab1";

OracleClob clob1 = new OracleClob(oc);
OracleClob clob2 = new OracleClob(oc);
OracleClob clob3 = new OracleClob(oc);
OracleClob clob4 = new OracleClob(oc);
OracleClob clob5 = new OracleClob(oc);
OracleClob clob6 = new OracleClob(oc);

OracleDataReader reader = await cmd.ExecuteReaderAsync();

await reader.ReadAsync(CancellationToken.None);
using (OracleClob clob = reader.GetOracleClob(0))
{
    //asynchronously copy clob data
    Int64 charsCopied1 = await clob.CopyToAsync(0, clob1, 0, clob.Length);
    Console.WriteLine("chars copied to clob1 = " + charsCopied1);

    //asynchronously copy clob data
    Int64 charsCopied2 = await clob.CopyToAsync(0, clob2, 0, clob.Length,
CancellationTokencancellationToken.None);
    Console.WriteLine("chars copied to clob2 = " + charsCopied2);

    //asynchronously copy clob data
    Int64 charsCopied3 = await clob.CopyToAsync(clob3, 0);
    Console.WriteLine("chars copied to clob3 = " + charsCopied3);

    //asynchronously copy clob data
    Int64 charsCopied4 = await clob.CopyToAsync(clob4, 0, CancellationToken.None);
    Console.WriteLine("chars copied to clob4 = " + charsCopied4);

    //asynchronously copy clob data
    Int64 charsCopied5 = await clob.CopyToAsync(clob5);
    Console.WriteLine("chars copied to clob5 = " + charsCopied5);

    //asynchronously copy clob data
    Int64 charsCopied6 = await clob.CopyToAsync(clob6, CancellationToken.None);
    Console.WriteLine("chars copied to clob6 = " + charsCopied6);
}
}
}
}

```

## CopyToAsync(Int64, OracleClob, Int64, Int64)

This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

### Declaration

```
// C#  
public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64 dst_offset, Int64  
amount)
```

### Parameters

- *src\_offset*  
The offset (in characters) in the current instance, from which the data is read.
- *obj*  
The OracleClob object to which the data is copied.
- *dst\_offset*  
The offset (in characters) at which the OracleClob object is copied.
- *amount*  
The amount of data to be copied.

### Return Value

Task<Int64> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(Int64, OracleClob, Int64, Int64, CancellationToken)

This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

### Declaration

```
// C#  
public Task<Int64> CopyToAsync(Int64 src_offset, OracleClob obj, Int64 dst_offset, Int64  
amount, CancellationToken cancellationToken)
```

**Parameters**

- *src\_offset*  
The offset (in characters) in the current instance, from which the data is read.
- *obj*  
The OracleClob object to which the data is copied.
- *dst\_offset*  
The offset (in characters) at which the OracleClob object is copied.
- *amount*  
The amount of data to be copied.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task.

**Return Value**

Task<Int64> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Exceptions**

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The *src\_offset*, the *dst\_offset*, or the *amount* parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

**See Also**

## CopyToAsync(OracleClob, Int64)

This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

**Declaration**

```
// C#  
public async Task<Int64> CopyToAsync(OracleClob obj, Int64 dst_offset)
```

**Parameters**

- *obj*

The `OracleClob` object to which the data is copied.

- `dst_offset`

The offset (in characters) at which the `OracleClob` object is copied.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `dst_offset` is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleClob, Int64, CancellationTokens)

This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

### Declaration

```
// C#
public async Task<Int64> CopyToAsync(OracleClob obj, Int64 dst_offset, CancellationTokens cancellationTokens)
```

### Parameters

- `obj`  
The `OracleClob` object to which the data is copied.
- `dst_offset`  
The offset (in characters) at which the `OracleClob` object is copied.
- `cancellationTokens`  
The input cancellation token which can be used by the application to cancel the task.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `ArgumentOutOfRangeException` - The `dst_offset` parameter is less than 0.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

## CopyToAsync(OracleClob)

This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

### Declaration

```
// C#  
public async Task<Int64> CopyToAsync(OracleClob obj)
```

### Parameters

- *obj*  
The `OracleClob` object to which the data is copied.

### Return Value

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## CopyToAsync(OracleClob, CancellationToken)

This method returns a Task-based asynchronous version of `OracleClob.CopyTo()`, which copies data from the current instance to the provided `OracleClob` object.

**Declaration**

```
// C#  
public async Task<Int64> CopyToAsync(OracleClob obj, CancellationToken cancellationToken)
```

**Parameters**

- *obj*  
The `OracleClob` object to which the data is copied.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task.

**Return Value**

`Task<Int64>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Exceptions**

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - This exception is thrown if any of the following conditions exist:
  - The `OracleConnection` is not open or has been closed during the lifetime of the object.
  - The LOB object parameter has a different connection than the object.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Dispose

This instance method releases resources allocated by this object.

**Declaration**

```
public void Dispose();
```

**Implements**

IDisposable

**Remarks**

The object cannot be reused after being disposed. Although some properties can still be accessed, their values cannot be accountable. Since resources are freed, method calls can lead to exceptions.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## EndChunkWrite

This instance method closes the CLOB referenced by the current OracleClob instance.

**Declaration**

```
// C#  
public void EndChunkWrite();
```

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

**Remarks**

Index updates occur immediately if write operation(s) are deferred by the BeginChunkWrite method.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Erase

Erase erases part or all data.

### Overload List:

- [Erase\(\)](#)

This instance method erases all data.

- [Erase\(Int64, Int64\)](#)

This instance method replaces the specified amount of data (in characters) starting from the specified offset with zero-byte fillers (in characters).

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Erase()

This instance method erases all data.

### Declaration

```
// C#  
public Int64 Erase();
```

### Return Value

The number of characters erased.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Erase(Int64, Int64)

This instance method replaces the specified amount of data (in characters) starting from the specified offset with zero-byte fillers (in characters).

### Declaration

```
// C#  
public Int64 Erase(Int64 offset, Int64 amount);
```

**Parameters**

- *offset*  
The offset.
- *amount*  
The amount of data.

**Return Value**

The actual number of characters erased.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The *offset* or *amount* parameter is less than 0.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Flush

This method is not supported.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the current instance.

**Declaration**

```
// C#  
public override int GetHashCode();
```

**Return Value**

An int representing a hash code.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## IsEqual

This instance method compares the LOB data referenced by two OracleClob.

**Declaration**

```
// C#  
public bool IsEqual(OracleClob obj);
```

**Parameters**

- *obj*  
An OracleClob object.

**Return Value**

Returns true if the current OracleClob and the provided OracleClob refer to the same LOB. Otherwise, returns false.

**Remarks**

Note that this method can return true even if the two OracleClob objects returns false for == or Equals() because two different OracleClob instances can refer to the same LOB.

The provided object and the current instance must be using the same connection, that is, the same OracleConnection object.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Read

Read reads a specified amount from the current instance and populates the array buffer.

**Overload List:**

- [Read\(byte \[\], int, int\)](#)  
This instance method reads a specified amount of bytes from the current instance and populates the byte array buffer.
- [Read\(char \[\], int, int\)](#)  
This instance method reads a specified amount of characters from the current instance and populates the character array buffer.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Read(byte [], int, int)

Overrides Stream

This instance method reads a specified amount of bytes from the current instance and populates the byte array buffer.

**Declaration**

```
// C#  
public override int Read(byte [] buffer, int offset, int count);
```

**Parameters**

- *buffer*  
The byte array buffer that is populated.
- *offset*  
The offset (in bytes) at which the buffer is populated.
- *count*  
The amount of bytes to be read.

**Return Value**

The number of bytes read from the CLOB.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

## Remarks

Both *offset* and *count* must be even numbers for CLOB and NCLOB because every two bytes represent a Unicode character.

The LOB data is read starting from the position specified by the *Position* property, which must also be an even number.

OracleClob is free to return fewer bytes than requested, even if the end of the stream has not been reached.

### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleClob Class](#)
- [OracleClob Members](#)

## Read(char [ ], int, int)

This instance method reads a specified amount of characters from the current instance and populates the character array buffer.

### Declaration

```
// C#  
public int Read(char[ ] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The character array buffer that is populated.
- *offset*  
The offset (in characters) at which the buffer is populated.
- *count*  
The amount of characters to be read.

### Return Value

The return value indicates the number of characters read from the CLOB.

### Exceptions

*ObjectDisposedException* - The object is already disposed.

*InvalidOperationException* - The *OracleConnection* is not open or has been closed during the lifetime of the object.

*ArgumentOutOfRangeException* - This exception is thrown if any of the following conditions exist:

- The *offset* or the *count* is less than 0.

- The *offset* is greater than or equal to the *buffer.Length*.
- The *offset* and the *count* together are greater than *buffer.Length*.

### Remarks

Handles all CLOB and NCLOB data as Unicode.

The LOB data is read starting from the position specified by the *Position* property.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class ReadSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleClob clob = new OracleClob(con);

        // Write 3 chars, starting at buffer offset 1
        char[] writeBuffer = new char[4] {'a', 'b', 'c', 'd'};
        clob.Write(writeBuffer, 1, 3);

        // Reset the Position (in bytes) for Read
        clob.Position = 2;

        // Read 2 chars into buffer starting at buffer offset 1
        char[] readBuffer = new char[4];
        int charsRead = clob.Read(readBuffer, 1, 2);

        // Prints "charsRead = 2"
        Console.WriteLine("charsRead = " + charsRead);

        // Prints "readBuffer = cd "
        Console.Write("readBuffer = ");
        for(int index = 0; index < readBuffer.Length; index++)
        {
            Console.Write(readBuffer[index]);
        }
        Console.WriteLine();

        clob.Close();
        clob.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## ReadAsync

ReadAsync returns a Task-based asynchronous version of `OracleClob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

**Overload List:**

- [ReadAsync\(byte\[\], int, int, CancellationToken\)](#)  
ReadAsync returns a Task-based asynchronous version of `OracleClob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.
- [ReadAsync\(byte\[\], int, int\)](#)  
ReadAsync returns a Task-based asynchronous version of `OracleClob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.
- [ReadAsync\(char\[\], int, int\)](#)  
ReadAsync returns a Task-based asynchronous version of `OracleClob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.
- [ReadAsync\(char\[\], int, int, CancellationToken\)](#)  
ReadAsync returns a Task-based asynchronous version of `OracleClob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

**Example (includes all overloads)**

```
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";

            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationToken.None);

            OracleCommand cmd = oc.CreateCommand();
```

```
cmd.CommandText = " select clob_column from tab1";

OracleDataReader reader = await cmd.ExecuteReaderAsync();

await reader.ReadAsync(CancellationToken.None);

using (var clob = reader.GetOracleClob(0))
{
    char[] charBuffer = new char[128];
    byte[] byteBuffer = new byte[128];

    //asynchronously read clob data
    int bytesRead = await clob.ReadAsync(byteBuffer, 0, 64);
    Console.WriteLine("Bytes Read: " + bytesRead);

    //asynchronously read clob data
    bytesRead = await clob.ReadAsync(byteBuffer, 64, 64, CancellationToken.None);
    Console.WriteLine("Bytes Read: " + bytesRead);

    //asynchronously read clob data
    int charsRead = await clob.ReadAsync(charBuffer, 0, 64);
    Console.WriteLine("Chars Read: " + charsRead);

    //asynchronously read clob data
    charsRead = await clob.ReadAsync(charBuffer, 64, 64, CancellationToken.None);
    Console.WriteLine("Chars Read: " + charsRead);
}
}
```

## ReadAsync(byte[], int, int, CancellationToken)

This method returns a Task-based asynchronous version of `OracleClob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

### Declaration

```
// C#
public override Task<int> ReadAsync(byte[] buffer, int offset, int count,
    CancellationToken cancellationToken)
```

### Parameters

- *buffer*  
The byte array buffer that is populated.
- *offset*  
The offset (in bytes) at which the buffer is populated.

- *count*  
The amount of bytes to be read.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task.

### Return Value

Task<int> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

Stream

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

## ReadAsync(byte[], int, int)

This method calls into the `ReadAsync` implementation with argument 'cancellationToken' passed as `Cancellation.Token.None`.

### Declaration

```
// C#  
public Task<int> ReadAsync(byte[] buffer, int offset, int count)
```

### Parameters

- *buffer*  
The byte array buffer that is populated.
- *offset*  
The offset (in bytes) at which the buffer is populated.
- *count*

The amount of bytes to be read.

### Return Value

`Task<int>` object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

Stream

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

## ReadAsync(char[], int, int)

This method calls into the `ReadAsync` implementation with argument 'cancellationToken' passed as `CancellationToken.None`.

### Declaration

```
// C#  
public Task<int> ReadAsync(char[] buffer, int offset, int count)
```

### Parameters

- *buffer*  
The character array buffer that is populated.
- *offset*  
The offset (in characters) at which the buffer is populated.
- *count*  
The amount of characters to be read.

### Return Value

Task<int> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

## ReadAsync(char[], int, int, CancellationToken)

This method returns a Task-based asynchronous version of `OracleClob.Read()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

### Declaration

```
// C#  
public Task<int> ReadAsync(char[] buffer, int offset, int count, CancellationToken  
cancellationToken)
```

### Parameters

- *buffer*  
The character array buffer that is populated.
- *offset*  
The offset (in characters) at which the buffer is populated.
- *count*  
The amount of characters to be read.
- *cancellationToken*  
The input cancellation token which can be used by the application to cancel the task.

### Return Value

Task<int> object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.

## Search

Search searches for a character pattern in the current instance of `OracleClob`.

### Overload List:

- [Search\(byte\[\], Int64, Int64\)](#)  
This instance method searches for a character pattern, represented by the byte array, in the current instance of `OracleClob`.
- [Search\(char\[\], Int64, Int64\)](#)  
This instance method searches for a character pattern in the current instance of `OracleClob`.

#### ① See Also

## Search(byte[ ], Int64, Int64)

This instance method searches for a character pattern, represented by the byte array, in the current instance of `OracleClob`.

### Declaration

```
// C#  
public int Search(byte[] val, Int64 offset, Int64 nth);
```

### Parameters

- *val*  
A Unicode byte array.
- *offset*  
The 0-based offset (in characters) starting from which the `OracleClob` is searched.
- *nth*  
The specific occurrence (1-based) of the match for which the absolute offset (in characters) is returned.

### Return Value

Returns the absolute *offset* of the start of the matched pattern (in bytes) for the *nth* occurrence of the match. Otherwise, 0 is returned.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:

- The *offset* is less than 0.
- The *nth* is less than or equal to 0.
- The *nth* is greater than or equal to `OracleClob.MaxValue`.
- The *offset* is greater than or equal to `OracleClob.MaxValue`.

### Remarks

The `byte[ ]` is converted to Unicode before the search is made.

The limit of the search pattern is 16383 bytes.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)

## Search(char[ ], Int64, Int64)

This instance method searches for a character pattern in the current instance of `OracleClob`.

### Declaration

```
// C#  
public Int64 Search(char [ ] val, Int64 offset, Int64 nth);
```

### Parameters

- *val*  
The Unicode string being searched for.
- *offset*  
The 0-based offset (in characters) starting from which the `OracleClob` is searched.
- *nth*  
The specific occurrence (1-based) of the match for which the absolute offset (in characters) is returned.

### Return Value

Returns the absolute *offset* of the start of the matched pattern (in characters) for the *nth* occurrence of the match. Otherwise, 0 is returned.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:

- The *offset* is less than 0.
- The *nth* is less than or equal to 0.
- The *val*.Length doubled is greater than 16383.
- The *nth* is greater than or equal to `OracleClob.MaxValue`.
- The *offset* is greater than or equal to `OracleClob.MaxValue`.

### Remarks

The limit of the search pattern is 16383 bytes.

**Example**

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class SearchSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleClob clob = new OracleClob(con);

        // Write 7 chars, starting at buffer offset 0
        char[] buffer = new char[7] {'a', 'b', 'c', 'd', 'a', 'b', 'c'};
        clob.Write(buffer, 0, 7);

        // Search for the 2nd occurrence of a char pattern 'bc'
        // starting at offset 1 in the OracleBlob
        char[] pattern = new char[2] {'b', 'c'};
        long posFound = clob.Search(pattern, 1, 2);

        // Prints "posFound = 6"
        Console.WriteLine("posFound = " + posFound);

        clob.Close();
        clob.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## Seek

Overrides Stream

This instance method sets the position on the current LOB stream.

**Declaration**

```
// C#
public override Int64 Seek(Int64 offset, SeekOrigin origin);
```

**Parameters**

- *offset*  
A byte offset relative to origin.
- *origin*  
A value of type `System.IO.SeekOrigin` indicating the reference point used to obtain the new position.

**Return Value**

Returns an `Int64` that indicates the position.

**Exceptions**

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

**Remarks**

If *offset* is negative, the new position precedes the position specified by *origin* by the number of characters specified by *offset*.

If *offset* is zero, the new position is the position specified by *origin*.

If *offset* is positive, the new position follows the position specified by *origin* by the number of characters specified by *offset*.

`SeekOrigin.Begin` specifies the beginning of a stream.

`SeekOrigin.Current` specifies the current position within a stream.

`SeekOrigin.End` specifies the end of a stream.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## SetLength

Overrides `Stream`

This instance method trims or truncates the CLOB value to the specified length (in characters).

**Declaration**

```
// C#  
public override void SetLength(Int64 newlen);
```

**Parameters**

- *newlen*  
The desired length of the current stream in characters.

**Exceptions**

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The `OracleConnection` is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - The *newlen* parameter is greater than 0.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Write

This instance method writes data from the provided array buffer into the `OracleClob`.

**Overload List:**

- [Write\(byte\[\], int, int\)](#)  
This instance method writes data from the provided byte array buffer into the `OracleClob`.
- [Write\(char\[\], int, int\)](#)  
This instance method writes data from the provided character array buffer into the `OracleClob`.

## WriteAsync

`WriteAsync` returns a Task-based asynchronous version of `OracleClob.Write()`, which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

**Overload List:**

- [WriteAsync\(byte\[\], int, int\)](#)

WriteAsync returns a Task-based asynchronous version of OracleClob.Write(), which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

- [WriteAsync\(byte\[\], int, int, CancellationToken\)](#)

WriteAsync returns a Task-based asynchronous version of OracleClob.Write(), which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

- [WriteAsync\(char\[\], int, int\)](#)

WriteAsync returns a Task-based asynchronous version of OracleClob.Write(), which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

- [WriteAsync\(char\[\], int, int, CancellationToken\)](#)

WriteAsync returns a Task-based asynchronous version of OracleClob.Write(), which reads a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

#### Example (includes all overloads)

```
using Oracle.ManagedDataAccess.Client;
using Oracle.ManagedDataAccess.Types;
using System;
using System.Threading;
using System.Threading.Tasks;

namespace AsyncApp
{
    class AsyncDemo
    {
        static async Task Main(string[] args)
        {
            string connectionString = "User Id=HR; Password=<PASSWORD>; Data Source=oracle;";

            OracleConnection oc = new OracleConnection(connectionString);
            await oc.OpenAsync(CancellationToken.None);

            OracleClob clob = new OracleClob(oc);

            char[] writeBufferChar = new char[4] {'a', 'b', 'c', 'd'};
            byte[] writeBufferByte = new byte[4] {1, 2, 3, 4};

            //Write data to Character Large Object, asynchronously
            await clob.WriteAsync(writeBufferByte, 0, 4);
            Console.WriteLine("clob.Length = " + clob.Length);

            //Write data to Character Large Object, asynchronously
            await clob.WriteAsync(writeBufferByte, 0, 4, CancellationToken.None);
            Console.WriteLine("clob.Length = " + clob.Length);

            //Write data to Character Large Object, asynchronously
            await clob.WriteAsync(writeBufferChar, 0, 4);
            Console.WriteLine("clob.Length = " + clob.Length);

            //Write data to Character Large Object, asynchronously
            await clob.WriteAsync(writeBufferChar, 0, 4, CancellationToken.None);
            Console.WriteLine("clob.Length = " + clob.Length);
        }
    }
}
```

## WriteAsync(byte[], int, int)

This method calls into the WriteAsync implementation with argument 'cancellationToken' passed as CancellationToken.None.

### Declaration

```
// C#  
public Task WriteAsync(byte[] buffer, int offset, int count)
```

### Parameters

- *buffer*  
The byte array buffer that provides the data.
- *offset*  
The 0-based offset (in bytes) from which the buffer is read.
- *count*  
The amount of bytes to be written into the OracleClob.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

Stream

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.
  - The offset, the count, or the Position is not even.

## WriteAsync(byte[], int, int, CancellationToken)

This method returns a Task-based asynchronous version of `OracleClob.Write()`, which writes a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

### Declaration

```
// C#  
public override Task WriteAsync(byte[] buffer, int offset, int count, CancellationToken  
cancellationTokentoken)
```

### Parameters

- *buffer*  
The byte array buffer that provides the data.
- *offset*  
The 0-based offset (in bytes) from which the buffer is read.
- *count*  
The amount of bytes to be written into the `OracleClob`.
- *cancellationTokentoken*  
The input cancellation token which can be used by the application to cancel the task.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Implements

Stream

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.
  - The offset, the count, or the `Position` is not even.

## WriteAsync(char[], int, int)

This method calls into the WriteAsync implementation with argument 'cancellationToken' passed as CancellationToken.None.

**Declaration**

```
// C#  
public Task WriteAsync(char[] buffer, int offset, int count)
```

**Parameters**

- *buffer*  
The character array buffer that provides the data.
- *offset*  
The 0-based offset (in characters) from which the buffer is read.
- *count*  
The amount of characters to be written into the OracleClob.

**Return Value**

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

**Exceptions**

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.
  - The offset, the count, or the `Position` is not even.

## WriteAsync(char[], int, int, CancellationToken)

This method returns a Task-based asynchronous version of `OracleClob.Write()`, which writes a specified number of bytes from the ODP.NET LOB instance and populates the buffer.

### Declaration

```
// C#  
public Task WriteAsync(char[] buffer, int offset, int count, CancellationToken  
cancellationTokentoken)
```

### Parameters

- *buffer*  
The character array buffer that provides the data.
- *offset*  
The 0-based offset (in characters) from which the buffer is read.
- *count*  
The amount of characters to be written into the `OracleClob`.
- *cancellationTokentoken*  
The input cancellation token which can be used by the application to cancel the task.

### Return Value

Task object representing the asynchronous operation immediately without blocking the calling thread for the whole duration of the query execution.

### Exceptions

- `ObjectDisposedException` - The object is already disposed.
- `InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.
- `ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:
  - The offset or the count parameter is less than 0.
  - The offset is greater than or equal to the `buffer.Length`.
  - The offset and the count together are greater than the `buffer.Length`.
  - The offset, the count, or the `Position` is not even.

## Write(byte[ ], int, int)

Overrides Stream

This instance method writes data from the provided byte array buffer into the OracleClob.

### Declaration

```
// C#  
public override void Write(byte[ ] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The byte array buffer that represents a Unicode string.
- *offset*  
The offset (in bytes) from which the buffer is read.
- *count*  
The amount of data (in bytes) from the buffer to be written into the OracleClob.

### Exceptions

ObjectDisposedException - The object is already disposed.

InvalidOperationException - The OracleConnection is not open or has been closed during the lifetime of the object.

ArgumentOutOfRangeException - This exception is thrown if any of the following conditions exist:

- The *offset* or the *count* is less than 0.
- The *offset* is greater than or equal to the *buffer.Length*.
- The *offset* and the *count* together are greater than the *buffer.Length*.
- The *offset*, the *count*, or the *Position* is not even.

### Remarks

Both *offset* and *count* must be even numbers for CLOB and NCLOB because every two bytes represent a Unicode character.

The LOB data is read starting from the position specified by the *Position* property. The *Position* property must be an even number.

If necessary, proper data conversion is carried out from the client character set to the database character set.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleClob Class](#)
- [OracleClob Members](#)

## Write(char[ ], int, int)

This instance method writes data from the provided character array buffer into the `OracleClob`.

### Declaration

```
// C#  
public void Write(char[ ] buffer, int offset, int count);
```

### Parameters

- *buffer*  
The character array buffer that is written to the `OracleClob`.
- *offset*  
The offset (in characters) from which the *buffer* is read.
- *count*  
The amount (in characters) from the buffer that is to be written into the `OracleClob`.

### Exceptions

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

`ArgumentOutOfRangeException` - This exception is thrown if any of the following conditions exist:

- The *offset* or the *count* is less than 0.
- The *offset* is greater than or equal to the *buffer.Length*.
- The *offset* and the *count* together are greater than *buffer.Length*.
- The Position is not even.

### Remarks

Handles all CLOB and NCLOB data as Unicode.

The LOB data is read starting from the position specified by the `Position` property.

If necessary, proper data conversion is carried out from the client character set to the database character set.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class WriteSample
{
    static void Main()
    {
        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        OracleClob clob = new OracleClob(con);

        // Set the Position for the Write;
        clob.Position = 0;

        // Begin ChunkWrite to improve performance
        // Index updates occur only once after EndChunkWrite
        clob.BeginChunkWrite();

        // Write to the OracleClob in 5 chunks of 2 chars each
        char[] c = new char[2] {'a', 'b'};
        for (int index = 0; index < 5; index++)
        {
            clob.Write(c, 0, c.Length);
        }
        clob.EndChunkWrite();

        // Prints "clob.Value = ababababab"
        Console.WriteLine("clob.Value = " + clob.Value);

        clob.Close();
        clob.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## OracleRefCursor Class

An OracleRefCursor object represents an Oracle REF CURSOR..

Class Inheritance

System.Object  
    System.MarshalRefByObject  
        Oracle.DataAccess.Types.OracleRefCursor

Declaration

```
// C#  
public sealed class OracleRefCursor : MarshalByRefObject, IDisposable, INullable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

To minimize the number of open server cursors, OracleRefReader objects should be explicitly disposed.

Example

```
// Database Setup  
/*  
connect scott/tiger@oracle  
CREATE OR REPLACE FUNCTION MyFunc(refcur_out OUT SYS_REFCURSOR)  
    RETURN SYS_REFCURSOR IS refcur_ret SYS_REFCURSOR;  
BEGIN  
    OPEN refcur_ret FOR SELECT * FROM EMP;  
    OPEN refcur_out FOR SELECT * FROM DEPT;  
    RETURN refcur_ret;  
END MyFunc;  
/  
*/  
  
// C#  
  
using System;  
using System.Data;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;
```

```
class OracleRefCursorSample
{
    static void Main()
    {
        // Example demonstrates how to use REF CURSORS returned from
        // PL/SQL Stored Procedures or Functions
        // Create the PL/SQL Function MyFunc as defined previously

        string constr = "User Id=scott;Password=tiger;Data Source=oracle";
        OracleConnection con = new OracleConnection(constr);
        con.Open();

        // Create an OracleCommand
        OracleCommand cmd = new OracleCommand("MyFunc", con);
        cmd.CommandType = CommandType.StoredProcedure;

        // Bind the parameters
        // p1 is the RETURN REF CURSOR bound to SELECT * FROM EMP;
        OracleParameter p1 =
            cmd.Parameters.Add("refcur_ret", OracleDbType.RefCursor);
        p1.Direction = ParameterDirection.ReturnValue;

        // p2 is the OUT REF CURSOR bound to SELECT * FROM DEPT
        OracleParameter p2 =
            cmd.Parameters.Add("refcur_out", OracleDbType.RefCursor);
        p2.Direction = ParameterDirection.Output;

        // Execute the command
        cmd.ExecuteNonQuery();

        // Construct an OracleDataReader from the REF CURSOR
        OracleDataReader reader1 = ((OracleRefCursor)p1.Value).GetDataReader();

        // Prints "reader1.GetName(0) = EMPNO"
        Console.WriteLine("reader1.GetName(0) = " + reader1.GetName(0));

        // Construct an OracleDataReader from the REF CURSOR
        OracleDataReader reader2 = ((OracleRefCursor)p2.Value).GetDataReader();

        // Prints "reader2.GetName(0) = DEPTNO"
        Console.WriteLine("reader2.GetName(0) = " + reader2.GetName(0));

        reader1.Close();
        reader1.Dispose();

        reader2.Close();
        reader2.Dispose();

        p1.Dispose();
        p2.Dispose();

        cmd.Dispose();

        con.Close();
        con.Dispose();
    }
}
```

## OracleRefCursor Members

OracleRefCursor members are listed in the following tables.

### OracleRefCursor Static Methods

OracleRefCursor static methods are listed in [Table 13-28](#).

**Table 13-28 OracleRefCursor Static Methods**

| Methods                | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

### OracleRefCursor Static Fields

OracleRefCursor static field is listed in [Table 13-29](#).

**Table 13-29 OracleRefCursor Static Field**

| Methods              | Description                                                                 |
|----------------------|-----------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an OracleRefCursor instance |

### OracleRefCursor Properties

OracleRefCursor properties are listed in [Table 13-30](#).

**Table 13-30 OracleRefCursor Properties**

| Properties                 | Description                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------|
| <a href="#">Connection</a> | A reference to the OracleConnection used to fetch the REF CURSOR data                            |
| <a href="#">FetchSize</a>  | Specifies the size that the OracleDataReader internal cache needs to store result set data       |
| <a href="#">IsNull</a>     | Indicates whether or not the OracleRefCursor is null                                             |
| <a href="#">RowSize</a>    | Specifies the amount of memory the OracleRefcursor internal cache needs to store one row of data |

**Table 13-30 (Cont.) OracleRefCursor Properties**

| Properties                              | Description                                                                                                                 |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">RowsToFetchPerRoundTrip</a> | Specifies the total number of rows to retrieve per database round trip<br><i>Not Available in ODP.NET, Unmanaged Driver</i> |

**OracleRefCursor Instance Methods**

OracleRefCursor instance methods are listed in [Table 13-31](#).

**Table 13-31 OracleRefCursor Instance Methods**

| Methods                       | Description                                                    |
|-------------------------------|----------------------------------------------------------------|
| <a href="#">Dispose</a>       | Disposes the resources allocated by the OracleRefCursor object |
| Equals                        | Inherited from System.Object (Overloaded)                      |
| <a href="#">GetDataReader</a> | Returns an OracleDataReader object for the REF CURSOR          |
| GetHashCode                   | Inherited from System.Object                                   |
| GetType                       | Inherited from System.Object                                   |
| ToString                      | Inherited from System.Object                                   |

## Connection

This property refers to the OracleConnection used to fetch the REF CURSOR data.

**Declaration**

```
// C#  
public OracleConnection Connection {get;}
```

**Property Value**

An OracleConnection.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

This property is bound to a REF CURSOR once it is set. After the OracleRefCursor object is created by the constructor, this property is initially null. An OracleRefCursor object can be bound to a REF CURSOR after a command execution.

If the connection is closed or returned to the connection pool, the OracleRefCursor is placed in an uninitialized state and no operation can be carried out from it. However, the uninitialized OracleRefCursor can be reassigned to another REF CURSOR.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRefCursor Class](#)
- [OracleRefCursor Members](#)

## FetchSize

This property specifies the size that the `OracleDataReader` internal cache needs to store result set data.

**Declaration**

```
// C#  
public long FetchSize {get; set;}
```

**Property Value**

A long that specifies the size (in bytes) of the `OracleRefCursor` internal cache.

**Exceptions**

`ArgumentException` - The `FetchSize` value specified is invalid.

**Remarks**

Default = 131072.

The `FetchSize` property value is inherited by the `OracleCommand` that created the `OracleRefCursor` object. The `FetchSize` property on the `OracleDataReader` object determines the amount of data the `OracleRefCursor` fetches into its internal cache for each database round-trip.

This property is useful if the `OracleRefCursor` is explicitly used to fill the `DataSet` or `DataTable` through the `OracleDataAdapter`, because it can provide control on how the data of the `REF CURSOR` is fetched.

If an `OracleDataReader` object is created from the `OracleRefCursor`, the resulting `OracleDataReader` object inherits the `FetchSize` value of the `OracleDataReader` object. However, the inherited value can be overridden, if it is set before the first invocation of the `OracleDataReader` `Read` method for the given result set, by setting the `OracleDataReader` `FetchSize` property.

The `RowSize` and `FetchSize` properties handle UDT and XMLType data differently than other scalar data types. Because only a reference to the UDT and XMLType data is stored in the ODP.NET's internal cache, the `RowSize` property accounts for only the memory needed for the reference (which is very small) and not the actual size of the UDT and XMLType data. Thus, applications can inadvertently fetch a large number of UDT or XMLType instances from the database in a single database round-trip. This is because the actual size of UDT and XMLType data does not count against the `FetchSize`, and it would require numerous UDT and XMLType references to fill up the default cache size of 131072 bytes. Therefore, when fetching UDT or XMLType data, the `FetchSize` property must be appropriately configured to control the number of UDT and XMLType instances that are to be fetched, rather than the amount of the actual UDT and XMLType data to be fetched.

NOTE: For LOB and LONG data types, only the sizes specified in the `InitialLOBFetchSize` and `InitialLONGFetchSize` properties are accounted for by the `RowSize` property in addition to the metadata and reference information that is maintained by the cache for each LOB in the select list.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRefCursor Class](#)
- [OracleRefCursor Members](#)

## IsNull

This property indicates whether or not the `OracleRefCursor` is null.

#### Declaration

```
// C#  
public bool IsNull {get;}
```

#### Property Value

Returns true if the `OracleRefCursor` represents a null value. Returns false otherwise.

#### Exception

`ObjectDisposedException` - The object is already disposed.

`InvalidOperationException` - The `OracleConnection` is not open or has been closed during the lifetime of the object.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRefCursor Class](#)
- [OracleRefCursor Members](#)

## RowSize

This property specifies the amount of memory the `OracleRefCursor` internal cache needs to store one row of data.

#### Declaration

```
// C#  
public long RowSize {get;}
```

### Property Value

A long that indicates the amount of memory (in bytes) that an `OracleRefCursor` needs to store one row of data for the executed query.

### Remarks

The `RowSize` property is set to a nonzero value when the `OracleRefCursor` object is created. This property can be used at design time or dynamically during run time, to set the `FetchSize`, based on number of rows. For example, to enable the `OracleRefCursor` to fetch *N* rows for each database round-trip, the `OracleRefCursor` `FetchSize` property can be set dynamically to `RowSize * N`. Note that for the `FetchSize` to take effect appropriately, it must be set before the it is used to fill the `DataSet/DataTable` using `OracleDataAdapter`.

If an `OracleDataReader` is obtained from the `OracleRefCursor` through the `GetDataReader` method, the resulting `OracleDataReader` will have its `FetchSize` property set to the `FetchSize` value of the `OracleRefCursor`.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRefCursor Class](#)
- [OracleRefCursor Members](#)

## RowsToFetchPerRoundTrip

This property specifies the total number of rows to retrieve per database round trip.

### Declaration

```
// C#  
public Int64 RowsToFetchPerRoundTrip { get; set; }
```

### Property Type

`System.Int64`

### Remarks

This property has no default value. If it is not set, then ODP.NET ignores this property.

The row data fetched in a single round trip applies to scalar types only, such as `NUMBER` and `VARCHAR2` columns. If reference data types, such as `LOBs`, `UDTs`, and `XMLType`, exist in the result set, they are retrieved in separate round trips. These reference types can have their own fetch tuning parameters as reference type data sizes can vary in size from row to row, sometimes significantly.

`RowsToFetchPerRoundTrip` can be set before or after the `OracleCommand` executes on `OracleConnection`, `OracleCommand`, `OracleDataReader`, or `OracleRefCursor`. The value can also be changed after initial data fetches so that more or fewer rows are fetched on subsequent round trips. For `OracleConfiguration`, this property can only be set before the first connection opens.

# OracleRefCursor Instance Methods

OracleRefCursor instance methods are listed in [Table 13-35](#).

**Table 13-35 OracleRefCursor Instance Methods**

| Methods                       | Description                                                    |
|-------------------------------|----------------------------------------------------------------|
| <a href="#">Dispose</a>       | Disposes the resources allocated by the OracleRefCursor object |
| Equals                        | Inherited from System.Object (Overloaded)                      |
| <a href="#">GetDataReader</a> | Returns an OracleDataReader object for the REF CURSOR          |
| GetHashCode                   | Inherited from System.Object                                   |
| GetType                       | Inherited from System.Object                                   |
| ToString                      | Inherited from System.Object                                   |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRefCursor Class](#)
- [OracleRefCursor Members](#)

## Dispose

This instance method disposes of the resources allocated by the OracleRefCursor object.

**Declaration**

```
// C#  
public void Dispose();
```

**Implements**

IDisposable

**Remarks**

The object cannot be reused after being disposed.

Once Dispose( ) is called, the object of OracleRefCursor is in an uninitialized state. Although some properties can still be accessed, their values may not be accountable. Since resources are freed, method calls can lead to exceptions.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRefCursor Class](#)
- [OracleRefCursor Members](#)

## GetDataReader

This instance method returns an `OracleDataReader` object for the REF CURSOR.

**Declaration**

```
// C#  
public OracleDataReader GetDataReader();
```

**Return Value**

`OracleDataReader`

**Remarks**

Using the `OracleDataReader`, rows can be fetched from the REF CURSOR.

# Oracle Data Provider for .NET Types Structures

This chapter describes the ODP.NET Types structures.

This chapter contains these topics:

- [OracleBinary Structure](#)
- [OracleBoolean Structure](#)
- [OracleDate Structure](#)
- [OracleDecimal Structure](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalYM Structure](#)
- [OracleString Structure](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampTZ Structure](#)
- [INullable Interface](#)

## OracleBinary Structure

The OracleBinary structure represents a variable-length stream of binary data to be stored in or retrieved from a database.

### Class Inheritance

System.Object  
    System.ValueType  
        Oracle.DataAccess.Types.OracleBinary

### Declaration

```
// C#  
public struct OracleBinary : IComparable, INullable, IXmlSerializable
```

### Requirements

| Provider | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver      | ODP.NET Core                 |
|----------|---------------------------|------------------------------|------------------------------|
| Assembly | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll | Oracle.ManagedDataAccess.dll |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;

class OracleBinarySample
{
    static void Main(string[] args)
    {
        // Initialize the OracleBinary structures
        OracleBinary binary1= new OracleBinary(new byte[] {1,2,3,4,5});
        OracleBinary binary2 = new OracleBinary(new byte[] {1,2,3});
        OracleBinary binary3 = new OracleBinary(new byte[] {4,5});
        OracleBinary binary4 = binary2 + binary3;

        // Compare binary1 and binary4; they're equal
        if (binary1 == binary4)
            Console.WriteLine("The two OracleBinary structs are equal");
        else
            Console.WriteLine("The two OracleBinary structs are different");
    }
}
```

## OracleBinary Members

OracleBinary members are listed in the following tables:

### OracleBinary Constructors

OracleBinary constructors are listed in [Table 14-1](#)

**Table 14-1 OracleBinary Constructors**

| Constructor                              | Description                                           |
|------------------------------------------|-------------------------------------------------------|
| <a href="#">OracleBinary Constructor</a> | Instantiates a new instance of OracleBinary structure |

### OracleBinary Static Fields

The OracleBinary static fields are listed in [Table 14-2](#).

**Table 14-2 OracleBinary Static Fields**

| Field                | Description                                                                               |
|----------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an instance of the OracleBinary structure |

### OracleBinary Static Methods

The OracleBinary static methods are listed in [Table 14-3](#).

**Table 14-3 OracleBinary Static Methods**

| Methods                            | Description                                                                               |
|------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Concat</a>             | Returns the concatenation of two OracleBinary structures                                  |
| <a href="#">Equals</a>             | Determines if two OracleBinary values are equal (Overloaded)                              |
| <a href="#">GetXsdType</a>         | Returns the XML Schema definition language (XSD) of the specified XmlSchemaSet            |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleBinary values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleBinary values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleBinary values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleBinary values is less than or equal to the second    |
| <a href="#">NotEquals</a>          | Determines if two OracleBinary values are not equal                                       |

### OracleBinary Static Operators

The OracleBinary static operators are listed in [Table 14-4](#).

**Table 14-4 OracleBinary Static Operators**

| Operator                       | Description                                                                               |
|--------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Concatenates two OracleBinary values                                                      |
| <a href="#">operator ==</a>    | Determines if two OracleBinary values are equal                                           |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleBinary values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleBinary values is greater than or equal to the second |
| <a href="#">operator !=</a>    | Determines if two OracleBinary values are not equal                                       |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleBinary value is less than the second                 |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleBinary value is less than or equal to the second     |

**OracleBinary Static Type Conversion Operators**

The OracleBinary static type conversion operators are listed in [Table 14-5](#).

**Table 14-5 OracleBinary Static Type Conversion Operators**

| Operator                                       | Description                                             |
|------------------------------------------------|---------------------------------------------------------|
| <a href="#">explicit operator byte[]</a>       | Converts an instance value to a byte array              |
| <a href="#">implicit operator OracleBinary</a> | Converts an instance value to an OracleBinary structure |

**OracleBinary Properties**

The OracleBinary properties are listed in [Table 14-6](#).

**Table 14-6 OracleBinary Properties**

| Properties             | Description                                                             |
|------------------------|-------------------------------------------------------------------------|
| <a href="#">IsNull</a> | Indicates whether or not the current instance has a null value          |
| <a href="#">Item</a>   | Obtains the particular byte in an OracleBinary structure using an index |
| <a href="#">Length</a> | Returns the length of the binary data                                   |
| <a href="#">Value</a>  | Returns the binary data that is stored in an OracleBinary structure     |

**OracleBinary Instance Methods**

The OracleBinary instance methods are listed in [Table 14-7](#).

**Table 14-7 OracleBinary Instance Methods**

| Methods                   | Description                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a> | Compares the current instance to an object and returns an integer that represents their relative values |

**Table 14-7 (Cont.) OracleBinary Instance Methods**

| Methods                     | Description                                                         |
|-----------------------------|---------------------------------------------------------------------|
| <a href="#">Equals</a>      | Determines if two objects contain the same binary data (Overloaded) |
| <a href="#">GetHashCode</a> | Returns a hash code for the current instance                        |
| GetType                     | Inherited from System.Object                                        |
| <a href="#">ToString</a>    | Converts the current OracleBinary structure to a string             |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)

## OracleBinary Constructor

The OracleBinary constructor instantiates a new instance of the OracleBinary structure and sets its value to the provided array of bytes.

**Declaration**

```
// C#  
public OracleBinary(byte[ ] bytes);
```

**Parameters**

- *bytes*  
A byte array.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## OracleBinary Static Fields

The OracleBinary static fields are listed in [Table 14-8](#).

**Table 14-8 OracleBinary Static Fields**

| Field                | Description                                                                               |
|----------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an instance of the OracleBinary structure |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## Null

This static field represents a null value that can be assigned to an instance of the OracleBinary structure.

**Declaration**

```
// C#  
public static readonly OracleBinary Null;
```

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## OracleBinary Static Methods

The OracleBinary static methods are listed in [Table 14-9](#).

**Table 14-9 OracleBinary Static Methods**

| Methods                            | Description                                                                               |
|------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Concat</a>             | Returns the concatenation of two OracleBinary structures                                  |
| <a href="#">Equals</a>             | Determines if two OracleBinary values are equal (Overloaded)                              |
| <a href="#">GetXsdType</a>         | Returns the XML Schema definition language (XSD) of the specified XmlSchemaSet            |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleBinary values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleBinary values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleBinary values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleBinary values is less than or equal to the second    |
| <a href="#">NotEquals</a>          | Determines if two OracleBinary values are not equal                                       |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## Concat

This method returns the concatenation of two OracleBinary structures.

**Declaration**

```
// C#  
public static OracleBinary Concat(OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first OracleBinary.
- *value2*  
The second OracleBinary.

**Return Value**

An OracleBinary.

**Remarks**

If either argument has a null value, the returned OracleBinary structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## Equals

This method determines if two OracleBinary values are equal.

**Declaration**

```
// C#  
public static bool Equals(OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*

The first `OracleBinary`.

- *value2*

The second `OracleBinary`.

### Return Value

Returns true if two `OracleBinary` values are equal; otherwise returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## GetXsdType

This method returns the XML Schema definition language (XSD) of the specified `XmlSchemaSet`.

### Declaration

```
// C#  
public static XmlQualifiedName GetXsdType(XmlSchemaSet schemaSet);
```

### Parameters

- *schemaSet*  
An `XmlSchemaSet`.

### Return Value

Returns a string that indicates the XSD of the specified `XmlSchemaSet`.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## GreaterThan

This method determines whether or not the first of two `OracleBinary` values is greater than the second.

### Declaration

```
// C#  
public static bool GreaterThan(OracleBinary value1, OracleBinary value2);
```

### Parameters

- *value1*  
The first `OracleBinary`.
- *value2*  
The second `OracleBinary`.

### Return Value

Returns true if the first of two `OracleBinary` values is greater than the second; otherwise returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class GreaterThanSample  
{  
    static void Main(string[] args)  
    {  
        OracleBinary binary1 = OracleBinary.Null;  
        OracleBinary binary2 = new OracleBinary(new byte[] {1});  
  
        // Compare two OracleBinary structs; binary1 < binary2  
        if (OracleBinary.GreaterThan(binary1, binary2))  
            Console.WriteLine("binary1 > binary2");  
        else  
            Console.WriteLine("binary1 < binary2");  
    }  
}
```

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## GreaterThanOrEqual

This method determines whether or not the first of two `OracleBinary` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool GreaterThanOrEqual(OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first `OracleBinary`.
- *value2*  
The second `OracleBinary`.

**Return Value**

Returns `true` if the first of two `OracleBinary` values is greater than or equal to the second; otherwise returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## LessThan

This method determines whether or not the first of two `OracleBinary` values is less than the second.

**Declaration**

```
// C#  
public static bool LessThan(OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first OracleBinary.
- *value2*  
The second OracleBinary.

**Return Value**

Returns true if the first of two OracleBinary values is less than the second; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleBinary that has a value is greater than an OracleBinary that has a null value.
- Two OracleBinaries that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## LessThanOrEqual

This method determines whether or not the first of two OracleBinary values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool LessThanOrEqual(OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first OracleBinary.
- *value2*  
The second OracleBinary.

**Return Value**

Returns true if the first of two `OracleBinary` values is less than or equal to the second; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## NotEquals

This method determines whether or not two `OracleBinary` values are not equal.

**Declaration**

```
// C#  
public static bool NotEquals(OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first `OracleBinary`.
- *value2*  
The second `OracleBinary`.

**Return Value**

Returns true if two `OracleBinary` values are not equal; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

# OracleBinary Static Operators

The OracleBinary static operators are listed in [Table 14-10](#).

**Table 14-10 OracleBinary Static Operators**

| Operator                       | Description                                                                               |
|--------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Concatenates two OracleBinary values                                                      |
| <a href="#">operator ==</a>    | Determines if two OracleBinary values are equal                                           |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleBinary values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleBinary values is greater than or equal to the second |
| <a href="#">operator !=</a>    | Determines if two OracleBinary values are not equal                                       |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleBinary value is less than the second                 |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleBinary value is less than or equal to the second     |

## operator +

This method concatenates two OracleBinary values.

**Declaration**

```
// C#  
public static OracleBinary operator + (OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first OracleBinary.

- *value2*  
The second OracleBinary.

**Return Value**

OracleBinary

**Remarks**

If either argument has a null value, the returned OracleBinary structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## operator ==

This method determines if two OracleBinary values are equal.

**Declaration**

```
// C#  
public static bool operator == (OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first OracleBinary.
- *value2*  
The second OracleBinary.

**Return Value**

Returns true if they are the same; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleBinary that has a value is greater than an OracleBinary that has a null value.
- Two OracleBinaries that contain a null value are equal.

### ① See Also

## operator >

This method determines if the first of two `OracleBinary` values is greater than the second.

### Declaration

```
// C#  
public static bool operator > (OracleBinary value1, OracleBinary value2);
```

### Parameters

- *value1*  
The first `OracleBinary`.
- *value2*  
The second `OracleBinary`.

### Return Value

Returns `true` if the first of two `OracleBinary` values is greater than the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class OperatorSample  
{  
    static void Main(string[] args)  
    {  
        OracleBinary binary1 = OracleBinary.Null;  
        OracleBinary binary2 = new OracleBinary(new byte[] {1});  
  
        // Compare two OracleBinary structs; binary1 < binary2  
        if (binary1 > binary2)  
            Console.WriteLine("binary1 > binary2");  
        else  
            Console.WriteLine("binary1 < binary2");  
    }  
}
```

```
}  
}
```

## operator >=

This method determines if the first of two `OracleBinary` values is greater than or equal to the second.

### Declaration

```
// C#  
public static bool operator >= (OracleBinary value1, OracleBinary value2);
```

### Parameters

- *value1*  
The first `OracleBinary`.
- *value2*  
The second `OracleBinary`.

### Return Value

Returns `true` if the first of two `OracleBinary` values is greater than or equal to the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## operator !=

This method determines if two `OracleBinary` values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first OracleBinary.
- *value2*  
The second OracleBinary.

**Return Value**

Returns true if the two OracleBinary values are not equal; otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

**operator <**

This method determines if the first of two OracleBinary values is less than the second.

**Declaration**

```
// C#  
public static bool operator < ( OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first OracleBinary.
- *value2*  
The second OracleBinary.

**Return Value**

Returns true if the first of two OracleBinary values is less than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleBinary that has a value is greater than an OracleBinary that has a null value.
- Two OracleBinaries that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## operator <=

This method determines if the first of two `OracleBinary` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool operator <= (OracleBinary value1, OracleBinary value2);
```

**Parameters**

- *value1*  
The first `OracleBinary`.
- *value2*  
The second `OracleBinary`.

**Return Value**

Returns `true` if the first of two `OracleBinary` values is less than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

## OracleBinary Static Type Conversion Operators

The `OracleBinary` static type conversion operators are listed in [Table 14-11](#).

**Table 14-11 OracleBinary Static Type Conversion Operators**

| Operator                                       | Description                                             |
|------------------------------------------------|---------------------------------------------------------|
| <a href="#">explicit operator byte[]</a>       | Converts an instance value to a byte array              |
| <a href="#">implicit operator OracleBinary</a> | Converts an instance value to an OracleBinary structure |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## explicit operator byte[]

This method converts an OracleBinary value to a byte array.

**Declaration**

```
// C#  
public static explicit operator byte[] (OracleBinary val);
```

**Parameters**

- *val*  
An OracleBinary.

**Return Value**

A byte array.

**Exceptions**

OracleNullValueException - The OracleBinary structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## implicit operator OracleBinary

This method converts a byte array to an OracleBinary structure.

**Declaration**

```
// C#  
public static implicit operator OracleBinary(byte[ ] bytes);
```

**Parameters**

- *bytes*  
A byte array.

**Return Value**

OracleBinary

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## OracleBinary Properties

The OracleBinary properties are listed in [Table 14-12](#).

**Table 14-12 OracleBinary Properties**

| Properties             | Description                                                             |
|------------------------|-------------------------------------------------------------------------|
| <a href="#">IsNull</a> | Indicates whether or not the current instance has a null value          |
| <a href="#">Item</a>   | Obtains the particular byte in an OracleBinary structure using an index |
| <a href="#">Length</a> | Returns the length of the binary data                                   |
| <a href="#">Value</a>  | Returns the binary data that is stored in an OracleBinary structure     |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## IsNull

This property indicates whether or not the current instance has a null value.

**Declaration**

```
// C#  
public bool IsNull {get;}
```

**Property Value**

Returns true if the current instance has a null value; otherwise returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## Item

This property obtains the particular byte in an OracleBinary structure using an index.

**Declaration**

```
// C#  
public byte this[int index] {get;}
```

**Property Value**

A byte in the specified index.

**Exceptions**

OracleNullValueException - The current instance has a null value.

**Example**

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class ItemSample  
{  
    static void Main(string[] args)  
    {  
        OracleBinary binary = new OracleBinary(new byte[] {1,2,3,4});  
  
        // Prints the value 4  
        Console.WriteLine(binary[binary.Length - 1]);  
    }  
}
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## Length

This property returns the length of the binary data.

### Declaration

```
// C#  
public int length {get;}
```

### Property Value

Length of the binary data.

### Exceptions

OracleNullValueException - The current instance has a null value.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class LengthSample  
{  
    static void Main(string[] args)  
    {  
        OracleBinary binary = new OracleBinary(new byte[] {1,2,3,4});  
  
        // Prints the value 4  
        Console.WriteLine(binary.Length);  
    }  
}
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

- [OracleBinary Members](#)

## Value

This property returns the binary data that is stored in the OracleBinary structure.

**Declaration**

```
// C#  
public byte[] Value {get;}
```

**Property Value**

Binary data.

**Exceptions**

OracleNullValueException - The current instance has a null value.

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

# OracleBinary Instance Methods

The OracleBinary instance methods are listed in [Table 14-13](#).

**Table 14-13 OracleBinary Instance Methods**

| Methods                     | Description                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current instance to an object and returns an integer that represents their relative values |
| <a href="#">Equals</a>      | Determines if two objects contain the same binary data (Overloaded)                                     |
| <a href="#">GetHashCode</a> | Returns a hash code for the current instance                                                            |
| GetType                     | Inherited from System.Object                                                                            |
| <a href="#">ToString</a>    | Converts the current OracleBinary structure to a string                                                 |

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

# CompareTo

This method compares the current instance to an object and returns an integer that represents their relative values

## Declaration

```
// C#  
public int CompareTo(object obj);
```

## Parameters

- *obj*

The object being compared.

## Return Value

The method returns a number that is:

- Less than zero: if the current OracleBinary instance value is less than *obj*.
- Zero: if the current OracleBinary instance and *obj* values have the same binary data.
- Greater than zero: if the current OracleBinary instance value is greater than *obj*.

## Implements

Comparable

## Exceptions

ArgumentException - The parameter is not of type OracleBinary.

## Remarks

The following rules apply to the behavior of this method.

- The comparison must be between OracleBinarys. For example, comparing an OracleBinary instance with an OracleTimeStamp instance is not allowed. When an OracleBinary is compared with a different type, an ArgumentException is thrown.
- Any OracleBinary that has a value is greater than an OracleBinary that has a null value.
- Two OracleBinarys that contain a null value are equal.

## Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class CompareToSample  
{  
    static void Main(string[] args)  
    {  
        OracleBinary binary1 = new OracleBinary(new byte[] {1,2,3});  
        OracleBinary binary2 = new OracleBinary(new byte[] {1,2,3,4});  
  
        // Compare  
        if (binary1.CompareTo(binary2) == 0)  
            Console.WriteLine("binary1 is the same as binary2");  
        else  
            Console.WriteLine("binary1 is different from binary2");  
    }  
}
```

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## Equals

This method determines whether or not an object is an instance of `OracleBinary`, and has the same binary data as the current instance.

**Declaration**

```
// C#  
public override bool Equals(object obj);
```

**Parameters**

- *obj*  
The object being compared.

**Return Value**

Returns `true` if *obj* is an instance of `OracleBinary`, and has the same binary data as the current instance; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleBinary` that has a value is greater than an `OracleBinary` that has a null value.
- Two `OracleBinary`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## GetHashCode

Overrides `Object`

This method returns a hash code for the `OracleBinary` instance.

**Declaration**

```
// C#  
public override int GetHashCode();
```

**Return Value**

An int that represents the hash.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## ToString

Overrides Object

This method converts an OracleBinary instance to a string instance.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

string

**Remarks**

If the current OracleBinary instance has a null value, the returned string "null".

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBinary Structure](#)
- [OracleBinary Members](#)

## OracleBoolean Structure

The OracleBoolean structure represents a logical value that is either TRUE or FALSE.

ODP.NET, Unmanaged Driver can access Oracle Database PL/SQL Booleans in Oracle Database Release 12.1 and later. ODP.NET Core and ODP.NET, Managed Driver can access Oracle Database PL/SQL Booleans in Oracle Database Release 12.2 and later. Starting with version 23, all ODP.NET providers support Boolean table columns introduced in Oracle AI Database 26ai.

OracleBoolean can use the following string literals as TRUE or FALSE values. These values are accepted in a case insensitive manner.

Table 14-14 Accepted OracleBoolean Values

| TRUE values | False values |
|-------------|--------------|
| true        | false        |
| t           | f            |
| yes         | no           |
| y           | n            |
| on          | off          |
| 1           | 0            |

If whitespace is present before or after the string literals, then the whitespace is not considered upon .NET Boolean conversion.

If the string literals are anything other than those listed above, then an `InvalidCastException` will be returned when trying to read the value.

Class Inheritance

System.Object  
    System.ValueType  
        Oracle.DataAccess.Types.OracleBoolean

Declaration

```
// C#  
public struct OracleBoolean : IComparable, INullable, IXmlSerializable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

A `OracleBoolean` structure represents three possible values: TRUE, FALSE, and NULL. A non-zero value is interpreted as TRUE.

### Example

```
// C#
using System;
using System.Data;
using Oracle.DataAccess.Types; // for use with ODP.NET, Unmanaged Driver
// using Oracle.ManagedDataAccess.Types; // for use with ODP.NET, Managed Driver

class OracleBooleanSample
{
    static void Main(string[] args)
    {
        OracleBoolean oracleBoolean1 = new OracleBoolean(true);
        OracleBoolean oracleBoolean2 = new OracleBoolean(0);

        Console.WriteLine("oracleBoolean1 : " + oracleBoolean1);
        Console.WriteLine("oracleBoolean2 : " + oracleBoolean2);
    }
}
```

## OracleBoolean Members

OracleBoolean members are listed in the following tables:

### OracleBoolean Constructors

OracleBoolean constructors are listed in [Table 14-15](#)

**Table 14-15 OracleBoolean Constructors**

| Constructor                                | Description                                                         |
|--------------------------------------------|---------------------------------------------------------------------|
| <a href="#">OracleBoolean Constructors</a> | Instantiates a new instance of OracleBoolean structure (Overloaded) |

### OracleBoolean Static Fields

The OracleBoolean static fields are listed in [Table 14-16](#).

**Table 14-16 OracleBoolean Static Fields**

| Field                 | Description                                                                |
|-----------------------|----------------------------------------------------------------------------|
| <a href="#">False</a> | Represents a false value that can be assigned to an OracleBoolean instance |
| <a href="#">Null</a>  | Represents a null value that can be assigned to an OracleBoolean instance  |
| <a href="#">One</a>   | Indicates a constant representing the positive one value                   |
| <a href="#">True</a>  | Represents a true value that can be assigned to an OracleBoolean instance  |
| <a href="#">Zero</a>  | Indicates a constant representing the zero value                           |

**OracleBoolean Static Methods**

OracleBoolean static methods are listed in [Table 14-17](#)

**Table 14-17 OracleBoolean Static Methods**

| Methods                             | Description                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">And</a>                 | Returns the result of bitwise AND operation of two OracleBoolean instances                             |
| <a href="#">Equals</a>              | Determines whether or not the two OracleBoolean values are equal                                       |
| <a href="#">GreaterThan</a>         | Determines whether or not the first of two OracleBoolean values is greater than the second             |
| <a href="#">GreaterThanOrEquals</a> | Determines whether or not the first of two OracleBoolean values is greater than or equal to the second |
| <a href="#">LessThan</a>            | Determines whether or not the first of two OracleBoolean values is less than the second                |
| <a href="#">LessThanOrEquals</a>    | Determines whether or not the first of two OracleBoolean values is less than or equal to the second    |
| <a href="#">NotEquals</a>           | Determines whether or not two OracleBoolean values are not equal                                       |
| <a href="#">OnesComplement</a>      | Returns the result of a one's complement operation on the specified OracleBoolean value                |
| <a href="#">Or</a>                  | Returns the result of bitwise OR operation of two OracleBoolean instances                              |
| <a href="#">Parse</a>               | Returns an OracleBoolean structure and sets its value using a string                                   |
| <a href="#">Xor</a>                 | Returns the result of a bitwise exclusive OR operation of two OracleBoolean instances                  |

**OracleBoolean Static Operators**

The OracleBoolean static operators are listed in [Table 14-18](#).

**Table 14-18 OracleBoolean Static Operators**

| Field                          | Description                                                                                            |
|--------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">operator &gt;</a>  | Determines whether or not the first of two OracleBoolean values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines whether or not the first of two OracleBoolean values is greater than or equal to the second |
| <a href="#">operator &lt;</a>  | Determines whether or not the first of two OracleBoolean values is less than the second                |
| <a href="#">operator &lt;=</a> | Determines whether or not the first of two OracleBoolean values is less than or equal to the second    |
| <a href="#">operator ==</a>    | Indicates whether or not the two OracleBoolean instances are equal                                     |
| <a href="#">operator !=</a>    | Determines whether or not two OracleBoolean values are not equal                                       |
| <a href="#">operator !</a>     | Determines the result of a NOT operation on a OracleBoolean                                            |
| <a href="#">operator ~</a>     | Returns the result of a one's complement operation on the specified OracleBoolean value                |
| <a href="#">operator false</a> | Determines whether or not the specified OracleBoolean value is false                                   |
| <a href="#">operator true</a>  | Determines whether or not the specified OracleBoolean value is true                                    |
| <a href="#">operator &amp;</a> | Returns the result of bitwise AND operation of two OracleBoolean instances                             |
| <a href="#">operator  </a>     | Returns the result of bitwise OR operation of two OracleBoolean instances                              |
| <a href="#">operator ^</a>     | Returns the result of bitwise exclusive OR operation of two OracleBoolean instances                    |

**The OracleBoolean Static Type conversions**

The OracleBoolean static type conversions are listed in [Table 14-19](#)

**Table 14-19 OracleBoolean Static Type Conversions**

| Field                                           | Description                                                     |
|-------------------------------------------------|-----------------------------------------------------------------|
| <a href="#">implicit operator OracleBoolean</a> | Returns the OracleBoolean representation of a boolean value     |
| <a href="#">explicit operator bool</a>          | Returns the boolean representation of the OracleBoolean value   |
| <a href="#">explicit operator OracleBoolean</a> | Converts a structure to an OracleBoolean structure (Overloaded) |

**OracleBoolean Properties**

The OracleBoolean properties are listed in [Table 14-26](#).

**Table 14-20 OracleBoolean Properties**

| Properties                | Description                                                         |
|---------------------------|---------------------------------------------------------------------|
| <a href="#">ByteValue</a> | Returns a byte that represents the OracleBoolean structure          |
| <a href="#">IsFalse</a>   | Indicates whether or not the value of the current instance is false |

**Table 14-20 (Cont.) OracleBoolean Properties**

| Properties             | Description                                                        |
|------------------------|--------------------------------------------------------------------|
| <a href="#">IsNull</a> | Indicates whether or not the current instance has a null value     |
| <a href="#">IsTrue</a> | Indicates whether or not the value of the current instance is true |
| <a href="#">Value</a>  | Returns a boolean value that represents the current instance       |

### OracleBoolean Instance Methods

The OracleBoolean instance methods are listed in [Table 14-21](#).

**Table 14-21 OracleBoolean Instance Methods**

| Method                      | Description                                                                                                                                      |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current instance to the supplied object and returns an integer that represents their relative values                                |
| <a href="#">Equals</a>      | Determines whether or not an object is an instance of OracleBoolean, and whether or not the value of the object is equal to the current instance |
| <a href="#">GetHashCode</a> | Returns a hash code for the current instance                                                                                                     |
| <a href="#">ToString</a>    | Returns the string representation of the current instance                                                                                        |

## OracleBoolean Constructors

The OracleBoolean constructors instantiates a new instance of the OracleBoolean structure.

### Overload List:

- [OracleBoolean\(bool\)](#)

This constructor creates a new instance of the OracleBoolean structure and sets its value to the supplied Boolean value.

- [OracleBoolean\(int\)](#)

This constructor creates a new instance of the OracleBoolean structure and sets its value to the supplied Int32 value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## OracleBoolean(bool)

This constructor creates a new instance of the `OracleBoolean` structure and sets its value to the supplied `Boolean` value.

### Declaration

```
// C#  
public OracleBoolean(bool value) ;
```

### Parameters

- *value*  
The provided `Boolean` value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## OracleBoolean(int)

This constructor creates a new instance of the `OracleBoolean` structure and sets its value to the supplied `Int32` value.

### Declaration

```
// C#  
public OracleBoolean(int value)
```

### Parameters

- *value*  
The provided `Int32` value.

# OracleBoolean Static Fields

The OracleBoolean static fields are listed in [Table 14-22](#).

**Table 14-22 OracleBoolean Static Fields**

| Field                 | Description                                                                |
|-----------------------|----------------------------------------------------------------------------|
| <a href="#">False</a> | Represents a false value that can be assigned to an OracleBoolean instance |
| <a href="#">Null</a>  | Represents a null value that can be assigned to an OracleBoolean instance  |
| <a href="#">One</a>   | Indicates a constant representing the positive one value                   |
| <a href="#">True</a>  | Represents a true value that can be assigned to an OracleBoolean instance  |
| <a href="#">Zero</a>  | Indicates a constant representing the zero value                           |

📘 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

# False

This static field represents a false value that can be assigned to an OracleBoolean instance.

**Declaration**

```
// C#  
public static readonly OracleBoolean False;
```

📘 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## Null

This static field represents a null value that can be assigned to an OracleBoolean instance.

### Declaration

```
// C#  
public static readonly OracleBoolean Null;
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## One

This static field indicates a constant representing the positive one value.

### Declaration

```
// C#  
public static readonly OracleBoolean One;
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## True

This static field represents a true value that can be assigned to an OracleBoolean instance.

### Declaration

```
// C#  
public static readonly OracleBoolean True;
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## Zero

This static field indicates a constant representing the zero value.

### Declaration

```
// C#  
public static readonly OracleBoolean Zero;
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## OracleBoolean Static Methods

OracleBoolean static methods are listed in [Table 14-23](#)

**Table 14-23 OracleBoolean Static Methods**

| Methods                             | Description                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">And</a>                 | Returns the result of bitwise AND operation of two OracleBoolean instances                             |
| <a href="#">Equals</a>              | Determines whether or not the two OracleBoolean values are equal                                       |
| <a href="#">GreaterThan</a>         | Determines whether or not the first of two OracleBoolean values is greater than the second             |
| <a href="#">GreaterThanOrEquals</a> | Determines whether or not the first of two OracleBoolean values is greater than or equal to the second |
| <a href="#">LessThan</a>            | Determines whether or not the first of two OracleBoolean values is less than the second                |
| <a href="#">LessThanOrEquals</a>    | Determines whether or not the first of two OracleBoolean values is less than or equal to the second    |
| <a href="#">NotEquals</a>           | Determines whether or not two OracleBoolean values are not equal                                       |
| <a href="#">OnesComplement</a>      | Returns the result of a one's complement operation on the specified OracleBoolean value                |
| <a href="#">Or</a>                  | Returns the result of bitwise OR operation of two OracleBoolean instances                              |
| <a href="#">Parse</a>               | Returns an OracleBoolean structure and sets its value using a string                                   |
| <a href="#">Xor</a>                 | Returns the result of a bitwise exclusive OR operation of two OracleBoolean instances                  |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## And

This method returns the result of bitwise AND operation of two OracleBoolean instances.

### Declaration

```
// C#  
public static OracleBoolean And(OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An OracleBoolean instance
- *value2*  
An OracleBoolean instance

### Return Value

An OracleBoolean that contains the value of the result of bitwise AND operation of two OracleBoolean instances.

### Remarks

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## Equals

This method returns an OracleBoolean that indicates whether or not the two OracleBoolean instances are equal.

### Declaration

```
// C#  
public static OracleBoolean Equal(OracleBoolean value1, OracleBoolean value2);
```

**Parameters**

- *value1*  
An OracleBoolean instance
- *value2*  
An OracleBoolean instance

**Return Value**

An OracleBoolean that is true if the specified two OracleBoolean instances are equal; otherwise, returns an OracleBoolean that is false.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## GreaterThan

This method determines if the first of two OracleBoolean values is greater than the second.

**Declaration**

```
// C#  
public static OracleBoolean GreaterThan(OracleBoolean value1, OracleBoolean value2);
```

**Parameters**

- *value1*  
The first OracleBoolean
- *value2*  
The second OracleBoolean

**Return Value**

An OracleBoolean that is true if the first of two OracleBoolean values is greater than the second; otherwise, returns false.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## GreaterThanOrEquals

This method determines if the first of two `OracleBoolean` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static OracleBoolean GreaterThanOrEquals(OracleBoolean value1, OracleBoolean  
value2);
```

**Parameters**

- *value1*  
The first `OracleBoolean`
- *value2*  
The second `OracleBoolean`

**Return Value**

An `OracleBoolean` that is true if the first of two `OracleBoolean` values is greater than or equal to the second; otherwise, returns false.

**Remarks**

If either of the specified `OracleBoolean` instances is null, an `OracleBoolean` with a null value will be returned.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## LessThan

This method determines if the first of two `OracleBoolean` values is less than the second.

**Declaration**

```
// C#  
public static OracleBoolean LessThan(OracleBoolean value1, OracleBoolean value2);
```

**Parameters**

- *value1*  
The first OracleBoolean
- *value2*  
The second OracleBoolean

**Return Value**

An OracleBoolean that is true if the first of two OracleBoolean values is less than the second; otherwise, returns false.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## LessThanOrEquals

This method determines if the first of two OracleBoolean values is less or equal than the second.

**Declaration**

```
// C#  
public static OracleBoolean LessThanOrEquals(OracleBoolean value1, OracleBoolean value2);
```

**Parameters**

- *value1*  
The first OracleBoolean
- *value2*  
The second OracleBoolean

**Return Value**

An OracleBoolean that is true if the first of two OracleBoolean values is less than or equal to the second; otherwise, returns false.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## NotEquals

This method determines if two OracleBoolean values are not equal.

**Declaration**

```
// C#  
public static OracleBoolean NotEquals(OracleBoolean value1, OracleBoolean value2);
```

**Parameters**

- *value1*  
The first OracleBoolean
- *value2*  
The second OracleBoolean

**Return Value**

An OracleBoolean that is true if two OracleBoolean values are not equal; otherwise, returns false.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## OnesComplement

This method returns the result of a one's complement operation on the specified OracleBoolean value.

**Declaration**

```
// C#  
public static OracleBoolean OnesComplement(OracleBoolean value1);
```

**Parameters**

- *value1*  
An OracleBoolean instance

**Return Value**

An OracleBoolean that contains the value of the result of a one's complement operation on the specified OracleBoolean value.

**Remarks**

If the specified OracleBoolean instance is null, an OracleBoolean with a null value will be returned.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## Or

This method returns the result of bitwise OR operation of two OracleBoolean instances.

**Declaration**

```
// C#  
public static OracleBoolean Or(OracleBoolean value1, OracleBoolean value2);
```

**Parameters**

- *value1*  
An OracleBoolean instance
- *value2*  
An OracleBoolean instance

**Return Value**

An OracleBoolean that contains the value of the result of bitwise OR operation of two OracleBoolean instances.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## Parse

This method converts a string to an OracleBoolean.

### Declaration

```
// C#  
public static OracleBoolean Parse(string str);
```

### Parameters

- *str*  
The string being converted.

### Return Value

A new OracleBoolean structure.

### Exceptions

ArgumentNullException – The *str* parameter is null.

IndexOutOfRangeException – The *str* parameter is an empty string.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## Xor

This method returns the result of a bitwise exclusive OR operation of two OracleBoolean instances.

### Declaration

```
// C#  
public static OracleBoolean Xor(OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An OracleBoolean instance

- `value2`  
An OracleBoolean instance

**Return Value**

An OracleBoolean that contains the value of the result of bitwise exclusive OR operation of two OracleBoolean instances.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## OracleBoolean Static Operators

The OracleBoolean static operators are listed in [Table 14-24](#).

**Table 14-24 OracleBoolean Static Operators**

| Field                          | Description                                                                                            |
|--------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">operator &gt;</a>  | Determines whether or not the first of two OracleBoolean values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines whether or not the first of two OracleBoolean values is greater than or equal to the second |
| <a href="#">operator &lt;</a>  | Determines whether or not the first of two OracleBoolean values is less than the second                |
| <a href="#">operator &lt;=</a> | Determines whether or not the first of two OracleBoolean values is less than or equal to the second    |
| <a href="#">operator ==</a>    | Indicates whether or not the two OracleBoolean instances are equal                                     |
| <a href="#">operator !=</a>    | Determines whether or not two OracleBoolean values are not equal                                       |
| <a href="#">operator !</a>     | Determines the result of a NOT operation on a OracleBoolean                                            |
| <a href="#">operator ~</a>     | Returns the result of a one's complement operation on the specified OracleBoolean value                |
| <a href="#">operator false</a> | Determines whether or not the specified OracleBoolean value is false                                   |
| <a href="#">operator true</a>  | Determines whether or not the specified OracleBoolean value is true                                    |
| <a href="#">operator &amp;</a> | Returns the result of bitwise AND operation of two OracleBoolean instances                             |
| <a href="#">operator  </a>     | Returns the result of bitwise OR operation of two OracleBoolean instances                              |

Table 14-24 (Cont.) OracleBoolean Static Operators

| Field                      | Description                                                                         |
|----------------------------|-------------------------------------------------------------------------------------|
| <a href="#">operator ^</a> | Returns the result of bitwise exclusive OR operation of two OracleBoolean instances |

operator >

This method determines whether or not the first of two OracleBoolean values is greater than the second.

**Declaration**

```
// C#
public static operator > (OracleBoolean value1, OracleBoolean value2);
```

**Parameters**

- *value1*  
An OracleBoolean instance
- *value2*  
An OracleBoolean instance

**Return Value**

An OracleBoolean that is true if the first of two OracleBoolean values is greater than the second; otherwise, returns false.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator >=

This method determines whether or not the first of two `OracleBoolean` values is greater than or equal to the second.

### Declaration

```
// C#  
public static operator >= (OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An `OracleBoolean` instance
- *value2*  
An `OracleBoolean` instance

### Return Value

An `OracleBoolean` that is true if the first of two `OracleBoolean` values is greater than or equal to the second; otherwise, returns false.

### Remarks

If either of the specified `OracleBoolean` instances is null, an `OracleBoolean` with a null value will be returned.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator <

This method determines whether or not the first of two `OracleBoolean` values is less than the second.

### Declaration

```
// C#  
public static operator < (OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An `OracleBoolean` instance
- *value2*  
An `OracleBoolean` instance

### Return Value

An OracleBoolean that is true if the first of two OracleBoolean values is less than the second; otherwise, returns false.

### Remarks

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator <=

This method determines whether or not the first of two OracleBoolean values is less than or equal to the second.

### Declaration

```
// C#  
public static operator <= (OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An OracleBoolean instance
- *value2*  
An OracleBoolean instance

### Return Value

An OracleBoolean that is true if the first of two OracleBoolean values is less than or equal to the second; otherwise, returns false.

### Remarks

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator ==

This method returns an `OracleBoolean` that indicates whether or not the two `OracleBoolean` instances are equal.

### Declaration

```
// C#  
public static operator == (OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An `OracleBoolean` instance
- *value2*  
An `OracleBoolean` instance

### Return Value

An `OracleBoolean` that is true if the specified two `OracleBoolean` instances are equal; otherwise, returns false.

### Remarks

If either of the specified `OracleBoolean` instances is null, an `OracleBoolean` with a null value will be returned.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator !=

This method determines whether or not two `OracleBoolean` values are not equal.

### Declaration

```
// C#  
public static operator != (OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An `OracleBoolean` instance
- *value2*  
An `OracleBoolean` instance

**Return Value**

An OracleBoolean that is true if two OracleBoolean values are not equal; otherwise, returns false.

**Remarks**

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

**operator !**

This method determines the result of a NOT operation on a OracleBoolean.

**Declaration**

```
// C#  
public static operator ! (OracleBoolean value1);
```

**Parameters**

- *value1*  
An OracleBoolean instance

**Return Value**

An OracleBoolean that is true if the specified OracleBoolean value is true; otherwise, returns false.

**Remarks**

If the specified OracleBoolean instance is null, an OracleBoolean with a null value will be returned.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator ~

This method returns the result of a one's complement operation on the specified OracleBoolean value.

### Declaration

```
// C#  
public static operator ~ (OracleBoolean value1);
```

### Parameters

- *value1*  
An OracleBoolean instance

### Return Value

An OracleBoolean that contains the value of the result of a one's complement operation on the specified OracleBoolean value.

### Remarks

If the specified OracleBoolean instance is null, an OracleBoolean with a null value will be returned.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator false

This method determines whether or not the specified OracleBoolean value is false.

### Declaration

```
// C#  
public static operator false (OracleBoolean value1);
```

### Parameters

- *value1*  
An OracleBoolean instance

### Return Value

An OracleBoolean that is true if specified OracleBoolean value is false; otherwise, returns false.

### Remarks

This property will return false if the current instance is null.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator true

This method determines whether or not the specified OracleBoolean value is true.

### Declaration

```
// C#  
public static operator true (OracleBoolean value1);
```

### Parameters

- *value1*  
An OracleBoolean instance

### Return Value

An OracleBoolean that is true if specified OracleBoolean value is true; otherwise, returns false.

### Remarks

This property will return false if the current instance is null.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator &

This method returns the result of bitwise AND operation of two OracleBoolean instances.

### Declaration

```
// C#  
public static operator & (OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An OracleBoolean instance
- *value2*

An OracleBoolean instance

### Return Value

An OracleBoolean that contains the value of the result of bitwise AND operation of two OracleBoolean instances.

### Remarks

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## operator |

This method returns the result of bitwise OR operation of two OracleBoolean instances.

### Declaration

```
// C#  
public static operator | (OracleBoolean value1, OracleBoolean value2);
```

### Parameters

- *value1*  
An OracleBoolean instance
- *value2*  
An OracleBoolean instance

### Return Value

An OracleBoolean that contains the value of the result of bitwise OR operation of two OracleBoolean instances.

### Remarks

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

operator ^

This method returns the result of bitwise exclusive OR operation of two OracleBoolean instances.

Declaration

```
// C#
public static operator ^ (OracleBoolean value1, OracleBoolean value2);
```

Parameters

- *value1*  
An OracleBoolean instance
- *value2*  
An OracleBoolean instance

Return Value

An OracleBoolean that contains the value of the result of bitwise exclusive OR operation of two OracleBoolean instances.

Remarks

If either of the specified OracleBoolean instances is null, an OracleBoolean with a null value will be returned.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

- [OracleBoolean Members](#)

OracleBoolean Static Type Conversions

The OracleBoolean static type conversions are listed in [Table 14-25](#)

Table 14-25 OracleBoolean Static Type Conversions

| Field                                           | Description                                                     |
|-------------------------------------------------|-----------------------------------------------------------------|
| <a href="#">implicit operator OracleBoolean</a> | Returns the OracleBoolean representation of a boolean value     |
| <a href="#">explicit operator bool</a>          | Returns the boolean representation of the OracleBoolean value   |
| <a href="#">explicit operator OracleBoolean</a> | Converts a structure to an OracleBoolean structure (Overloaded) |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## implicit operator OracleBoolean

This method returns the OracleBoolean representation of a boolean value.

**Declaration**

```
// C#  
public static implicit operator OracleBoolean(bool value1);
```

**Parameters**

- *value1*  
An OracleBoolean instance

**Return Value**

An OracleBoolean.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator bool

This method returns the boolean representation of the OracleBoolean value.

**Declaration**

```
// C#  
public static explicit operator bool(OracleBoolean value1);
```

**Parameters**

- *value1*  
An OracleBoolean structure

**Return Value**

A boolean

### Exception

OracleNullValueException – OracleBoolean has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean

explicit operator OracleBoolean converts the provided structure to an OracleBoolean structure.

### Overload List

- [explicit operator OracleBoolean\(byte\)](#)  
This method converts the supplied byte to an OracleBoolean structure.
- [explicit operator OracleBoolean\(Decimal\)](#)  
This method converts the supplied Decimal to an OracleBoolean structure.
- [explicit operator OracleBoolean\(Double\)](#)  
This method converts the supplied Double to an OracleBoolean structure.
- [explicit operator OracleBoolean\(Int16\)](#)  
This method converts the supplied Int16 to an OracleBoolean structure.
- [explicit operator OracleBoolean\(int\)](#)  
This method converts the supplied int to an OracleBoolean structure.
- [explicit operator OracleBoolean\(Int64\)](#)  
This method converts the supplied Int64 to an OracleBoolean structure.
- [explicit operator OracleBoolean\(Single\)](#)  
This method converts the supplied Single to an OracleBoolean structure.
- [explicit operator OracleBoolean\(String\)](#)  
This method converts the supplied String to an OracleBoolean structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(byte)

This method converts the supplied byte to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(byte value1);
```

### Parameters

- *value1*  
A byte

### Return Value

An OracleBoolean structure.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(Decimal)

This method converts the supplied Decimal to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(Decimal value1);
```

### Parameters

- *value1*  
A Decimal

### Return Value

An OracleBoolean structure.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(Double)

This method converts the supplied Double to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(Double value1);
```

### Parameters

- *value1*  
A Double

### Return Value

An OracleBoolean structure.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(Int16)

This method converts the supplied Int16 to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(Int16 value1);
```

### Parameters

- *value1*  
An Int16

### Return Value

An OracleBoolean structure.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(int)

This method converts the supplied int to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(int value1);
```

### Parameters

- *value1*  
An int

### Return Value

An OracleBoolean structure.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(Int64)

This method converts the supplied Int64 to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(Int64 value1);
```

### Parameters

- *value1*  
An Int64

### Return Value

An OracleBoolean structure.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(Single)

This method converts the supplied Single to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(Single value1);
```

### Parameters

- *value1*  
A Single

### Return Value

An OracleBoolean structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## explicit operator OracleBoolean(String)

This method converts the supplied String to an OracleBoolean structure.

### Declaration

```
// C#  
public static explicit operator OracleBoolean(String value1);
```

### Parameters

- *value1*  
A String

### Return Value

An OracleBoolean structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## OracleBoolean Properties

The OracleBoolean properties are listed in [Table 14-26](#).

**Table 14-26 OracleBoolean Properties**

| Properties                | Description                                                         |
|---------------------------|---------------------------------------------------------------------|
| <a href="#">ByteValue</a> | Returns a byte that represents the OracleBoolean structure          |
| <a href="#">IsFalse</a>   | Indicates whether or not the value of the current instance is false |
| <a href="#">IsNull</a>    | Indicates whether or not the current instance has a null value      |
| <a href="#">IsTrue</a>    | Indicates whether or not the value of the current instance is true  |
| <a href="#">Value</a>     | Returns a boolean value that represents the current instance        |

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## ByteValue

This property returns a byte that represents the OracleBoolean structure.

### Declaration

```
// C#  
public byte ByteValue {get;}
```

### Property Value

A byte that represents the value of OracleBoolean structure.

### Exceptions

OracleNullValueException – The current instance has a null value.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## IsFalse

This property indicates whether or not the value of the current instance is false.

**Declaration**

```
// C#  
public bool IsFalse {get;}
```

**Property Value**

A bool value that returns true if the current instance is false; otherwise, returns false.

**Remarks**

This property will return false if the current instance is null.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

**Declaration**

```
// C#  
public bool IsNull {get;}
```

**Property Value**

A bool value that returns true if the current instance has a null value; otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## IsTrue

This property indicates whether or not the value of the current instance is true.

**Declaration**

```
// C#  
public bool IsTrue {get;}
```

**Property Value**

A bool value that returns true if the current instance is true; otherwise, returns false.

Remarks

This property will return false if the current instance is null.

See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

Value

This property returns a boolean value that represents the current instance.

Declaration

```
// C#  
public bool Value {get;}
```

Property Value

A bool value that returns true if the current instance is true; otherwise, returns false.

Exceptions

OracleNullValueException – The current instance has a null value.

See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

OracleBoolean Instance Methods

The OracleBoolean instance methods are listed in [Table 14-27](#).

Table 14-27 OracleBoolean Instance Methods

| Method                      | Description                                                                                                                                      |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current instance to the supplied object and returns an integer that represents their relative values                                |
| <a href="#">Equals</a>      | Determines whether or not an object is an instance of OracleBoolean, and whether or not the value of the object is equal to the current instance |
| <a href="#">GetHashCode</a> | Returns a hash code for the current instance                                                                                                     |

Table 14-27 (Cont.) OracleBoolean Instance Methods

| Method                   | Description                                               |
|--------------------------|-----------------------------------------------------------|
| <a href="#">ToString</a> | Returns the string representation of the current instance |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## CompareTo

This method compares the current instance to the supplied object and returns an integer that represents their relative values.

**Declaration**

```
// C#  
public int CompareTo(object obj);
```

**Parameter**

- *obj*  
The supplied instance.

**Return Value**

The method returns a number:

- Less than zero: if the value of the current instance is less than *obj*.
- Zero: if the value of the current instance is equal to *obj*.
- Greater than zero: if the value of the current instance is greater than *obj*.

**Implements**

Comparable

**Exceptions**

ArgumentException - The parameter is not of type OracleBoolean.

**Remarks**

The following rules apply to the behavior of this method.

- The comparison must be between OracleBoolean. For example, comparing an OracleBoolean instance with an OracleBinary instance is not allowed. When an OracleBoolean is compared with a different type, an ArgumentException is thrown.

- Any OracleBoolean that has a value compares greater than an OracleBoolean that has a null value.
- Two OracleBoolean that contain a null value are equal.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## Equals

Overrides Object

This method determines whether or not an object is an instance of OracleBoolean, and whether or not the value of the object is equal to the current instance.

#### Declaration

```
// C#  
public override bool Equals(object obj);
```

#### Parameter

- obj  
An OracleBoolean instance.

#### Return Value

Returns true if obj is an instance of OracleBoolean, and the value of obj is equal to the current instance; otherwise, returns false.

#### Remarks

The following rules apply to the behavior of this method.

- Any OracleBoolean that has a value compares greater than an OracleBoolean that has a null value.
- Two OracleBooleans that contain a null value are equal.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the current instance.

### Declaration

```
// C#  
public override int GetHashCode();
```

### Return Value

Returns a hash code.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

## ToString

Overrides Object

This method returns the string representation of the current instance.

### Declaration

```
// C#  
public override string ToString();
```

### Return Value

Returns the OracleBoolean value in a string representation.

### Remarks

If the current instance has a null value, the returned string is null.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleBoolean Structure](#)
- [OracleBoolean Members](#)

# OracleDate Structure

The OracleDate structure represents the Oracle DATE data type to be stored in or retrieved from a database. Each OracleDate stores the following information: year, month, day, hour, minute, and second.

### Class Inheritance

System.Object  
    System.ValueType  
        Oracle.DataAccess.Types.OracleDate

### Declaration

```
// C#  
public struct OracleDate : IComparable, INullable, IXmlSerializable
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
using Oracle.DataAccess.Client;  
  
class OracleDateSample  
{  
    static void Main(string[] args)  
    {  
        // Initialize the dates to the lower and upper boundaries  
        OracleDate date1 = OracleDate.MinValue;  
        OracleDate date2 = OracleDate.MaxValue;  
        OracleDate date3 = new OracleDate(DateTime.MinValue);  
        OracleDate date4 = new OracleDate(DateTime.MaxValue);  
  
        // Set the thread's DateFormat for output  
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
```

```

info.DateFormat = "DD-MON-YYYY BC";
OracleGlobalization.SetThreadInfo(info);

// Print the lower and upper boundaries
Console.WriteLine("OracleDate ranges from\n{0}\nto\n{1}\n",
    date1, date2);
Console.WriteLine(".NET DateTime ranges from\n{0}\nto\n{1}\n",
    date3, date4);
}
}

```

## OracleDate Members

OracleDate members are listed in the following tables:

### OracleDate Constructors

OracleDate constructors are listed in [Table 14-28](#)

**Table 14-28 OracleDate Constructors**

| Constructor                             | Description                                                      |
|-----------------------------------------|------------------------------------------------------------------|
| <a href="#">OracleDate Constructors</a> | Instantiates a new instance of OracleDate structure (Overloaded) |

### OracleDate Static Fields

The OracleDate static fields are listed in [Table 14-29](#).

**Table 14-29 OracleDate Static Fields**

| Field                    | Description                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an OracleDate structure, which is December 31, 9999 23:59:59 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an OracleDate structure, which is January 1, -4712 0:0:0     |

**Table 14-29 (Cont.) OracleDate Static Fields**

| Field                | Description                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to the value of an OracleDate structure instance |

**OracleDate Static Methods**

The OracleDate static methods are listed in [Table 14-30](#).

**Table 14-30 OracleDate Static Methods**

| Methods                            | Description                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleDate values are equal (Overloaded)                              |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleDate values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleDate values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleDate values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleDate values is less than or equal to the second    |
| <a href="#">NotEquals</a>          | Determines if two OracleDate values are not equal                                       |
| <a href="#">GetSysDate</a>         | Returns an OracleDate structure that represents the current date and time               |
| <a href="#">Parse</a>              | Returns an OracleDate structure and sets its value using a string                       |

**OracleDate Static Operators**

The OracleDate static operators are listed in [Table 14-31](#).

**Table 14-31 OracleDate Static Operators**

| Operator                       | Description                                                                             |
|--------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">operator ==</a>    | Determines if two OracleDate values are the same                                        |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleDate values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleDate values is greater than or equal to the second |
| <a href="#">operator !=</a>    | Determines if the two OracleDate values are not equal                                   |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleDate values is less than the second                |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleDate values is less than or equal to the second    |

**OracleDate Static Type Conversions**

The OracleDate static type conversions are listed in [Table 14-32](#).

**Table 14-32 OracleDate Static Type Conversions**

| Operator                                     | Description                                                  |
|----------------------------------------------|--------------------------------------------------------------|
| <a href="#">explicit operator DateTime</a>   | Converts a structure to a DateTime structure                 |
| <a href="#">explicit operator OracleDate</a> | Converts a structure to an OracleDate structure (Overloaded) |

**OracleDate Properties**

The OracleDate properties are listed in [Table 14-33](#).

**Table 14-33 OracleDate Properties**

| Properties              | Description                                                                     |
|-------------------------|---------------------------------------------------------------------------------|
| <a href="#">BinData</a> | Gets an array of bytes that represents an Oracle DATE in Oracle internal format |
| <a href="#">Day</a>     | Gets the day component of an OracleDate method                                  |
| <a href="#">IsNull</a>  | Indicates whether or not the current instance has a null value                  |
| <a href="#">Hour</a>    | Gets the hour component of an OracleDate                                        |
| <a href="#">Minute</a>  | Gets the minute component of an OracleDate                                      |
| <a href="#">Month</a>   | Gets the month component of an OracleDate                                       |
| <a href="#">Second</a>  | Gets the second component of an OracleDate                                      |
| <a href="#">Value</a>   | Gets the date and time that is stored in the OracleDate structure               |
| <a href="#">Year</a>    | Gets the year component of an OracleDate                                        |

**OracleDate Methods**

The OracleDate methods are listed in [Table 14-34](#).

**Table 14-34 OracleDate Methods**

| Methods                           | Description                                                                                                         |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>         | Compares the current OracleDate instance to an object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>            | Determines whether or not an object has the same date and time as the current OracleDate instance (Overloaded)      |
| <a href="#">GetHashCode</a>       | Returns a hash code for the OracleDate instance                                                                     |
| <a href="#">GetDaysBetween</a>    | Calculates the number of days between the current OracleDate instance and an OracleDate structure                   |
| <a href="#">GetType</a>           | Inherited from System.Object                                                                                        |
| <a href="#">ToOracleTimeStamp</a> | Converts the current OracleDate structure to an OracleTimeStamp structure                                           |
| <a href="#">ToString</a>          | Converts the current OracleDate structure to a string                                                               |

**See Also**

- [OracleDate Structure](#)

## OracleDate Constructors

The OracleDate constructors instantiates a new instance of the OracleDate structure.

**Overload List:**

- [OracleDate\(DateTime\)](#)  
This constructor creates a new instance of the OracleDate structure and sets its value for date and time using the supplied DateTime value.
- [OracleDate\(string\)](#)  
This constructor creates a new instance of the OracleDate structure and sets its value using the supplied string.
- [OracleDate\(int, int, int\)](#)  
This constructor creates a new instance of the OracleDate structure and set its value for date using the supplied year, month, and day.
- [OracleDate\(int, int, int, int, int, int\)](#)  
This constructor creates a new instance of the OracleDate structure and set its value for time using the supplied year, month, day, hour, minute, and second.
- [OracleDate\(byte \[ \]\)](#)  
This constructor creates a new instance of the OracleDate structure and sets its value to the provided byte array, which is in the internal Oracle DATE format.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## OracleDate(DateTime)

This constructor creates a new instance of the OracleDate structure and sets its value for date and time using the supplied DateTime value.

**Declaration**

```
// C#  
public OracleDate (DateTime dt);
```

### Parameters

- *dt*  
The provided DateTime value.

### Remarks

The OracleDate structure only supports up to a second precision. The time value in the provided DateTime structure that has a precision smaller than second is ignored.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## OracleDate(string)

This constructor creates a new instance of the OracleDate structure and sets its value using the supplied string.

### Declaration

```
// C#  
public OracleDate (string dateStr);
```

### Parameters

- *dateStr*  
A string that represents an Oracle DATE.

### Exceptions

ArgumentException - The *dateStr* is an invalid string representation of an Oracle DATE or the *dateStr* is not in the date format specified by the thread's OracleGlobalization.DateFormat property, which represents the Oracle NLS\_DATE\_FORMAT parameter.

ArgumentNullException - The *dateStr* is null.

### Remarks

The names and abbreviations used for months and days are in the language specified by the DateLanguage and Calendar properties of the thread's OracleGlobalization object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
using Oracle.DataAccess.Client;
```

```
class OracleDateSample
{
    static void Main(string[] args)
    {
        // Set the thread's DateFormat for the OracleDate constructor
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.DateFormat = "YYYY-MON-DD";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleDate from a string using the DateFormat specified.
        OracleDate date = new OracleDate("1999-DEC-01");

        // Set a different DateFormat for the thread
        info.DateFormat = "MM/DD/YYYY";
        OracleGlobalization.SetThreadInfo(info);

        // Print "12/01/1999"
        Console.WriteLine(date.ToString());
    }
}
```

## OracleDate(int, int, int)

This constructor creates a new instance of the `OracleDate` structure and set its value for date using the supplied year, month, and day.

### Declaration

```
// C#
public OracleDate (int year, int month, int day);
```

### Parameters

- *year*  
The supplied year. Range of *year* is (-4712 to 9999).
- *month*  
The supplied month. Range of *month* is (1 to 12).
- *day*  
The supplied day. Range of *day* is (1 to 31).

## Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleDate` (that is, the day is out of range for the month).

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## OracleDate(int, int, int, int, int, int)

This constructor creates a new instance of the `OracleDate` structure and set its value for time using the supplied year, month, day, hour, minute, and second.

### Declaration

```
// C#  
public OracleDate (int year, int month, int day, int hour, int minute, int second);
```

### Parameters

- *year*  
The supplied year. Range of *year* is (-4712 to 9999).
- *month*  
The supplied month. Range of *month* is (1 to 12).
- *day*  
The supplied day. Range of *day* is (1 to 31).
- *hour*  
The supplied hour. Range of *hour* is (0 to 23).
- *minute*  
The supplied minute. Range of *minute* is (0 to 59).
- *second*  
The supplied second. Range of *second* is (0 to 59).

## Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleDate` (that is, the day is out of range for the month).

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)

## OracleDate(byte [ ])

This constructor creates a new instance of the `OracleDate` structure and sets its value to the provided byte array, which is in the internal Oracle DATE format.

**Declaration**

```
// C#  
public OracleDate(byte [] bytes);
```

**Parameters**

- *bytes*

A byte array that represents Oracle DATE in the internal Oracle DATE format.

**Exceptions**

`ArgumentException` - *bytes* is null or *bytes* is not in internal Oracle DATE format or *bytes* is not a valid Oracle DATE.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)

## OracleDate Static Fields

The `OracleDate` static fields are listed in [Table 14-35](#).

**Table 14-35 OracleDate Static Fields**

| Field                    | Description                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an <code>OracleDate</code> structure, which is December 31, 9999 23:59:59 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an <code>OracleDate</code> structure, which is January 1, -4712 0:0:0     |
| <a href="#">Null</a>     | Represents a null value that can be assigned to the value of an <code>OracleDate</code> structure instance      |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## MaxValue

This static field represents the maximum valid date for an `OracleDate` structure, which is December 31, 9999 23:59:59.

### Declaration

```
// C#  
public static readonly OracleDate MaxValue;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## MinValue

This static field represents the minimum valid date for an `OracleDate` structure, which is January 1, -4712.

### Declaration

```
// C#  
public static readonly OracleDate MinValue;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Null

This static field represents a null value that can be assigned to the value of an `OracleDate` instance.

Declaration

```
// C#  
public static readonly OracleDate Null;
```

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

OracleDate Static Methods

The OracleDate static methods are listed in [Table 14-36](#).

Table 14-36 OracleDate Static Methods

| Methods                            | Description                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleDate values are equal (Overloaded)                              |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleDate values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleDate values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleDate values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleDate values is less than or equal to the second    |
| <a href="#">NotEquals</a>          | Determines if two OracleDate values are not equal                                       |
| <a href="#">GetSysDate</a>         | Returns an OracleDate structure that represents the current date and time               |
| <a href="#">Parse</a>              | Returns an OracleDate structure and sets its value using a string                       |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

Equals

Overloads Object

This method determines if two OracleDate values are equal.

**Declaration**

```
// C#  
public static bool Equals(OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first OracleDate.
- *value2*  
The second OracleDate.

**Return Value**

Returns true if two OracleDate values are equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleDate that has a value compares greater than an OracleDate that has a null value.
- Two OracleDates that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## GreaterThan

This method determines if the first of two OracleDate values is greater than the second.

**Declaration**

```
// C#  
public static bool GreaterThan(OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first OracleDate.
- *value2*  
The second OracleDate.

**Return Value**

Returns true if the first of two OracleDate values is greater than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## GreaterThanOrEqual

This method determines if the first of two `OracleDate` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool GreaterThanOrEqual(OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first `OracleDate`.
- *value2*  
The second `OracleDate`.

**Return Value**

Returns `true` if the first of two `OracleDate` values is greater than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## LessThan

This method determines if the first of two `OracleDate` values is less than the second.

**Declaration**

```
// C#  
public static bool LessThan(OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first `OracleDate`.
- *value2*  
The second `OracleDate`.

**Return Value**

Returns `true` if the first of two `OracleDate` values is less than the second. Otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## LessThanOrEqual

This method determines if the first of two `OracleDate` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool LessThanOrEqual(OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first OracleDate.
- *value2*  
The second OracleDate.

**Return Value**

Returns true if the first of two OracleDate values is less than or equal to the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleDate that has a value compares greater than an OracleDate that has a null value.
- Two OracleDates that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## NotEquals

This method determines if two OracleDate values are not equal.

**Declaration**

```
// C#  
public static bool NotEquals(OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first OracleDate.
- *value2*  
The second OracleDate.

**Return Value**

Returns true if two OracleDate values are not equal; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleDate that has a value compares greater than an OracleDate that has a null value.
- Two OracleDates that contain a null value are equal.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## GetSysDate

This method gets an OracleDate structure that represents the current date and time.

### Declaration

```
// C#  
public static OracleDate GetSysDate ();
```

### Return Value

An OracleDate structure that represents the current date and time.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Parse

This method gets an OracleDate structure and sets its value for date and time using the supplied string.

### Declaration

```
// C#  
public static OracleDate Parse (string dateStr);
```

### Parameters

- *dateStr*  
A string that represents an Oracle DATE.

### Return Value

An OracleDate structure.

### Exceptions

**ArgumentException** - The *dateStr* is an invalid string representation of an Oracle DATE or the *dateStr* is not in the date format specified by the thread's OracleGlobalization.DateFormat property, which represents the Oracle NLS\_DATE\_FORMAT parameter.

**ArgumentNullException** - The *dateStr* is null.

### Remarks

The names and abbreviations used for months and days are in the language specified by the DateLanguage and Calendar properties of the thread's OracleGlobalization object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;
using Oracle.DataAccess.Client;

class ParseSample
{
    static void Main(string[] args)
    {
        // Set the thread's DateFormat for the OracleDate constructor
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.DateFormat = "YYYY-MON-DD";
        OracleGlobalization.SetThreadInfo(info);

        // Construct OracleDate from a string using the DateFormat specified
        OracleDate date = OracleDate.Parse("1999-DEC-01");

        // Set a different DateFormat on the thread for ToString()
        info.DateFormat = "MM-DD-YY";
        OracleGlobalization.SetThreadInfo(info);

        // Print "12-01-1999"
        Console.WriteLine(date.ToString());
    }
}
```

# OracleDate Static Operators

The OracleDate static operators are listed in [Table 14-37](#).

**Table 14-37 OracleDate Static Operators**

| Operator                       | Description                                                                             |
|--------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">operator ==</a>    | Determines if two OracleDate values are the same                                        |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleDate values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleDate values is greater than or equal to the second |
| <a href="#">operator !=</a>    | Determines if the two OracleDate values are not equal                                   |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleDate values is less than the second                |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleDate values is less than or equal to the second    |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## operator ==

This method determines if two OracleDate values are the same.

**Declaration**

```
// C#
public static bool operator == (OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*

The first `OracleDate`.

- `value2`

The second `OracleDate`.

### Return Value

Returns `true` if they are the same; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## operator >

This method determines if the first of two `OracleDate` values is greater than the second.

### Declaration

```
// C#  
public static bool operator > (OracleDate value1, OracleDate value2);
```

### Parameters

- `value1`

The first `OracleDate`.

- `value2`

The second `OracleDate`.

### Return Value

Returns `true` if the first of two `OracleDate` values is greater than the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## operator >=

This method determines if the first of two `OracleDate` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool operator >= (OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first `OracleDate`.
- *value2*  
The second `OracleDate`.

**Return Value**

Returns `true` if the first of two `OracleDate` values is greater than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## operator !=

This method determines if the two `OracleDate` values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first OracleDate.
- *value2*  
The second OracleDate.

**Return Value**

Returns true if the two OracleDate values are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleDate that has a value compares greater than an OracleDate that has a null value.
- Two OracleDates that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

**operator <**

This method determines if the first of two OracleDate values is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first OracleDate.
- *value2*  
The second OracleDate.

**Return Value**

Returns true if the first of two OracleDate values is less than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

**① See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

**operator <=**

This method determines if the first of two `OracleDate` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool operator <= (OracleDate value1, OracleDate value2);
```

**Parameters**

- *value1*  
The first `OracleDate`.
- *value2*  
The second `OracleDate`.

**Return Value**

Returns `true` if the first of two `OracleDate` values is less than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

# OracleDate Static Type Conversions

The OracleDate static type conversions are listed in [Table 14-38](#).

**Table 14-38 OracleDate Static Type Conversions**

| Operator                                     | Description                                                  |
|----------------------------------------------|--------------------------------------------------------------|
| <a href="#">explicit operator DateTime</a>   | Converts a structure to a DateTime structure                 |
| <a href="#">explicit operator OracleDate</a> | Converts a structure to an OracleDate structure (Overloaded) |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## explicit operator DateTime

This method converts an OracleDate structure to a DateTime structure.

**Declaration**

```
// C#
public static explicit operator DateTime(OracleDate val);
```

**Parameters**

- `val`  
An OracleDate structure.

**Return Value**

A DateTime structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## explicit operator OracleDate

explicit operator OracleDate converts the provided structure to an OracleDate structure.

**Overload List:**

- [explicit operator OracleDate\(DateTime\)](#)  
This method converts a DateTime structure to an OracleDate structure.
- [explicit operator OracleDate\(OracleTimeStamp\)](#)  
This method converts an OracleTimeStamp structure to an OracleDate structure.
- [explicit operator OracleDate\(string\)](#)  
This method converts the supplied string to an OracleDate structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## explicit operator OracleDate(DateTime)

This method converts a DateTime structure to an OracleDate structure.

**Declaration**

```
// C#  
public static explicit operator OracleDate(DateTime dt);
```

**Parameters**

- *dt*  
A DateTime structure.

**Return Value**

An OracleDate structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## explicit operator OracleDate(OracleTimeStamp)

This method converts an `OracleTimeStamp` structure to an `OracleDate` structure.

**Declaration**

```
// C#  
public explicit operator OracleDate(OracleTimeStamp ts);
```

**Parameters**

- *ts*  
`OracleTimeStamp`

**Return Value**

The returned `OracleDate` structure contains the date and time in the `OracleTimeStamp` structure.

**Remarks**

The precision of the `OracleTimeStamp` value can be lost during the conversion.

If the `OracleTimeStamp` structure has a null value, the returned `OracleDate` structure also has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## explicit operator OracleDate(string)

This method converts the supplied string to an `OracleDate` structure.

**Declaration**

```
// C#  
public explicit operator OracleDate (string dateStr);
```

**Parameters**

- *dateStr*

A string representation of an Oracle DATE.

### Return Value

The returned `OracleDate` structure contains the date and time in the string *dateStr*.

### Exceptions

`ArgumentNullException` - The *dateStr* is null.

`ArgumentException` - This exception is thrown if any of the following conditions exist:

- The *dateStr* is an invalid string representation of an Oracle DATE.
- The *dateStr* is not in the date format specified by the thread's `OracleGlobalization.DateFormat` property, which represents the Oracle NLS\_DATE\_FORMAT parameter.

### Remarks

The names and abbreviations used for months and days are in the language specified by the `DateLanguage` and `Calendar` properties of the thread's `OracleGlobalization` object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class OracleDateSample
{
    static void Main(string[] args)
    {
        // Set the thread's DateFormat to a specific format
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.DateFormat = "YYYY-MON-DD";
        OracleGlobalization.SetThreadInfo(info);

        // Construct OracleDate from a string using the DateFormat specified
        OracleDate date = (OracleDate)"1999-DEC-01";

        // Set a different DateFormat on the thread for ToString()
        info.DateFormat = "MON DD YY";
        OracleGlobalization.SetThreadInfo(info);

        // Prints "DEC 01 99"
        Console.WriteLine(date.ToString());
    }
}
```

### ① See Also

## OracleDate Properties

The OracleDate properties are listed in [Table 14-39](#).

**Table 14-39 OracleDate Properties**

| Properties              | Description                                                                     |
|-------------------------|---------------------------------------------------------------------------------|
| <a href="#">BinData</a> | Gets an array of bytes that represents an Oracle DATE in Oracle internal format |
| <a href="#">Day</a>     | Gets the day component of an OracleDate method                                  |
| <a href="#">IsNull</a>  | Indicates whether or not the current instance has a null value                  |
| <a href="#">Hour</a>    | Gets the hour component of an OracleDate                                        |
| <a href="#">Minute</a>  | Gets the minute component of an OracleDate                                      |
| <a href="#">Month</a>   | Gets the month component of an OracleDate                                       |
| <a href="#">Second</a>  | Gets the second component of an OracleDate                                      |
| <a href="#">Value</a>   | Gets the date and time that is stored in the OracleDate structure               |
| <a href="#">Year</a>    | Gets the year component of an OracleDate                                        |

## BinData

This property gets a array of bytes that represents an Oracle DATE in Oracle internal format.

### Declaration

```
// C#  
public byte[] BinData{get;}
```

### Property Value

An array of bytes.

### Exceptions

OracleNullValueException - OracleDate has a null value.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Day

This property gets the day component of an OracleDate.

### Declaration

```
// C#  
public int Day{get;}
```

### Property Value

A number that represents the day. Range of Day is (1 to 31).

### Exceptions

OracleNullValueException - OracleDate has a null value.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

### Declaration

```
// C#  
public bool IsNull{get;}
```

### Property Value

Returns true if the current instance has a null value; otherwise, returns false.

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Hour

This property gets the hour component of an `OracleDate`.

### Declaration

```
// C#  
public int Hour {get;}
```

### Property Value

A number that represents Hour. Range of Hour is (0 to 23).

### Exceptions

`OracleNullValueException` - `OracleDate` has a null value.

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Minute

This property gets the minute component of an `OracleDate`.

### Declaration

```
// C#  
public int Minute {get;}
```

### Property Value

A number that represents Minute. Range of Minute is (0 to 59).

### Exceptions

`OracleNullValueException` - `OracleDate` has a null value.

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Month

This property gets the month component of an `OracleDate`.

### Declaration

```
// C#  
public int Month {get;}
```

### Property Value

A number that represents Month. Range of Month is (1 to 12).

### Exceptions

`OracleNullValueException` - `OracleDate` has a null value.

### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Second

This property gets the second component of an `OracleDate`.

### Declaration

```
// C#  
public int Second {get;}
```

### Property Value

A number that represents Second. Range of Second is (0 to 59).

### Exceptions

`OracleNullValueException` - `OracleDate` has a null value.

**① See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Value

This property specifies the date and time that is stored in the OracleDate structure.

**Declaration**

```
// C#  
public DateTime Value {get;}
```

**Property Value**

A DateTime.

**Exceptions**

OracleNullValueException - OracleDate has a null value.

**① See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Year

This property gets the year component of an OracleDate.

**Declaration**

```
// C#  
public int Year {get;}
```

**Property Value**

A number that represents Year. Range of Year is (-4712 to 9999).

**Exceptions**

OracleNullValueException - OracleDate has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## OracleDate Methods

The OracleDate methods are listed in [Table 14-40](#).

**Table 14-40 OracleDate Methods**

| Methods                           | Description                                                                                                         |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>         | Compares the current OracleDate instance to an object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>            | Determines whether or not an object has the same date and time as the current OracleDate instance (Overloaded)      |
| <a href="#">GetHashCode</a>       | Returns a hash code for the OracleDate instance                                                                     |
| <a href="#">GetDaysBetween</a>    | Calculates the number of days between the current OracleDate instance and an OracleDate structure                   |
| <a href="#">GetType</a>           | Inherited from System.Object                                                                                        |
| <a href="#">ToOracleTimeStamp</a> | Converts the current OracleDate structure to an OracleTimeStamp structure                                           |
| <a href="#">ToString</a>          | Converts the current OracleDate structure to a string                                                               |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## CompareTo

This method compares the current OracleDate instance to an object, and returns an integer that represents their relative values.

**Declaration**

```
// C#  
public int CompareTo(object obj);
```

**Parameters**

- *obj*  
An object.

### Return Value

The method returns:

- Less than zero: if the current `OracleDate` instance value is less than that of *obj*.
- Zero: if the current `OracleDate` instance and *obj* values are equal.
- Greater than zero: if the current `OracleDate` instance value is greater than *obj*.

### Implements

`Comparable`

### Exceptions

`ArgumentException` - The *obj* parameter is not an instance of `OracleDate`.

### Remarks

The following rules apply to the behavior of this method.

- The comparison must be between `OracleDates`. For example, comparing an `OracleDate` instance with an `OracleBinary` instance is not allowed. When an `OracleDate` is compared with a different type, an `ArgumentException` is thrown.
- Any `OracleDate` that has a value compares greater than an `OracleDate` that has a null value.
- Two `OracleDates` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## Equals

This method determines whether or not an object has the same date and time as the current `OracleDate` instance.

### Declaration

```
// C#  
public override bool Equals( object obj);
```

### Parameters

- *obj*  
An object.

### Return Value

Returns true if *obj* has the same type as the current instance and represents the same date and time; otherwise returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleDate that has a value compares greater than an OracleDate that has a null value.
- Two OracleDates that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the OracleDate instance.

### Declaration

```
// C#  
public override int GetHashCode();
```

### Return Value

A number that represents the hash code.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## GetDaysBetween

This method calculates the number of days between the current OracleDate instance and the supplied OracleDate structure.

### Declaration

```
// C#  
public int GetDaysBetween (OracleDate val);
```

**Parameters**

- *val*  
An OracleDate structure.

**Return Value**

The number of days between the current OracleDate instance and the OracleDate structure.

**Exceptions**

OracleNullValueException - The current instance or the supplied OracleDate structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## ToOracleTimeStamp

This method converts the current OracleDate structure to an OracleTimeStamp structure.

**Declaration**

```
// C#  
public OracleTimeStamp ToOracleTimeStamp();
```

**Return Value**

An OracleTimeStamp structure.

**Remarks**

The returned OracleTimeStamp structure has date and time in the current instance.

If the OracleDate instance has a null value, the returned OracleTimeStamp structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDate Structure](#)
- [OracleDate Members](#)

## ToString

Overrides ValueType

This method converts the current OracleDate structure to a string.

### Declaration

```
// C#  
public override string ToString();
```

### Return Value

A string.

### Remarks

The returned value is a string representation of the OracleDate in the format specified by the thread's OracleGlobalization.DateFormat property. The names and abbreviations used for months and days are in the language specified by the thread's OracleGlobalization.DateLanguage and OracleGlobalization.Calendar properties. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class ToStringSample  
{  
    static void Main(string[] args)  
    {  
        // Set the thread's DateFormat to a specific format  
        OracleGlobalization info = OracleGlobalization.GetClientInfo();  
        info.DateFormat = "YYYY-MON-DD";  
        OracleGlobalization.SetThreadInfo(info);  
  
        // Construct OracleDate from a string using the DateFormat specified  
        OracleDate date = (OracleDate)"1999-DEC-01";  
  
        // Set a different DateFormat on the thread for ToString()  
        info.DateFormat = "YYYY/MM/DD";  
        OracleGlobalization.SetThreadInfo(info);  
  
        // Prints "1999/12/01"  
        Console.WriteLine(date.ToString());  
    }  
}
```

# OracleDecimal Structure

The OracleDecimal structure represents an Oracle NUMBER in the database or any Oracle numeric value.

### Class Inheritance

System.Object  
    System.ValueType  
        Oracle.DataAccess.Types.OracleDecimal

### Declaration

```
// C#  
public struct OracleDecimal : IComparable, INullable, IXmlSerializable
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

OracleDecimal can store up to 38 precision, while the .NET Decimal data type can only hold up to 28 precision. When accessing the OracleDecimal.Value property from an OracleDecimal that has a value greater than 28 precision, an exception is thrown. To retrieve the actual value of OracleDecimal, use the OracleDecimal.ToString() method. Another

approach is to obtain the OracleDecimal value as a byte array in an internal Oracle NUMBER format through the BinData property.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;

class OracleDecimalSample
{
    static void Main(string[] args)
    {
        // Illustrates the range of OracleDecimal vs. .NET decimal
        OracleDecimal decimal1 = OracleDecimal.MinValue;
        OracleDecimal decimal2 = OracleDecimal.MaxValue;
        OracleDecimal decimal3 = new OracleDecimal(decimal.MinValue);
        OracleDecimal decimal4 = new OracleDecimal(decimal.MaxValue);

        // Print the ranges
        Console.WriteLine("OracleDecimal can range from\n{0}\nto\n{1}\n",
            decimal1, decimal2);
        Console.WriteLine(".NET decimal can range from\n{0}\nto\n{1}",
            decimal3, decimal4);
    }
}
```

## OracleDecimal Members

OracleDecimal members are listed in the following tables:

## OracleDecimal Constructors

OracleDecimal constructors are listed in [Table 14-41](#)

**Table 14-41 OracleDecimal Constructors**

| Constructor                                | Description                                                         |
|--------------------------------------------|---------------------------------------------------------------------|
| <a href="#">OracleDecimal Constructors</a> | Instantiates a new instance of OracleDecimal structure (Overloaded) |

## OracleDecimal Static Fields

The OracleDecimal static fields are listed in [Table 14-42](#).

**Table 14-42 OracleDecimal Static Fields**

| Field                        | Description                                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------|
| <a href="#">MaxPrecision</a> | A constant representing the maximum precision, which is 38                                       |
| <a href="#">MaxScale</a>     | A constant representing the maximum scale, which is 127                                          |
| <a href="#">MaxValue</a>     | A constant representing the maximum value for this structure, which is $9.9...9 \times 10^{125}$ |
| <a href="#">MinScale</a>     | A constant representing the minimum scale, which is -84                                          |
| <a href="#">MinValue</a>     | A constant representing the minimum value for this structure, which is $-1.0 \times 10^{130}$    |
| <a href="#">NegativeOne</a>  | A constant representing the negative one value                                                   |
| <a href="#">Null</a>         | Represents a null value that can be assigned to an OracleDecimal instance                        |
| <a href="#">One</a>          | A constant representing the positive one value                                                   |
| <a href="#">Pi</a>           | A constant representing the numeric Pi value                                                     |
| <a href="#">Zero</a>         | A constant representing the zero value                                                           |

## OracleDecimal Static (Comparison) Methods

The OracleDecimal static (comparison) methods are listed in [Table 14-43](#).

**Table 14-43 OracleDecimal Static (Comparison) Methods**

| Methods                            | Description                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleDecimal values are equal (Overloaded)                              |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleDecimal values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleDecimal values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleDecimal values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleDecimal values is less than or equal to the second.   |
| <a href="#">NotEquals</a>          | Determines if two OracleDecimal values are not equal                                       |

**OracleDecimal Static (Manipulation) Methods**

The OracleDecimal static (manipulation) methods are listed in [Table 14-44](#).

**Table 14-44 OracleDecimal Static (Manipulation) Methods**

| Methods                            | Description                                                                                                                                                                            |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Abs</a>                | Returns the absolute value of an OracleDecimal                                                                                                                                         |
| <a href="#">Add</a>                | Adds two OracleDecimal structures                                                                                                                                                      |
| <a href="#">AdjustScale</a>        | Returns a new OracleDecimal with the specified number of digits and indicates whether or not to round or truncate the number if the scale is less than original                        |
| <a href="#">Ceiling</a>            | Returns a new OracleDecimal structure with its value set to the ceiling of an OracleDecimal structure                                                                                  |
| <a href="#">ConvertToPrecScale</a> | Returns a new OracleDecimal structure with a new precision and scale                                                                                                                   |
| <a href="#">Divide</a>             | Divides one OracleDecimal value by another                                                                                                                                             |
| <a href="#">Floor</a>              | Returns a new OracleDecimal structure with its value set to the floor of an OracleDecimal structure                                                                                    |
| <a href="#">Max</a>                | Returns the maximum value of the two supplied OracleDecimal structures                                                                                                                 |
| <a href="#">Min</a>                | Returns the minimum value of the two supplied OracleDecimal structures                                                                                                                 |
| <a href="#">Mod</a>                | Returns a new OracleDecimal structure with its value set to the modulus of two OracleDecimal structures                                                                                |
| <a href="#">Multiply</a>           | Returns a new OracleDecimal structure with its value set to the result of multiplying two OracleDecimal structures                                                                     |
| <a href="#">Negate</a>             | Returns a new OracleDecimal structure with its value set to the negation of the supplied OracleDecimal structure                                                                       |
| <a href="#">Parse</a>              | Converts a string to an OracleDecimal                                                                                                                                                  |
| <a href="#">Round</a>              | Returns a new OracleDecimal structure with its value set to that of the supplied OracleDecimal structure and rounded off to the specified place                                        |
| <a href="#">SetPrecision</a>       | Returns a new OracleDecimal structure with a new specified precision.                                                                                                                  |
| <a href="#">Shift</a>              | Returns a new OracleDecimal structure with its value set to that of the supplied OracleDecimal structure, and its decimal place shifted to the specified number of places to the right |
| <a href="#">Sign</a>               | Determines the sign of an OracleDecimal structure                                                                                                                                      |
| <a href="#">Sqrt</a>               | Returns a new OracleDecimal structure with its value set to the square root of the supplied OracleDecimal structure                                                                    |
| <a href="#">Subtract</a>           | Returns a new OracleDecimal structure with its value set to result of subtracting one OracleDecimal structure from another                                                             |
| <a href="#">Truncate</a>           | Truncates the OracleDecimal at a specified position                                                                                                                                    |

**OracleDecimal Static (Logarithmic) Methods**

The OracleDecimal static (logarithmic) methods are listed in [Table 14-45](#).

**Table 14-45 OracleDecimal Static (Logarithmic) Methods**

| Methods             | Description                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Exp</a> | Returns a new OracleDecimal structure with its value set to e raised to the supplied power                                                 |
| <a href="#">Log</a> | Returns the supplied OracleDecimal structure with its value set to the logarithm of the supplied OracleDecimal structure (Overloaded)      |
| <a href="#">Pow</a> | Returns a new OracleDecimal structure with its value set to the supplied OracleDecimal structure raised to the supplied power (Overloaded) |

**OracleDecimal Static (Trigonometric) Methods**

The OracleDecimal static (trigonometric) methods are listed in [Table 14-46](#).

**Table 14-46 OracleDecimal Static (Trigonometric) Methods**

| Methods               | Description                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">Acos</a>  | Returns an angle in radians whose cosine is the supplied OracleDecimal structure                       |
| <a href="#">Asin</a>  | Returns an angle in radians whose sine is the supplied OracleDecimal structure                         |
| <a href="#">Atan</a>  | Returns an angle in radians whose tangent is the supplied OracleDecimal structure                      |
| <a href="#">Atan2</a> | Returns an angle in radians whose tangent is the quotient of the two supplied OracleDecimal structures |
| <a href="#">Cos</a>   | Returns the cosine of the supplied angle in radians                                                    |
| <a href="#">Sin</a>   | Returns the sine of the supplied angle in radians                                                      |
| <a href="#">Tan</a>   | Returns the tangent of the supplied angle in radians                                                   |
| <a href="#">Cosh</a>  | Returns the hyperbolic cosine of the supplied angle in radians                                         |
| <a href="#">Sinh</a>  | Returns the hyperbolic sine of the supplied angle in radians                                           |
| <a href="#">Tanh</a>  | Returns the hyperbolic tangent of the supplied angle in radians                                        |

**OracleDecimal Static (Comparison) Operators**

The OracleDecimal static (comparison) operators are listed in [Table 14-47](#).

**Table 14-47 OracleDecimal Static (Comparison) Operators**

| Operator                       | Description                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds two OracleDecimal values                                                              |
| <a href="#">operator /</a>     | Divides one OracleDecimal value by another                                                 |
| <a href="#">operator ==</a>    | Determines if the two OracleDecimal values are equal                                       |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleDecimal values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleDecimal values is greater than or equal to the second |

**Table 14-47 (Cont.) OracleDecimal Static (Comparison) Operators**

| Operator                       | Description                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">operator !=</a>    | Determines if the two OracleDecimal values are not equal                                                 |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleDecimal values is less than the second                              |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleDecimal values is less than or equal to the second                  |
| <a href="#">operator *</a>     | Multiplies two OracleDecimal structures                                                                  |
| <a href="#">operator -</a>     | Subtracts one OracleDecimal structure from another                                                       |
| <a href="#">operator -</a>     | Negates an OracleDecimal structure                                                                       |
| <a href="#">operator %</a>     | Returns a new OracleDecimal structure with its value set to the modulus of two OracleDecimal structures. |

**OracleDecimal Static Operators (Conversion from .NET Type to OracleDecimal)**

The OracleDecimal static operators (Conversion from .NET Type to OracleDecimal) are listed in [Table 14-48](#).

**Table 14-48 OracleDecimal Static Operators (Conversion from .NET Type to OracleDecimal)**

| Operator                                        | Description                                                           |
|-------------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">implicit operator OracleDecimal</a> | Converts an instance value to an OracleDecimal structure (Overloaded) |
| <a href="#">explicit operator OracleDecimal</a> | Converts an instance value to an OracleDecimal structure (Overloaded) |

**OracleDecimal Static Operators (Conversion from OracleDecimal to .NET)**

The OracleDecimal static operators (Conversion from OracleDecimal to .NET) are listed in [Table 14-49](#).

**Table 14-49 OracleDecimal Static Operators (Conversion from OracleDecimal to .NET)**

| Operator                                  | Description                                                   |
|-------------------------------------------|---------------------------------------------------------------|
| <a href="#">explicit operator byte</a>    | Returns the byte representation of the OracleDecimal value    |
| <a href="#">explicit operator decimal</a> | Returns the decimal representation of the OracleDecimal value |
| <a href="#">explicit operator double</a>  | Returns the double representation of the OracleDecimal value  |
| <a href="#">explicit operator short</a>   | Returns the short representation of the OracleDecimal value   |
| <a href="#">explicit operator int</a>     | Returns the int representation of the OracleDecimal value     |
| <a href="#">explicit operator long</a>    | Returns the long representation of the OracleDecimal value    |
| <a href="#">explicit operator float</a>   | Returns the float representation of the OracleDecimal value   |

**OracleDecimal Properties**

The OracleDecimal properties are listed in [Table 14-50](#).

**Table 14-50 OracleDecimal Properties**

| Properties                 | Description                                                                      |
|----------------------------|----------------------------------------------------------------------------------|
| <a href="#">BinData</a>    | Returns a byte array that represents the Oracle NUMBER in Oracle internal format |
| <a href="#">Format</a>     | Specifies the format for ToString()                                              |
| <a href="#">IsInt</a>      | Indicates whether or not the current instance is an integer                      |
| <a href="#">IsNull</a>     | Indicates whether or not the current instance has a null value                   |
| <a href="#">IsPositive</a> | Indicates whether or not the current instance is greater than 0                  |
| <a href="#">IsZero</a>     | Indicates whether or not the current instance has a zero value                   |
| <a href="#">Value</a>      | Returns a decimal value                                                          |

**OracleDecimal Instance Methods**

The OracleDecimal instance methods are listed in [Table 14-51](#).

**Table 14-51 OracleDecimal Instance Methods**

| Method                      | Description                                                                                                                                                   |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current instance to the supplied object and returns an integer that represents their relative values                                             |
| <a href="#">Equals</a>      | Determines whether or not an object is an instance of OracleDecimal, and whether or not the value of the object is equal to the current instance (Overloaded) |
| <a href="#">GetHashCode</a> | Returns a hash code for the current instance                                                                                                                  |
| GetType                     | Inherited from System.Object                                                                                                                                  |
| <a href="#">ToByte</a>      | Returns the byte representation of the current instance                                                                                                       |
| <a href="#">ToDouble</a>    | Returns the double representation of the current instance                                                                                                     |
| <a href="#">ToInt16</a>     | Returns the Int16 representation of the current instance                                                                                                      |
| <a href="#">ToInt32</a>     | Returns the Int32 representation of the current instance                                                                                                      |
| <a href="#">ToInt64</a>     | Returns the Int64 representation of the current instance                                                                                                      |
| <a href="#">ToSingle</a>    | Returns the Single representation of the current instance                                                                                                     |
| <a href="#">ToString</a>    | Overloads Object.ToString()<br>Returns the string representation of the current instance                                                                      |

## OracleDecimal Constructors

The OracleDecimal constructors instantiate a new instance of the OracleDecimal structure.

**Overload List:**

- [OracleDecimal\(byte \[\]\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied byte array, which is in an Oracle NUMBER format.
- [OracleDecimal\(decimal\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `Decimal` value.
- [OracleDecimal\(double\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied double value.
- [OracleDecimal\(int\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `Int32` value.
- [OracleDecimal\(float\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `Single` value.
- [OracleDecimal\(long\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `Int64` value.
- [OracleDecimal\(string\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied string value.
- [OracleDecimal\(string, string\)](#)  
This constructor creates a new instance of the `OracleDecimal` structure with the supplied string value and number format.

**See Also**

## OracleDecimal(byte [])

This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied byte array, which is in an Oracle NUMBER format.

**Declaration**

```
// C#  
public OracleDecimal(byte [] bytes);
```

**Parameters**

- *bytes*

A byte array that represents an Oracle NUMBER in an internal Oracle format.

**Exceptions**

**ArgumentException** - The *bytes* parameter is not in a internal Oracle NUMBER format or *bytes* has an invalid value.

**ArgumentNullException** - The *bytes* parameter is null.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal(decimal)

This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `Decimal` value.

**Declaration**

```
// C#  
public OracleDecimal(decimal decX);
```

**Parameters**

- *decX*

The provided `Decimal` value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal(double)

This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `double` value.

**Declaration**

```
// C#  
public OracleDecimal(double doubleX)
```

**Parameters**

- *doubleX*  
The provided double value.

**Exceptions**

OverflowException - The value of the supplied double is greater than the maximum value or less than the minimum value of OracleDecimal.

**Remarks**

OracleDecimal contains the following values depending on the provided double value:

- double.PositiveInfinity: positive infinity value
- double.NegativeInfinity: negative infinity value.
- double.NaN: null value

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal(int)

This constructor creates a new instance of the OracleDecimal structure and sets its value to the supplied Int32 value.

**Declaration**

```
// C#  
public OracleDecimal(int intX);
```

**Parameters**

- *intX*  
The provided Int32 value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal(float)

This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `Single` value.

### Declaration

```
// C#  
public OracleDecimal(float floatX);
```

### Parameters

- *floatX*  
The provided float value.

### Remarks

`OracleDecimal` contains the following values depending on the provided float value:

`float.PositiveInfinity`: positive infinity value

`float.NegativeInfinity`: negative infinity value

`float.NaN`: null value

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal(long)

This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied `Int64` value.

### Declaration

```
// C#  
public OracleDecimal(long longX);
```

### Parameters

- *longX*  
The provided `Int64` value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal(string)

This constructor creates a new instance of the `OracleDecimal` structure and sets its value to the supplied string value.

### Declaration

```
// C#  
public OracleDecimal(string numStr);
```

### Parameters

- *numStr*  
The provided string value.

### Exceptions

`ArgumentException` - The *numStr* parameter is an invalid string representation of an `OracleDecimal`.

`ArgumentNullException` - The *numStr* parameter is null.

`OverflowException` - The value of *numStr* is greater than the maximum value or less than the minimum value of `OracleDecimal`.

input string format is incorrect - The locale's numeric separator is a comma(,).

## OracleDecimal(string, string)

This constructor creates a new instance of the `OracleDecimal` structure with the supplied string value and number format.

## Declaration

```
// C#  
public OracleDecimal(string numStr, string format);
```

## Parameters

- *numStr*  
The provided string value.
- *format*  
The provided number format.

## Exceptions

**ArgumentException** - The *numStr* parameter is an invalid string representation of an *OracleDecimal* or the *numStr* is not in the numeric format specified by *format*.

**ArgumentNullException** - The *numStr* parameter is null.

**OverflowException** - The value of *numStr* parameter is greater than the maximum value or less than the minimum value of *OracleDecimal*.

## Remarks

If the numeric format includes decimal and group separators, then the provided string must use those characters defined by the *OracleGlobalization.NumericCharacters* of the thread.

If the numeric format includes the currency symbol, ISO currency symbol, or the dual currency symbol, then the provided string must use those symbols defined by the *OracleGlobalization.Currency*, *OracleGlobalization.ISOCurrency*, and *OracleGlobalization.DualCurrency* properties respectively.

## Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class OracleDecimalSample  
{  
    static void Main(string[] args)  
    {  
        // Set the nls parameters related to currency  
        OracleGlobalization info = OracleGlobalization.GetClientInfo();  
        info.Currency = "$";  
        info.NumericCharacters = ".";,  
        OracleGlobalization.SetThreadInfo(info);  
  
        // Construct an OracleDecimal using a valid numeric format  
        OracleDecimal dec = new OracleDecimal("$2,222.22", "L9G999D99");  
  
        // Print "$2,222.22"  
        Console.WriteLine(dec.ToString());  
    }  
}
```

# OracleDecimal Static Fields

The OracleDecimal static fields are listed in [Table 14-52](#).

**Table 14-52 OracleDecimal Static Fields**

| Field                        | Description                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">MaxPrecision</a> | A constant representing the maximum precision, which is 38                                         |
| <a href="#">MaxScale</a>     | A constant representing the maximum scale, which is 127                                            |
| <a href="#">MaxValue</a>     | A constant representing the maximum value for this structure, which is 9.9...9 x 10 <sup>125</sup> |
| <a href="#">MinScale</a>     | A constant representing the minimum scale, which is -84                                            |
| <a href="#">MinValue</a>     | A constant representing the minimum value for this structure, which is -1.0 x 10 <sup>130</sup>    |
| <a href="#">NegativeOne</a>  | A constant representing the negative one value                                                     |
| <a href="#">Null</a>         | Represents a null value that can be assigned to an OracleDecimal instance                          |
| <a href="#">One</a>          | A constant representing the positive one value                                                     |
| <a href="#">Pi</a>           | A constant representing the numeric Pi value                                                       |
| <a href="#">Zero</a>         | A constant representing the zero value                                                             |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

- [OracleDecimal Structure](#)

## MaxPrecision

This static field represents the maximum precision, which is 38.

**Declaration**

```
// C#  
public static readonly byte MaxPrecision;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## MaxScale

This static field a constant representing the maximum scale, which is 127.

### Declaration

```
// C#  
public static readonly byte MaxScale;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## MaxValue

This static field indicates a constant representing the maximum value for this structure, which is  $9.9...9 \times 10^{125}$  (38 nines followed by 88 zeroes).

### Declaration

```
// C#  
public static readonly OracleDecimal MaxValue;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## MinScale

This static field indicates a constant representing the maximum scale, which is -84.

### Declaration

```
// C#  
public static readonly int MinScale;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## MinValue

This static field indicates a constant representing the minimum value for this structure, which is  $-1.0 \times 10^{130}$ .

### Declaration

```
// C#  
public static readonly OracleDecimal MinValue;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## NegativeOne

This static field indicates a constant representing the negative one value.

### Declaration

```
// C#  
public static readonly OracleDecimal NegativeOne;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Null

This static field represents a null value that can be assigned to an `OracleDecimal` instance.

### Declaration

```
// C#  
public static readonly OracleDecimal Null;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## One

This static field indicates a constant representing the positive one value.

### Declaration

```
// C#  
public static readonly OracleDecimal One;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Pi

This static field indicates a constant representing the numeric Pi value.

### Declaration

```
// C#  
public static readonly OracleDecimal Pi;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Zero

This static field indicates a constant representing the zero value.

### Declaration

```
// C#  
public static readonly OracleDecimal Zero;
```

# OracleDecimal Static (Comparison) Methods

The OracleDecimal static (comparison) methods are listed in [Table 14-53](#).

**Table 14-53 OracleDecimal Static (Comparison) Methods**

| Methods                            | Description                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleDecimal values are equal (Overloaded)                              |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleDecimal values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleDecimal values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleDecimal values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleDecimal values is less than or equal to the second.   |
| <a href="#">NotEquals</a>          | Determines if two OracleDecimal values are not equal                                       |

## Equals

This method determines if two OracleDecimal values are equal.

**Declaration**

```
// C#
public static bool Equals(OracleDecimal value1, OracleDecimal value2);
```

**Parameters**

- *value1*  
The first OracleDecimal.
- *value2*

The second `OracleDecimal`.

### Return Value

Returns true if two `OracleDecimal` values are equal; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## GreaterThan

This method determines if the first of two `OracleDecimal` values is greater than the second.

### Declaration

```
// C#  
public static bool GreaterThan(OracleDecimal value1, OracleDecimal value2);
```

### Parameters

- *value1*  
The first `OracleDecimal`.
- *value2*  
The second `OracleDecimal`.

### Return Value

Returns true if the first of two `OracleDecimal` values is greater than the second; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## GreaterThanOrEqual

This method determines if the first of two `OracleDecimal` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool GreaterThanOrEqual(OracleDecimal value1, OracleDecimal value2);
```

**Parameters**

- *value1*  
The first `OracleDecimal`.
- *value2*  
The second `OracleDecimal`.

**Return Value**

Returns `true` if the first of two `OracleDecimal` values is greater than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## LessThan

This method determines if the first of two `OracleDecimal` values is less than the second.

**Declaration**

```
// C#  
public static bool LessThan(OracleDecimal value1, OracleDecimal value2);
```

**Parameters**

- *value1*  
The first OracleDecimal.
- *value2*  
The second OracleDecimal.

**Return Value**

Returns true if the first of two OracleDecimal values is less than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleDecimal that has a value compares greater than an OracleDecimal that has a null value.
- Two OracleDecimals that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## LessThanOrEqual

This method determines if the first of two OracleDecimal values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool LessThanOrEqual(OracleDecimal value1, OracleDecimal value2);
```

**Parameters**

- *value1*  
The first OracleDecimal.
- *value2*  
The second OracleDecimal.

### Return Value

Returns true if the first of two `OracleDecimal` values is less than or equal to the second; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## NotEquals

This method determines if two `OracleDecimal` values are not equal.

### Declaration

```
// C#  
public static bool NotEquals(OracleDecimal value1, OracleDecimal value2);
```

### Parameters

- *value1*  
The first `OracleDecimal`.
- *value2*  
The second `OracleDecimal`.

### Return Value

Returns true if two `OracleDecimal` values are not equal; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

## OracleDecimal Static (Manipulation) Methods

The OracleDecimal static (manipulation) methods are listed in [Table 14-54](#).

**Table 14-54 OracleDecimal Static (Manipulation) Methods**

| Methods                            | Description                                                                                                                                                                            |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Abs</a>                | Returns the absolute value of an OracleDecimal                                                                                                                                         |
| <a href="#">Add</a>                | Adds two OracleDecimal structures                                                                                                                                                      |
| <a href="#">AdjustScale</a>        | Returns a new OracleDecimal with the specified number of digits and indicates whether or not to round or truncate the number if the scale is less than original                        |
| <a href="#">Ceiling</a>            | Returns a new OracleDecimal structure with its value set to the ceiling of an OracleDecimal structure                                                                                  |
| <a href="#">ConvertToPrecScale</a> | Returns a new OracleDecimal structure with a new precision and scale                                                                                                                   |
| <a href="#">Divide</a>             | Divides one OracleDecimal value by another                                                                                                                                             |
| <a href="#">Floor</a>              | Returns a new OracleDecimal structure with its value set to the floor of an OracleDecimal structure                                                                                    |
| <a href="#">Max</a>                | Returns the maximum value of the two supplied OracleDecimal structures                                                                                                                 |
| <a href="#">Min</a>                | Returns the minimum value of the two supplied OracleDecimal structures                                                                                                                 |
| <a href="#">Mod</a>                | Returns a new OracleDecimal structure with its value set to the modulus of two OracleDecimal structures                                                                                |
| <a href="#">Multiply</a>           | Returns a new OracleDecimal structure with its value set to the result of multiplying two OracleDecimal structures                                                                     |
| <a href="#">Negate</a>             | Returns a new OracleDecimal structure with its value set to the negation of the supplied OracleDecimal structure                                                                       |
| <a href="#">Parse</a>              | Converts a string to an OracleDecimal                                                                                                                                                  |
| <a href="#">Round</a>              | Returns a new OracleDecimal structure with its value set to that of the supplied OracleDecimal structure and rounded off to the specified place                                        |
| <a href="#">SetPrecision</a>       | Returns a new OracleDecimal structure with a new specified precision.                                                                                                                  |
| <a href="#">Shift</a>              | Returns a new OracleDecimal structure with its value set to that of the supplied OracleDecimal structure, and its decimal place shifted to the specified number of places to the right |
| <a href="#">Sign</a>               | Determines the sign of an OracleDecimal structure                                                                                                                                      |

**Table 14-54 (Cont.) OracleDecimal Static (Manipulation) Methods**

| Methods                  | Description                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Sqrt</a>     | Returns a new OracleDecimal structure with its value set to the square root of the supplied OracleDecimal structure        |
| <a href="#">Subtract</a> | Returns a new OracleDecimal structure with its value set to result of subtracting one OracleDecimal structure from another |
| <a href="#">Truncate</a> | Truncates the OracleDecimal at a specified position                                                                        |

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDecimal Members](#)

## Abs

This method returns the absolute value of an OracleDecimal.

**Declaration**

```
// C#  
public static OracleDecimal Abs(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal.

**Return Value**

The absolute value of an OracleDecimal.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Add

This method adds two OracleDecimal structures.

**Declaration**

```
// C#  
public static OracleDecimal Add(OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
The first OracleDecimal.
- *val2*  
The second OracleDecimal.

**Return Value**

Returns an OracleDecimal structure.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## AdjustScale

This method returns a new OracleDecimal with the specified number of digits and indicates whether or not to round or truncate the number if the scale is less than the original.

**Declaration**

```
// C#  
public static OracleDecimal AdjustScale(OracleDecimal val, int digits,  
    bool fRound);
```

**Parameters**

- *val*  
An OracleDecimal.
- *digits*  
The number of digits.
- *fRound*  
Indicates whether or not to round or truncate the number. Setting it to true rounds the number and setting it to false truncates the number.

**Return Value**

An OracleDecimal.

### Remarks

If the supplied `OracleDecimal` has a null value, the returned `OracleDecimal` has a null value.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;

class AdjustScaleSample
{
    static void Main(string[] args)
    {
        OracleDecimal dec1 = new OracleDecimal(5.555);

        // Adjust Scale to 2 with rounding off
        OracleDecimal dec2 = OracleDecimal.AdjustScale(dec1, 2, true);

        // Prints 5.56
        Console.WriteLine(dec2.ToString());

        // Adjust Scale to 2 with truncation
        OracleDecimal dec3 = OracleDecimal.AdjustScale(dec1, 2, false);

        // Prints 5.55
        Console.WriteLine(dec3.ToString());
    }
}
```

## Ceiling

This method returns a new `OracleDecimal` structure with its value set to the ceiling of the supplied `OracleDecimal`.

### Declaration

```
// C#
public static OracleDecimal Ceiling(OracleDecimal val);
```

### Parameters

- `val`  
An `OracleDecimal`.

### Return Value

A new `OracleDecimal` structure.

**Remarks**

If either argument has a null value, the returned `OracleDecimal` has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ConvertToPrecScale

This method returns a new `OracleDecimal` structure with a new precision and scale.

**Declaration**

```
// C#
public static OracleDecimal ConvertToPrecScale(OracleDecimal val
    int precision, int scale);
```

**Parameters**

- *val*  
An `OracleDecimal` structure.
- *precision*  
The precision. Range of precision is 1 to 38.
- *scale*  
The number of digits to the right of the decimal point. Range of scale is -84 to 127.

**Return Value**

A new `OracleDecimal` structure.

**Remarks**

If the supplied `OracleDecimal` has a null value, the returned `OracleDecimal` has a null value.

**Example**

```
// C#

using System;
using Oracle.DataAccess.Types;

class ConvertToPrecScaleSample
{
    static void Main(string[] args)
    {
        OracleDecimal dec1 = new OracleDecimal(555.6666);

        // Set the precision of od to 5 and scale to 2
    }
}
```

```
OracleDecimal dec2 = OracleDecimal.ConvertToPrecScale(dec1,5,2);

// Prints 555.67
Console.WriteLine(dec2.ToString());

// Set the precision of od to 3 and scale to 0
OracleDecimal dec3 = OracleDecimal.ConvertToPrecScale(dec1,3,0);

// Prints 556
Console.WriteLine(dec3.ToString());
    }
}
```

## Divide

This method divides one `OracleDecimal` value by another.

### Declaration

```
// C#
public static OracleDecimal Divide(OracleDecimal val1, OracleDecimal val2);
```

### Parameters

- `val1`  
An `OracleDecimal`.
- `val2`  
An `OracleDecimal`.

### Return Value

A new `OracleDecimal` structure.

### Remarks

If either argument has a null value, the returned `OracleDecimal` has a null value.

#### 📘 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Floor

This method returns a new `OracleDecimal` structure with its value set to the floor of the supplied `OracleDecimal` structure.

### Declaration

```
// C#  
public static OracleDecimal Floor(OracleDecimal val);
```

### Parameters

- *val*  
An `OracleDecimal` structure.

### Return Value

A new `OracleDecimal` structure.

### Remarks

If either argument has a null value, the returned `OracleDecimal` has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Max

This method returns the maximum value of the two supplied `OracleDecimal` structures.

### Declaration

```
// C#  
public static OracleDecimal Max(OracleDecimal val1, OracleDecimal val2);
```

### Parameters

- *val1*  
An `OracleDecimal` structure.
- *val2*  
An `OracleDecimal` structure.

### Return Value

An `OracleDecimal` structure that has the greater value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Min

This method returns the minimum value of the two supplied OracleDecimal structures.

### Declaration

```
// C#  
public static OracleDecimal Min(OracleDecimal val1, OracleDecimal val2);
```

### Parameters

- *val1*  
An OracleDecimal structure.
- *val2*  
An OracleDecimal structure.

### Return Value

An OracleDecimal structure that has the smaller value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Mod

This method returns a new OracleDecimal structure with its value set to the modulus of two OracleDecimal structures.

### Declaration

```
// C#  
public static OracleDecimal Mod(OracleDecimal val1, OracleDecimal divider);
```

### Parameters

- *val1*  
An OracleDecimal structure.
- *divider*

An OracleDecimal structure.

**Return Value**

An OracleDecimal.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Multiply

This method returns a new OracleDecimal structure with its value set to the result of multiplying two OracleDecimal structures.

**Declaration**

```
// C#  
public static OracleDecimal Multiply(OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
An OracleDecimal structure.
- *val2*  
An OracleDecimal structure.

**Return Value**

A new OracleDecimal structure.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Negate

This method returns a new `OracleDecimal` structure with its value set to the negation of the supplied `OracleDecimal` structures.

### Declaration

```
// C#  
public static OracleDecimal Negate(OracleDecimal val);
```

### Parameters

- *val*  
An `OracleDecimal` structure.

### Return Value

A new `OracleDecimal` structure.

### Remarks

If either argument has a null value, the returned `OracleDecimal` has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Parse

This method converts a string to an `OracleDecimal`.

### Declaration

```
// C#  
public static OracleDecimal Parse (string str);
```

### Parameters

- *str*  
The string being converted.

### Return Value

A new `OracleDecimal` structure.

### Exceptions

`ArgumentException` - The *numStr* parameter is an invalid string representation of an `OracleDecimal`.

`ArgumentNullException` - The *numStr* parameter is null.

OverflowException - The value of *numStr* is greater than the maximum value or less than the minimum value of OracleDecimal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

- ["Globalization Support "](#)

## Round

This method returns a new OracleDecimal structure with its value set to that of the supplied OracleDecimal structure and rounded off to the specified place.

### Declaration

```
// C#  
public static OracleDecimal Round(OracleDecimal val, int decplace);
```

### Parameters

- *val*  
An OracleDecimal structure.
- *decplace*  
The specified decimal place. If the value is positive, the function rounds the OracleDecimal structure to the right of the decimal point. If the value is negative, the function rounds to the left of the decimal point.

### Return Value

An OracleDecimal structure.

### Remarks

If the supplied OracleDecimal structure has a null value, the returned OracleDecimal has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## SetPrecision

This method returns a new `OracleDecimal` structure with a new specified precision.

### Declaration

```
// C#  
public static OracleDecimal SetPrecision(OracleDecimal val, int precision);
```

### Parameters

- *val*  
An `OracleDecimal` structure.
- *precision*  
The specified precision. Range of precision is 1 to 38.

### Return Value

An `OracleDecimal` structure.

### Remarks

The returned `OracleDecimal` is rounded off if the specified precision is smaller than the precision of *val*.

If *val* has a null value, the returned `OracleDecimal` has a null value.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class SetPrecisionSample  
{  
    static void Main(string[] args)  
    {  
        OracleDecimal dec1 = new OracleDecimal(555.6666);  
  
        // Set the precision of dec1 to 3  
        OracleDecimal dec2 = OracleDecimal.SetPrecision(dec1, 3);  
  
        // Prints 556  
        Console.WriteLine(dec2.ToString());  
  
        // Set the precision of dec1 to 4  
        OracleDecimal dec3 = OracleDecimal.SetPrecision(dec1, 4);  
  
        // Prints 555.7  
        Console.WriteLine(dec3.ToString());  
    }  
}
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)

## Shift

This method returns a new `OracleDecimal` structure with its value set to that of the supplied `OracleDecimal` structure, and its decimal place shifted to the specified number of places to the right.

### Declaration

```
// C#  
public static OracleDecimal Shift(OracleDecimal val, int decplaces);
```

### Parameters

- *val*  
An `OracleDecimal` structure.
- *decplaces*  
The specified number of places to be shifted.

### Return Value

An `OracleDecimal` structure.

### Remarks

If the supplied `OracleDecimal` structure has a null value, the returned `OracleDecimal` has a null value.

If *decplaces* is negative, the shift is to the left.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Sign

This method determines the sign of an `OracleDecimal` structure.

**Declaration**

```
// C#  
public static int Sign(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal structure.

**Return Value**

- -1: if the supplied OracleDecimal < 0
- 0: if the supplied OracleDecimal == 0
- 1: if the supplied OracleDecimal > 0

**Exceptions**

OracleNullValueException - The argument has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Sqrt

This method returns a new OracleDecimal structure with its value set to the square root of the supplied OracleDecimal structure.

**Declaration**

```
// C#  
public static OracleDecimal Sqrt(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal structure.

**Return Value**

An OracleDecimal structure.

**Exceptions**

ArgumentOutOfRangeException - The provided OracleDecimal structure is less than zero.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Subtract

This method returns a new `OracleDecimal` structure with its value set to result of subtracting one `OracleDecimal` structure from another.

**Declaration**

```
// C#  
public static OracleDecimal Subtract(OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
An `OracleDecimal` structure.
- *val2*  
An `OracleDecimal` structure.

**Return Value**

An `OracleDecimal` structure.

**Remarks**

If either argument has a null value, the returned `OracleDecimal` has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Truncate

This method truncates the `OracleDecimal` at a specified position.

**Declaration**

```
// C#  
public static OracleDecimal Truncate(OracleDecimal val, int pos);
```

**Parameters**

- *val*

An OracleDecimal structure.

- *pos*  
The specified position. If the value is positive, the function truncates the OracleDecimal structure to the right of the decimal point. If the value is negative, it truncates the OracleDecimal structure to the left of the decimal point.

**Return Value**

An OracleDecimal structure.

**Remarks**

If the supplied OracleDecimal structure has a null value, the returned OracleDecimal has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

OracleDecimal Static (Logarithmic) Methods

The OracleDecimal static (logarithmic) methods are listed in [Table 14-55](#).

**Table 14-55 OracleDecimal Static (Logarithmic) Methods**

| Methods             | Description                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Exp</a> | Returns a new OracleDecimal structure with its value set to e raised to the supplied power                                                 |
| <a href="#">Log</a> | Returns the supplied OracleDecimal structure with its value set to the logarithm of the supplied OracleDecimal structure (Overloaded)      |
| <a href="#">Pow</a> | Returns a new OracleDecimal structure with its value set to the supplied OracleDecimal structure raised to the supplied power (Overloaded) |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

Exp

This method returns a new OracleDecimal structure with its value set to e raised to the supplied OracleDecimal.

**Declaration**

```
// C#  
public static OracleDecimal Exp(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal structure.

**Return Value**

An OracleDecimal structure.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Log

Log returns the supplied OracleDecimal structure with its value set to the logarithm of the supplied OracleDecimal structure.

**Overload List:**

- [Log\(OracleDecimal\)](#)  
This method returns a new OracleDecimal structure with its value set to the natural logarithm (base e) of the supplied OracleDecimal structure.
- [Log\(OracleDecimal, int\)](#)  
This method returns the supplied OracleDecimal structure with its value set to the logarithm of the supplied OracleDecimal structure in the supplied base.
- [Log\(OracleDecimal, OracleDecimal\)](#)  
This method returns the supplied OracleDecimal structure with its value set to the logarithm of the supplied OracleDecimal structure in the supplied base.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Log(OracleDecimal)

This method returns a new `OracleDecimal` structure with its value set to the natural logarithm (base e) of the supplied `OracleDecimal` structure.

### Declaration

```
// C#  
public static OracleDecimal Log(OracleDecimal val);
```

### Parameters

- *val*  
An `OracleDecimal` structure whose logarithm is to be calculated.

### Return Value

Returns a new `OracleDecimal` structure with its value set to the natural logarithm (base e) of *val*.

### Exceptions

`ArgumentOutOfRangeException` - The supplied `OracleDecimal` value is less than zero.

### Remarks

If the supplied `OracleDecimal` structure has a null value, the returned `OracleDecimal` has a null value.

If the supplied `OracleDecimal` structure has zero value, the result is undefined, and the returned `OracleDecimal` structure has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Log(OracleDecimal, int)

This method returns the supplied `OracleDecimal` structure with its value set to the logarithm of the supplied `OracleDecimal` structure in the supplied base.

### Declaration

```
// C#  
public static OracleDecimal Log(OracleDecimal val, int logBase);
```

### Parameters

- *val*  
An `OracleDecimal` structure whose logarithm is to be calculated.

- *logBase*

An int that specifies the base of the logarithm.

### Return Value

A new `OracleDecimal` structure with its value set to the logarithm of *val* in the supplied base.

### Exceptions

`ArgumentOutOfRangeException` - Either argument is less than zero.

### Remarks

If either argument has a null value, the returned `OracleDecimal` has a null value.

If both arguments have zero value, the result is undefined, and the returned `OracleDecimal` structure has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Log(OracleDecimal, OracleDecimal)

This method returns the supplied `OracleDecimal` structure with its value set to the logarithm of the supplied `OracleDecimal` structure in the supplied base.

### Declaration

```
// C#  
public static OracleDecimal Log(OracleDecimal val, OracleDecimal logBase);
```

### Parameters

- *val*  
An `OracleDecimal` structure whose logarithm is to be calculated.
- *logBase*  
An `OracleDecimal` structure that specifies the base of the logarithm.

### Return Value

Returns the logarithm of *val* in the supplied base.

### Exceptions

`ArgumentOutOfRangeException` - Either the *val* or *logBase* parameter is less than zero.

### Remarks

If either argument has a null value, the returned `OracleDecimal` has a null value.

If both arguments have zero value, the result is undefined, and the returned `OracleDecimal` structure has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Pow

`Pow` returns a new `OracleDecimal` structure with its value set to the supplied `OracleDecimal` structure raised to the supplied power.

#### Overload List:

- [Pow\(OracleDecimal, int\)](#)  
This method returns a new `OracleDecimal` structure with its value set to the supplied `OracleDecimal` value raised to the supplied `Int32` power.
- [Pow\(OracleDecimal, OracleDecimal\)](#)  
This method returns a new `OracleDecimal` structure with its value set to the supplied `OracleDecimal` structure raised to the supplied `OracleDecimal` power.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Pow(OracleDecimal, int)

This method returns a new `OracleDecimal` structure with its value set to the supplied `OracleDecimal` value raised to the supplied `Int32` power.

#### Declaration

```
// C#  
public static OracleDecimal Pow(OracleDecimal val, int power);
```

#### Parameters

- *val*  
An `OracleDecimal` structure.
- *power*  
An `int` value that specifies the power.

**Return Value**

An OracleDecimal structure.

**Remarks**

If the supplied OracleDecimal structure has a null value, the returned OracleDecimal has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Pow(OracleDecimal, OracleDecimal)

This method returns a new OracleDecimal structure with its value set to the supplied OracleDecimal structure raised to the supplied OracleDecimal power.

**Declaration**

```
// C#  
public static OracleDecimal Pow(OracleDecimal val, OracleDecimal power);
```

**Parameters**

- *val*  
An OracleDecimal structure.
- *power*  
An OracleDecimal structure that specifies the power.

**Return Value**

An OracleDecimal structure.

**Remarks**

If the supplied OracleDecimal structure has a null value, the returned OracleDecimal has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal Static (Trigonometric) Methods

The OracleDecimal static (trigonometric) methods are listed in [Table 14-56](#).

**Table 14-56 OracleDecimal Static (Trigonometric) Methods**

| Methods               | Description                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">Acos</a>  | Returns an angle in radians whose cosine is the supplied OracleDecimal structure                       |
| <a href="#">Asin</a>  | Returns an angle in radians whose sine is the supplied OracleDecimal structure                         |
| <a href="#">Atan</a>  | Returns an angle in radians whose tangent is the supplied OracleDecimal structure                      |
| <a href="#">Atan2</a> | Returns an angle in radians whose tangent is the quotient of the two supplied OracleDecimal structures |
| <a href="#">Cos</a>   | Returns the cosine of the supplied angle in radians                                                    |
| <a href="#">Sin</a>   | Returns the sine of the supplied angle in radians                                                      |
| <a href="#">Tan</a>   | Returns the tangent of the supplied angle in radians                                                   |
| <a href="#">Cosh</a>  | Returns the hyperbolic cosine of the supplied angle in radians                                         |
| <a href="#">Sinh</a>  | Returns the hyperbolic sine of the supplied angle in radians                                           |
| <a href="#">Tanh</a>  | Returns the hyperbolic tangent of the supplied angle in radians                                        |

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Acos

This method returns an angle in radians whose cosine is the supplied OracleDecimal structure.

### Declaration

```
// C#  
public static OracleDecimal Acos(OracleDecimal val);
```

### Parameters

- *val*  
An OracleDecimal structure. Range is (-1 to 1).

### Return Value

An OracleDecimal structure that represents an angle in radians.

**Remarks**

If either argument has a null value, the returned `OracleDecimal` has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Asin

This method returns an angle in radians whose sine is the supplied `OracleDecimal` structure.

**Declaration**

```
// C#  
public static OracleDecimal Asin(OracleDecimal val);
```

**Parameters**

- `val`  
An `OracleDecimal` structure. Range is (-1 to 1).

**Return Value**

An `OracleDecimal` structure that represents an angle in radians.

**Remarks**

If either argument has a null value, the returned `OracleDecimal` has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Atan

This method returns an angle in radians whose tangent is the supplied `OracleDecimal` structure.

**Declaration**

```
// C#  
public static OracleDecimal Atan(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal.

**Return Value**

An OracleDecimal structure that represents an angle in radians.

**Remarks**

If the argument has a null value, the returned OracleDecimal has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Atan2

This method returns an angle in radians whose tangent is the quotient of the two supplied OracleDecimal structures.

**Declaration**

```
// C#  
public static OracleDecimal Atan2(OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
An OracleDecimal structure that represents the y-coordinate.
- *val2*  
An OracleDecimal structure that represents the x-coordinate.

**Return Value**

An OracleDecimal structure that represents an angle in radians.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Cos

This method returns the cosine of the supplied angle in radians.

**Declaration**

```
// C#  
public static OracleDecimal Cos(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal structure that represents an angle in radians.

**Return Value**

An OracleDecimal instance.

**Exceptions**

ArgumentOutOfRangeException - The *val* parameter is positive or negative infinity.

**Remarks**

If either argument has a null value, the returned OracleDecimal has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Sin

This method returns the sine of the supplied angle in radians.

**Declaration**

```
// C#  
public static OracleDecimal Sin(OracleDecimal val);
```

**Parameters**

- *val*

An OracleDecimal structure.

### Return Value

An OracleDecimal structure that represents an angle in radians.

### Exceptions

ArgumentOutOfRangeException - The *val* parameter is positive or negative infinity.

### Remarks

If either argument has a null value, the returned OracleDecimal has a null value.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Tan

This method returns the tangent of the supplied angle in radians.

### Declaration

```
// C#  
public static OracleDecimal Tan(OracleDecimal val);
```

### Parameters

- *val*  
An OracleDecimal structure that represents an angle in radians.

### Return Value

An OracleDecimal instance.

### Exceptions

ArgumentOutOfRangeException - The *val* parameter is positive or negative infinity.

### Remarks

If either argument has a null value, the returned OracleDecimal has a null value.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Cosh

This method returns the hyperbolic cosine of the supplied angle in radians.

### Declaration

```
// C#  
public static OracleDecimal Cosh(OracleDecimal val);
```

### Parameters

- *val*  
An OracleDecimal structure that represents an angle in radians.

### Return Value

An OracleDecimal instance.

### Remarks

If either argument has a null value, the returned OracleDecimal has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Sinh

This method returns the hyperbolic sine of the supplied angle in radians.

### Declaration

```
// C#  
public static OracleDecimal Sinh(OracleDecimal val);
```

### Parameters

- *val*  
An OracleDecimal structure that represents an angle in radians.

### Return Value

An OracleDecimal instance.

### Remarks

If either argument has a null value, the returned OracleDecimal has a null value.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

Tanh

This method returns the hyperbolic tangent of the supplied angle in radians.

Declaration

```
// C#
public static OracleDecimal Tanh(OracleDecimal val);
```

Parameters

- `val`  
An `OracleDecimal` structure that represents an angle in radians.

Return Value

An `OracleDecimal` instance.

Remarks

If either argument has a null value, the returned `OracleDecimal` has a null value.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

OracleDecimal Static (Comparison) Operators

The `OracleDecimal` static (comparison) operators are listed in [Table 14-57](#).

Table 14-57 OracleDecimal Static (Comparison) Operators

| Operator                      | Description                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>    | Adds two <code>OracleDecimal</code> values                                                  |
| <a href="#">operator /</a>    | Divides one <code>OracleDecimal</code> value by another                                     |
| <a href="#">operator ==</a>   | Determines if the two <code>OracleDecimal</code> values are equal                           |
| <a href="#">operator &gt;</a> | Determines if the first of two <code>OracleDecimal</code> values is greater than the second |

**Table 14-57 (Cont.) OracleDecimal Static (Comparison) Operators**

| Operator                       | Description                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleDecimal values is greater than or equal to the second               |
| <a href="#">operator !=</a>    | Determines if the two OracleDecimal values are not equal                                                 |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleDecimal values is less than the second                              |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleDecimal values is less than or equal to the second                  |
| <a href="#">operator *</a>     | Multiplies two OracleDecimal structures                                                                  |
| <a href="#">operator -</a>     | Subtracts one OracleDecimal structure from another                                                       |
| <a href="#">operator -</a>     | Negates an OracleDecimal structure                                                                       |
| <a href="#">operator%</a>      | Returns a new OracleDecimal structure with its value set to the modulus of two OracleDecimal structures. |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

**operator +**

This method adds two OracleDecimal values.

**Declaration**

```
// C#
public static OracleDecimal operator + (OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
The first OracleDecimal.
- *val2*  
The second OracleDecimal.

**Return Value**

An OracleDecimal structure.

**Remarks**

If either operand has a null value, the returned OracleDecimal has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator /

This method divides one OracleDecimal value by another.

**Declaration**

```
/ C#  
public static OracleDecimal operator / (OracleDecimal val1, OracleDecimal val2)
```

**Parameters**

- *val1*  
The first OracleDecimal.
- *val2*  
The second OracleDecimal.

**Return Value**

An OracleDecimal structure.

**Remarks**

If either operand has a null value, the returned OracleDecimal has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator ==

This method determines if two OracleDecimal values are equal.

**Declaration**

```
// C#  
public static bool operator == (OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*

The first `OracleDecimal`.

- `val2`

The second `OracleDecimal`.

### Return Value

Returns `true` if their values are equal; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator >

This method determines if the first of two `OracleDecimal` values is greater than the second.

### Declaration

```
// C#  
public static bool operator > (OracleDecimal val1, OracleDecimal val2);
```

### Parameters

- `val1`

The first `OracleDecimal`.

- `val2`

The second `OracleDecimal`.

### Return Value

Returns `true` if the two `OracleDecimal` values are not equal; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator >=

This method determines if the first of two `OracleDecimal` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool operator >= (OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- `val1`  
The first `OracleDecimal`.
- `val2`  
The second `OracleDecimal`.

**Return Value**

Returns `true` if the first of two `OracleDecimal` values is greater than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator !=

This method determines if the first of two `OracleDecimal` values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
The first OracleDecimal.
- *val2*  
The second OracleDecimal.

**Return Value**

Returns true if the two OracleDecimal values are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleDecimal that has a value compares greater than an OracleDecimal that has a null value.
- Two OracleDecimals that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

**operator <**

This method determines if the first of two OracleDecimal values is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
The first OracleDecimal.
- *val2*  
The second OracleDecimal.

**Return Value**

Returns true if the first of two OracleDecimal values is less than the second; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator <=

This method determines if the first of two `OracleDecimal` values is less than or equal to the second.

### Declaration

```
// C#  
public static bool operator <= (OracleDecimal val1, OracleDecimal val2);
```

### Parameters

- *val1*  
The first `OracleDecimal`.
- *val2*  
The second `OracleDecimal`.

### Return Value

Returns `true` if the first of two `OracleDecimal` values is less than or equal to the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator \*

This method multiplies two OracleDecimal structures.

**Declaration**

```
// C#  
public static OracleDecimal operator * (OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*  
The first OracleDecimal.
- *val2*  
The second OracleDecimal.

**Return Value**

A new OracleDecimal structure.

**Remarks**

If either operand has a null value, the returned OracleDecimal has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator -

This method subtracts one OracleDecimal structure from another.

**Declaration**

```
// C#  
public static OracleDecimal operator - (OracleDecimal val1, OracleDecimal val2);
```

**Parameters**

- *val1*

The first OracleDecimal.

- `val2`

The second OracleDecimal.

### Return Value

A new OracleDecimal structure.

### Remarks

If either operand has a null value, the returned OracleDecimal has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## operator -

This method negates the supplied OracleDecimal structure.

### Declaration

```
// C#  
public static OracleDecimal operator - (OracleDecimal val);
```

### Parameters

- `val`  
An OracleDecimal.

### Return Value

A new OracleDecimal structure.

### Remarks

If the supplied OracleDecimal structure has a null value, the returned OracleDecimal has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

operator%

This method returns a new OracleDecimal structure with its value set to the modulus of two OracleDecimal structures.

Declaration

```
// C#
public static OracleDecimal operator % (OracleDecimal val,
    OracleDecimal divider);
```

Parameters

- *val*  
An OracleDecimal.
- *divider*  
An OracleDecimal.

Return Value

A new OracleDecimal structure.

Remarks

If either operand has a null value, the returned OracleDecimal has a null value.

OracleDecimal Static Operators (Conversion from .NET Type to OracleDecimal)

The OracleDecimal static operators (Conversion from .NET Type to OracleDecimal) are listed in [Table 14-58](#).

**Table 14-58 OracleDecimal Static Operators (Conversion from .NET Type to OracleDecimal)**

| Operator                                        | Description                                                           |
|-------------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">implicit operator OracleDecimal</a> | Converts an instance value to an OracleDecimal structure (Overloaded) |
| <a href="#">explicit operator OracleDecimal</a> | Converts an instance value to an OracleDecimal structure (Overloaded) |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## implicit operator OracleDecimal

implicit operator OracleDecimal returns the OracleDecimal representation of a value.

### Overload List:

- [implicit operator OracleDecimal\(decimal\)](#)  
This method returns the OracleDecimal representation of a decimal value.
- [implicit operator OracleDecimal\(int\)](#)  
This method returns the OracleDecimal representation of an int value.
- [implicit operator OracleDecimal\(long\)](#)  
This method returns the OracleDecimal representation of a long value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## implicit operator OracleDecimal(decimal)

This method returns the OracleDecimal representation of a decimal value.

### Declaration

```
// C#  
public static implicit operator OracleDecimal(decimal val);
```

### Parameters

- *val*  
A decimal value.

### Return Value

An OracleDecimal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## implicit operator OracleDecimal(int)

This method returns the `OracleDecimal` representation of an `int` value.

**Declaration**

```
// C#  
public static implicit operator OracleDecimal(int val);
```

**Parameters**

- `val`  
An `int` value.

**Return Value**

An `OracleDecimal`.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## implicit operator OracleDecimal(long)

This method returns the `OracleDecimal` representation of a `long` value.

**Declaration**

```
// C#  
public static implicit operator OracleDecimal(long val);
```

**Parameters**

- `val`  
A `long` value.

**Return Value**

An `OracleDecimal`.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator OracleDecimal

OracleDecimal returns the OracleDecimal representation of a value.

**Overload List:**

- [explicit operator OracleDecimal\(double\)](#)  
This method returns the OracleDecimal representation of a double.
- [explicit operator OracleDecimal\(string\)](#)  
This method returns the OracleDecimal representation of a string.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator OracleDecimal(double)

This method returns the OracleDecimal representation of a double.

**Declaration**

```
// C#  
public static explicit operator OracleDecimal(double val);
```

**Parameters**

- *val*  
A double.

**Return Value**

An OracleDecimal.

**Exceptions**

OverflowException - The value of the supplied double is greater than the maximum value of OracleDecimal or less than the minimum value of OracleDecimal.

### Remarks

OracleDecimal contains the following values depending on the provided double value:

- `double.PositiveInfinity`: positive infinity value
- `double.NegativeInfinity`: negative infinity value.
- `double.NaN`: null value

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator OracleDecimal(string)

This method returns the `OracleDecimal` representation of a string.

### Declaration

```
// C#  
public static explicit operator OracleDecimal(string numStr);
```

### Parameters

- *numStr*  
A string that represents a numeric value.

### Return Value

An `OracleDecimal`.

### Exceptions

`ArgumentException` - The *numStr* parameter is an invalid string representation of an `OracleDecimal`.

#### ① See Also

## OracleDecimal Static Operators (Conversion from OracleDecimal to .NET)

The OracleDecimal static operators (Conversion from OracleDecimal to .NET) are listed in [Table 14-59](#).

**Table 14-59 OracleDecimal Static Operators (Conversion from OracleDecimal to .NET)**

| Operator                                  | Description                                                   |
|-------------------------------------------|---------------------------------------------------------------|
| <a href="#">explicit operator byte</a>    | Returns the byte representation of the OracleDecimal value    |
| <a href="#">explicit operator decimal</a> | Returns the decimal representation of the OracleDecimal value |
| <a href="#">explicit operator double</a>  | Returns the double representation of the OracleDecimal value  |
| <a href="#">explicit operator short</a>   | Returns the short representation of the OracleDecimal value   |
| <a href="#">explicit operator int</a>     | Returns the int representation of the OracleDecimal value     |
| <a href="#">explicit operator long</a>    | Returns the long representation of the OracleDecimal value    |
| <a href="#">explicit operator float</a>   | Returns the float representation of the OracleDecimal value   |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

### explicit operator byte

This method returns the byte representation of the OracleDecimal value.

#### Declaration

```
// C#  
public static explicit operator byte(OracleDecimal val);
```

#### Parameters

- *val*  
An OracleDecimal structure.

#### Return Value

A byte.

### Exceptions

OracleNullValueException - OracleDecimal has a null value.

OverflowException- The byte cannot represent the supplied OracleDecimal structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator decimal

This method returns the decimal representation of the OracleDecimal value.

### Declaration

```
// C#  
public static explicit operator decimal(OracleDecimal val);
```

### Parameters

- *val*  
An OracleDecimal structure.

### Return Value

A decimal.

### Exceptions

OracleNullValueException - The OracleDecimal has a null value.

OverflowException - The decimal cannot represent the supplied OracleDecimal structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator double

This method returns the double representation of the OracleDecimal value.

**Declaration**

```
// C#  
public static explicit operator double(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal structure.

**Return Value**

A double.

**Exceptions**

OracleNullValueException - The OracleDecimal has a null value.

OverflowException - The double cannot represent the supplied OracleDecimal structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator short

This method returns the short representation of the OracleDecimal value.

**Declaration**

```
// C#  
public static explicit operator short(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal structure.

**Return Value**

A short.

**Exceptions**

OracleNullValueException - The OracleDecimal has a null value.

OverflowException - The short cannot represent the supplied OracleDecimal structure.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator int

This method returns the int representation of the OracleDecimal value.

### Declaration

```
// C#  
public static explicit operator int(OracleDecimal val);
```

### Parameters

- *val*  
An OracleDecimal structure.

### Return Value

An int.

### Exceptions

OracleNullValueException - The OracleDecimal has a null value.

OverflowException - The int cannot represent the supplied OracleDecimal structure.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator long

This method returns the long representation of the OracleDecimal value.

### Declaration

```
// C#  
public static explicit operator long(OracleDecimal val);
```

### Parameters

- *val*  
An OracleDecimal structure.

**Return Value**

A long.

**Exceptions**

OracleNullValueException - The OracleDecimal has a null value.

OverflowException - The long cannot represent the supplied OracleDecimal structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## explicit operator float

This method returns the float representation of the OracleDecimal value.

**Declaration**

```
// C#  
public static explicit operator float(OracleDecimal val);
```

**Parameters**

- *val*  
An OracleDecimal structure.

**Return Value**

A float.

**Exceptions**

OracleNullValueException - The OracleDecimal has a null value.

OverflowException - The float cannot represent the supplied OracleDecimal structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## OracleDecimal Properties

The OracleDecimal properties are listed in [Table 14-60](#).

**Table 14-60 OracleDecimal Properties**

| Properties                 | Description                                                                      |
|----------------------------|----------------------------------------------------------------------------------|
| <a href="#">BinData</a>    | Returns a byte array that represents the Oracle NUMBER in Oracle internal format |
| <a href="#">Format</a>     | Specifies the format for ToString()                                              |
| <a href="#">IsInt</a>      | Indicates whether or not the current instance is an integer                      |
| <a href="#">IsNull</a>     | Indicates whether or not the current instance has a null value                   |
| <a href="#">IsPositive</a> | Indicates whether or not the current instance is greater than 0                  |
| <a href="#">IsZero</a>     | Indicates whether or not the current instance has a zero value                   |
| <a href="#">Value</a>      | Returns a decimal value                                                          |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## BinData

This property returns a byte array that represents the Oracle NUMBER in an internal Oracle format.

**Declaration**

```
// C#  
public byte[] BinData {get;}
```

**Property Value**

A byte array that represents the Oracle NUMBER in an internal Oracle format.

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Format

This property specifies the format for ToString().

### Declaration

```
// C#  
public string Format {get; set;}
```

### Property Value

The string which specifies the format.

### Remarks

Format is used when ToString() is called on an instance of an OracleDecimal. It is useful if the ToString() method needs a specific currency symbol, group, or decimal separator as part of a string.

By default, this property is null which indicates that no special formatting is used.

The decimal and group separator characters are specified by the thread's OracleGlobalization.NumericCharacters.

The currency symbols are specified by the following thread properties:

- OracleGlobalization.Currency
- OracleGlobalization.ISOCurrency
- OracleGlobalization.DualCurrency

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## IsInt

This property indicates whether or not the current instance is an integer value.

### Declaration

```
// C#  
public bool IsInt {get;}
```

### Property Value

A bool value that returns true if the current instance is an integer value; otherwise, returns false.

### Exceptions

OracleNullValueException - The current instance has a null value.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## IsNull

This property indicates whether or not the current instance has a null value.

### Declaration

```
// C#  
public bool IsNull {get;}
```

### Property Value

A bool value that returns true if the current instance has a null value; otherwise, returns false.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## IsPositive

This property indicates whether or not the value of the current instance is greater than 0.

### Declaration

```
// C#  
public bool IsPositive {get;}
```

### Property Value

A bool value that returns true if the current instance is greater than 0; otherwise, returns false.

### Exceptions

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## IsZero

This property indicates whether or not the current instance has a zero value.

### Declaration

```
// C#  
public bool IsZero{get;}
```

### Property Value

A bool value that returns true if the current instance has a zero value; otherwise, returns false.

### Exceptions

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## Value

This method returns a decimal value.

### Declaration

```
// C#  
public decimal Value {get;}
```

### Property Value

A decimal value.

### Exceptions

OracleNullValueException - The current instance has a null value.

OverflowException - The decimal cannot represent the supplied OracleDecimal structure.

**Remarks**

Precision can be lost when the decimal value is obtained from an `OracleDecimal`. See Remarks under "[OracleDecimal Structure](#)" for further information.

## OracleDecimal Instance Methods

The `OracleDecimal` instance methods are listed in [Table 14-61](#).

**Table 14-61 OracleDecimal Instance Methods**

| Method                      | Description                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current instance to the supplied object and returns an integer that represents their relative values                                                           |
| <a href="#">Equals</a>      | Determines whether or not an object is an instance of <code>OracleDecimal</code> , and whether or not the value of the object is equal to the current instance (Overloaded) |
| <a href="#">GetHashCode</a> | Returns a hash code for the current instance                                                                                                                                |
| <a href="#">GetType</a>     | Inherited from <code>System.Object</code>                                                                                                                                   |
| <a href="#">ToByte</a>      | Returns the byte representation of the current instance                                                                                                                     |
| <a href="#">ToDouble</a>    | Returns the double representation of the current instance                                                                                                                   |
| <a href="#">ToInt16</a>     | Returns the Int16 representation of the current instance                                                                                                                    |
| <a href="#">ToInt32</a>     | Returns the Int32 representation of the current instance                                                                                                                    |
| <a href="#">ToInt64</a>     | Returns the Int64 representation of the current instance                                                                                                                    |
| <a href="#">ToSingle</a>    | Returns the Single representation of the current instance                                                                                                                   |
| <a href="#">ToString</a>    | Overloads <code>Object.ToString()</code><br>Returns the string representation of the current instance                                                                       |

## CompareTo

This method compares the current instance to the supplied object and returns an integer that represents their relative values.

### Declaration

```
// C#  
public int CompareTo(object obj);
```

### Parameters

- *obj*  
The supplied instance.

### Return Value

The method returns a number:

- Less than zero: if the value of the current instance is less than *obj*.
- Zero: if the value of the current instance is equal to *obj*.
- Greater than zero: if the value of the current instance is greater than *obj*.

### Implements

IComparable

### Exceptions

ArgumentException - The parameter is not of type OracleDecimal.

### Remarks

The following rules apply to the behavior of this method.

- The comparison must be between OracleDecimals. For example, comparing an OracleDecimal instance with an OracleBinary instance is not allowed. When an OracleDecimal is compared with a different type, an ArgumentException is thrown.
- Any OracleDecimal that has a value compares greater than an OracleDecimal that has a null value.
- Two OracleDecimals that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)

## Equals

Overrides Object

This method determines whether or not an object is an instance of `OracleDecimal`, and whether or not the value of the object is equal to the current instance.

### Declaration

```
// C#  
public override bool Equals(object obj);
```

### Parameters

- *obj*  
An `OracleDecimal` instance.

### Return Value

Returns `true` if *obj* is an instance of `OracleDecimal`, and the value of *obj* is equal to the current instance; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleDecimal` that has a value compares greater than an `OracleDecimal` that has a null value.
- Two `OracleDecimals` that contain a null value are equal.

- [OracleDecimal Structure](#)

## GetHashCode

Overrides `Object`

This method returns a hash code for the current instance.

### Declaration

```
// C#  
public override int GetHashCode();
```

### Return Value

Returns a hash code.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ToByte

This method returns the byte representation of the current instance.

**Declaration**

```
// C#  
public byte ToByte();
```

**Return Value**

A byte.

**Exceptions**

OverflowException - The byte cannot represent the current instance.

OracleNullValueException - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ToDouble

This method returns the double representation of the current instance.

**Declaration**

```
// C#  
public double ToDouble();
```

**Return Value**

A double.

**Exceptions**

OverflowException - The double cannot represent the current instance.

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ToInt16

This method returns the Int16 representation of the current instance.

### Declaration

```
// C#  
public short ToInt16();
```

### Return Value

A short.

### Exceptions

OverflowException - The short cannot represent the current instance.

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ToInt32

This method returns the Int32 representation of the current instance.

### Declaration

```
// C#  
public int ToInt32();
```

### Return Value

An int.

### Exceptions

OverflowException - The int cannot represent the current instance.

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ToInt64

This method returns the Int64 representation of the current instance.

### Declaration

```
// C#  
public long ToInt64();
```

### Return Value

A long.

### Exceptions

OverflowException - The long cannot represent the current instance.

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ToSingle

This method returns the Single representation of the current instance.

### Declaration

```
// C#  
public float ToSingle();
```

### Return Value

A float.

### Exceptions

OverflowException - The float cannot represent the current instance.

OracleNullValueException - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleDecimal Members](#)
- [OracleDecimal Structure](#)

## ToString

Overrides Object

This method returns the string representation of the current instance.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

Returns the number in a string returns and a period (.) as a numeric separator.

**Remarks**

If the current instance has a null value, the returned string is "null".

The returned value is a string representation of an `OracleDecimal` in the numeric format specified by the `Format` property.

The decimal and group separator characters are specified by the thread's `OracleGlobalization.NumericCharacters`.

The currency symbols are specified by the following thread properties:

- `OracleGlobalization.Currency`
- `OracleGlobalization.ISOCurrency`
- `OracleGlobalization.DualCurrency`

If the numeric format is not specified, an Oracle default value is used.

# OracleIntervalDS Structure

The OracleIntervalDS structure represents the Oracle INTERVAL DAY TO SECOND data type to be stored in or retrieved from a database. Each OracleIntervalDS stores a period of time in term of days, hours, minutes, seconds, and fractional seconds.

## Class Inheritance

```
System.Object
    System.ValueType
        Oracle.DataAccess.Types.OracleIntervalDS
```

## Declaration

```
// C#
public struct OracleIntervalDS : IComparable, INullable, IXmlSerializable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#

using System;
using Oracle.DataAccess.Types;

class OracleIntervalDSSample
{
    static void Main()
    {
        OracleIntervalDS iDSMax = OracleIntervalDS.MaxValue;
        double totalDays = iDSMax.TotalDays;

        totalDays -= 1;
        OracleIntervalDS iDSMax_1 = new OracleIntervalDS(totalDays);

        // Calculate the difference
        OracleIntervalDS iDSDiff = iDSMax - iDSMax_1;
```

```
// Prints "idSDiff.ToString() = +0000000000 23:59:59.999999999"  
Console.WriteLine("idSDiff.ToString() = " + idSDiff.ToString());  
}  
}
```

## OracleIntervalDS Members

OracleIntervalDS members are listed in the following tables:

### OracleIntervalDS Constructors

OracleIntervalDS constructors are listed in [Table 14-62](#)

**Table 14-62 OracleIntervalDS Constructors**

| Constructor                                   | Description                                                            |
|-----------------------------------------------|------------------------------------------------------------------------|
| <a href="#">OracleIntervalDS Constructors</a> | Instantiates a new instance of OracleIntervalDS structure (Overloaded) |

### OracleIntervalDS Static Fields

The OracleIntervalDS static fields are listed in [Table 14-63](#).

**Table 14-63 OracleIntervalDS Static Fields**

| Field                    | Description                                                                  |
|--------------------------|------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid time interval for an OracleIntervalDS structure |
| <a href="#">MinValue</a> | Represents the minimum valid time interval for an OracleIntervalDS structure |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an OracleIntervalDS instance |

**Table 14-63 (Cont.) OracleIntervalDS Static Fields**

| Field                | Description                                               |
|----------------------|-----------------------------------------------------------|
| <a href="#">Zero</a> | Represents a zero value for an OracleIntervalDS structure |

**OracleIntervalDS Static Methods**

The OracleIntervalDS static methods are listed in [Table 14-64](#).

**Table 14-64 OracleIntervalDS Static Methods**

| Methods                            | Description                                                                                                    |
|------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines whether or not two OracleIntervalDS values are equal (Overloaded)                                   |
| <a href="#">GreaterThan</a>        | Determines whether or not one OracleIntervalDS value is greater than another                                   |
| <a href="#">GreaterThanOrEqual</a> | Determines whether or not one OracleIntervalDS value is greater than or equal to another                       |
| <a href="#">LessThan</a>           | Determines whether or not one OracleIntervalDS value is less than another                                      |
| <a href="#">LessThanOrEqual</a>    | Determines whether or not one OracleIntervalDS value is less than or equal to another                          |
| <a href="#">NotEquals</a>          | Determines whether or not two OracleIntervalDS values are not equal                                            |
| <a href="#">Parse</a>              | Returns an OracleIntervalDS structure and sets its value for time interval using a string                      |
| <a href="#">SetPrecision</a>       | Returns a new instance of an OracleIntervalDS with the specified day precision and fractional second precision |

**OracleIntervalDS Static Operators**

The OracleIntervalDS static operators are listed in [Table 14-65](#).

**Table 14-65 OracleIntervalDS Static Operators**

| Operator                       | Description                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds two OracleIntervalDS values                                                         |
| <a href="#">operator ==</a>    | Determines whether or not two OracleIntervalDS values are equal                          |
| <a href="#">operator &gt;</a>  | Determines whether or not one OracleIntervalDS value is greater than another             |
| <a href="#">operator &gt;=</a> | Determines whether or not one OracleIntervalDS value is greater than or equal to another |
| <a href="#">operator !=</a>    | Determines whether or not two OracleIntervalDS values are not equal                      |

**Table 14-65 (Cont.) OracleIntervalDS Static Operators**

| Operator                       | Description                                                                           |
|--------------------------------|---------------------------------------------------------------------------------------|
| <a href="#">operator &lt;</a>  | Determines whether or not one OracleIntervalDS value is less than another             |
| <a href="#">operator &lt;=</a> | Determines whether or not one OracleIntervalDS value is less than or equal to another |
| <a href="#">operator -</a>     | Subtracts one OracleIntervalDS value from another                                     |
| <a href="#">operator -</a>     | Negates an OracleIntervalDS structure                                                 |
| <a href="#">operator *</a>     | Multiplies an OracleIntervalDS value by a number                                      |
| <a href="#">operator /</a>     | Divides an OracleIntervalDS value by a number                                         |

**OracleIntervalDS Type Conversions**

The OracleIntervalDS type conversions are listed in [Table 14-66](#).

**Table 14-66 OracleIntervalDS Type Conversions**

| Operator                                           | Description                                                    |
|----------------------------------------------------|----------------------------------------------------------------|
| <a href="#">explicit operator TimeSpan</a>         | Converts an OracleIntervalDS structure to a TimeSpan structure |
| <a href="#">explicit operator OracleIntervalDS</a> | Converts a string to an OracleIntervalDS structure             |
| <a href="#">implicit operator OracleIntervalDS</a> | Converts a TimeSpan structure to an OracleIntervalDS structure |

**OracleIntervalDS Properties**

The OracleIntervalDS properties are listed in [Table 14-67](#).

**Table 14-67 OracleIntervalDS Properties**

| Properties                   | Description                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>      | Returns an array of bytes that represents the Oracle INTERVAL DAY TO SECOND in Oracle internal format |
| <a href="#">Days</a>         | Gets the days component of an OracleIntervalDS                                                        |
| <a href="#">Hours</a>        | Gets the hours component of an OracleIntervalDS                                                       |
| <a href="#">IsNull</a>       | Indicates whether or not the current instance has a null value                                        |
| <a href="#">Milliseconds</a> | Gets the milliseconds component of an OracleIntervalDS                                                |
| <a href="#">Minutes</a>      | Gets the minutes component of an OracleIntervalDS                                                     |
| <a href="#">Nanoseconds</a>  | Gets the nanoseconds component of an OracleIntervalDS                                                 |
| <a href="#">Seconds</a>      | Gets the seconds component of an OracleIntervalDS                                                     |
| <a href="#">TotalDays</a>    | Returns the total number, in days, that represent the time period in the OracleIntervalDS structure   |

**Table 14-67 (Cont.) OracleIntervalDS Properties**

| Properties            | Description                                                                  |
|-----------------------|------------------------------------------------------------------------------|
| <a href="#">Value</a> | Specifies the time interval that is stored in the OracleIntervalDS structure |

### OracleIntervalDS Methods

The OracleIntervalDS methods are listed in [Table 14-68](#).

**Table 14-68 OracleIntervalDS Methods**

| Methods                     | Description                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current OracleIntervalDS instance to an object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>      | Determines whether or not the specified object has the same time interval as the current instance (Overloaded)            |
| <a href="#">GetHashCode</a> | Returns a hash code for the OracleIntervalDS instance                                                                     |
| GetType                     | Inherited from System.Object                                                                                              |
| <a href="#">ToString</a>    | Converts the current OracleIntervalDS structure to a string                                                               |

## OracleIntervalDS Constructors

OracleIntervalDS constructors create a new instance of the OracleIntervalDS structure.

### Overload List:

- [OracleIntervalDS\(TimeSpan\)](#)  
This constructor creates a new instance of the OracleIntervalDS structure and sets its value using a TimeSpan structure.
- [OracleIntervalDS\(string\)](#)  
This constructor creates a new instance of the OracleIntervalDS structure and sets its value using a string that indicates a period of time.
- [OracleIntervalDS\(double\)](#)  
This constructor creates a new instance of the OracleIntervalDS structure and sets its value using the total number of days.

- [OracleIntervalDS\(int, int, int, int, double\)](#)

This constructor creates a new instance of the `OracleIntervalDS` structure and sets its value using the supplied days, hours, minutes, seconds and milliseconds.

- [OracleIntervalDS\(int, int, int, int, int\)](#)

This constructor creates a new instance of the `OracleIntervalDS` structure and sets its value using the supplied days, hours, minutes, seconds, and nanoseconds.

- [OracleIntervalDS\(byte\[\]\)](#)

This constructor creates a new instance of the `OracleIntervalDS` structure and sets its value to the provided byte array, which is in an internal Oracle INTERVAL DAY TO SECOND format.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalDS(TimeSpan)

This constructor creates a new instance of the `OracleIntervalDS` structure and sets its value using a `TimeSpan` structure.

### Declaration

```
// C#  
public OracleIntervalDS(TimeSpan ts);
```

### Parameters

- *ts*

A `TimeSpan` structure.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalDS(string)

This constructor creates a new instance of the `OracleIntervalDS` structure and sets its value using a string that indicates a period of time.

### Declaration

```
// C#  
public OracleIntervalDS(string intervalStr);
```

### Parameters

- *intervalStr*

A string representing the Oracle INTERVAL DAY TO SECOND.

### Exceptions

ArgumentException - The *intervalStr* parameter is not in the valid format or has an invalid value.

ArgumentNullException - The *intervalStr* parameter is null.

### Remarks

The value specified in the supplied *intervalStr* must be in Day HH:MI:SSxFF format.

### Example

"1 2:3:4.99" means 1 day, 2 hours, 3 minutes, 4 seconds, and 990 milliseconds or 1 day, 2 hours, 3 minutes, 4 seconds, and 990000000 nanoseconds.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalDS(double)

This constructor creates a new instance of the OracleIntervalDS structure and sets its value using the total number of days.

### Declaration

```
// C#  
public OracleIntervalDS(double totalDays);
```

### Parameters

- *totalDays*

The supplied total number of days for a time interval. Range of days is  $-1000,000,000 < totalDays < 1000,000,000$ .

### Exceptions

ArgumentOutOfRangeException - The argument value for one or more of the parameters is out of the specified range.

**ArgumentException** - The argument values of the parameters cannot be used to construct a valid `OracleIntervalDS`.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalDS(int, int, int, int, double)

This constructor creates a new instance of the `OracleIntervalDS` structure and sets its value using the supplied days, hours, minutes, seconds, and milliseconds.

### Declaration

```
// C#
public OracleIntervalDS (int days, int hours, int minutes, int seconds,
    double milliseconds);
```

### Parameters

- *days*  
The days provided. Range of day is (-999,999,999 to 999,999,999).
- *hours*  
The hours provided. Range of hour is (-23 to 23).
- *minutes*  
The minutes provided. Range of minute is (-59 to 59).
- *seconds*  
The seconds provided. Range of second is (-59 to 59).
- *milliseconds*  
The milliseconds provided. Range of millisecond is (- 999.999999 to 999.999999).

### Exceptions

**ArgumentOutOfRangeException** - The argument value for one or more of the parameters is out of the specified range.

**ArgumentException** - The argument values of the parameters cannot be used to construct a valid `OracleIntervalDS`.

### Remarks

The sign of all the arguments must be the same.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalDS(int, int, int, int, int)

This constructor creates a new instance of the `OracleIntervalDS` structure and sets its value using the supplied days, hours, minutes, seconds, and nanoseconds.

### Declaration

```
// C#  
public OracleIntervalDS (int days, int hours, int minutes, int seconds,  
    int nanoseconds);
```

### Parameters

- *days*  
The days provided. Range of day is (-999,999,999 to 999,999,999).
- *hours*  
The hours provided. Range of hour is (-23 to 23).
- *minutes*  
The minutes provided. Range of minute is (-59 to 59).
- *seconds*  
The seconds provided. Range of second is (-59 to 59).
- *nanoseconds*  
The nanoseconds provided. Range of nanosecond is (-999,999,999 to 999,999,999)

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleIntervalDS`.

### Remarks

The sign of all the arguments must be the same.

OracleIntervalDS(byte[ ])

This constructor creates a new instance of the OracleIntervalDS structure and sets its value to the provided byte array, which is in an internal Oracle INTERVAL DAY TO SECOND format.

Declaration

```
// C#
public OracleIntervalDS (byte[ ] bytes);
```

Parameters

- *bytes*  
A byte array that is in an internal Oracle INTERVAL DAY TO SECOND format.

Exceptions

ArgumentException - bytes is not in internal Oracle INTERVAL DAY TO SECOND format, or bytes is not a valid Oracle INTERVAL DAY TO SECOND.

ArgumentNullException - bytes is null.

OracleIntervalDS Static Fields

The OracleIntervalDS static fields are listed in [Table 14-69](#).

Table 14-69 OracleIntervalDS Static Fields

| Field                    | Description                                                                  |
|--------------------------|------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid time interval for an OracleIntervalDS structure |
| <a href="#">MinValue</a> | Represents the minimum valid time interval for an OracleIntervalDS structure |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an OracleIntervalDS instance |
| <a href="#">Zero</a>     | Represents a zero value for an OracleIntervalDS structure                    |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## MaxValue

This static field represents the maximum value for an OracleIntervalDS structure.

**Declaration**

```
// C#  
public static readonly OracleIntervalDS MaxValue;
```

**Remarks**

Maximum values:

- Day: 999999999
- hour: 23
- minute is 59
- second: 59
- nanosecond: 999999999

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## MinValue

This static field represents the minimum value for an OracleIntervalDS structure.

**Declaration**

```
// C#  
public static readonly OracleIntervalDS MinValue;
```

**Remarks**

Minimum values:

- Day: -999999999
- hour: -23
- minute: -59

- second: -59
- nanosecond: -999999999

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Null

This static field represents a null value that can be assigned to an `OracleIntervalDS` instance.

#### Declaration

```
// C#  
public static readonly OracleIntervalDS Null;
```

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Zero

This static field represents a zero value for an `OracleIntervalDS` structure.

#### Declaration

```
// C#  
public static readonly OracleIntervalDS Zero;
```

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

- [OracleIntervalDS Members](#)

## OracleIntervalDS Static Methods

The `OracleIntervalDS` static methods are listed in [Table 14-70](#).

Table 14-70 OracleIntervalDS Static Methods

| Methods                            | Description                                                                                                    |
|------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines whether or not two OracleIntervalDS values are equal (Overloaded)                                   |
| <a href="#">GreaterThan</a>        | Determines whether or not one OracleIntervalDS value is greater than another                                   |
| <a href="#">GreaterThanOrEqual</a> | Determines whether or not one OracleIntervalDS value is greater than or equal to another                       |
| <a href="#">LessThan</a>           | Determines whether or not one OracleIntervalDS value is less than another                                      |
| <a href="#">LessThanOrEqual</a>    | Determines whether or not one OracleIntervalDS value is less than or equal to another                          |
| <a href="#">NotEquals</a>          | Determines whether or not two OracleIntervalDS values are not equal                                            |
| <a href="#">Parse</a>              | Returns an OracleIntervalDS structure and sets its value for time interval using a string                      |
| <a href="#">SetPrecision</a>       | Returns a new instance of an OracleIntervalDS with the specified day precision and fractional second precision |

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Equals

This static method determines whether or not two OracleIntervalDS values are equal.

### Declaration

```
// C#
public static bool Equals(OracleIntervalDS val1, OracleIntervalDS val2);
```

### Parameters

- *val1*  
The first OracleIntervalDS.
- *val2*  
The second OracleIntervalDS.

### Return Value

If the two OracleIntervalDS structures represent the same time interval, returns true; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## GreaterThan

This static method determines whether or not the first of two `OracleIntervalDS` values is greater than the second.

### Declaration

```
// C#  
public static bool GreaterThan(OracleIntervalDS val1, OracleIntervalDS  
    val2);
```

### Parameters

- `val1`  
The first `OracleIntervalDS`.
- `val2`  
The second `OracleIntervalDS`.

### Return Value

Returns `true` if the first of two `OracleIntervalDS` values is greater than the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## GreaterThanOrEqual

This static method determines whether or not the first of two `OracleIntervalDS` values is greater than or equal to the second.

**Declaration**

```
// C#
public static bool GreaterThanOrEqual(OracleIntervalDS val1,
    OracleIntervalDS val2);
```

**Parameters**

- `val1`  
The first `OracleIntervalDS`.
- `val2`  
The second `OracleIntervalDS`.

**Return Value**

Returns `true` if the first of two `OracleIntervalDS` values is greater than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## LessThan

This static method determines whether or not the first of two `OracleIntervalDS` values is less than the second.

**Declaration**

```
// C#  
public static bool LessThan(OracleIntervalDS val1, OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first OracleIntervalDS.
- *val2*  
The second OracleIntervalDS.

**Return Value**

Returns true if the first of two OracleIntervalDS values is less than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalDS that has a value compares greater than an OracleIntervalDS that has a null value.
- Two OracleIntervalDSs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## LessThanOrEqual

This static method determines whether or not the first of two OracleIntervalDS values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool LessThanOrEqual(OracleIntervalDS val1, OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first OracleIntervalDS.
- *val2*  
The second OracleIntervalDS.

**Return Value**

Returns true if the first of two `OracleIntervalDS` values is less than or equal to the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## NotEquals

This static method determines whether or not two `OracleIntervalDS` values are not equal.

**Declaration**

```
// C#  
public static bool NotEquals(OracleIntervalDS val1, OracleIntervalDS val2);
```

**Parameters**

- `val1`  
The first `OracleIntervalDS`.
- `val2`  
The second `OracleIntervalDS`.

**Return Value**

Returns true if two `OracleIntervalDS` values are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Parse

This static method returns an `OracleIntervalDS` instance and sets its value for time interval using a string.

### Declaration

```
// C#  
public static OracleIntervalDS Parse(string intervalStr);
```

### Parameters

- *intervalStr*  
A string representing the Oracle INTERVAL DAY TO SECOND.

### Return Value

Returns an `OracleIntervalDS` instance representing the time interval from the supplied string.

### Exceptions

`ArgumentException` - The *intervalStr* parameter is not in the valid format or *intervalStr* has an invalid value.

`ArgumentNullException` - The *intervalStr* parameter is null.

### Remarks

The value specified in *intervalStr* must be in Day HH:MI:SSxFF format.

### Example

"1 2:3:4.99" means 1 day, 2 hours, 3 minutes, 4 seconds, and 990 milliseconds or 1 day, 2 hours, 3 minutes, 4 seconds, and 990000000 nanoseconds.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## SetPrecision

This static method returns a new instance of an `OracleIntervalDS` with the specified day precision and fractional second precision.

### Declaration

```
// C#  
public static OracleIntervalDS SetPrecision(OracleIntervalDS value1,  
    int dayPrecision, int fracSecPrecision);
```

### Parameters

- *value1*  
An `OracleIntervalDS` structure.
- *dayPrecision*  
The day precision provided. Range of day precision is (0 to 9).
- *fracSecPrecision*  
The fractional second precision provided. Range of fractional second precision is (0 to 9).

### Return Value

An `OracleIntervalDS` instance.

### Exceptions

`ArgumentOutOfRangeException` - An argument value is out of the specified range.

### Remarks

Depending on the value specified in the supplied *dayPrecision*, 0 or more leading zeros are displayed in the string returned by `ToString()`.

The value specified in the supplied *fracSecPrecision* is used to perform a rounding off operation on the supplied `OracleIntervalDS` value. Depending on this value, 0 or more trailing zeros are displayed in the string returned by `ToString()`.

### Example

The `OracleIntervalDS` with a value of "1 2:3:4.99" results in the string "001 2:3:4.99000" when `SetPrecision()` is called, with the day precision set to 3 and fractional second precision set to 5.

# OracleIntervalDS Static Operators

The OracleIntervalDS static operators are listed in [Table 14-71](#).

**Table 14-71 OracleIntervalDS Static Operators**

| Operator                       | Description                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds two OracleIntervalDS values                                                         |
| <a href="#">operator ==</a>    | Determines whether or not two OracleIntervalDS values are equal                          |
| <a href="#">operator &gt;</a>  | Determines whether or not one OracleIntervalDS value is greater than another             |
| <a href="#">operator &gt;=</a> | Determines whether or not one OracleIntervalDS value is greater than or equal to another |
| <a href="#">operator !=</a>    | Determines whether or not two OracleIntervalDS values are not equal                      |
| <a href="#">operator &lt;</a>  | Determines whether or not one OracleIntervalDS value is less than another                |
| <a href="#">operator &lt;=</a> | Determines whether or not one OracleIntervalDS value is less than or equal to another    |
| <a href="#">operator -</a>     | Subtracts one OracleIntervalDS value from another                                        |
| <a href="#">operator -</a>     | Negates an OracleIntervalDS structure                                                    |
| <a href="#">operator *</a>     | Multiplies an OracleIntervalDS value by a number                                         |
| <a href="#">operator /</a>     | Divides an OracleIntervalDS value by a number                                            |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator +

This static operator adds two OracleIntervalDS values.

**Declaration**

```
// C#
public static OracleIntervalDS operator + (OracleIntervalDS val1,
    OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first OracleIntervalDS.
- *val2*

The second `OracleIntervalDS`.

**Return Value**

An `OracleIntervalDS`.

**Remarks**

If either argument has a null value, the returned `OracleIntervalDS` structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator ==

This static operator determines if two `OracleIntervalDS` values are equal.

**Declaration**

```
// C#
public static bool operator == (OracleIntervalDS val1,
    OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first `OracleIntervalDS`.
- *val2*  
The second `OracleIntervalDS`.

**Return Value**

Returns true if the two `OracleIntervalDS` values are the same; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator >

This static operator determines if the first of two `OracleIntervalDS` values is greater than the second.

**Declaration**

```
// C#  
public static bool operator > (OracleIntervalDS val1,  
    OracleIntervalDS val2);
```

**Parameters**

- `val1`  
The first `OracleIntervalDS`.
- `val2`  
The second `OracleIntervalDS`.

**Return Value**

Returns true if one `OracleIntervalDS` value is greater than another; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator >=

This static operator determines if the first of two `OracleIntervalDS` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool operator >= (OracleIntervalDS val1,  
    OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first OracleIntervalDS.
- *val2*  
The second OracleIntervalDS.

**Return Value**

Returns true if the first of two OracleIntervalDS values is greater than or equal to the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalDS that has a value compares greater than an OracleIntervalDS that has a null value.
- Two OracleIntervalDSs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

**operator !=**

This static operator determines if the two OracleIntervalDS values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleIntervalDS val1,  
    OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first OracleIntervalDS.
- *val2*  
The second OracleIntervalDS.

**Return Value**

Returns true if the two OracleIntervalDS values are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalDS that has a value compares greater than an OracleIntervalDS that has a null value.
- Two OracleIntervalDSs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

**operator <**

This static operator determines if the first of two OracleIntervalDS values is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleIntervalDS val1,  
    OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first OracleIntervalDS.
- *val2*  
The second OracleIntervalDS.

**Return Value**

Returns true if the first of two OracleIntervalDS values is less than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalDS that has a value compares greater than an OracleIntervalDS that has a null value.
- Two OracleIntervalDSs that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator <=

This static operator determines if the first of two `OracleIntervalDS` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool operator <= (OracleIntervalDS val1,  
    OracleIntervalDS val2);
```

**Parameters**

- `val1`  
The first `OracleIntervalDS`.
- `val2`  
The second `OracleIntervalDS`.

**Return Value**

Returns `true` if the first of two `OracleIntervalDS` values is less than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator -

This static operator subtracts one `OracleIntervalDS` structure from another.

**Declaration**

```
// C#  
public static OracleIntervalDS operator - (OracleIntervalDS val1,  
    OracleIntervalDS val2);
```

**Parameters**

- *val1*  
The first OracleIntervalDS.
- *val2*  
The second OracleIntervalDS.

**Return Value**

An OracleIntervalDS structure.

**Remarks**

If either argument has a null value, the returned OracleIntervalDS structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

**operator -**

This static operator negates the supplied OracleIntervalDS structure.

**Declaration**

```
// C#  
public static OracleIntervalDS operator - (OracleIntervalDS val);
```

**Parameters**

- *val*  
An OracleIntervalDS.

**Return Value**

An OracleIntervalDS structure.

**Remarks**

If the supplied OracleIntervalDS structure has a null value, the returned OracleIntervalDS structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator \*

This static operator multiplies an `OracleIntervalDS` value by a number.

**Declaration**

```
// C#
public static OracleIntervalDS operator * (OracleIntervalDS val1,
    int multiplier);
```

**Parameters**

- *val1*  
The first `OracleIntervalDS`.
- *multiplier*  
A multiplier.

**Return Value**

A new `OracleIntervalDS` instance.

**Remarks**

If the `OracleIntervalDS` structure has a null value, the returned `OracleIntervalDS` structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## operator /

This static operator divides an `OracleIntervalDS` value by a number.

**Declaration**

```
// C#
public static OracleIntervalDS operator / (OracleIntervalDS val1,
    int divisor);
```

Parameters

- *val1*  
The first OracleIntervalDS.
- *divisor*  
A divisor.

Return Value

An OracleIntervalDS structure.

Remarks

If the OracleIntervalDS structure has a null value, the returned OracleIntervalDS structure has a null value.

# OracleIntervalDS Type Conversions

The OracleIntervalDS type conversions are listed in [Table 14-72](#).

Table 14-72 OracleIntervalDS Type Conversions

| Operator                                           | Description                                                    |
|----------------------------------------------------|----------------------------------------------------------------|
| <a href="#">explicit operator TimeSpan</a>         | Converts an OracleIntervalDS structure to a TimeSpan structure |
| <a href="#">explicit operator OracleIntervalDS</a> | Converts a string to an OracleIntervalDS structure             |
| <a href="#">implicit operator OracleIntervalDS</a> | Converts a TimeSpan structure to an OracleIntervalDS structure |

① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## explicit operator TimeSpan

This type conversion operator converts an OracleIntervalDS structure to a TimeSpan structure.

### Declaration

```
// C#  
public static explicit operator TimeSpan(OracleIntervalDS val);
```

### Parameters

- *val*  
An OracleIntervalDS instance.

### Return Value

A TimeSpan structure.

### Exceptions

OracleNullValueException - The OracleIntervalDS structure has a null value.

### Remarks

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## explicit operator OracleIntervalDS

This type conversion operator converts a string to an OracleIntervalDS structure.

### Declaration

```
// C#  
public static explicit operator OracleIntervalDS (string intervalStr);
```

### Parameters

- *intervalStr*  
A string representation of an Oracle INTERVAL DAY TO SECOND.

### Return Value

An OracleIntervalDS structure.

### Exceptions

ArgumentException - The supplied *intervalStr* parameter is not in the correct format or has an invalid value.

ArgumentNullException - The *intervalStr* parameter is null.

### Remarks

The returned OracleIntervalDS structure contains the same time interval represented by the supplied *intervalStr*. The value specified in the supplied *intervalStr* must be in Day HH:MI:SSxFF format.

### Example

"1 2:3:4.99" means 1 day, 2 hours, 3 minutes 4 seconds and 990 milliseconds or 1 day, 2 hours, 3 minutes 4 seconds and 990000000 nanoseconds.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## implicit operator OracleIntervalDS

This type conversion operator converts a TimeSpan structure to an OracleIntervalDS structure.

### Declaration

```
// C#  
public static implicit operator OracleIntervalDS(TimeSpan val);
```

### Parameters

- *val*  
A TimeSpan instance.

### Return Value

An OracleIntervalDS structure.

### Remarks

The returned OracleIntervalDS structure contains the same days, hours, seconds, and milliseconds as the supplied TimeSpan *val*.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalDS Properties

The OracleIntervalDS properties are listed in [Table 14-73](#).

**Table 14-73 OracleIntervalDS Properties**

| Properties                   | Description                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>      | Returns an array of bytes that represents the Oracle INTERVAL DAY TO SECOND in Oracle internal format |
| <a href="#">Days</a>         | Gets the days component of an OracleIntervalDS                                                        |
| <a href="#">Hours</a>        | Gets the hours component of an OracleIntervalDS                                                       |
| <a href="#">IsNull</a>       | Indicates whether or not the current instance has a null value                                        |
| <a href="#">Milliseconds</a> | Gets the milliseconds component of an OracleIntervalDS                                                |
| <a href="#">Minutes</a>      | Gets the minutes component of an OracleIntervalDS                                                     |
| <a href="#">Nanoseconds</a>  | Gets the nanoseconds component of an OracleIntervalDS                                                 |
| <a href="#">Seconds</a>      | Gets the seconds component of an OracleIntervalDS                                                     |
| <a href="#">TotalDays</a>    | Returns the total number, in days, that represent the time period in the OracleIntervalDS structure   |
| <a href="#">Value</a>        | Specifies the time interval that is stored in the OracleIntervalDS structure                          |

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## BinData

This property returns an array of bytes that represents the Oracle INTERVAL DAY TO SECOND in Oracle internal format.

### Declaration

```
// C#  
public byte[] BinData {get;}
```

### Property Value

A byte array that represents an Oracle INTERVAL DAY TO SECOND in Oracle internal format.

### Exceptions

OracleNullValueException - The current instance has a null value.

## Remarks

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Days

This property gets the days component of an `OracleIntervalDS`.

### Declaration

```
// C#  
public int Days {get;}
```

### Property Value

An `int` representing the days component.

### Exceptions

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Hours

This property gets the hours component of an `OracleIntervalDS`.

### Declaration

```
// C#  
public int Hours {get;}
```

### Property Value

An `int` representing the hours component.

### Exceptions

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

### Declaration

```
// C#  
public bool IsNull {get;}
```

### Property Value

Returns true if the current instance has a null value; otherwise, returns false.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Milliseconds

This property gets the milliseconds component of an OracleIntervalDS.

### Declaration

```
// C#  
public double Milliseconds {get;}
```

### Property Value

A double that represents milliseconds component.

### Exceptions

OracleNullValueException - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Minutes

This property gets the minutes component of an `OracleIntervalDS`.

**Declaration**

```
// C#  
public int Minutes {get;}
```

**Property Value**

A `int` that represents minutes component.

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Nanoseconds

This property gets the nanoseconds component of an `OracleIntervalDS`.

**Declaration**

```
// C#  
public int Nanoseconds {get;}
```

**Property Value**

An `int` that represents nanoseconds component.

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Seconds

This property gets the seconds component of an `OracleIntervalDS`.

### Declaration

```
// C#  
public int Seconds {get;}
```

### Property Value

An `int` that represents seconds component.

### Exceptions

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## TotalDays

This property returns the total number, in days, that represent the time period in the `OracleIntervalDS` structure.

### Declaration

```
// C#  
public double TotalDays {get;}
```

### Property Value

A `double` that represents the total number of days.

### Exceptions

`OracleNullValueException` - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Value

This property specifies the time interval that is stored in the OracleIntervalDS structure.

**Declaration**

```
// C#  
public TimeSpan Value {get;}
```

**Property Value**

A time interval.

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalDS Methods

The OracleIntervalDS methods are listed in [Table 14-74](#).

**Table 14-74 OracleIntervalDS Methods**

| Methods                     | Description                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current OracleIntervalDS instance to an object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>      | Determines whether or not the specified object has the same time interval as the current instance (Overloaded)            |
| <a href="#">GetHashCode</a> | Returns a hash code for the OracleIntervalDS instance                                                                     |
| GetType                     | Inherited from System.Object                                                                                              |
| <a href="#">ToString</a>    | Converts the current OracleIntervalDS structure to a string                                                               |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## CompareTo

This method compares the current `OracleIntervalDS` instance to an object, and returns an integer that represents their relative values.

**Declaration**

```
// C#  
public int CompareTo(object obj);
```

**Parameters**

- *obj*  
The object being compared to.

**Return Value**

The method returns:

- Less than zero: if the current `OracleIntervalDS` represents a shorter time interval than *obj*.
- Zero: if the current `OracleIntervalDS` and *obj* represent the same time interval.
- Greater than zero: if the current `OracleIntervalDS` represents a longer time interval than *obj*.

**Implements**

`IComparable`

**Exceptions**

`ArgumentException` - The *obj* parameter is not of type `OracleIntervalDS`.

**Remarks**

The following rules apply to the behavior of this method.

- The comparison must be between `OracleIntervalDS`s. For example, comparing an `OracleIntervalDS` instance with an `OracleBinary` instance is not allowed. When an `OracleIntervalDS` is compared with a different type, an `ArgumentException` is thrown.
- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## Equals

This method determines whether or not the specified object has the same time interval as the current instance.

**Declaration**

```
// C#  
public override bool Equals(object obj);
```

**Parameters**

- *obj*  
The specified object.

**Return Value**

Returns true if *obj* is of type `OracleIntervalDS` and has the same time interval as the current instance; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalDS` that has a value compares greater than an `OracleIntervalDS` that has a null value.
- Two `OracleIntervalDS`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## GetHashCode

Overrides `Object`

This method returns a hash code for the `OracleIntervalDS` instance.

**Declaration**

```
// C#  
public override int GetHashCode();
```

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## ToString

Overrides Object

This method converts the current OracleIntervalDS structure to a string.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

Returns a string.

**Remarks**

If the current instance has a null value, the returned string contains "null".

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalDS Structure](#)
- [OracleIntervalDS Members](#)

## OracleIntervalYM Structure

The OracleIntervalYM structure represents the Oracle INTERVAL YEAR TO MONTH data type to be stored in or retrieved from a database. Each OracleIntervalYM stores a period of time in years and months.

**Class Inheritance**

System.Object

System.ValueType

Oracle.DataAccess.Types.OracleIntervalYM

**Declaration**

```
// C#  
public struct OracleIntervalYM : IComparable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#

using System;
using Oracle.DataAccess.Types;

class OracleIntervalYMSample
{
    static void Main()
    {
        OracleIntervalYM iYMMax = OracleIntervalYM.MaxValue;
        double totalYears = iYMMax.TotalYears;

        totalYears -= 1;
        OracleIntervalYM iYMMax_1 = new OracleIntervalYM(totalYears);

        // Calculate the difference
        OracleIntervalYM iYMDiff = iYMMax - iYMMax_1;

        // Prints "iYMDiff.ToString() = +000000001-00"
        Console.WriteLine("iYMDiff.ToString() = " + iYMDiff.ToString());
    }
}
```

**① See Also**

## OracleIntervalYM Members

OracleIntervalYM members are listed in the following tables:

### OracleIntervalYM Constructors

OracleIntervalYM constructors are listed in [Table 14-75](#)

**Table 14-75 OracleIntervalYM Constructors**

| Constructor                                   | Description                                                            |
|-----------------------------------------------|------------------------------------------------------------------------|
| <a href="#">OracleIntervalYM Constructors</a> | Instantiates a new instance of OracleIntervalYM structure (Overloaded) |

### OracleIntervalYM Static Fields

The OracleIntervalYM static fields are listed in [Table 14-76](#).

**Table 14-76 OracleIntervalYM Static Fields**

| Field                    | Description                                                                  |
|--------------------------|------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum value for an OracleIntervalYM structure               |
| <a href="#">MinValue</a> | Represents the minimum value for an OracleIntervalYM structure               |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an OracleIntervalYM instance |
| <a href="#">Zero</a>     | Represents a zero value for an OracleIntervalYM structure                    |

### OracleIntervalYM Static Methods

The OracleIntervalYM static methods are listed in [Table 14-77](#).

**Table 14-77 OracleIntervalYM Static Methods**

| Methods                            | Description                                                                               |
|------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines whether or not two OracleIntervalYM values are equal (Overloaded)              |
| <a href="#">GreaterThan</a>        | Determines whether or not one OracleIntervalYM value is greater than another              |
| <a href="#">GreaterThanOrEqual</a> | Determines whether or not one OracleIntervalYM value is greater than or equal to another  |
| <a href="#">LessThan</a>           | Determines whether or not one OracleIntervalYM value is less than another                 |
| <a href="#">LessThanOrEqual</a>    | Determines whether or not one OracleIntervalYM value is less than or equal to another     |
| <a href="#">NotEquals</a>          | Determines whether two OracleIntervalYM values are not equal                              |
| <a href="#">Parse</a>              | Returns an OracleIntervalYM structure and sets its value for time interval using a string |
| <a href="#">SetPrecision</a>       | Returns a new instance of an OracleIntervalYM with the specified year precision.          |

**OracleIntervalYM Static Operators**

The OracleIntervalYM static operators are listed in [Table 14-78](#).

**Table 14-78 OracleIntervalYM Static Operators**

| Operator                       | Description                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds two OracleIntervalYM values                                                         |
| <a href="#">operator ==</a>    | Determines whether or not two OracleIntervalYM values are equal                          |
| <a href="#">operator &gt;</a>  | Determines whether or not one OracleIntervalYM value is greater than another             |
| <a href="#">operator &gt;=</a> | Determines whether or not one OracleIntervalYM value is greater than or equal to another |
| <a href="#">operator !=</a>    | Determines whether two OracleIntervalYM values are not equal                             |
| <a href="#">operator &lt;</a>  | Determines whether or not one OracleIntervalYM value is less than another                |
| <a href="#">operator &lt;=</a> | Determines whether or not one OracleIntervalYM value is less than or equal to another    |
| <a href="#">operator -</a>     | Subtracts one OracleIntervalYM value from another                                        |
| <a href="#">operator -</a>     | Negates an OracleIntervalYM structure                                                    |
| <a href="#">operator *</a>     | Multiplies an OracleIntervalYM value by a number                                         |
| <a href="#">operator /</a>     | Divides an OracleIntervalYM value by a number                                            |

**OracleIntervalYM Type Conversions**

The OracleIntervalYM conversions are listed in [Table 14-79](#).

**Table 14-79 OracleIntervalYM Type Conversions**

| Operator                                           | Description                                                    |
|----------------------------------------------------|----------------------------------------------------------------|
| <a href="#">explicit operator long</a>             | Converts an OracleIntervalYM structure to a number             |
| <a href="#">explicit operator OracleIntervalYM</a> | Converts a string to an OracleIntervalYM structure             |
| <a href="#">implicit operator OracleIntervalYM</a> | Converts the number of months to an OracleIntervalYM structure |

### OracleIntervalYM Properties

The OracleIntervalYM properties are listed in [Table 14-80](#).

**Table 14-80 OracleIntervalYM Properties**

| Properties                 | Description                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>    | Returns an array of bytes that represents the Oracle INTERVAL YEAR TO MONTH in an Oracle internal format         |
| <a href="#">IsNull</a>     | Indicates whether or not the current instance has a null value                                                   |
| <a href="#">Months</a>     | Gets the months component of an OracleIntervalYM                                                                 |
| <a href="#">TotalYears</a> | Returns the total number, in years, that represents the period of time in the current OracleIntervalYM structure |
| <a href="#">Value</a>      | Specifies the total number of months that is stored in the OracleIntervalYM structure                            |
| <a href="#">Years</a>      | Gets the years component of an OracleIntervalYM                                                                  |

### OracleIntervalYM Methods

The OracleIntervalYM methods are listed in [Table 14-81](#).

**Table 14-81 OracleIntervalYM Methods**

| Methods                     | Description                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current OracleIntervalYM instance to the supplied object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>      | Determines whether or not the specified object has the same time interval as the current instance (Overloaded)                      |
| <a href="#">GetHashCode</a> | Returns a hash code for the OracleIntervalYM instance                                                                               |
| GetType                     | Inherited from System.Object                                                                                                        |
| <a href="#">ToString</a>    | Converts the current OracleIntervalYM structure to a string                                                                         |

## OracleIntervalYM Constructors

The OracleIntervalYM constructors creates a new instance of the OracleIntervalYM structure.

### Overload List:

- [OracleIntervalYM\(long\)](#)  
This method creates a new instance of the OracleIntervalYM structure using the supplied total number of months for a period of time.
- [OracleIntervalYM\(string\)](#)  
This method creates a new instance of the OracleIntervalYM structure and sets its value using the supplied string.
- [OracleIntervalYM\(double\)](#)  
This method creates a new instance of the OracleIntervalYM structure and sets its value using the total number of years.
- [OracleIntervalYM\(int, int\)](#)  
This method creates a new instance of the OracleIntervalYM structure and sets its value using years and months.
- [OracleIntervalYM\(byte\[\] \)](#)  
This method creates a new instance of the OracleIntervalYM structure and sets its value to the provided byte array, which is in an internal Oracle INTERVAL DAY TO SECOND format.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## OracleIntervalYM(long)

This method creates a new instance of the OracleIntervalYM structure using the supplied total number of months for a period of time.

### Declaration

```
// C#  
public OracleIntervalYM (long totalMonths);
```

### Parameters

- *totalMonths*

The number of total months for a time interval. Range is  $-12,000,000,000 < totalMonths < 12,000,000,000$ .

### Exceptions

ArgumentOutOfRangeException - The *totalMonths* parameter is out of the specified range.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## OracleIntervalYM(string)

This method creates a new instance of the OracleIntervalYM structure and sets its value using the supplied string.

### Declaration

```
// C#  
public OracleIntervalYM (string intervalStr);
```

### Parameters

- *intervalStr*

A string representing the Oracle INTERVAL YEAR TO MONTH.

### Remarks

The value specified in the supplied *intervalStr* must be in Year-Month format.

### Exceptions

ArgumentException - The *intervalStr* parameter is not in the valid format or *intervalStr* has an invalid value.

ArgumentNullException - The *intervalStr* parameter is null.

### Example

"1-2" means 1 year and 2 months.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## OracleIntervalYM(double)

This method creates a new instance of the `OracleIntervalYM` structure and sets its value using the total number of years.

**Declaration**

```
// C#  
public OracleIntervalYM (double totalYears);
```

**Parameters**

- *totalYears*  
Number of total years. Range is  $-1,000,000,000 < totalYears < 1,000,000,000$ .

**Exceptions**

`ArgumentOutOfRangeException` - The *totalYears* parameter is out of the specified range.

`ArgumentException` - The *totalYears* parameter cannot be used to construct a valid `OracleIntervalYM`.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## OracleIntervalYM(int, int)

This method creates a new instance of the `OracleIntervalYM` structure and sets its value using years and months.

**Declaration**

```
// C#  
public OracleIntervalYM (int years, int months);
```

**Parameters**

- *years*  
Number of years. Range of year is  $(-999,999,999 \text{ to } 999,999,999)$ .
- *months*

Number of months. Range of month is (-11 to 11).

### Remarks

The sign of all the arguments must be the same.

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleIntervalYM`.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## OracleIntervalYM(byte[ ])

This method creates a new instance of the `OracleIntervalYM` structure and sets its value to the provided byte array, which is in an internal Oracle INTERVAL DAY TO SECOND format.

### Declaration

```
// C#  
public OracleIntervalYM (byte[] bytes);
```

### Parameters

- *bytes*  
A byte array that is in an internal Oracle INTERVAL YEAR TO MONTH format.

### Exceptions

`ArgumentException` - The supplied byte array is not in an internal Oracle INTERVAL YEAR TO MONTH format or the supplied byte array has an invalid value.

`ArgumentNullException` - *bytes* is null.

### Remarks

The supplied byte array must be in an internal Oracle INTERVAL YEAR TO MONTH format.

# OracleIntervalYM Static Fields

The OracleIntervalYM static fields are listed in [Table 14-82](#).

**Table 14-82 OracleIntervalYM Static Fields**

| Field                    | Description                                                                  |
|--------------------------|------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum value for an OracleIntervalYM structure               |
| <a href="#">MinValue</a> | Represents the minimum value for an OracleIntervalYM structure               |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an OracleIntervalYM instance |
| <a href="#">Zero</a>     | Represents a zero value for an OracleIntervalYM structure                    |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## MaxValue

This static field represents the maximum value for an OracleIntervalYM structure.

**Declaration**

```
// C#
public static readonly OracleIntervalYM MaxValue;
```

**Remarks**

Year is 999999999 and Month is 11.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## MinValue

This static field represents the minimum value for an OracleIntervalYM structure.

### Declaration

```
// C#  
public static readonly OracleIntervalYM MinValue;
```

### Remarks

Year is -999999999 and Month is -11.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Null

This static field represents a null value that can be assigned to an OracleIntervalYM instance.

### Declaration

```
// C#  
public static readonly OracleIntervalYM Null;
```

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Zero

This static field represents a zero value for an OracleIntervalYM structure.

### Declaration

```
// C#  
public static readonly OracleIntervalDS Zero;
```

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## OracleIntervalYM Static Methods

The OracleIntervalYM static methods are listed in [Table 14-83](#).

**Table 14-83 OracleIntervalYM Static Methods**

| Methods                            | Description                                                                               |
|------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines whether or not two OracleIntervalYM values are equal (Overloaded)              |
| <a href="#">GreaterThan</a>        | Determines whether or not one OracleIntervalYM value is greater than another              |
| <a href="#">GreaterThanOrEqual</a> | Determines whether or not one OracleIntervalYM value is greater than or equal to another  |
| <a href="#">LessThan</a>           | Determines whether or not one OracleIntervalYM value is less than another                 |
| <a href="#">LessThanOrEqual</a>    | Determines whether or not one OracleIntervalYM value is less than or equal to another     |
| <a href="#">NotEquals</a>          | Determines whether two OracleIntervalYM values are not equal                              |
| <a href="#">Parse</a>              | Returns an OracleIntervalYM structure and sets its value for time interval using a string |
| <a href="#">SetPrecision</a>       | Returns a new instance of an OracleIntervalYM with the specified year precision.          |

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Equals

This static method determines whether or not two OracleIntervalYM values are equal.

**Declaration**

```
// C#  
public static bool Equals(OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
An OracleIntervalYM structure.
- *val2*  
An OracleIntervalYM structure.

**Return Value**

Returns true if two OracleIntervalYM values represent the same time interval, otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## GreaterThan

This static method determines whether or not the first of two OracleIntervalYM values is greater than the second.

**Declaration**

```
// C#  
public static bool GreaterThan(OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

**Return Value**

Returns true if the first of two OracleIntervalYM values is greater than the second; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleIntervalYM` that has a value compares greater than an `OracleIntervalYM` that has a null value.
- Two `OracleIntervalYMs` that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## GreaterThanOrEqual

This static method determines whether or not the first of two `OracleIntervalYM` values is greater than or equal to the second.

### Declaration

```
// C#  
public static bool GreaterThanOrEqual(OracleIntervalYM val1,  
    OracleIntervalYM val2);
```

### Parameters

- `val1`  
The first `OracleIntervalYM`.
- `val2`  
The second `OracleIntervalYM`.

### Return Value

Returns `true` if the first of two `OracleIntervalYM` values is greater than or equal to the second; otherwise returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleIntervalYM` that has a value compares greater than an `OracleIntervalYM` that has a null value.
- Two `OracleIntervalYMs` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## LessThan

This static method determines whether or not the first of two `OracleIntervalYM` values is less than the second.

**Declaration**

```
// C#  
public static bool LessThan(OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first `OracleIntervalYM`.
- *val2*  
The second `OracleIntervalYM`.

**Return Value**

Returns `true` if the first of two `OracleIntervalYM` values is less than the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalYM` that has a value compares greater than an `OracleIntervalYM` that has a null value.
- Two `OracleIntervalYMs` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## LessThanOrEqual

This static method determines whether or not the first of two `OracleIntervalYM` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool LessThanOrEqual(OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

**Return Value**

Returns true if the first of two OracleIntervalYM values is less than or equal to the second. Returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## NotEquals

This static method determines whether two OracleIntervalYM values are not equal.

**Declaration**

```
// C#  
public static bool NotEquals(OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

**Return Value**

Returns true if two OracleIntervalYM values are not equal. Returns false otherwise.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Parse

This static method returns an OracleIntervalYM structure and sets its value for time interval using a string.

### Declaration

```
// C#  
public static OracleIntervalYM Parse (string intervalStr);
```

### Parameters

- *intervalStr*  
A string representing the Oracle INTERVAL YEAR TO MONTH.

### Return Value

Returns an OracleIntervalYM structure.

### Exceptions

ArgumentException - The *intervalStr* parameter is not in the valid format or *intervalStr* has an invalid value.

ArgumentNullException - The *intervalStr* parameter is null.

### Remarks

The value specified in the supplied *intervalStr* must be in the Year-Month format.

### Example

"1-2" means 1 year and 2 months.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## SetPrecision

This static method returns a new instance of an `OracleIntervalYM` with the specified year precision.

### Declaration

```
// C#
public static OracleIntervalYM SetPrecision(OracleIntervalYM value1,
    int yearPrecision);
```

### Parameters

- *value1*  
An `OracleIntervalYM` structure.
- *yearPrecision*  
The year precision provided. Range of year precision is (0 to 9).

### Return Value

An `OracleIntervalDS` instance.

### Exceptions

`ArgumentOutOfRangeException` - *yearPrecision* is out of the specified range.

### Remarks

Depending on the value specified in the supplied *yearPrecision*, 0 or more leading zeros are displayed in the string returned by `ToString()`.

### Example

An `OracleIntervalYM` with a value of "1-2" results in the string "001-2" when `SetPrecision()` is called with the year precision set to 3.

# OracleIntervalYM Static Operators

The OracleIntervalYM static operators are listed in [Table 14-84](#).

**Table 14-84 OracleIntervalYM Static Operators**

| Operator                       | Description                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds two OracleIntervalYM values                                                         |
| <a href="#">operator ==</a>    | Determines whether or not two OracleIntervalYM values are equal                          |
| <a href="#">operator &gt;</a>  | Determines whether or not one OracleIntervalYM value is greater than another             |
| <a href="#">operator &gt;=</a> | Determines whether or not one OracleIntervalYM value is greater than or equal to another |
| <a href="#">operator !=</a>    | Determines whether two OracleIntervalYM values are not equal                             |
| <a href="#">operator &lt;</a>  | Determines whether or not one OracleIntervalYM value is less than another                |
| <a href="#">operator &lt;=</a> | Determines whether or not one OracleIntervalYM value is less than or equal to another    |
| <a href="#">operator -</a>     | Subtracts one OracleIntervalYM value from another                                        |
| <a href="#">operator -</a>     | Negates an OracleIntervalYM structure                                                    |
| <a href="#">operator *</a>     | Multiplies an OracleIntervalYM value by a number                                         |
| <a href="#">operator /</a>     | Divides an OracleIntervalYM value by a number                                            |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## operator +

This static operator adds two OracleIntervalYM values.

**Declaration**

```
// C#
public static OracleIntervalYM operator + (OracleIntervalYM val1,
    OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

**Return Value**

OracleIntervalYM

**Remarks**

If either argument has a null value, the returned OracleIntervalYM structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

**operator ==**

This static operator determines if two OracleIntervalYM values are equal.

**Declaration**

```
// C#  
public static bool operator == (OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

**Return Value**

Returns true if they are equal; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## operator >

This static operator determines if the first of two `OracleIntervalYM` values is greater than the second.

### Declaration

```
// C#  
public static bool operator > (OracleIntervalYM val1, OracleIntervalYM val2);
```

### Parameters

- *val1*  
The first `OracleIntervalYM`.
- *val2*  
The second `OracleIntervalYM`.

### Return Value

Returns true if one `OracleIntervalYM` value is greater than another; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleIntervalYM` that has a value compares greater than an `OracleIntervalYM` that has a null value.
- Two `OracleIntervalYMs` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

- [OracleIntervalYM Members](#)

## operator >=

This static operator determines if the first of two `OracleIntervalYM` values is greater than or equal to the second.

### Declaration

```
// C#  
public static bool operator >= (OracleIntervalYM val1, OracleIntervalYM val2);
```

### Parameters

- *val1*  
The first `OracleIntervalYM`.
- *val2*

The second OracleIntervalYM.

### Return Value

Returns true if one OracleIntervalYM value is greater than or equal to another; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## operator !=

This static operator determines whether two OracleIntervalYM values are not equal.

### Declaration

```
// C#  
public static bool operator != (OracleIntervalYM val1, OracleIntervalYM val2)
```

### Parameters

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

### Return Value

Returns true if two OracleIntervalYM values are not equal; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## operator <

This static operator determines if the first of two `OracleIntervalYM` values is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- `val1`  
The first `OracleIntervalYM`.
- `val2`  
The second `OracleIntervalYM`.

**Return Value**

Returns `true` if the first of two `OracleIntervalYM` values is less than the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleIntervalYM` that has a value compares greater than an `OracleIntervalYM` that has a null value.
- Two `OracleIntervalYMs` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## operator <=

This static operator determines if the first of two `OracleIntervalYM` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool operator <= (OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

**Return Value**

Returns true if the first of two OracleIntervalYM values is less than or equal to the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

**operator -**

This static operator subtracts one OracleIntervalYM structure from another.

**Declaration**

```
// C#  
public static OracleIntervalYM operator - (OracleIntervalYM val1, OracleIntervalYM val2);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *val2*  
The second OracleIntervalYM.

**Return Value**

An OracleIntervalYM structure.

**Remarks**

If either argument has a null value, the returned OracleIntervalYM structure has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

**operator -**

This static operator negates an OracleIntervalYM structure.

**Declaration**

```
// C#  
public static OracleIntervalYM operator - (OracleIntervalYM val);
```

**Parameters**

- *val*  
An OracleIntervalYM.

**Return Value**

An OracleIntervalYM structure.

**Remarks**

If the supplied OracleIntervalYM structure has a null value, the returned OracleIntervalYM structure has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

**operator \***

This static operator multiplies an OracleIntervalYM value by a number.

**Declaration**

```
// C#  
public static OracleIntervalYM operator * (OracleIntervalYM val1, int multiplier);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *multiplier*  
A multiplier.

**Return Value**

An OracleIntervalYM structure.

**Remarks**

If the supplied OracleIntervalYM structure has a null value, the returned OracleIntervalYM structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## operator /

This static operator divides an OracleIntervalYM value by a number.

**Declaration**

```
// C#  
public static OracleIntervalYM operator / (OracleIntervalYM val1, int divisor);
```

**Parameters**

- *val1*  
The first OracleIntervalYM.
- *divisor*  
A divisor.

**Return Value**

An OracleIntervalYM structure.

**Remarks**

If the supplied OracleIntervalYM structure has a null value, the returned OracleIntervalYM structure has a null value.

# OracleIntervalYM Type Conversions

The OracleIntervalYM conversions are listed in [Table 14-85](#).

**Table 14-85 OracleIntervalYM Type Conversions**

| Operator                                           | Description                                                    |
|----------------------------------------------------|----------------------------------------------------------------|
| <a href="#">explicit operator long</a>             | Converts an OracleIntervalYM structure to a number             |
| <a href="#">explicit operator OracleIntervalYM</a> | Converts a string to an OracleIntervalYM structure             |
| <a href="#">implicit operator OracleIntervalYM</a> | Converts the number of months to an OracleIntervalYM structure |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## explicit operator long

This type conversion operator converts an OracleIntervalYM to a number that represents the number of months in the time interval.

**Declaration**

```
// C#
public static explicit operator long (OracleIntervalYM val);
```

**Parameters**

- *val*  
An OracleIntervalYM structure.

**Return Value**

A long number in months.

## Exceptions

OracleNullValueException - The OracleIntervalYM structure has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## explicit operator OracleIntervalYM

This type conversion operator converts the string *intervalStr* to an OracleIntervalYM structure.

### Declaration

```
// C#  
public static explicit operator OracleIntervalYM (string intervalStr);
```

### Parameters

- *intervalStr*

A string representation of an Oracle INTERVAL YEAR TO MONTH.

### Return Value

An OracleIntervalYM structure.

### Exceptions

ArgumentException - The supplied *intervalStr* parameter is not in the correct format or has an invalid value.

ArgumentNullException - The *intervalStr* parameter is null.

### Remarks

The returned OracleIntervalDS structure contains the same time interval represented by the supplied *intervalStr*. The value specified in the supplied *intervalStr* must be in Year-Month format.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

# implicit operator OracleIntervalYM

This type conversion operator converts the total number of months as time interval to an OracleIntervalYM structure.

## Declaration

```
// C#
public static implicit operator OracleIntervalYM (long months);
```

## Parameters

- months*  
The number of months to be converted. Range is  $(-999,999,999 * 12) - 11 \leq months \leq (999,999,999 * 12) + 11$ .

## Return Value

An OracleIntervalYM structure.

## Exceptions

ArgumentOutOfRangeException - The *months* parameter is out of the specified range.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

# OracleIntervalYM Properties

The OracleIntervalYM properties are listed in [Table 14-86](#).

**Table 14-86 OracleIntervalYM Properties**

| Properties                 | Description                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>    | Returns an array of bytes that represents the Oracle INTERVAL YEAR TO MONTH in an Oracle internal format         |
| <a href="#">IsNull</a>     | Indicates whether or not the current instance has a null value                                                   |
| <a href="#">Months</a>     | Gets the months component of an OracleIntervalYM                                                                 |
| <a href="#">TotalYears</a> | Returns the total number, in years, that represents the period of time in the current OracleIntervalYM structure |
| <a href="#">Value</a>      | Specifies the total number of months that is stored in the OracleIntervalYM structure                            |
| <a href="#">Years</a>      | Gets the years component of an OracleIntervalYM                                                                  |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## BinData

This property returns an array of bytes that represents the Oracle INTERVAL YEAR TO MONTH in Oracle internal format.

### Declaration

```
// C#  
public byte[] BinData {get;}
```

### Property Value

A byte array that represents an Oracle INTERVAL YEAR TO MONTH in Oracle internal format.

### Exceptions

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## IsNull

This property indicates whether or not the value has a null value.

### Declaration

```
// C#  
public bool IsNull {get;}
```

### Property Value

Returns true if value has a null value; otherwise, returns false.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Months

This property gets the months component of an OracleIntervalYM.

### Declaration

```
// C#  
public int Months {get;}
```

### Property Value

An int representing the months component.

### Exceptions

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## TotalYears

This property returns the total number, in years, that represents the period of time in the current OracleIntervalYM structure.

### Declaration

```
// C#  
public double TotalYears {get;}
```

### Property Value

A double representing the total number of years.

### Exceptions

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Value

This property gets the total number of months that is stored in the OracleIntervalYM structure.

### Declaration

```
// C#  
public long Value {get;}
```

### Property Value

The total number of months representing the time interval.

### Exceptions

OracleNullValueException - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Years

This property gets the years component of an OracleIntervalYM.

### Declaration

```
// C#  
public int Years {get;}
```

### Property Value

An int representing the years component.

### Exceptions

OracleNullValueException - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## OracleIntervalYM Methods

The OracleIntervalYM methods are listed in [Table 14-87](#).

**Table 14-87 OracleIntervalYM Methods**

| Methods                     | Description                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>   | Compares the current OracleIntervalYM instance to the supplied object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>      | Determines whether or not the specified object has the same time interval as the current instance (Overloaded)                      |
| <a href="#">GetHashCode</a> | Returns a hash code for the OracleIntervalYM instance                                                                               |
| GetType                     | Inherited from System.Object                                                                                                        |
| <a href="#">ToString</a>    | Converts the current OracleIntervalYM structure to a string                                                                         |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## CompareTo

This method compares the current OracleIntervalYM instance to the supplied object, and returns an integer that represents their relative values.

**Declaration**

```
// C#  
public int CompareTo(object obj);
```

**Parameters**

- *obj*  
The supplied object.

**Return Value**

The method returns a number:

Less than zero: if the current `OracleIntervalYM` represents a shorter time interval than *obj*.

Zero: if the current `OracleIntervalYM` and *obj* represent the same time interval.

Greater than zero: if the current `OracleIntervalYM` represents a longer time interval than *obj*.

### Implements

`IComparable`

### Exceptions

`ArgumentException` - The *obj* parameter is not of type `OracleIntervalYM`.

### Remarks

The following rules apply to the behavior of this method.

- The comparison must be between `OracleIntervalYMs`. For example, comparing an `OracleIntervalYM` instance with an `OracleBinary` instance is not allowed. When an `OracleIntervalYM` is compared with a different type, an `ArgumentException` is thrown.
- Any `OracleIntervalYM` that has a value compares greater than an `OracleIntervalYM` that has a null value.
- Two `OracleIntervalYMs` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## Equals

Overrides `Object`

This method determines whether or not the specified object has the same time interval as the current instance.

### Declaration

```
// C#  
public override bool Equals(object obj);
```

### Parameters

- *obj*  
The supplied object.

### Return Value

Returns `true` if the specified object instance is of type `OracleIntervalYM` and has the same time interval; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleIntervalYM that has a value compares greater than an OracleIntervalYM that has a null value.
- Two OracleIntervalYMs that contain a null value are equal.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the OracleIntervalYM instance.

**Declaration**

```
// C#  
public override int GetHashCode();
```

**Return Value**

An int representing a hash code.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

## ToString

Overrides Object

This method converts the current OracleIntervalYM structure to a string.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

A string that represents the current OracleIntervalYM structure.

Remarks

If the current instance has a null value, the returned string contain "null".

See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleIntervalYM Structure](#)
- [OracleIntervalYM Members](#)

OracleString Structure

The OracleString structure represents a variable-length stream of characters to be stored in or retrieved from a database.

Class Inheritance

System.Object  
    System.ValueType  
        Oracle.DataAccess.Types.OracleString

Declaration

```
// C#  
public struct OracleString : IComparable, INullable, IXmlSerializable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;
```

```
class OracleStringSample
{
    static void Main()
    {
        // Initialize OracleString structs
        OracleString string1 = new OracleString("AAA");

        // Display the string "AAA"
        Console.WriteLine("{0} has length of {1}", string1, string1.Length);

        // Contatenate characters to string1 until the length is 5
        while (string1.Length < 5)
            string1 = OracleString.Concat(string1, "a");

        // Display the string of "AAAAa"
        Console.WriteLine("{0} has length of {1}", string1, string1.Length);
    }
}
```

## OracleString Members

OracleString members are listed in the following tables:

### OracleString Constructors

OracleString constructors are listed in [Table 14-88](#)

**Table 14-88 OracleString Constructors**

| Constructor                               | Description                                                        |
|-------------------------------------------|--------------------------------------------------------------------|
| <a href="#">OracleString Constructors</a> | Instantiates a new instance of OracleString structure (Overloaded) |

### OracleString Static Fields

The OracleString static fields are listed in [Table 14-89](#).

**Table 14-89    OracleString Static Fields**

| Field                | Description                                                                               |
|----------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an instance of the OracleString structure |

**OracleString Static Methods**

The OracleString static methods are listed in [Table 14-90](#).

**Table 14-90    OracleString Static Methods**

| Methods                            | Description                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">Concat</a>             | Concatenates two OracleString instances and returns a new OracleString instance that represents the result |
| <a href="#">Equals</a>             | Determines if two OracleString values are equal (Overloaded)                                               |
| <a href="#">GreaterThan</a>        | Determines whether or not the first of two OracleString values is greater than the second                  |
| <a href="#">GreaterThanOrEqual</a> | Determines whether or not the first of two OracleString values is greater than or equal to the second      |
| <a href="#">LessThan</a>           | Determines whether or not the first of two OracleString values is less than the second                     |
| <a href="#">LessThanOrEqual</a>    | Determines whether or not the first of two OracleString values is less than or equal to the second         |
| <a href="#">NotEquals</a>          | Determines whether two OracleString values are not equal                                                   |

**OracleString Static Operators**

The OracleString static operators are listed in [Table 14-91](#).

**Table 14-91    OracleString Static Operators**

| Operator                       | Description                                                                               |
|--------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Concatenates two OracleString values                                                      |
| <a href="#">operator ==</a>    | Determines if two OracleString values are equal                                           |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleString values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleString values is greater than or equal to the second |
| <a href="#">operator !=</a>    | Determines if the two OracleString values are not equal                                   |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleString values is less than the second                |

**Table 14-91 (Cont.) OracleString Static Operators**

| Operator                       | Description                                         |
|--------------------------------|-----------------------------------------------------|
| <a href="#">operator &lt;=</a> | Determines if two OracleString values are not equal |

### OracleString Type Conversions

The OracleString type conversions are listed in [Table 14-92](#).

**Table 14-92 OracleString Type Conversions**

| Operator                                       | Description                                              |
|------------------------------------------------|----------------------------------------------------------|
| <a href="#">explicit operator string</a>       | Converts the supplied OracleString to a string instance  |
| <a href="#">implicit operator OracleString</a> | Converts the supplied string to an OracleString instance |

### OracleString Properties

The OracleString properties are listed in [Table 14-93](#).

**Table 14-93 OracleString Properties**

| Properties                    | Description                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------|
| <a href="#">IsCaseIgnored</a> | Indicates whether or not case should be ignored when performing string comparison |
| <a href="#">IsNull</a>        | Indicates whether or not the current instance has a null value                    |
| <a href="#">Item</a>          | Obtains the particular character in an OracleString using an index.               |
| <a href="#">Length</a>        | Returns the length of the OracleString                                            |
| <a href="#">Value</a>         | Returns the string data that is stored in the OracleString structure.             |

### OracleString Methods

The OracleString methods are listed in [Table 14-94](#).

**Table 14-94 OracleString Methods**

| Methods                   | Description                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Clone</a>     | Returns a copy of the current OracleString instance                                                                             |
| <a href="#">CompareTo</a> | Compares the current OracleString instance to the supplied object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>    | Determines whether or not an object has the same string value as the current OracleString structure (Overloaded)                |

Table 14-94 (Cont.) OracleString Methods

| Methods                            | Description                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">GetHashCode</a>        | Returns a hash code for the OracleString instance                                                          |
| <a href="#">GetNonUnicodeBytes</a> | Returns an array of bytes, containing the contents of the OracleString, in the client character set format |
| <a href="#">GetType</a>            | Inherited from System.Object                                                                               |
| <a href="#">GetUnicodeBytes</a>    | Returns an array of bytes, containing the contents of the OracleString, in Unicode format                  |
| <a href="#">ToString</a>           | Converts the current OracleString instance to a string                                                     |

## OracleString Constructors

The OracleString constructors create new instances of the OracleString structure.

### Overload List:

- [OracleString\(string\)](#)  
This constructor creates a new instance of the OracleString structure and sets its value using a string.
- [OracleString\(string, bool\)](#)  
This constructor creates a new instance of the OracleString structure and sets its value using a string and specifies if case is ignored in comparison.
- [OracleString\(byte \[\], bool\)](#)  
This constructor creates a new instance of the OracleString structure and sets its value using a byte array and specifies if the supplied byte array is Unicode encoded.
- [OracleString\(byte \[\], bool, bool\)](#)  
This constructor creates a new instance of the OracleString structure and sets its value using a byte array and specifies the following: if the supplied byte array is Unicode encoded and if case is ignored in comparison.
- [OracleString\(byte \[\], int, int, bool\)](#)  
This constructor creates a new instance of the OracleString structure and sets its value using a byte array, and specifies the following: the starting index in the byte array, the number of bytes to copy from the byte array, and if the supplied byte array is Unicode encoded.
- [OracleString\(byte \[\], int, int, bool, bool\)](#)

This constructor creates a new instance of the `OracleString` structure and sets its value using a byte array, and specifies the following: the starting index in the byte array, the number of bytes to copy from the byte array, if the supplied byte array is Unicode encoded, and if case is ignored in comparison.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString(string)

This constructor creates a new instance of the `OracleString` structure and sets its value using a string.

#### Declaration

```
// C#  
public OracleString(string data);
```

#### Parameters

- *data*  
A string value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString(string, bool)

This constructor creates a new instance of the `OracleString` structure and sets its value using a string and specifies if case is ignored in comparison.

#### Declaration

```
// C#  
public OracleString(string data, bool isCaseIgnored);
```

#### Parameters

- *data*  
A string value.
- *isCaseIgnored*

Specifies if case is ignored in comparison. Specifies true if case is to be ignored; otherwise, specifies false.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString(byte [ ], bool)

This constructor creates a new instance of the `OracleString` structure and sets its value using a byte array and specifies if the supplied byte array is Unicode encoded.

### Declaration

```
// C#  
public OracleString(byte[] data, bool fUnicode);
```

### Parameters

- *data*  
Byte array data for the new `OracleString`.
- *fUnicode*  
Specifies if the supplied data is Unicode encoded. Specifies true if Unicode encoded; otherwise, false.

### Exceptions

`ArgumentNullException` - The *data* parameter is null.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString(byte [ ], bool, bool)

This constructor creates a new instance of the `OracleString` structure and sets its value using a byte array and specifies the following: if the supplied byte array is Unicode encoded and if case is ignored in comparison.

### Declaration

```
// C#  
public OracleString(byte[] data, bool fUnicode, bool isCaseIgnored);
```

### Parameters

- *data*  
Byte array data for the new OracleString.
- *fUnicode*  
Specifies if the supplied data is Unicode encoded. Specifies true if Unicode encoded; otherwise, false.
- *isCaseIgnored*  
Specifies if case is ignored in comparison. Specifies true if case is to be ignored; otherwise, specifies false.

### Exceptions

ArgumentNullException - The *data* parameter is null.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString(byte [ ], int, int, bool)

This constructor creates a new instance of the OracleString structure and sets its value using a byte array, and specifies the following: the starting index in the byte array, the number of bytes to copy from the byte array, and if the supplied byte array is Unicode encoded.

### Declaration

```
// C#  
public OracleString(byte[] data, int index, int count, bool fUnicode);
```

### Parameters

- *data*  
Byte array data for the new OracleString.
- *index*  
The starting index to copy from *data*.
- *count*  
The number of bytes to copy.
- *fUnicode*  
Specifies if the supplied data is Unicode encoded. Specifies true if Unicode encoded; otherwise, false.

### Exceptions

ArgumentNullException - The *data* parameter is null.

ArgumentOutOfRangeException - The *count* parameter is less than zero.

IndexOutOfRangeException - The *index* parameter is greater than or equal to the length of *data* or less than zero.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString(byte [ ], int, int, bool, bool)

This constructor creates a new instance of the `OracleString` structure and sets its value using a byte array, and specifies the following: the starting index in the byte array, the number of bytes to copy from the byte array, if the supplied byte array is Unicode encoded, and if case is ignored in comparison.

### Declaration

```
// C#
public OracleString(byte[] data, int index, int count, bool fUnicode,
    bool isCaseIgnored);
```

### Parameters

- *data*  
Byte array data for the new `OracleString`.
- *index*  
The starting index to copy from *data*.
- *count*  
The number of bytes to copy.
- *fUnicode*  
Specifies if the supplied data is Unicode encoded. Specifies true if Unicode encoded; otherwise, false.
- *isCaseIgnored*  
Specifies if case is ignored in comparison. Specifies true if case is to be ignored; otherwise, specifies false.

### Exceptions

ArgumentNullException - The *data* parameter is null.

ArgumentOutOfRangeException - The *count* parameter is less than zero.

IndexOutOfRangeException - The *index* parameter is greater than or equal to the length of *data* or less than zero.

# OracleString Static Fields

The OracleString static fields are listed in [Table 14-95](#).

**Table 14-95    OracleString Static Fields**

| Field                | Description                                                                               |
|----------------------|-------------------------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an instance of the OracleString structure |

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

# Null

This static field represents a null value that can be assigned to an instance of the OracleString structure.

**Declaration**

```
// C#  
public static readonly OracleString Null;
```

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString Static Methods

The OracleString static methods are listed in [Table 14-96](#).

**Table 14-96** OracleString Static Methods

| Methods                            | Description                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">Concat</a>             | Concatenates two OracleString instances and returns a new OracleString instance that represents the result |
| <a href="#">Equals</a>             | Determines if two OracleString values are equal (Overloaded)                                               |
| <a href="#">GreaterThan</a>        | Determines whether or not the first of two OracleString values is greater than the second                  |
| <a href="#">GreaterThanOrEqual</a> | Determines whether or not the first of two OracleString values is greater than or equal to the second      |
| <a href="#">LessThan</a>           | Determines whether or not the first of two OracleString values is less than the second                     |
| <a href="#">LessThanOrEqual</a>    | Determines whether or not the first of two OracleString values is less than or equal to the second         |
| <a href="#">NotEquals</a>          | Determines whether two OracleString values are not equal                                                   |

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## Concat

This static method concatenates two OracleString instances and returns a new OracleString instance that represents the result.

### Declaration

```
// C#  
public static OracleString Concat(OracleString str1, OracleString str2);
```

### Parameters

- *str1*  
The first OracleString.
- *str2*  
The second OracleString.

### Return Value

An OracleString.

**Remarks**

If either argument has a null value, the returned `OracleString` structure has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleString Structure](#)
- [OracleString Members](#)

## Equals

**Overloads Object**

This static method determines whether or not the two `OracleStrings` being compared are equal.

**Declaration**

```
// C#  
public static bool Equals(OracleString str1, OracleString str2);
```

**Parameters**

- *str1*  
The first `OracleString`.
- *str2*  
The second `OracleString`.

**Return Value**

Returns true if the two `OracleStrings` being compared are equal; returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleString Structure](#)
- [OracleString Members](#)

## GreaterThan

This static method determines whether or not the first of two `OracleString` values is greater than the second.

### Declaration

```
// C#  
public static bool GreaterThan(OracleString str1, OracleString str2);
```

### Parameters

- *str1*  
The first `OracleString`.
- *str2*  
The second `OracleString`.

### Return Value

Returns true if the first of two `OracleStrings` is greater than the second; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## GreaterThanOrEqual

This static method determines whether or not the first of two `OracleString` values is greater than or equal to the second.

### Declaration

```
// C#  
public static bool GreaterThanOrEqual(OracleString str1,  
    OracleString str2);
```

### Parameters

- *str1*  
The first `OracleString`.

- *str2*

The second `OracleString`.

### Return Value

Returns `true` if the first of two `OracleStrings` is greater than or equal to the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## LessThan

This static method determines whether or not the first of two `OracleString` values is less than the second.

### Declaration

```
// C#  
public static bool LessThan(OracleString str1, OracleString str2);
```

### Parameters

- *str1*  
The first `OracleString`.
- *str2*  
The second `OracleString`.

### Return Value

Returns `true` if the first is less than the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## LessThanOrEqual

This static method determines whether or not the first of two `OracleString` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool LessThanOrEqual(OracleString str1, OracleString str2);
```

**Parameters**

- *str1*  
The first `OracleString`.
- *str2*  
The second `OracleString`.

**Return Value**

Returns `true` if the first is less than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## NotEquals

This static method determines whether two `OracleString` values are not equal.

**Declaration**

```
// C#  
public static bool NotEquals(OracleString str1, OracleString str2);
```

**Parameters**

- *str1*  
The first OracleString.
- *str2*  
The second OracleString.

**Return Value**

Returns true if the two OracleString instances are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleString that has a value is greater than an OracleString that has a null value.
- Two OracleStrings that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString Static Operators

The OracleString static operators are listed in [Table 14-97](#).

**Table 14-97 OracleString Static Operators**

| Operator                       | Description                                                                               |
|--------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Concatenates two OracleString values                                                      |
| <a href="#">operator ==</a>    | Determines if two OracleString values are equal                                           |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleString values is greater than the second             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleString values is greater than or equal to the second |
| <a href="#">operator !=</a>    | Determines if the two OracleString values are not equal                                   |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleString values is less than the second                |
| <a href="#">operator &lt;=</a> | Determines if two OracleString values are not equal                                       |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## operator +

This static operator concatenates two `OracleString` values.

**Declaration**

```
// C#  
public static OracleString operator + (OracleString value1, OracleString value2);
```

**Parameters**

- *value1*  
The first `OracleString`.
- *value2*  
The second `OracleString`.

**Return Value**

An `OracleString`.

**Remarks**

If either argument has a null value, the returned `OracleString` structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## operator ==

This static operator determines if two `OracleString` values are equal.

**Declaration**

```
// C#  
public static bool operator == (OracleString value1, OracleString value2);
```

**Parameters**

- *value1*

The first `OracleString`.

- `value2`

The second `OracleString`.

### Return Value

Returns true if two `OracleString` values are equal; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleString Structure](#)
- [OracleString Members](#)

## operator >

This static operator determines if the first of two `OracleString` values is greater than the second.

### Declaration

```
// C#  
public static bool operator > (OracleString value1, OracleString value2);
```

### Parameters

- `value1`  
The first `OracleString`.
- `value2`  
The second `OracleString`.

### Return Value

Returns true if the first of two `OracleString` values is greater than the second; otherwise returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## operator >=

This static operator determines if the first of two `OracleString` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool operator >= (OracleString value1, OracleString value2);
```

**Parameters**

- *value1*  
The first `OracleString`.
- *value2*  
The second `OracleString`.

**Return Value**

Returns `true` if the first of two `OracleString` values is greater than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## operator !=

This static operator determines if two `OracleString` values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleString value1, OracleString value2);
```

**Parameters**

- *value1*  
The first OracleString.
- *value2*  
The second OracleString.

**Return Value**

Returns true if two OracleString values are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleString that has a value is greater than an OracleString that has a null value.
- Two OracleStrings that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## operator <

This static operator determines if the first of two OracleStrings is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleString value1, OracleString value2);
```

**Parameters**

- *value1*  
The first OracleString.
- *value2*  
The second OracleString.

**Return Value**

Returns true if the first of two OracleStrings is less than the second; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` has a null value.
- Two `OracleStrings` that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## operator <=

This static operator determines if the first of two `OracleString` values is less than or equal to the second.

### Declaration

```
// C#  
public static bool operator <= (OracleString value1, OracleString value2);
```

### Parameters

- *value1*  
The first `OracleString`.
- *value2*  
The second `OracleString`.

### Return Value

Returns `true` if the first of two `OracleString` values is less than or equal to the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.
- Two `OracleStrings` that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)

## OracleString Type Conversions

The OracleString type conversions are listed in [Table 14-98](#).

**Table 14-98** OracleString Type Conversions

| Operator                                       | Description                                              |
|------------------------------------------------|----------------------------------------------------------|
| <a href="#">explicit operator string</a>       | Converts the supplied OracleString to a string instance  |
| <a href="#">implicit operator OracleString</a> | Converts the supplied string to an OracleString instance |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

- [OracleString Members](#)

## explicit operator string

This type conversion operator converts the supplied OracleString to a string.

### Declaration

```
//C#  
public static explicit operator string (OracleString value1);
```

### Parameters

- *value1*  
The supplied OracleString.

### Return Value

string

### Exceptions

OracleNullValueException - The OracleString structure has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

# implicit operator OracleString

This type conversion operator converts the supplied string to an OracleString.

## Declaration

```
// C#
public static implicit operator OracleString (string value1);
```

## Parameters

- *value1*  
The supplied string.

## Return Value

An OracleString.

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

# OracleString Properties

The OracleString properties are listed in [Table 14-99](#).

**Table 14-99    OracleString Properties**

| Properties                    | Description                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------|
| <a href="#">IsCaseIgnored</a> | Indicates whether or not case should be ignored when performing string comparison |
| <a href="#">IsNull</a>        | Indicates whether or not the current instance has a null value                    |
| <a href="#">Item</a>          | Obtains the particular character in an OracleString using an index.               |
| <a href="#">Length</a>        | Returns the length of the OracleString                                            |
| <a href="#">Value</a>         | Returns the string data that is stored in the OracleString structure.             |

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## IsCaseIgnored

This property indicates whether or not case should be ignored when performing string comparison.

### Declaration

```
//C#  
public bool IsCaseIgnored {get;set;}
```

### Property Value

Returns true if string comparison must ignore case; otherwise false.

### Remarks

Default value is true.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class IsCaseIgnoredSample  
{  
    static void Main()  
    {  
        OracleString string1 = new OracleString("aAaAa");  
        OracleString string2 = new OracleString("AaAaA");  
  
        // Ignore case for comparisons  
        string1.IsCaseIgnored = true;  
        string2.IsCaseIgnored = true;  
  
        // Same; Prints 0  
        Console.WriteLine(string1.CompareTo(string2));  
  
        // Make comparisons case sensitive  
        // Note that IsCaseIgnored must be set to false for both  
        //   OracleStrings; otherwise an exception is thrown  
        string1.IsCaseIgnored = false;  
        string2.IsCaseIgnored = false;  
  
        // Different; Prints nonzero value  
        Console.WriteLine(string1.CompareTo(string2));  
    }  
}
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## IsNull

This property indicates whether or not the current instance contains a null value.

### Declaration

```
// C#  
public bool IsNull {get;}
```

### Property Value

Returns true if the current instance contains has a null value; otherwise, returns false.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## Item

This property obtains the particular character in an OracleString using an index.

### Declaration

```
// C#  
public char Item {get;}
```

### Property Value

A char value.

### Exceptions

OracleNullValueException - The current instance has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## Length

This property returns the length of the OracleString.

**Declaration**

```
// C#  
public int Length {get;}
```

**Property Value**

A int value.

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleString Structure](#)
- [OracleString Members](#)

## Value

This property returns the string data that is stored in the OracleString.

**Declaration**

```
// C#  
public string Value {get;}
```

**Property Value**

The stored string value

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleString Methods

The OracleString methods are listed in [Table 14-100](#).

**Table 14-100    OracleString Methods**

| Methods                            | Description                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Clone</a>              | Returns a copy of the current OracleString instance                                                                             |
| <a href="#">CompareTo</a>          | Compares the current OracleString instance to the supplied object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>             | Determines whether or not an object has the same string value as the current OracleString structure (Overloaded)                |
| <a href="#">GetHashCode</a>        | Returns a hash code for the OracleString instance                                                                               |
| <a href="#">GetNonUnicodeBytes</a> | Returns an array of bytes, containing the contents of the OracleString, in the client character set format                      |
| <a href="#">GetType</a>            | Inherited from System.Object                                                                                                    |
| <a href="#">GetUnicodeBytes</a>    | Returns an array of bytes, containing the contents of the OracleString, in Unicode format                                       |
| <a href="#">ToString</a>           | Converts the current OracleString instance to a string                                                                          |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## Clone

This method creates a copy of an OracleString instance.

**Declaration**

```
// C#  
public OracleString Clone();
```

**Return Value**

An OracleString structure.

**Remarks**

The cloned object has the same property values as that of the object being cloned.

**Example**

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
  
class CloneSample  
{  
    static void Main()  
    {
```

```
OracleString str1 = new OracleString("aAaAa");
OracleString str2 = str1.Clone();

// The OracleStrings are same; Prints 0
Console.WriteLine(str1.CompareTo(str2));
}
}
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## CompareTo

This method compares the current `OracleString` instance to the supplied object, and returns an integer that represents their relative values.

### Declaration

```
// C#
public int CompareTo(object obj);
```

### Parameters

- *obj*  
The object being compared to the current instance.

### Return Value

The method returns a number that is:

- Less than zero: if the current `OracleString` value is less than *obj*.
- Zero: if the current `OracleString` value is equal to *obj*.
- Greater than zero: if the current `OracleString` value is greater than *obj*.

### Implements

`IComparable`

### Exceptions

`ArgumentException` - The *obj* parameter is not of type `OracleString`.

### Remarks

The following rules apply to the behavior of this method.

- The comparison must be between `OracleStrings`. For example, comparing an `OracleString` instance with an `OracleBinary` instance is not allowed. When an `OracleString` is compared with a different type, an `ArgumentException` is thrown.
- Any `OracleString` that has a value is greater than an `OracleString` that has a null value.

- Two OracleStrings that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## Equals

This method determines whether or not supplied object is an instance of OracleString and has the same values as the current OracleString instance.

### Declaration

```
// C#  
public override bool Equals(object obj);
```

### Parameters

- *obj*  
An object being compared.

### Return Value

Returns true if the supplied object is an instance of OracleString and has the same values as the current OracleString instance; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleString that has a value is greater than an OracleString that has a null value.
- Two OracleStrings that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the OracleString instance.

**Declaration**

```
// C#  
public override int GetHashCode();
```

**Return Value**

A number that represents the hash code.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## GetNonUnicodeBytes

This method returns an array of bytes, containing the contents of the `OracleString`, in the client character set format.

**Declaration**

```
// C#  
public byte[] GetNonUnicodeBytes();
```

**Return Value**

A byte array that contains the contents of the `OracleString` in the client character set format.

**Remarks**

If the current instance has a null value, an `OracleNullValueException` is thrown.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## GetUnicodeBytes

This method returns an array of bytes, containing the contents of the `OracleString` in Unicode format.

**Declaration**

```
// C#  
public byte[] GetUnicodeBytes();
```

**Return Value**

A byte array that contains the contents of the `OracleString` in Unicode format.

**Remarks**

If the current instance has a null value, an `OracleNullValueException` is thrown.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## ToString

Overrides `Object`

This method converts the current `OracleString` instance to a string.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

A string.

**Remarks**

If the current `OracleString` instance has a null value, the string contains "null".

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleString Structure](#)
- [OracleString Members](#)

## OracleTimeStamp Structure

The `OracleTimeStamp` structure represents the Oracle `TIMESTAMP` data type to be stored in or retrieved from a database. Each `OracleTimeStamp` stores the following information: year, month, day, hour, minute, second, and nanosecond.

**Class Inheritance**

`System.Object`

System.ValueType

Oracle.DataAccess.Types.OracleTimeStamp

### Declaration

```
// C#public struct OracleTimeStamp : IComparable, INullable, IXmlSerializable
```

### Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;

class OracleTimeStampSample
{
    static void Main()
    {
        OracleTimeStamp tsCurrent1 = OracleTimeStamp.GetSysDate();
        OracleTimeStamp tsCurrent2 = DateTime.Now;

        // Calculate the difference between tsCurrent1 and tsCurrent2
        OracleIntervalDS idsDiff = tsCurrent2.GetDaysBetween(tsCurrent1);

        // Calculate the difference using AddNanoseconds()
        int nanoDiff = 0;
        while (tsCurrent2 > tsCurrent1)
        {
            nanoDiff += 10;
            tsCurrent1 = tsCurrent1.AddNanoseconds(10);
        }
        Console.WriteLine("idsDiff.Nanoseconds = " + idsDiff.Nanoseconds);
        Console.WriteLine("nanoDiff = " + nanoDiff);
    }
}
```

## OracleTimeStamp Members

OracleTimeStamp members are listed in the following tables:

### OracleTimeStamp Constructors

OracleTimeStamp constructors are listed in [Table 14-101](#)

**Table 14-101 OracleTimeStamp Constructors**

| Constructor                                  | Description                                                           |
|----------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">OracleTimeStamp Constructors</a> | Instantiates a new instance of OracleTimeStamp structure (Overloaded) |

### OracleTimeStamp Static Fields

The OracleTimeStamp static fields are listed in [Table 14-102](#).

**Table 14-102 OracleTimeStamp Static Fields**

| Field                    | Description                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an OracleTimeStamp structure, which is December 31, 9999 23:59:59.999999999 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an OracleTimeStamp structure, which is January 1, -4712 0:0:0               |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an instance of the OracleTimeStamp structure                      |

### OracleTimeStamp Static Methods

The OracleTimeStamp static methods are listed in [Table 14-103](#).

**Table 14-103 OracleTimeStamp Static Methods**

| Methods                            | Description                                                                                  |
|------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleTimeStamp values are equal (Overloaded)                              |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleTimeStamp values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleTimeStamp values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleTimeStamp values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleTimeStamp values is less than or equal to the second    |
| <a href="#">NotEquals</a>          | Determines if two OracleTimeStamp values are not equal                                       |
| <a href="#">GetSysDate</a>         | Gets an OracleTimeStamp structure that represents the current date and time                  |
| <a href="#">Parse</a>              | Gets an OracleTimeStamp structure and sets its value using the supplied string               |
| <a href="#">SetPrecision</a>       | Returns a new instance of an OracleTimeStamp with the specified fractional second precision  |

**OracleTimeStamp Static Operators**

The OracleTimeStamp static operators are listed in [Table 14-104](#).

**Table 14-104 OracleTimeStamp Static Operators**

| Operator                       | Description                                                                                                                      |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds the supplied instance value to the supplied OracleTimeStamp and returns a new OracleTimeStamp structure (Overloaded)        |
| <a href="#">operator ==</a>    | Determines if two OracleTimeStamp values are equal                                                                               |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleTimeStamp values is greater than the second                                                 |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleTimeStamp values is greater than or equal to the second                                     |
| <a href="#">operator !=</a>    | Determines if the two OracleTimeStamp values are not equal                                                                       |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleTimeStamp values is less than the second                                                    |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleTimeStamp values is less than or equal to the second                                        |
| <a href="#">operator -</a>     | Subtracts the supplied instance value from the supplied OracleTimeStamp and returns a new OracleTimeStamp structure (Overloaded) |

## OracleTimeStamp Static Type Conversions

The OracleTimeStamp static type conversions are listed in [Table 14-105](#).

**Table 14-105 OracleTimeStamp Static Type Conversions**

| Operator                                          | Description                                                             |
|---------------------------------------------------|-------------------------------------------------------------------------|
| <a href="#">explicit operator OracleTimeStamp</a> | Converts an instance value to an OracleTimeStamp structure (Overloaded) |
| <a href="#">implicit operator OracleTimeStamp</a> | Converts an instance value to an OracleTimeStamp structure (Overloaded) |
| <a href="#">explicit operator DateTime</a>        | Converts an OracleTimeStamp value to a DateTime structure               |

## OracleTimeStamp Properties

The OracleTimeStamp properties are listed in [Table 14-106](#).

**Table 14-106 OracleTimeStamp Properties**

| Properties                  | Description                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">BinData</a>     | Returns an array of bytes that represents an Oracle TIMESTAMP in Oracle internal format |
| <a href="#">Day</a>         | Specifies the day component of an OracleTimeStamp                                       |
| <a href="#">IsNull</a>      | Indicates whether or not the OracleTimeStamp instance has a null value                  |
| <a href="#">Hour</a>        | Specifies the hour component of an OracleTimeStamp                                      |
| <a href="#">Millisecond</a> | Specifies the millisecond component of an OracleTimeStamp                               |
| <a href="#">Minute</a>      | Specifies the minute component of an OracleTimeStamp                                    |
| <a href="#">Month</a>       | Specifies the month component of an OracleTimeStamp                                     |
| <a href="#">Nanosecond</a>  | Specifies the nanosecond component of an OracleTimeStamp                                |
| <a href="#">Second</a>      | Specifies the second component of an OracleTimeStamp                                    |
| <a href="#">Value</a>       | Specifies the date and time that is stored in the OracleTimeStamp structure             |
| <a href="#">Year</a>        | Specifies the year component of an OracleTimeStamp                                      |

## OracleTimeStamp Methods

The OracleTimeStamp methods are listed in [Table 14-107](#).

Table 14-107 OracleTimeStamp Methods

| Methods                              | Description                                                                                                                                                                                    |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddDays</a>              | Adds the supplied number of days to the current instance                                                                                                                                       |
| <a href="#">AddHours</a>             | Adds the supplied number of hours to the current instance                                                                                                                                      |
| <a href="#">AddMilliseconds</a>      | Adds the supplied number of milliseconds to the current instance                                                                                                                               |
| <a href="#">AddMinutes</a>           | Adds the supplied number of minutes to the current instance                                                                                                                                    |
| <a href="#">AddMonths</a>            | Adds the supplied number of months to the current instance                                                                                                                                     |
| <a href="#">AddNanoseconds</a>       | Adds the supplied number of nanoseconds to the current instance                                                                                                                                |
| <a href="#">AddSeconds</a>           | Adds the supplied number of seconds to the current instance                                                                                                                                    |
| <a href="#">AddYears</a>             | Adds the supplied number of years to the current instance                                                                                                                                      |
| <a href="#">CompareTo</a>            | Compares the current OracleTimeStamp instance to an object, and returns an integer that represents their relative values                                                                       |
| <a href="#">Equals</a>               | Determines whether or not an object has the same date and time as the current OracleTimeStamp instance (Overloaded)                                                                            |
| <a href="#">GetHashCode</a>          | Returns a hash code for the OracleTimeStamp instance                                                                                                                                           |
| <a href="#">GetDaysBetween</a>       | Subtracts an OracleTimeStamp value from the current instance and returns an OracleIntervalDS that represents the time difference between the supplied OracleTimeStamp and the current instance |
| <a href="#">GetYearsBetween</a>      | Subtracts value1 from the current instance and returns an OracleIntervalYM that represents the difference between value1 and the current instance using OracleIntervalYM                       |
| GetType                              | Inherited from System.Object                                                                                                                                                                   |
| <a href="#">ToOracleDate</a>         | Converts the current OracleTimeStamp structure to an OracleDate structure                                                                                                                      |
| <a href="#">ToOracleTimeStampLTZ</a> | Converts the current OracleTimeStamp structure to an OracleTimeStampLTZ structure                                                                                                              |
| <a href="#">ToOracleTimeStampTZ</a>  | Converts the current OracleTimeStamp structure to an OracleTimeStampTZ structure                                                                                                               |
| <a href="#">ToString</a>             | Converts the current OracleTimeStamp structure to a string                                                                                                                                     |

## OracleTimeStamp Constructors

The `OracleTimeStamp` constructors create new instances of the `OracleTimeStamp` structure.

**Overload List:**

- [OracleTimeStamp\(DateTime\)](#)  
This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using the supplied `DateTime` value.
- [OracleTimeStamp\(string\)](#)  
This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value using the supplied string.
- [OracleTimeStamp\(int, int, int\)](#)  
This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date using year, month, and day.
- [OracleTimeStamp\(int, int, int, int, int, int\)](#)  
This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using year, month, day, hour, minute, and second.
- [OracleTimeStamp\(int, int, int, int, int, int, double\)](#)  
This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using year, month, day, hour, minute, second, and millisecond.
- [OracleTimeStamp\(int, int, int, int, int, int, int\)](#)  
This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using year, month, day, hour, minute, second, and nanosecond.
- [OracleTimeStamp\(byte \[\]\)](#)  
This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value to the provided byte array, which is in the internal Oracle `TIMESTAMP` format.

**① See Also**

## OracleTimeStamp(DateTime)

This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using the supplied `DateTime` value.

### Declaration

```
// C#  
public OracleTimeStamp (DateTime dt);
```

### Parameters

- *dt*  
The supplied `DateTime` value.

### Exceptions

`ArgumentException` - The *dt* parameter cannot be used to construct a valid `OracleTimeStamp`.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## OracleTimeStamp(string)

This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value using the supplied string.

### Declaration

```
// C#  
public OracleTimeStamp (string tsStr);
```

### Parameters

- *tsStr*  
A string that represents an Oracle `TIMESTAMP`.

### Exceptions

`ArgumentException` - The *tsStr* value is an invalid string representation of an Oracle `TIMESTAMP` or the supplied *tsStr* is not in the timestamp format specified by the `OracleGlobalization.TimestampFormat` property of the thread, which represents the Oracle `NLS_TIMESTAMP_FORMAT` parameter.

`ArgumentNullException` - The *tsStr* value is null.

### Remarks

The names and abbreviations used for months and days are in the language specified by the `DateLanguage` and `Calendar` properties of the thread's `OracleGlobalization` object. If any of

the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;
using Oracle.DataAccess.Client;

class OracleTimeStampSample
{
    static void Main()
    {
        // Set the nls_timestamp_format for the OracleTimeStamp(string)
        // constructor
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimestampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleTimeStamp from a string using the format specified.
        OracleTimeStamp ts = new OracleTimeStamp("11-NOV-1999 11:02:33.444 AM");

        // Set the nls_timestamp_format for the ToString() method
        info.TimestampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // Prints "1999-NOV-11 11:02:33.444000000 AM"
        Console.WriteLine(ts.ToString());
    }
}
```

## OracleTimeStamp(int, int, int)

This constructor creates a new instance of the OracleTimeStamp structure and sets its value for date using year, month, and day.

### Declaration

```
// C#
public OracleTimeStamp(int year, int month, int day);
```

### Parameters

- *year*  
The year provided. Range of year is (-4712 to 9999).
- *month*  
The month provided. Range of month is (1 to 12).
- *day*  
The day provided. Range of day is (1 to 31).

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStamp` (that is, the day is out of range for the month).

#### See Also

## OracleTimeStamp(int, int, int, int, int)

This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using year, month, day, hour, minute, and second.

### Declaration

```
// C#  
public OracleTimeStamp (int year, int month, int day, int hour,  
    int minute, int second);
```

### Parameters

- *year*  
The year provided. Range of year is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*

The minute provided. Range of *minute* is (0 to 59).

- *second*

The second provided. Range of *second* is (0 to 59).

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStamp` (that is, the day is out of range for the month).

## OracleTimeStamp(int, int, int, int, int, int, double)

This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using year, month, day, hour, minute, second, and millisecond.

### Declaration

```
// C#
public OracleTimeStamp(int year, int month, int day, int hour,
    int minute, int second, double millisecond);
```

### Parameters

- *year*  
The year provided. Range of year is (-4712 to 9999).
- *month*  
The month provided. Range of month is (1 to 12).
- *day*  
The day provided. Range of day is (1 to 31).
- *hour*  
The hour provided. Range of hour is (0 to 23).
- *minute*  
The minute provided. Range of minute is (0 to 59).
- *second*  
The second provided. Range of second is (0 to 59).
- *milliseconds*  
The milliseconds provided. Range of millisecond is (0 to 999.999999).

## Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStamp` (that is, the day is out of range for the month).

## OracleTimeStamp(int, int, int, int, int, int, int)

This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value for date and time using year, month, day, hour, minute, second, and nanosecond.

### Declaration

```
// C#  
public OracleTimeStamp (int year, int month, int day, int hour,  
    int minute, int second, int nanosecond);
```

### Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).
- *nanosecond*  
The nanosecond provided. Range of *nanosecond* is (0 to 999999999).

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStamp` (that is, the day is out of range for the month).

## OracleTimeStamp(byte [ ])

This constructor creates a new instance of the `OracleTimeStamp` structure and sets its value to the provided byte array, which is in the internal Oracle `TIMESTAMP` format.

### Declaration

```
// C#  
public OracleTimeStamp (byte[] bytes);
```

### Parameters

- *bytes*  
A byte array that represents an Oracle `TIMESTAMP` in Oracle internal format.

### Exceptions

`ArgumentException` - *bytes* is not in an internal Oracle `TIMESTAMP` format or *bytes* is not a valid Oracle `TIMESTAMP`.

`ArgumentNullException` - *bytes* is null.

## OracleTimeStamp Static Fields

The `OracleTimeStamp` static fields are listed in [Table 14-108](#).

Table 14-108 OracleTimeStamp Static Fields

| Field                    | Description                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an OracleTimeStamp structure, which is December 31, 9999 23:59:59.999999999 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an OracleTimeStamp structure, which is January 1, -4712 0:0:0               |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an instance of the OracleTimeStamp structure                      |

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

# MaxValue

This static field represents the maximum valid date and time for an OracleTimeStamp structure, which is December 31, 9999 23:59:59.999999999.

**Declaration**

```
// C#  
public static readonly OraTimestamp MaxValue;
```

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

# MinValue

This static field represents the minimum valid date and time for an OracleTimeStamp structure, which is January 1, -4712 0:0:0.

**Declaration**

```
// C#  
public static readonly OracleTimeStamp MinValue;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Null

This static field represents a null value that can be assigned to an instance of the OracleTimeStamp structure.

### Declaration

```
// C#  
public static readonly OracleTimeStamp Null;
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## OracleTimeStamp Static Methods

The OracleTimeStamp static methods are listed in [NOT\\_SUPPORTED](#).

### NOT\_SUPPORTED

| Methods                            | Description                                                                                  |
|------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleTimeStamp values are equal (Overloaded)                              |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleTimeStamp values is greater than the second             |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleTimeStamp values is greater than or equal to the second |
| <a href="#">LessThan</a>           | Determines if the first of two OracleTimeStamp values is less than the second                |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleTimeStamp values is less than or equal to the second    |
| <a href="#">NotEquals</a>          | Determines if two OracleTimeStamp values are not equal                                       |
| <a href="#">GetSysDate</a>         | Gets an OracleTimeStamp structure that represents the current date and time                  |
| <a href="#">Parse</a>              | Gets an OracleTimeStamp structure and sets its value using the supplied string               |

**NOT\_SUPPORTED**

| Methods                      | Description                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------|
| <a href="#">SetPrecision</a> | Returns a new instance of an OracleTimeStamp with the specified fractional second precision |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Equals

This static method determines if two OracleTimeStamp values are equal.

**Declaration**

```
// C#  
public static bool Equals(OracleTimeStamp value1, OracleTimeStamp value2);
```

**Parameters**

- *value1*  
The first OracleTimeStamp.
- *value2*  
The second OracleTimeStamp.

**Return Value**

Returns true if two OracleTimeStamp values are equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimeStamps that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## GreaterThan

This static method determines if the first of two `OracleTimeStamp` values is greater than the second.

### Declaration

```
// C#  
public static bool GreaterThan(OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

### Parameters

- *value1*  
The first `OracleTimeStamp`.
- *value2*  
The second `OracleTimeStamp`.

### Return Value

Returns `true` if the first of two `OracleTimeStamp` values is greater than the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStamp` that has a value is greater than an `OracleTimeStamp` that has a null value.
- Two `OracleTimeStamps` that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## GreaterThanOrEqual

This static method determines if the first of two `OracleTimeStamp` values is greater than or equal to the second.

### Declaration

```
// C#  
public static bool GreaterThanOrEqual(OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

### Parameters

- *value1*

The first `OracleTimeStamp`.

- `value2`

The second `OracleTimeStamp`.

### Return Value

Returns `true` if the first of two `OracleTimeStamp` values is greater than or equal to the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStamp` that has a value is greater than an `OracleTimeStamp` that has a null value.
- Two `OracleTimestamps` that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## LessThan

This static method determines if the first of two `OracleTimeStamp` values is less than the second.

### Declaration

```
// C#
public static bool LessThan(OracleTimeStamp value1,
    OracleTimeStamp value2);
```

### Parameters

- `value1`  
The first `OracleTimeStamp`.
- `value2`  
The second `OracleTimeStamp`.

### Return Value

Returns `true` if the first of two `OracleTimeStamp` values is less than the second. Returns `false` otherwise.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStamp` that has a value is greater than an `OracleTimeStamp` that has a null value.

- Two OracleTimeStamp values that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## LessThanOrEqual

This static method determines if the first of two OracleTimeStamp values is less than or equal to the second.

### Declaration

```
// C#  
public static bool LessThanOrEqual(OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

### Parameters

- *value1*  
The first OracleTimeStamp.
- *value2*  
The second OracleTimeStamp.

### Return Value

Returns true if the first of two OracleTimeStamp values is less than or equal to the second. Returns false otherwise.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimeStamp values that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## NotEquals

This static method determines if two OracleTimeStamp values are not equal.

**Declaration**

```
// C#  
public static bool NotEquals(OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

**Parameters**

- *value1*  
The first OracleTimeStamp.
- *value2*  
The second OracleTimeStamp.

**Return Value**

Returns true if two OracleTimeStamp values are not equal. Returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimestamps that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## GetSysDate

This static method gets an OracleTimeStamp structure that represents the current date and time.

**Declaration**

```
// C#  
public static OracleTimeStamp GetSysDate();
```

**Return Value**

An OracleTimeStamp structure that represents the current date and time.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Parse

This static method gets an `OracleTimeStamp` structure and sets its value using the supplied string.

**Declaration**

```
// C#  
public static OracleTimeStamp Parse(string datetime);
```

**Parameters**

- *datetime*  
A string that represents an Oracle TIMESTAMP.

**Return Value**

An `OracleTimeStamp` structure.

**Exceptions**

`ArgumentException` - The *tsStr* is an invalid string representation of an Oracle TIMESTAMP or the supplied *tsStr* is not in the timestamp format specified by the `OracleGlobalization.TimeStampFormat` property of the thread, which represents the Oracle `NLS_TIMESTAMP_FORMAT` parameter.

`ArgumentNullException` - The *tsStr* value is null.

**Remarks**

The names and abbreviations used for months and days are in the language specified by the `DateLanguage` and `Calendar` properties of the thread's `OracleGlobalization` object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

**Example**

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
using Oracle.DataAccess.Client;  
  
class ParseSample  
{  
    static void Main()  
    {  
        // Set the nls_timestamp_format for the Parse() method  
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
```

```
info.TimeStampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
OracleGlobalization.SetThreadInfo(info);

// construct OracleTimeStamp from a string using the format specified.
OracleTimeStamp ts =
    OracleTimeStamp.Parse("11-NOV-1999 11:02:33.444 AM");

// Set the nls_timestamp_format for the ToString() method
info.TimeStampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";
OracleGlobalization.SetThreadInfo(info);

// Prints "1999-NOV-11 11:02:33.444000000 AM"
Console.WriteLine(ts.ToString());
}
}
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## SetPrecision

This static method returns a new instance of an `OracleTimeStamp` with the specified fractional second precision.

### Declaration

```
// C#
public static OracleTimeStamp SetPrecision(OracleTimeStamp value1,
    int fracSecPrecision);
```

### Parameters

- *value1*  
The provided `OracleTimeStamp` object.
- *fracSecPrecision*  
The fractional second precision provided. Range of fractional second precision is (0 to 9).

### Return Value

An `OracleTimeStamp` structure with the specified fractional second precision.

### Exceptions

`ArgumentOutOfRangeException` - *fracSecPrecision* is out of the specified range.

**Remarks**

The value specified in the supplied *fracSecPrecision* is used to perform a rounding off operation on the supplied `OracleTimeStamp` value. Depending on this value, 0 or more trailing zeros are displayed in the string returned by `ToString()`.

**Example**

The `OracleTimeStamp` with a value of "December 31, 9999 23:59:59.99" results in the string "December 31, 9999 23:59:59.99000" when `SetPrecision()` is called with the fractional second precision set to 5.

- [OracleTimeStamp Members](#)

## OracleTimeStamp Static Operators

The `OracleTimeStamp` static operators are listed in [Table 14-110](#).

**Table 14-110 OracleTimeStamp Static Operators**

| Operator                       | Description                                                                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds the supplied instance value to the supplied <code>OracleTimeStamp</code> and returns a new <code>OracleTimeStamp</code> structure (Overloaded)        |
| <a href="#">operator ==</a>    | Determines if two <code>OracleTimeStamp</code> values are equal                                                                                            |
| <a href="#">operator &gt;</a>  | Determines if the first of two <code>OracleTimeStamp</code> values is greater than the second                                                              |
| <a href="#">operator &gt;=</a> | Determines if the first of two <code>OracleTimeStamp</code> values is greater than or equal to the second                                                  |
| <a href="#">operator !=</a>    | Determines if the two <code>OracleTimeStamp</code> values are not equal                                                                                    |
| <a href="#">operator &lt;</a>  | Determines if the first of two <code>OracleTimeStamp</code> values is less than the second                                                                 |
| <a href="#">operator &lt;=</a> | Determines if the first of two <code>OracleTimeStamp</code> values is less than or equal to the second                                                     |
| <a href="#">operator -</a>     | Subtracts the supplied instance value from the supplied <code>OracleTimeStamp</code> and returns a new <code>OracleTimeStamp</code> structure (Overloaded) |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator +

operator+ adds the supplied object to the OracleTimeStamp and returns a new OracleTimeStamp structure.

**Overload List:**

- [operator + \(OracleTimeStamp, OracleIntervalDS\)](#)  
This static operator adds the supplied OracleIntervalDS to the OracleTimeStamp and returns a new OracleTimeStamp structure.
- [operator + \(OracleTimeStamp, OracleIntervalYM\)](#)  
This static operator adds the supplied OracleIntervalYM to the supplied OracleTimeStamp and returns a new OracleTimeStamp structure.
- [operator + \(OracleTimeStamp, TimeSpan\)](#)  
This static operator adds the supplied TimeSpan to the supplied OracleTimeStamp and returns a new OracleTimeStamp structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator + (OracleTimeStamp, OracleIntervalDS)

This static operator adds the supplied OracleIntervalDS to the OracleTimeStamp and returns a new OracleTimeStamp structure.

**Declaration**

```
// C#  
public static operator + (OracleTimeStamp value1, OracleIntervalDS value2);
```

**Parameters**

- *value1*  
An OracleTimeStamp.
- *value2*  
An OracleIntervalDS.

**Return Value**

An OracleTimeStamp.

**Remarks**

If either parameter has a null value, the returned OracleTimeStamp has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

**operator + (OracleTimeStamp, OracleIntervalYM)**

This static operator adds the supplied OracleIntervalYM to the supplied OracleTimeStamp and returns a new OracleTimeStamp structure.

**Declaration**

```
// C#  
public static operator + (OracleTimeStamp value1, OracleIntervalYM value2);
```

**Parameters**

- *value1*  
An OracleTimeStamp.
- *value2*  
An OracleIntervalYM.

**Return Value**

An OracleTimeStamp.

**Remarks**

If either parameter has a null value, the returned OracleTimeStamp has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator + (OracleTimeStamp, TimeSpan)

This static operator adds the supplied TimeSpan to the supplied OracleTimeStamp and returns a new OracleTimeStamp structure.

### Declaration

```
// C#  
public static operator + (OracleTimeStamp value1, TimeSpan value2);
```

### Parameters

- *value1*  
An OracleTimeStamp.
- *value2*  
A TimeSpan.

### Return Value

An OracleTimeStamp.

### Remarks

If the OracleTimeStamp instance has a null value, the returned OracleTimeStamp has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator ==

This static operator determines if two OracleTimeStamp values are equal.

### Declaration

```
// C#  
public static bool operator == (OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

### Parameters

- *value1*  
The first OracleTimeStamp.
- *value2*  
The second OracleTimeStamp.

### Return Value

Returns true if they are the same; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimeStamps that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator >

This static operator determines if the first of two OracleTimeStamp values is greater than the second.

### Declaration

```
// C#  
public static bool operator > (OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

### Parameters

- *value1*  
The first OracleTimeStamp.
- *value2*  
The second OracleTimeStamp.

### Return Value

Returns true if the first OracleTimeStamp value is greater than the second; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimeStamps that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator >=

This static operator determines if the first of two `OracleTimeStamp` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool operator >= (OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStamp`.
- *value2*  
The second `OracleTimeStamp`.

**Return Value**

Returns `true` if the first `OracleTimeStamp` is greater than or equal to the second; otherwise returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStamp` that has a value is greater than an `OracleTimeStamp` that has a null value.
- Two `OracleTimestamps` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator !=

This static operator determines if two `OracleTimeStamp` values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

**Parameters**

- *value1*  
The first OracleTimeStamp.
- *value2*  
The second OracleTimeStamp.

**Return Value**

Returns true if two OracleTimeStamp values are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimestamps that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator <

This static operator determines if the first of two OracleTimeStamp values is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

**Parameters**

- *value1*  
The first OracleTimeStamp.
- *value2*  
The second OracleTimeStamp.

**Return Value**

Returns true if the first `OracleTimeStamp` is less than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStamp` that has a value is greater than an `OracleTimeStamp` that has a null value.
- Two `OracleTimeStamps` that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

**operator <=**

This static operator determines if the first of two `OracleTimeStamp` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool operator <= (OracleTimeStamp value1,  
    OracleTimeStamp value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStamp`.
- *value2*  
The second `OracleTimeStamp`.

**Return Value**

Returns true if the first `OracleTimeStamp` is less than or equal to the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStamp` that has a value is greater than an `OracleTimeStamp` that has a null value.
- Two `OracleTimeStamps` that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator -

operator - subtracts the supplied value, from the supplied OracleTimeStamp value, and returns a new OracleTimeStamp structure.

**Overload List:**

- [operator - \(OracleTimeStamp, OracleIntervalDS\)](#)  
This static operator subtracts the supplied OracleIntervalDS value, from the supplied OracleTimeStamp value, and return a new OracleTimeStamp structure.
- [operator - \(OracleTimeStamp, OracleIntervalYM\)](#)  
This static operator subtracts the supplied OracleIntervalYM value, from the supplied OracleTimeStamp value, and returns a new OracleTimeStamp structure.
- [operator - \(OracleTimeStamp, TimeSpan\)](#)  
This static operator subtracts the supplied TimeSpan value, from the supplied OracleTimeStamp value, and returns a new OracleTimeStamp structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator - (OracleTimeStamp, OracleIntervalDS)

This static operator subtracts the supplied OracleIntervalDS value, from the supplied OracleTimeStamp value, and return a new OracleTimeStamp structure.

**Declaration**

```
// C#  
public static operator - (OracleTimeStamp value1, OracleIntervalDS value2);
```

**Parameters**

- *value1*  
An OracleTimeStamp.
- *value2*  
An OracleIntervalDS instance.

**Return Value**

An OracleTimeStamp structure.

**Remarks**

If either parameter has a null value, the returned OracleTimeStamp has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

**operator - (OracleTimeStamp, OracleIntervalYM)**

This static operator subtracts the supplied OracleIntervalYM value, from the supplied OracleTimeStamp value, and returns a new OracleTimeStamp structure.

**Declaration**

```
// C#  
public static operator - (OracleTimeStamp value1, OracleIntervalYM value2);
```

**Parameters**

- *value1*  
An OracleTimeStamp.
- *value2*  
An OracleIntervalYM instance.

**Return Value**

An OracleTimeStamp structure.

**Remarks**

If either parameter has a null value, the returned OracleTimeStamp has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## operator - (OracleTimeStamp, TimeSpan)

This static operator subtracts the supplied TimeSpan value, from the supplied OracleTimeStamp value, and returns a new OracleTimeStamp structure.

### Declaration

```
// C#  
public static operator - (OracleTimeStamp value1, TimeSpan value2);
```

### Parameters

- *value1*  
An OracleTimeStamp.
- *value2*  
A TimeSpan instance.

### Return Value

An OracleTimeStamp structure.

### Remarks

If the OracleTimeStamp instance has a null value, the returned OracleTimeStamp structure has a null value.

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## OracleTimeStamp Static Type Conversions

The OracleTimeStamp static type conversions are listed in [Table 14-111](#).

**Table 14-111 OracleTimeStamp Static Type Conversions**

| Operator                                          | Description                                                             |
|---------------------------------------------------|-------------------------------------------------------------------------|
| <a href="#">explicit operator OracleTimeStamp</a> | Converts an instance value to an OracleTimeStamp structure (Overloaded) |
| <a href="#">implicit operator OracleTimeStamp</a> | Converts an instance value to an OracleTimeStamp structure (Overloaded) |
| <a href="#">explicit operator DateTime</a>        | Converts an OracleTimeStamp value to a DateTime structure               |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## explicit operator OracleTimeStamp

explicit operator OracleTimeStamp converts the supplied value to an OracleTimeStamp structure

**Overload List:**

- [explicit operator OracleTimeStamp\(OracleTimeStampLTZ\)](#)  
This static type conversion operator converts an OracleTimeStampLTZ value to an OracleTimeStamp structure.
- [explicit operator OracleTimeStamp\(OracleTimeStampTZ\)](#)  
This static type conversion operator converts an OracleTimeStampTZ value to an OracleTimeStamp structure.
- [explicit operator OracleTimeStamp\(string\)](#)  
This static type conversion operator converts the supplied string to an OracleTimeStamp structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## explicit operator OracleTimeStamp(OracleTimeStampLTZ)

This static type conversion operator converts an OracleTimeStampLTZ value to an OracleTimeStamp structure.

**Declaration**

```
// C#  
public static explicit operator OracleTimeStamp(OracleTimeStampLTZ value1);
```

**Parameters**

- *value1*  
An OracleTimeStampLTZ instance.

### Return Value

The returned `OracleTimeStamp` contains the date and time of the `OracleTimeStampLTZ` structure.

### Remarks

If the `OracleTimeStampLTZ` structure has a null value, the returned `OracleTimeStamp` structure also has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## explicit operator OracleTimeStamp(OracleTimeStampTZ)

This static type conversion operator converts an `OracleTimeStampTZ` value to an `OracleTimeStamp` structure.

### Declaration

```
// C#  
public static explicit operator OracleTimeStamp(OracleTimeStampTZ value1);
```

### Parameters

- *value1*  
An `OracleTimeStampTZ` instance.

### Return Value

The returned `OracleTimeStamp` contains the date and time information from *value1*, but the time zone information from *value1* is truncated.

### Remarks

If the `OracleTimeStampTZ` structure has a null value, the returned `OracleTimeStamp` structure also has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## explicit operator OracleTimeStamp(string)

This static type conversion operator converts the supplied string to an OracleTimeStamp structure.

### Declaration

```
// C#  
public static explicit operator OracleTimeStamp(string tsStr);
```

### Parameters

- *tsStr*  
A string representation of an Oracle TIMESTAMP.

### Return Value

An OracleTimeStamp.

### Exceptions

ArgumentException - The *tsStr* is an invalid string representation of an Oracle TIMESTAMP or the *tsStr* is not in the timestamp format specified by the thread's OracleGlobalization.TimeStampFormat property, which represents the Oracle NLS\_TIMESTAMP\_FORMAT parameter.

### Remarks

The names and abbreviations used for months and days are in the language specified by the DateLanguage and Calendar properties of the thread's OracleGlobalization object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
using Oracle.DataAccess.Client;  
  
class OracleTimeStampSample  
{  
    static void Main()  
    {  
        // Set the nls_timestamp_format for the explicit  
        // operator OracleTimeStamp(string)  
        OracleGlobalization info = OracleGlobalization.GetClientInfo();  
        info.TimeStampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";  
        OracleGlobalization.SetThreadInfo(info);  
  
        // construct OracleTimeStamp from a string using the format specified.  
        OracleTimeStamp ts = new OracleTimeStamp("11-NOV-1999 11:02:33.444 AM");  
  
        // Set the nls_timestamp_format for the ToString method  
        info.TimeStampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";  
        OracleGlobalization.SetThreadInfo(info);  
  
        // Prints "1999-NOV-11 11:02:33.444000000 AM"
```

```
        Console.WriteLine(ts.ToString());  
    }  
}
```

## implicit operator OracleTimeStamp

This static type conversion operator converts a value to an OracleTimeStamp structure.

#### Overload List:

- [implicit operator OracleTimeStamp\(OracleDate\)](#)  
This static type conversion operator converts an OracleDate value to an OracleTimeStamp structure.
- [implicit operator OracleTimeStamp\(DateTime\)](#)  
This static type conversion operator converts a DateTime value to an OracleTimeStamp structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## implicit operator OracleTimeStamp(OracleDate)

This static type conversion operator converts an OracleDate value to an OracleTimeStamp structure.

#### Declaration

```
// C#  
public static implicit operator OracleTimeStamp (OracleDate value1);
```

**Parameters**

- *value1*  
An OracleDate instance.

**Return Value**

An OracleTimeStamp structure that contains the date and time of the OracleDate structure, *value1*.

**Remarks**

If the OracleDate structure has a null value, the returned OracleTimeStamp structure also has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## implicit operator OracleTimeStamp(DateTime)

This static type conversion operator converts a DateTime value to an OracleTimeStamp structure.

**Declaration**

```
// C#  
public static implicit operator OracleTimeStamp(DateTime value);
```

**Parameters**

- *value*  
A DateTime instance.

**Return Value**

An OracleTimeStamp structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## explicit operator DateTime

This static type conversion operator converts an `OracleTimeStamp` value to a `DateTime` structure.

### Declaration

```
// C#  
public static explicit operator DateTime(OracleTimeStamp value1);
```

### Parameters

- *value1*  
An `OracleTimeStamp` instance.

### Return Value

A `DateTime` containing the date and time in the current instance.

### Exceptions

`OracleNullValueException` - The `OracleTimeStamp` structure has a null value.

### Remarks

The precision of the `OracleTimeStamp` can be lost during the conversion.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"

- [OracleTimeStamp Members](#)

## OracleTimeStamp Properties

The `OracleTimeStamp` properties are listed in [Table 14-112](#).

**Table 14-112 OracleTimeStamp Properties**

| Properties                  | Description                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">BinData</a>     | Returns an array of bytes that represents an Oracle TIMESTAMP in Oracle internal format |
| <a href="#">Day</a>         | Specifies the day component of an <code>OracleTimeStamp</code>                          |
| <a href="#">IsNull</a>      | Indicates whether or not the <code>OracleTimeStamp</code> instance has a null value     |
| <a href="#">Hour</a>        | Specifies the hour component of an <code>OracleTimeStamp</code>                         |
| <a href="#">Millisecond</a> | Specifies the millisecond component of an <code>OracleTimeStamp</code>                  |
| <a href="#">Minute</a>      | Specifies the minute component of an <code>OracleTimeStamp</code>                       |
| <a href="#">Month</a>       | Specifies the month component of an <code>OracleTimeStamp</code>                        |

Table 14-112 (Cont.) OracleTimeStamp Properties

| Properties                 | Description                                                                 |
|----------------------------|-----------------------------------------------------------------------------|
| <a href="#">Nanosecond</a> | Specifies the nanosecond component of an OracleTimeStamp                    |
| <a href="#">Second</a>     | Specifies the second component of an OracleTimeStamp                        |
| <a href="#">Value</a>      | Specifies the date and time that is stored in the OracleTimeStamp structure |
| <a href="#">Year</a>       | Specifies the year component of an OracleTimeStamp                          |

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

BinData

This property returns an array of bytes that represents an Oracle TIMESTAMP in Oracle internal format.

**Declaration**

```
// C#
public byte[] BinData {get;}
```

**Property Value**

A byte array that represents an Oracle TIMESTAMP in an internal format.

**Exceptions**

OracleNullValueException - The current instance has a null value.

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

Day

This property specifies the day component of an OracleTimeStamp.

**Declaration**

```
// C#
public int Day{get;}
```

**Property Value**

A number that represents the day. Range of Day is (1 to 31).

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

**Declaration**

```
// C#  
public bool IsNull{get;}
```

**Property Value**

Returns true if the current instance has a null value; otherwise, returns false.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Hour

This property specifies the hour component of an OracleTimeStamp.

**Declaration**

```
// C#  
public int Hour{get;}
```

**Property Value**

A number that represents the hour. Range of hour is (0 to 23).

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Millisecond

This property gets the millisecond component of an `OracleTimeStamp`.

**Declaration**

```
// C#  
public double Millisecond{get;}
```

**Property Value**

A number that represents a millisecond. Range of `Millisecond` is (0 to 999.999999).

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Minute

This property gets the minute component of an `OracleTimeStamp`.

**Declaration**

```
// C#  
public int Minute{get;}
```

**Property Value**

A number that represent a minute. Range of `Minute` is (0 to 59).

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Month

This property gets the month component of an `OracleTimeStamp`.

### Declaration

```
// C#  
public int Month{get;}
```

### Property Value

A number that represents a month. Range of `Month` is (1 to 12).

### Exceptions

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Nanosecond

This property gets the nanosecond component of an `OracleTimeStamp`.

### Declaration

```
// C#  
public int Nanosecond{get;}
```

### Property Value

A number that represents a nanosecond. Range of `Nanosecond` is (0 to 999999999).

### Exceptions

`OracleNullValueException` - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Second

This property gets the second component of an `OracleTimeStamp`.

**Declaration**

```
// C#  
public int Second{get;}
```

**Property Value**

A number that represents a second. Range of `Second` is (0 to 59).

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Value

This property specifies the date and time that is stored in the `OracleTimeStamp` structure.

**Declaration**

```
// C#  
public DateTime Value{get;}
```

**Property Value**

A `DateTime`.

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

Year

This property gets the year component of an OracleTimeStamp.

Declaration

```
// C#
public int Year{get;}
```

Property Value

A number that represents a year. The range of Year is (-4712 to 9999).

Exceptions

OracleNullValueException - The current instance has a null value.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

OracleTimeStamp Methods

The OracleTimeStamp methods are listed in [Table 14-113](#).

Table 14-113 OracleTimeStamp Methods

| Methods                         | Description                                                      |
|---------------------------------|------------------------------------------------------------------|
| <a href="#">AddDays</a>         | Adds the supplied number of days to the current instance         |
| <a href="#">AddHours</a>        | Adds the supplied number of hours to the current instance        |
| <a href="#">AddMilliseconds</a> | Adds the supplied number of milliseconds to the current instance |
| <a href="#">AddMinutes</a>      | Adds the supplied number of minutes to the current instance      |
| <a href="#">AddMonths</a>       | Adds the supplied number of months to the current instance       |
| <a href="#">AddNanoseconds</a>  | Adds the supplied number of nanoseconds to the current instance  |
| <a href="#">AddSeconds</a>      | Adds the supplied number of seconds to the current instance      |
| <a href="#">AddYears</a>        | Adds the supplied number of years to the current instance        |

Table 14-113 (Cont.) OracleTimeStamp Methods

| Methods                              | Description                                                                                                                                                                                    |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a>            | Compares the current OracleTimeStamp instance to an object, and returns an integer that represents their relative values                                                                       |
| <a href="#">Equals</a>               | Determines whether or not an object has the same date and time as the current OracleTimeStamp instance (Overloaded)                                                                            |
| <a href="#">GetHashCode</a>          | Returns a hash code for the OracleTimeStamp instance                                                                                                                                           |
| <a href="#">GetDaysBetween</a>       | Subtracts an OracleTimeStamp value from the current instance and returns an OracleIntervalDS that represents the time difference between the supplied OracleTimeStamp and the current instance |
| <a href="#">GetYearsBetween</a>      | Subtracts value1 from the current instance and returns an OracleIntervalYM that represents the difference between value1 and the current instance using OracleIntervalYM                       |
| GetType                              | Inherited from System.Object                                                                                                                                                                   |
| <a href="#">ToOracleDate</a>         | Converts the current OracleTimeStamp structure to an OracleDate structure                                                                                                                      |
| <a href="#">ToOracleTimeStampLTZ</a> | Converts the current OracleTimeStamp structure to an OracleTimeStampLTZ structure                                                                                                              |
| <a href="#">ToOracleTimeStampTZ</a>  | Converts the current OracleTimeStamp structure to an OracleTimeStampTZ structure                                                                                                               |
| <a href="#">ToString</a>             | Converts the current OracleTimeStamp structure to a string                                                                                                                                     |

#### See Also

## AddDays

This method adds the supplied number of days to the current instance.

### Declaration

```
// C#
public OracleTimeStamp AddDays(double days);
```

### Parameters

- *days*  
The supplied number of days. Range is  $(-1,000,000,000 < days < 1,000,000,000)$

### Return Value

An OracleTimeStamp.

### Exceptions

ArgumentOutOfRangeException - The argument value is out of the specified range.

OracleNullValueException - The current instance has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## AddHours

This method adds the supplied number of hours to the current instance.

### Declaration

```
// C#  
public OracleTimeStamp AddHours(double hours);
```

### Parameters

- *hours*  
The supplied number of hours. Range is  $(-24,000,000,000 < hours < 24,000,000,000)$ .

### Return Value

An OracleTimeStamp.

### Exceptions

ArgumentOutOfRangeException - The argument value is out of the specified range.

OracleNullValueException - The current instance has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## AddMilliseconds

This method adds the supplied number of milliseconds to the current instance.

**Declaration**

```
// C#  
public OracleTimeStamp AddMilliseconds(double milliseconds);
```

**Parameters**

- *milliseconds*

The supplied number of milliseconds. Range is  $(-8.64 * 10^{16} < \text{milliseconds} < 8.64 * 10^{16})$ .

**Return Value**

An OracleTimeStamp.

**Exceptions**

ArgumentOutOfRangeException - The argument value is out of the specified range.

OracleNullValueException - The current instance has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## AddMinutes

This method adds the supplied number of minutes to the current instance.

**Declaration**

```
// C#  
public OracleTimeStamp AddMinutes(double minutes);
```

**Parameters**

- *minutes*

The supplied number of minutes. Range is  $(-1,440,000,000,000 < \text{minutes} < 1,440,000,000,000)$ .

**Return Value**

An OracleTimeStamp.

**Exceptions**

ArgumentOutOfRangeException - The argument value is out of the specified range.

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## AddMonths

This method adds the supplied number of months to the current instance.

**Declaration**

```
// C#  
public OracleTimeStamp AddMonths(long months);
```

**Parameters**

- *months*

The supplied number of months. Range is  $(-12,000,000,000 < months < 12,000,000,000)$ .

**Return Value**

An OracleTimeStamp.

**Exceptions**

ArgumentOutOfRangeException - The argument value is out of the specified range.

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## AddNanoseconds

This method adds the supplied number of nanoseconds to the current instance.

**Declaration**

```
// C#  
public OracleTimeStamp AddNanoseconds(long nanoseconds);
```

**Parameters**

- *nanoseconds*

The supplied number of nanoseconds.

**Return Value**

An OracleTimeStamp.

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## AddSeconds

This method adds the supplied number of seconds to the current instance.

**Declaration**

```
// C#  
public OracleTimeStamp AddSeconds(double seconds);
```

**Parameters**

- *seconds*  
The supplied number of seconds. Range is  $(-8.64 * 10^{13} < \text{seconds} < 8.64 * 10^{13})$ .

**Return Value**

An OracleTimeStamp.

**Exceptions**

ArgumentOutOfRangeException - The argument value is out of the specified range.

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## AddYears

This method adds the supplied number of years to the current instance.

**Declaration**

```
// C#  
public OracleTimeStamp AddYears(int years);
```

**Parameters**

- *years*

The supplied number of years. Range is (-999,999,999 <= *years* <= 999,999,999)

**Return Value**

An OracleTimeStamp.

**Exceptions**

ArgumentOutOfRangeException - The argument value is out of the specified range.

OracleNullValueException - The current instance has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## CompareTo

This method compares the current OracleTimeStamp instance to an object, and returns an integer that represents their relative values.

**Declaration**

```
// C#  
public int CompareTo(object obj);
```

**Parameters**

- *obj*

The object being compared to the current OracleTimeStamp instance.

**Return Value**

The method returns a number that is:

Less than zero: if the current OracleTimeStamp instance value is less than that of *obj*.

Zero: if the current OracleTimeStamp instance and *obj* values are equal.

Greater than zero: if the current OracleTimeStamp instance value is greater than that of *obj*.

**Implements**

IComparable

### Exceptions

ArgumentException - The *obj* parameter is not of type OracleTimeStamp.

### Remarks

The following rules apply to the behavior of this method.

- The comparison must be between OracleTimestamps. For example, comparing an OracleTimeStamp instance with an OracleBinary instance is not allowed. When an OracleTimeStamp is compared with a different type, an ArgumentException is thrown.
- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimestamps that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## Equals

Overrides Object

This method determines whether or not an object has the same date and time as the current OracleTimeStamp instance.

### Declaration

```
// C#  
public override bool Equals(object obj);
```

### Parameters

- *obj*

The object being compared to the current OracleTimeStamp instance.

### Return Value

Returns true if the *obj* is of type OracleTimeStamp and represents the same date and time; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleTimeStamp that has a value is greater than an OracleTimeStamp that has a null value.
- Two OracleTimestamps that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the OracleTimeStamp instance.

**Declaration**

```
// C#  
public override int GetHashCode();
```

**Return Value**

A number that represents the hash code.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## GetDaysBetween

This method subtracts an OracleTimeStamp value from the current instance and returns an OracleIntervalDS that represents the time difference between the supplied OracleTimeStamp structure and the current instance.

**Declaration**

```
// C#  
public OracleIntervalDS GetDaysBetween(OracleTimeStamp value1);
```

**Parameters**

- *value1*  
The OracleTimeStamp value being subtracted.

**Return Value**

An OracleIntervalDS that represents the interval between two OracleTimeStamp values.

**Remarks**

If either the current instance or the parameter has a null value, the returned `OracleIntervalDS` has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## GetYearsBetween

This method subtracts an `OracleTimeStamp` value from the current instance and returns an `OracleIntervalYM` that represents the time difference between the `OracleTimeStamp` value and the current instance.

**Declaration**

```
// C#  
public OracleIntervalYM GetYearsBetween(OracleTimeStamp value1);
```

**Parameters**

- *value1*  
The `OracleTimeStamp` value being subtracted.

**Return Value**

An `OracleIntervalYM` that represents the interval between two `OracleTimeStamp` values.

**Remarks**

If either the current instance or the parameter has a null value, the returned `OracleIntervalYM` has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## ToOracleDate

This method converts the current `OracleTimeStamp` structure to an `OracleDate` structure.

**Declaration**

```
// C#  
public OracleDate ToOracleDate();
```

**Return Value**

The returned `OracleDate` contains the date and time in the current instance.

**Remarks**

The precision of the `OracleTimeStamp` value can be lost during the conversion.

If the value of the `OracleTimeStamp` has a null value, the value of the returned `OracleDate` structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## ToOracleTimeStampLTZ

This method converts the current `OracleTimeStamp` structure to an `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#  
public OracleTimeStampLTZ ToOracleTimeStampLTZ();
```

**Return Value**

The returned `OracleTimeStampLTZ` contains date and time in the current instance.

**Remarks**

If the value of the current instance has a null value, the value of the returned `OracleTimeStampLTZ` structure has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)

## ToOracleTimeStampTZ

This method converts the current `OracleTimeStamp` structure to an `OracleTimeStampTZ` structure.

### Declaration

```
// C#  
public OracleTimeStampTZ ToOracleTimeStampTZ();
```

### Return Value

The returned `OracleTimeStampTZ` contains the date and time from the `OracleTimeStamp` and the time zone from the `OracleGlobalization.TimeZone` of the thread.

### Remarks

If the value of the current instance has a null value, the value of the returned `OracleTimeStampTZ` structure has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStamp Structure](#)
- [OracleTimeStamp Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## ToString

Overrides `Object`

This method converts the current `OracleTimeStamp` structure to a string.

### Declaration

```
// C#  
public override string ToString();
```

### Return Value

A string that represents the same date and time as the current `OracleTimeStamp` structure.

### Remarks

The returned value is a string representation of an `OracleTimeStamp` in the format specified by the `OracleGlobalization.TimestampFormat` property of the thread.

The names and abbreviations used for months and days are in the language specified by the `OracleGlobalization's DateLanguage` and `Calendar` properties of the thread. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;
using Oracle.DataAccess.Client;

class ToStringSample
{
    static void Main()
    {
        // Set the nls_timestamp_format for the OracleTimeStamp(string)
        // constructor
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimestampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleTimeStamp from a string using the format specified.
        OracleTimeStamp ts = new OracleTimeStamp("11-NOV-1999 11:02:33.444 AM");

        // Set the nls_timestamp_format for the ToString() method
        info.TimestampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // Prints "1999-NOV-11 11:02:33.444000000 AM"
        Console.WriteLine(ts.ToString());
    }
}
```

## OracleTimeStampLTZ Structure

The OracleTimeStampLTZ structure represents the Oracle TIMESTAMP WITH LOCAL TIME ZONE data type to be stored in or retrieved from a database. Each OracleTimeStampLTZ stores the following information: year, month, day, hour, minute, second, and nanosecond.

### Class Inheritance

System.Object

System.ValueType

Oracle.DataAccess.Types.OracleTimeStampLTZ

## Declaration

```
// C#
public struct OracleTimeStampLTZ : IComparable, INullable, IXmlSerializable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#

using System;
using Oracle.DataAccess.Types;
using Oracle.DataAccess.Client;

class OracleTimeStampLTZSample
{
    static void Main()
    {
        // Illustrates usage of OracleTimeStampLTZ
        // Display Local Time Zone Name
        Console.WriteLine("Local Time Zone Name = " +
            OracleTimeStampLTZ.GetLocalTimeZoneName());
        OracleTimeStampLTZ tsLocal1 = OracleTimeStampLTZ.GetSysDate();
        OracleTimeStampLTZ tsLocal2 = DateTime.Now;

        // Calculate the difference between tsLocal1 and tsLocal2
        OracleIntervalDS idsDiff = tsLocal2.GetDaysBetween(tsLocal1);

        // Calculate the difference using AddNanoseconds()
        int nanoDiff = 0;
        while (tsLocal2 > tsLocal1)
        {
            nanoDiff += 10;
            tsLocal1 = tsLocal1.AddNanoseconds(10);
        }
        Console.WriteLine("idsDiff.Nanoseconds = " + idsDiff.Nanoseconds);
        Console.WriteLine("nanoDiff = " + nanoDiff);
    }
}
```

## OracleTimeStampLTZ Members

OracleTimeStampLTZ members are listed in the following tables:

### OracleTimeStampLTZ Constructors

OracleTimeStampLTZ constructors are listed in [Table 14-114](#)

**Table 14-114 OracleTimeStampLTZConstructors**

| Constructor                                     | Description                                                              |
|-------------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">OracleTimeStampLTZ Constructors</a> | Instantiates a new instance of OracleTimeStampLTZ structure (Overloaded) |

### OracleTimeStampLTZ Static Fields

The OracleTimeStampLTZ static fields are listed in [Table 14-115](#).

**Table 14-115 OracleTimeStampLTZ Static Fields**

| Field                    | Description                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an OracleTimeStampLTZ structure, which is December 31, 9999 23:59:59.999999999 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an OracleTimeStampLTZ structure, which is January 1, -4712 0:0:0               |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an instance of the OracleTimeStampLTZ structure                      |

### OracleTimeStampLTZ Static Methods

The OracleTimeStampLTZ static methods are listed in [Table 14-116](#).

**Table 14-116 OracleTimeStampLTZ Static Methods**

| Methods                                | Description                                                                                         |
|----------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>                 | Determines if two OracleTimeStampLTZ values are equal (Overloaded)                                  |
| <a href="#">GetLocalTimeZoneName</a>   | Gets the client's local time zone name                                                              |
| <a href="#">GetLocalTimeZoneOffset</a> | Gets the client's local time zone offset relative to UTC                                            |
| <a href="#">GetSysDate</a>             | Gets an OracleTimeStampLTZ structure that represents the current date and time                      |
| <a href="#">GreaterThan</a>            | Determines if the first of two OracleTimeStampLTZ values is greater than the second                 |
| <a href="#">GreaterThanOrEqual</a>     | Determines if the first of two OracleTimeStampLTZ values is greater than or equal to the second     |
| <a href="#">LessThan</a>               | Determines if the first of two OracleTimeStampLTZ values is less than the second                    |
| <a href="#">LessThanOrEqual</a>        | Determines if the first of two OracleTimeStampLTZ values is less than or equal to the second        |
| <a href="#">NotEquals</a>              | Determines if two OracleTimeStampLTZ values are not equal                                           |
| <a href="#">Parse</a>                  | Gets an OracleTimeStampLTZ structure and sets its value for date and time using the supplied string |
| <a href="#">SetPrecision</a>           | Returns a new instance of an OracleTimeStampLTZ with the specified fractional second precision      |

**OracleTimeStampLTZ Static Operators**

The OracleTimeStampLTZ static operators are listed in [Table 14-117](#).

**Table 14-117 OracleTimeStampLTZ Static Operators**

| Operator                       | Description                                                                                                                     |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds the supplied instance value to the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure (Overloaded) |
| <a href="#">operator ==</a>    | Determines if two OracleTimeStampLTZ values are equal                                                                           |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleTimeStampLTZ values is greater than the second                                             |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleTimeStampLTZ values is greater than or equal to the second                                 |
| <a href="#">operator !=</a>    | Determines if two OracleTimeStampLTZ values are not equal                                                                       |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleTimeStampLTZ values is less than the second                                                |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleTimeStampLTZ values is less than or equal to the second                                    |

**Table 14-117 (Cont.) OracleTimeStampLTZ Static Operators**

| Operator                   | Description                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator -</a> | Subtracts the supplied instance value from the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure (Overloaded) |

**OracleTimeStampLTZ Static Type Conversions**

The OracleTimeStampLTZ static type conversions are listed in [Table 14-118](#).

**Table 14-118 OracleTimeStampLTZ Static Type Conversions**

| Operator                                             | Description                                                                |
|------------------------------------------------------|----------------------------------------------------------------------------|
| <a href="#">explicit operator OracleTimeStampLTZ</a> | Converts an instance value to an OracleTimeStampLTZ structure (Overloaded) |
| <a href="#">implicit operator OracleTimeStampLTZ</a> | Converts an instance value to an OracleTimeStampLTZ structure (Overloaded) |
| <a href="#">explicit operator DateTime</a>           | Converts an OracleTimeStampLTZ value to a DateTime structure               |

**OracleTimeStampLTZ Properties**

The OracleTimeStampLTZ properties are listed in [Table 14-119](#).

**Table 14-119 OracleTimeStampLTZ Properties**

| Properties                  | Description                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>     | Returns an array of bytes that represents an Oracle TIMESTAMP WITH LOCAL TIME ZONE in Oracle internal format |
| <a href="#">Day</a>         | Specifies the day component of an OracleTimeStampLTZ                                                         |
| <a href="#">IsNull</a>      | Indicates whether or not the OracleTimeStampLTZ instance has a null value                                    |
| <a href="#">Hour</a>        | Specifies the hour component of an OracleTimeStampLTZ                                                        |
| <a href="#">Millisecond</a> | Specifies the millisecond component of an OracleTimeStampLTZ                                                 |
| <a href="#">Minute</a>      | Specifies the minute component of an OracleTimeStampLTZ                                                      |
| <a href="#">Month</a>       | Specifies the month component of an OracleTimeStampLTZ                                                       |
| <a href="#">Nanosecond</a>  | Specifies the nanosecond component of an OracleTimeStampLTZ                                                  |
| <a href="#">Second</a>      | Specifies the second component of an OracleTimeStampLTZ                                                      |
| <a href="#">Value</a>       | Specifies the date and time that is stored in the OracleTimeStampLTZ structure                               |

**Table 14-119 (Cont.) OracleTimeStampLTZ Properties**

| Properties           | Description                                           |
|----------------------|-------------------------------------------------------|
| <a href="#">Year</a> | Specifies the year component of an OracleTimeStampLTZ |

**OracleTimeStampLTZ Methods**

The OracleTimeStampLTZ methods are listed in [Table 14-120](#).

**Table 14-120 OracleTimeStampLTZ Methods**

| Methods                           | Description                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddDays</a>           | Adds the supplied number of days to the current instance                                                                   |
| <a href="#">AddHours</a>          | Adds the supplied number of hours to the current instance                                                                  |
| <a href="#">AddMilliseconds</a>   | Adds the supplied number of milliseconds to the current instance                                                           |
| <a href="#">AddMinutes</a>        | Adds the supplied number of minutes to the current instance                                                                |
| <a href="#">AddMonths</a>         | Adds the supplied number of months to the current instance                                                                 |
| <a href="#">AddNanoseconds</a>    | Adds the supplied number of nanoseconds to the current instance                                                            |
| <a href="#">AddSeconds</a>        | Adds the supplied number of seconds to the current instance                                                                |
| <a href="#">AddYears</a>          | Adds the supplied number of years to the current instance                                                                  |
| <a href="#">CompareTo</a>         | Compares the current OracleTimeStampLTZ instance to an object and returns an integer that represents their relative values |
| <a href="#">Equals</a>            | Determines whether or not an object has the same date and time as the current OracleTimeStampLTZ instance (Overloaded)     |
| <a href="#">GetHashCode</a>       | Returns a hash code for the OracleTimeStampLTZ instance                                                                    |
| <a href="#">GetDaysBetween</a>    | Subtracts an OracleTimeStampLTZ from the current instance and returns an OracleIntervalDS that represents the difference   |
| <a href="#">GetYearsBetween</a>   | Subtracts an OracleTimeStampLTZ from the current instance and returns an OracleIntervalYM that represents the difference   |
| GetType                           | Inherited from System.Object                                                                                               |
| <a href="#">ToOracleDate</a>      | Converts the current OracleTimeStampLTZ structure to an OracleDate structure                                               |
| <a href="#">ToOracleTimeStamp</a> | Converts the current OracleTimeStampLTZ structure to an OracleTimeStamp structure                                          |

Table 14-120 (Cont.) OracleTimeStampLTZ Methods

| Methods                             | Description                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">ToOracleTimeStampTZ</a> | Converts the current OracleTimeStampLTZ structure to an OracleTimeStampTZ structure |
| <a href="#">ToString</a>            | Converts the current OracleTimeStampLTZ structure to a string                       |
| <a href="#">ToUniversalTime</a>     | Converts the current local time to Coordinated Universal Time (UTC)                 |

## OracleTimeStampLTZ Constructors

The OracleTimeStampLTZ constructors create new instances of the OracleTimeStampLTZ structure.

#### Overload List:

- [OracleTimeStampLTZ\(DateTime\)](#)  
This constructor creates a new instance of the OracleTimeStampLTZ structure and sets its value for date and time using the supplied DateTime value.
- [OracleTimeStampLTZ\(string\)](#)  
This constructor creates a new instance of the OracleTimeStampLTZ structure and sets its value for date and time using the supplied string.
- [OracleTimeStampLTZ\(int, int, int\)](#)  
This constructor creates a new instance of the OracleTimeStampLTZ structure and sets its value for date using year, month, and day.
- [OracleTimeStampLTZ\(int, int, int, int, int, int\)](#)  
This constructor creates a new instance of the OracleTimeStampLTZ structure and sets its value for date and time using year, month, day, hour, minute, and second.
- [OracleTimeStampLTZ\(int, int, int, int, int, int, double\)](#)  
This constructor creates a new instance of the OracleTimeStampLTZ structure and sets its value for date and time using year, month, day, hour, minute, second, and millisecond.
- [OracleTimeStampLTZ\(int, int, int, int, int, int, int\)](#)  
This constructor creates a new instance of the OracleTimeStampLTZ structure and sets its value for date and time using year, month, day, hour, minute, second, and nanosecond.
- [OracleTimeStampLTZ\(byte \[ \]\)](#)

This constructor creates a new instance of the `OracleTimeStampLTZ` structure and sets its value to the provided byte array, which is in the internal Oracle `TIMESTAMP WITH LOCAL TIME ZONE` format.

#### 📘 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## OracleTimeStampLTZ(DateTime)

This constructor creates a new instance of the `OracleTimeStampLTZ` structure and sets its value for date and time using the supplied `DateTime` value.

### Declaration

```
// C#  
public OracleTimeStampLTZ (DateTime dt);
```

### Parameters

- *dt*  
The supplied `DateTime` value.

### Exceptions

`ArgumentException` - The *dt* parameter cannot be used to construct a valid `OracleTimeStampLTZ`.

#### 📘 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## OracleTimeStampLTZ(string)

This constructor creates a new instance of the `OracleTimeStampLTZ` structure and sets its value for date and time using the supplied string.

### Declaration

```
// C#  
public OracleTimeStampLTZ(string tsStr);
```

### Parameters

- *tsStr*

A string that represents an Oracle TIMESTAMP WITH LOCAL TIME ZONE.

### Exceptions

**ArgumentException** - The *tsStr* is an invalid string representation of an Oracle TIMESTAMP WITH LOCAL TIME ZONE or the supplied *tsStr* is not in the timestamp format specified by the `OracleGlobalization.TimeStampFormat` property of the thread, which represents the Oracle `NLS_TIMESTAMP_FORMAT` parameter.

**ArgumentNullException** - The *tsStr* value is null.

### Remarks

The names and abbreviations used for months and days are in the language specified by the `DateLanguage` and `Calendar` properties of the thread's `OracleGlobalization` object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class OracleTimeStampLTZSample
{
    static void Main()
    {
        // Set the nls_timestamp_format for the OracleTimeStampLTZ(string)
        // constructor
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimeStampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleTimeStampLTZ from a string using the format
        // specified.
        OracleTimeStampLTZ ts =
            new OracleTimeStampLTZ("11-NOV-1999 11:02:33.444 AM");

        // Set the nls_timestamp_format for the ToString() method
        info.TimeStampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // Prints "1999-NOV-11 11:02:33.444000000 AM"
        Console.WriteLine(ts.ToString());
    }
}
```

## OracleTimeStampLTZ(int, int, int)

This constructor creates a new instance of the `OracleTimeStampLTZ` structure and sets its value for date using year, month, and day.

**Declaration**

```
// C#  
public OracleTimeStampLTZ(int year, int month, int day);
```

**Parameters**

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).

**Exceptions**

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampLTZ` (that is, the day is out of range for the month).

## OracleTimeStampLTZ(int, int, int, int, int, int)

This constructor creates a new instance of the `OracleTimeStampLTZ` structure and sets its value for date and time using year, month, day, hour, minute, and second.

### Declaration

```
// C#  
public OracleTimeStampLTZ (int year, int month, int day, int hour,  
    int minute, int second);
```

### Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampLTZ` (that is, the day is out of range for the month).

## OracleTimeStampLTZ(int, int, int, int, int, int, double)

This constructor creates a new instance of the `OracleTimeStampLTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, and millisecond.

## Declaration

```
// C#  
public OracleTimeStampLTZ(int year, int month, int day, int hour, int minute, int  
second, double millisecond);
```

## Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).
- *milliSeconds*  
The milliseconds provided. Range of *millisecond* is (0 to 999.999999).

## Exceptions

ArgumentOutOfRangeException - The argument value for one or more of the parameters is out of the specified range.

ArgumentException - The argument values of the parameters cannot be used to construct a valid OracleTimeStampLTZ (that is, the day is out of range for the month).

## OracleTimeStampLTZ(int, int, int, int, int, int, int)

This constructor creates a new instance of the OracleTimeStampLTZ structure and sets its value for date and time using year, month, day, hour, minute, second, and nanosecond.

## Declaration

```
// C#  
public OracleTimeStampLTZ (int year, int month, int day, int hour,  
    int minute, int second, int nanosecond);
```

## Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).
- *nanosecond*  
The nanosecond provided. Range of *nanosecond* is (0 to 999999999).

## Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampLTZ` (that is, the day is out of range for the month).

## OracleTimeStampLTZ(byte [ ])

This constructor creates a new instance of the `OracleTimeStampLTZ` structure and sets its value to the provided byte array, which is in the internal Oracle `TIMESTAMP WITH LOCAL TIME ZONE` format.

Declaration

```
// C#
public OracleTimeStampLTZ (byte[] bytes);
```

Parameters

- bytes*  
A byte array that represents an Oracle TIMESTAMP WITH LOCAL TIME ZONE in Oracle internal format.

Exceptions

ArgumentException - *bytes* is not in an internal Oracle TIMESTAMP WITH LOCAL TIME ZONE format or *bytes* is not a valid Oracle TIMESTAMP WITH LOCAL TIME ZONE.

ArgumentNullException - *bytes* is null.

OracleTimeStampLTZ Static Fields

The OracleTimeStampLTZ static fields are listed in [Table 14-121](#).

Table 14-121 OracleTimeStampLTZ Static Fields

| Field                    | Description                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an OracleTimeStampLTZ structure, which is December 31, 9999 23:59:59.999999999 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an OracleTimeStampLTZ structure, which is January 1, -4712 0:0:0               |
| <a href="#">Null</a>     | Represents a null value that can be assigned to an instance of the OracleTimeStampLTZ structure                      |

 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## MaxValue

This static field represents the maximum valid date for an OracleTimeStampLTZ structure, which is December 31, 9999 23:59:59.999999999.

### Declaration

```
// C#  
public static readonly OracleTimeStampLTZ MaxValue;
```

### Remarks

This value is the maximum date and time in the client time zone.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## MinValue

This static field represents the minimum valid date for an OracleTimeStampLTZ structure, which is January 1, -4712 0:0:0.

### Declaration

```
// C#  
public static readonly OracleTimeStampLTZ MinValue;
```

### Remarks

This value is the minimum date and time in the client time zone.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Null

This static field represents a null value that can be assigned to an instance of the OracleTimeStampLTZ structure.

### Declaration

```
// C#  
public static readonly OracleTimeStampLTZ Null;
```

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## OracleTimeStampLTZ Static Methods

The OracleTimeStampLTZ static methods are listed in [Table 14-122](#).

**Table 14-122 OracleTimeStampLTZ Static Methods**

| Methods                                | Description                                                                                         |
|----------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>                 | Determines if two OracleTimeStampLTZ values are equal (Overloaded)                                  |
| <a href="#">GetLocalTimeZoneName</a>   | Gets the client's local time zone name                                                              |
| <a href="#">GetLocalTimeZoneOffset</a> | Gets the client's local time zone offset relative to UTC                                            |
| <a href="#">GetSysDate</a>             | Gets an OracleTimeStampLTZ structure that represents the current date and time                      |
| <a href="#">GreaterThan</a>            | Determines if the first of two OracleTimeStampLTZ values is greater than the second                 |
| <a href="#">GreaterThanOrEqual</a>     | Determines if the first of two OracleTimeStampLTZ values is greater than or equal to the second     |
| <a href="#">LessThan</a>               | Determines if the first of two OracleTimeStampLTZ values is less than the second                    |
| <a href="#">LessThanOrEqual</a>        | Determines if the first of two OracleTimeStampLTZ values is less than or equal to the second        |
| <a href="#">NotEquals</a>              | Determines if two OracleTimeStampLTZ values are not equal                                           |
| <a href="#">Parse</a>                  | Gets an OracleTimeStampLTZ structure and sets its value for date and time using the supplied string |
| <a href="#">SetPrecision</a>           | Returns a new instance of an OracleTimeStampLTZ with the specified fractional second precision      |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

- [OracleTimeStampLTZ Members](#)

## Equals

This static method determines if two OracleTimeStampLTZ values are equal.

**Declaration**

```
// C#  
public static bool Equals(OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampLTZ.
- *value2*  
The second OracleTimeStampLTZ.

**Return Value**

Returns true if two OracleTimeStampLTZ values are equal. Returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStampLTZ that has a value is greater than an OracleTimeStampLTZ that has a null value.
- Two OracleTimeStampLTZs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GetLocalTimeZoneName

This static method gets the client's local time zone name.

**Declaration**

```
// C#  
public static string GetLocalTimeZoneName();
```

**Return Value**

A string containing the local time zone.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GetLocalTimeZoneOffset

This static method gets the client's local time zone offset relative to Coordinated Universal Time (UTC).

**Declaration**

```
// C#  
public static TimeSpan GetLocalTimeZoneOffset( );
```

**Return Value**

A TimeSpan structure containing the local time zone hours and time zone minutes.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GetSysDate

This static method gets an OracleTimeStampLTZ structure that represents the current date and time.

**Declaration**

```
// C#  
public static OracleTimeStampLTZ GetSysDate();
```

**Return Value**

An OracleTimeStampLTZ structure that represents the current date and time.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GreaterThan

This static method determines if the first of two `OracleTimeStampLTZ` values is greater than the second.

### Declaration

```
// C#  
public static bool GreaterThan(OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

### Parameters

- *value1*  
The first `OracleTimeStampLTZ`.
- *value2*  
The second `OracleTimeStampLTZ`.

### Return Value

Returns `true` if the first of two `OracleTimeStampLTZ` values is greater than the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.
- Two `OracleTimeStampLTZ`s that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GreaterThanOrEqual

This static method determines if the first of two `OracleTimeStampLTZ` values is greater than or equal to the second.

### Declaration

```
// C#  
public static bool GreaterThanOrEqual(OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

### Parameters

- *value1*

The first `OracleTimeStampLTZ`.

- *value2*

The second `OracleTimeStampLTZ`.

### Return Value

Returns `true` if the first of two `OracleTimeStampLTZ` values is greater than or equal to the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.
- Two `OracleTimeStampLTZ`s that contain a null value are equal.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## LessThan

This static method determines if the first of two `OracleTimeStampLTZ` values is less than the second.

### Declaration

```
// C#  
public static bool LessThan(OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

### Parameters

- *value1*  
The first `OracleTimeStampLTZ`.
- *value2*  
The second `OracleTimeStampLTZ`.

### Return Value

Returns `true` if the first of two `OracleTimeStampLTZ` values is less than the second. Returns `false` otherwise.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.

- Two OracleTimeStampLTZs that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## LessThanOrEqual

This static method determines if the first of two OracleTimeStampLTZ values is less than or equal to the second.

### Declaration

```
// C#
public static bool LessThanOrEqual(OracleTimeStampLTZ value1,
    OracleTimeStampLTZ value2);
```

### Parameters

- *value1*  
The first OracleTimeStampLTZ.
- *value2*  
The second OracleTimeStampLTZ.

### Return Value

Returns true if the first of two OracleTimeStampLTZ values is less than or equal to the second. Returns false otherwise.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleTimeStampLTZ that has a value is greater than an OracleTimeStampLTZ that has a null value.
- Two OracleTimeStampLTZs that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## NotEquals

This static method determines if two OracleTimeStampLTZ values are not equal.

**Declaration**

```
// C#  
public static bool NotEquals(OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampLTZ.
- *value2*  
The second OracleTimeStampLTZ.

**Return Value**

Returns true if two OracleTimeStampLTZ values are not equal. Returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStampLTZ that has a value is greater than an OracleTimeStampLTZ that has a null value.
- Two OracleTimeStampLTZs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Parse

This static method creates an OracleTimeStampLTZ structure and sets its value using the supplied string.

**Declaration**

```
// C#  
public static OracleTimeStampLTZ Parse(string tsStr);
```

**Parameters**

- *tsStr*  
A string that represents an Oracle TIMESTAMP WITH LOCAL TIME ZONE.

**Return Value**

An OracleTimeStampLTZ structure.

## Exceptions

**ArgumentException** - The *tsStr* parameter is an invalid string representation of an Oracle **TIMESTAMP WITH LOCAL TIME ZONE** or the *tsStr* is not in the timestamp format specified by the `OracleGlobalization.TimeStampFormat` property of the thread, which represents the Oracle `NLS_TIMESTAMP_FORMAT` parameter.

**ArgumentNullException** - The *tsStr* value is null.

## Remarks

The names and abbreviations used for months and days are in the language specified by the `DateLanguage` and `Calendar` properties of the thread's `OracleGlobalization` object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

## Example

```
// C#

using System;
using Oracle.DataAccess.Types;
using Oracle.DataAccess.Client;

class ParseSample
{
    static void Main()
    {
        // Set the nls_timestamp_format for the Parse() method
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimeStampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleTimeStampLTZ from a string using the format specified.
        OracleTimeStampLTZ ts =
            OracleTimeStampLTZ.Parse("11-NOV-1999 11:02:33.444 AM");

        // Set the nls_timestamp_format for the ToString() method
        info.TimeStampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // Prints "1999-NOV-11 11:02:33.444000000 AM"
        Console.WriteLine(ts.ToString());
    }
}
```

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## SetPrecision

This static method returns a new instance of an `OracleTimeStampLTZ` with the specified fractional second precision.

### Declaration

```
// C#  
public static OracleTimeStampLTZ SetPrecision(OracleTimeStampLTZ value1,  
    int fracSecPrecision);
```

### Parameters

- *value1*  
The provided `OracleTimeStampLTZ` object.
- *fracSecPrecision*  
The fractional second precision provided. Range of fractional second precision is (0 to 9).

### Return Value

An `OracleTimeStampLTZ` structure with the specified fractional second precision

### Exceptions

`ArgumentOutOfRangeException` - *fracSecPrecision* is out of the specified range.

### Remarks

The value specified in the supplied *fracSecPrecision* parameter is used to perform a rounding off operation on the supplied `OracleTimeStampLTZ` value. Depending on this value, 0 or more trailing zeros are displayed in the string returned by `ToString()`.

### Example

The `OracleTimeStampLTZ` with a value of "December 31, 9999 23:59:59.99" results in the string "December 31, 9999 23:59:59.99000" when `SetPrecision()` is called with the fractional second precision set to 5.

## OracleTimeStampLTZ Static Operators

The `OracleTimeStampLTZ` static operators are listed in [Table 14-123](#).

**Table 14-123 OracleTimeStampLTZ Static Operators**

| Operator                       | Description                                                                                                                            |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds the supplied instance value to the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure (Overloaded)        |
| <a href="#">operator ==</a>    | Determines if two OracleTimeStampLTZ values are equal                                                                                  |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleTimeStampLTZ values is greater than the second                                                    |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleTimeStampLTZ values is greater than or equal to the second                                        |
| <a href="#">operator !=</a>    | Determines if two OracleTimeStampLTZ values are not equal                                                                              |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleTimeStampLTZ values is less than the second                                                       |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleTimeStampLTZ values is less than or equal to the second                                           |
| <a href="#">operator -</a>     | Subtracts the supplied instance value from the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure (Overloaded) |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

**operator +**

operator + adds the supplied value to the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure.

**Overload List:**

- [operator + \(OracleTimeStampLTZ, OracleIntervalDS\)](#)  
This static operator adds the supplied OracleIntervalDS to the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure.
- [operator + \(OracleTimeStampLTZ, OracleIntervalYM\)](#)  
This static operator adds the supplied OracleIntervalYM to the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure.
- [operator + \(OracleTimeStampLTZ, TimeSpan\)](#)  
This static operator adds the supplied TimeSpan to the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator + (OracleTimeStampLTZ, OracleIntervalDS)

This static operator adds the supplied `OracleIntervalDS` to the supplied `OracleTimeStampLTZ` and returns a new `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#
public static operator +(OracleTimeStampLTZ value1,
    OracleIntervalDS value2);
```

**Parameters**

- *value1*  
An `OracleTimeStampLTZ`.
- *value2*  
An `OracleIntervalDS`.

**Return Value**

An `OracleTimeStampLTZ`.

**Remarks**

If either parameter has a null value, the returned `OracleTimeStampLTZ` has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator + (OracleTimeStampLTZ, OracleIntervalYM)

This static operator adds the supplied `OracleIntervalYM` to the supplied `OracleTimeStampLTZ` and returns a new `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#
public static operator +(OracleTimeStampLTZ value1,
    OracleIntervalYM value2);
```

**Parameters**

- *value1*  
An OracleTimeStampLTZ.
- *value2*  
An OracleIntervalYM.

**Return Value**

An OracleTimeStampLTZ.

**Remarks**

If either parameter has a null value, the returned OracleTimeStampLTZ has a null value.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator + (OracleTimeStampLTZ, TimeSpan)

This static operator adds the supplied TimeSpan to the supplied OracleTimeStampLTZ and returns a new OracleTimeStampLTZ structure.

**Declaration**

```
// C#  
public static operator +(OracleTimeStampLTZ value1, TimeSpan value2);
```

**Parameters**

- *value1*  
An OracleTimeStampLTZ.
- *value2*  
A TimeSpan.

**Return Value**

An OracleTimeStampLTZ.

**Remarks**

If the OracleTimeStampLTZ instance has a null value, the returned OracleTimeStampLTZ has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator ==

This static operator determines if two `OracleTimeStampLTZ` values are equal.

**Declaration**

```
// C#  
public static bool operator == (OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStampLTZ`.
- *value2*  
The second `OracleTimeStampLTZ`.

**Return Value**

Returns `true` if they are the same; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.
- Two `OracleTimeStampLTZ`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## operator >

This static operator determines if the first of two `OracleTimeStampLTZ` values is greater than the second.

**Declaration**

```
// C#  
public static bool operator > (OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampLTZ.
- *value2*  
The second OracleTimeStampLTZ.

**Return Value**

Returns true if the first OracleTimeStampLTZ value is greater than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStampLTZ that has a value is greater than an OracleTimeStampLTZ that has a null value.
- Two OracleTimeStampLTZs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

**operator >=**

This static operator determines if the first of two OracleTimeStampLTZ values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool operator >= (OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

**Parameters**

- *value1*  
An OracleTimeStampLTZ.
- *value2*  
The second OracleTimeStampLTZ.

**Return Value**

Returns true if the first `OracleTimeStampLTZ` is greater than or equal to the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.
- Two `OracleTimeStampLTZ`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

**operator !=**

This static operator determines if two `OracleTimeStampLTZ` values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStampLTZ`.
- *value2*  
The second `OracleTimeStampLTZ`.

**Return Value**

Returns true if two `OracleTimeStampLTZ` values are not equal; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.
- Two `OracleTimeStampLTZ`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator <

This static operator determines if the first of two `OracleTimeStampLTZ` values is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStampLTZ`.
- *value2*  
The second `OracleTimeStampLTZ`.

**Return Value**

Returns `true` if the first `OracleTimeStampLTZ` is less than the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.
- Two `OracleTimeStampLTZ`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator <=

This static operator determines if the first of two `OracleTimeStampLTZ` values is less than or equal to the second.

## Declaration

```
// C#  
public static bool operator <= (OracleTimeStampLTZ value1,  
    OracleTimeStampLTZ value2);
```

## Parameters

- *value1*  
The first OracleTimeStampLTZ.
- *value2*  
The second OracleTimeStampLTZ.

## Return Value

Returns true if the first OracleTimeStampLTZ is less than or equal to the second; otherwise, returns false.

## Remarks

The following rules apply to the behavior of this method.

- Any OracleTimeStampLTZ that has a value is greater than an OracleTimeStampLTZ that has a null value.
- Two OracleTimeStampLTZs that contain a null value are equal.

## operator -

operator - subtracts the supplied value, from the supplied OracleTimeStampLTZ value, and returns a new OracleTimeStampLTZ structure.

### Overload List:

- [operator - \(OracleTimeStampLTZ, OracleIntervalDS\)](#)  
This static operator subtracts the supplied OracleIntervalDS value, from the supplied OracleTimeStampLTZ value, and return a new OracleTimeStampLTZ structure.
- [operator - \(OracleTimeStampLTZ, OracleIntervalYM\)](#)  
This static operator subtracts the supplied OracleIntervalYM value, from the supplied OracleTimeStampLTZ value, and returns a new OracleTimeStampLTZ structure.
- [operator - \(OracleTimeStampLTZ, TimeSpan\)](#)  
This static operator subtracts the supplied TimeSpan value, from the supplied OracleTimeStampLTZ value, and returns a new OracleTimeStampLTZ structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator - (OracleTimeStampLTZ, OracleIntervalDS)

This static operator subtracts the supplied `OracleIntervalDS` value, from the supplied `OracleTimeStampLTZ` value, and return a new `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#  
public static operator - (OracleTimeStampLTZ value1,  
    OracleIntervalDS value2);
```

**Parameters**

- *value1*  
An `OracleTimeStampLTZ`.
- *value2*  
An `OracleIntervalDS` instance.

**Return Value**

An `OracleTimeStampLTZ` structure.

**Remarks**

If either parameter has a null value, the returned `OracleTimeStampLTZ` has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator - (OracleTimeStampLTZ, OracleIntervalYM)

This static operator subtracts the supplied `OracleIntervalYM` value, from the supplied `OracleTimeStampLTZ` value, and returns a new `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#  
public static operator - (OracleTimeStampLTZ value1,  
    OracleIntervalYM value2);
```

**Parameters**

- *value1*  
An OracleTimeStampLTZ.
- *value2*  
An OracleIntervalYM.

**Return Value**

An OracleTimeStampLTZ structure.

**Remarks**

If either parameter has a null value, the returned OracleTimeStampLTZ has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## operator - (OracleTimeStampLTZ, TimeSpan)

This static operator subtracts the supplied TimeSpan value, from the supplied OracleTimeStampLTZ value, and returns a new OracleTimeStampLTZ structure.

**Declaration**

```
// C#  
public static operator -(OracleTimeStampLTZ value1, TimeSpan value2);
```

**Parameters**

- *value1*  
An OracleTimeStampLTZ.
- *value2*  
A TimeSpan.

**Return Value**

An OracleTimeStampLTZ structure.

**Remarks**

If the OracleTimeStampLTZ instance has a null value, the returned OracleTimeStampLTZ structure has a null value.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

# OracleTimeStampLTZ Static Type Conversions

The OracleTimeStampLTZ static type conversions are listed in [Table 14-124](#).

**Table 14-124 OracleTimeStampLTZ Static Type Conversions**

| Operator                                             | Description                                                                |
|------------------------------------------------------|----------------------------------------------------------------------------|
| <a href="#">explicit operator OracleTimeStampLTZ</a> | Converts an instance value to an OracleTimeStampLTZ structure (Overloaded) |
| <a href="#">implicit operator OracleTimeStampLTZ</a> | Converts an instance value to an OracleTimeStampLTZ structure (Overloaded) |
| <a href="#">explicit operator DateTime</a>           | Converts an OracleTimeStampLTZ value to a DateTime structure               |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## explicit operator OracleTimeStampLTZ

explicit operator OracleTimeStampLTZ converts the supplied value to an OracleTimeStampLTZ structure.

**Overload List:**

- [explicit operator OracleTimeStampLTZ\(OracleTimeStamp\)](#)  
This static type conversion operator converts an OracleTimeStamp value to an OracleTimeStampLTZ structure.
- [explicit operator OracleTimeStampLTZ\(OracleTimeStampTZ\)](#)  
This static type conversion operator converts an OracleTimeStampTZ value to an OracleTimeStampLTZ structure.
- [explicit operator OracleTimeStampLTZ\(string\)](#)  
This static type conversion operator converts the supplied string to an OracleTimeStampLTZ structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## explicit operator OracleTimeStampLTZ(OracleTimeStamp)

This static type conversion operator converts an `OracleTimeStamp` value to an `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#  
public static explicit operator OracleTimeStampLTZ (OracleTimeStamp value1);
```

**Parameters**

- *value1*  
An `OracleTimeStamp`.

**Return Value**

The `OracleTimeStampLTZ` structure contains the date and time of the `OracleTimeStampTZ` structure.

**Remarks**

If the `OracleTimeStamp` structure has a null value, the returned `OracleTimeStampLTZ` structure also has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## explicit operator OracleTimeStampLTZ(OracleTimeStampTZ)

This static type conversion operator converts an `OracleTimeStampTZ` value to an `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#  
public static explicit operator OracleTimeStampLTZ  
(OracleTimeStampTZ value1);
```

**Parameters**

- *value1*  
An OracleTimeStampTZ instance.

**Return Value**

The OracleTimeStampLTZ structure contains the date and time in the OracleTimeStampTZ structure (which is normalized to the client local time zone).

**Remarks**

If the OracleTimeStampTZ structure has a null value, the returned OracleTimeStampLTZ structure also has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## explicit operator OracleTimeStampLTZ(string)

This static type conversion operator converts the supplied string to an OracleTimeStampLTZ structure.

**Declaration**

```
// C#  
public static explicit operator OracleTimeStampLTZ (string tsStr);
```

**Parameters**

- *tsStr*  
A string representation of an Oracle TIMESTAMP WITH LOCAL TIME ZONE.

**Return Value**

A OracleTimeStampLTZ.

**Exceptions**

ArgumentException - The *tsStr* parameter is an invalid string representation of an Oracle TIMESTAMP WITH LOCAL TIME ZONE or the *tsStr* is not in the timestamp format specified by the thread's OracleGlobalization.TimeStampFormat property, which represents the Oracle NLS\_TIMESTAMP\_FORMAT parameter.

**Remarks**

The names and abbreviations used for months and days are in the language specified by the DateLanguage and Calendar properties of the thread's OracleGlobalization object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#

using System;
using Oracle.DataAccess.Types;
using Oracle.DataAccess.Client;

class OracleTimeStampLTZSample
{
    static void Main()
    {
        // Set the nls_timestamp_format for the OracleTimeStampLTZ(string)
        // constructor
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimestampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleTimeStampLTZ from a string using the format specified.
        OracleTimeStampLTZ ts =
            new OracleTimeStampLTZ("11-NOV-1999 11:02:33.444 AM");

        // Set the nls_timestamp_format for the ToString() method
        info.TimestampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";
        OracleGlobalization.SetThreadInfo(info);

        // Prints "1999-NOV-11 11:02:33.444000000 AM"
        Console.WriteLine(ts.ToString());
    }
}
```

## implicit operator OracleTimeStampLTZ

implicit operator OracleTimeStampLTZ converts the supplied structure to an OracleTimeStampLTZ structure.

### Overload List:

- [implicit operator OracleTimeStampLTZ\(OracleDate\)](#)

This static type conversion operator converts an OracleDate value to an OracleTimeStampLTZ structure.

- [implicit operator OracleTimeStampLTZ\(DateTime\)](#)

This static type conversion operator converts a DateTime structure to an OracleTimeStampLTZ structure.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## implicit operator OracleTimeStampLTZ(OracleDate)

This static type conversion operator converts an OracleDate value to an OracleTimeStampLTZ structure.

### Declaration

```
// C#  
public static implicit operator OracleTimeStampLTZ(OracleDate value1);
```

### Parameters

- *value1*  
An OracleDate.

### Return Value

The returned OracleTimeStampLTZ structure contains the date and time in the OracleDate structure.

### Remarks

If the OracleDate structure has a null value, the returned OracleTimeStampLTZ structure also has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## implicit operator OracleTimeStampLTZ(DateTime)

This static type conversion operator converts a DateTime structure to an OracleTimeStampLTZ structure.

**Declaration**

```
// C#  
public static implicit operator OracleTimeStampLTZ(DateTime value1);
```

**Parameters**

- *value1*  
A DateTime structure.

**Return Value**

An OracleTimeStampLTZ structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## explicit operator DateTime

This static type conversion operator converts an OracleTimeStampLTZ value to a DateTime structure.

**Declaration**

```
// C#  
public static explicit operator DateTime(OracleTimeStampLTZ value1);
```

**Parameters**

- *value1*  
An OracleTimeStampLTZ instance.

**Return Value**

A DateTime that contains the date and time in the current instance.

**Exceptions**

OracleNullValueException - The OracleTimeStampLTZ structure has a null value.

**Remarks**

The precision of the OracleTimeStampLTZ value can be lost during the conversion.

OracleTimeStampLTZ Properties

The OracleTimeStampLTZ properties are listed in [Table 14-125](#).

Table 14-125 OracleTimeStampLTZ Properties

| Properties                  | Description                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>     | Returns an array of bytes that represents an Oracle TIMESTAMP WITH LOCAL TIME ZONE in Oracle internal format |
| <a href="#">Day</a>         | Specifies the day component of an OracleTimeStampLTZ                                                         |
| <a href="#">IsNull</a>      | Indicates whether or not the OracleTimeStampLTZ instance has a null value                                    |
| <a href="#">Hour</a>        | Specifies the hour component of an OracleTimeStampLTZ                                                        |
| <a href="#">Millisecond</a> | Specifies the millisecond component of an OracleTimeStampLTZ                                                 |
| <a href="#">Minute</a>      | Specifies the minute component of an OracleTimeStampLTZ                                                      |
| <a href="#">Month</a>       | Specifies the month component of an OracleTimeStampLTZ                                                       |
| <a href="#">Nanosecond</a>  | Specifies the nanosecond component of an OracleTimeStampLTZ                                                  |
| <a href="#">Second</a>      | Specifies the second component of an OracleTimeStampLTZ                                                      |
| <a href="#">Value</a>       | Specifies the date and time that is stored in the OracleTimeStampLTZ structure                               |
| <a href="#">Year</a>        | Specifies the year component of an OracleTimeStampLTZ                                                        |

BinData

This property returns an array of bytes that represents an Oracle TIMESTAMP WITH LOCAL TIME ZONE in Oracle internal format.

Declaration

```
// C#
public byte[] BinData {get;}
```

**Property Value**

A byte array that represents an Oracle TIMESTAMP WITH LOCAL TIME ZONE internal format.

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Day

This property specifies the day component of an OracleTimeStampLTZ.

**Declaration**

```
// C#  
public int Day{get;}
```

**Property Value**

A number that represents the day. Range of Day is (1 to 31).

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

**Declaration**

```
// C#  
public bool IsNull{get;}
```

**Property Value**

Returns true if the current instance contains a null value; otherwise, returns false.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Hour

This property specifies the hour component of an `OracleTimeStampLTZ`.

**Declaration**

```
// C#  
public int Hour{get;}
```

**Property Value**

A number that represents the hour. Range of Hour is (0 to 23).

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Millisecond

This property gets the millisecond component of an `OracleTimeStampLTZ`.

**Declaration**

```
// C#  
public double Millisecond{get;}
```

**Property Value**

A number that represents a millisecond. Range of Millisecond is (0 to 999.999999)

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Minute

This property gets the minute component of an `OracleTimeStampLTZ`.

**Declaration**

```
// C#  
public int Minute{get;}
```

**Property Value**

A number that represent a minute. Range of Minute is (0 to 59).

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Month

This property gets the month component of an `OracleTimeStampLTZ`.

**Declaration**

```
// C#  
public int Month{get;}
```

**Property Value**

A number that represents a month. Range of Month is (1 to 12).

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Nanosecond

This property gets the nanosecond component of an `OracleTimeStampLTZ`.

### Declaration

```
// C#  
public int Nanosecond{get;}
```

### Property Value

A number that represents a nanosecond. Range of `Nanosecond` is (0 to 999999999).

### Exceptions

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Second

This property gets the second component of an `OracleTimeStampLTZ`.

### Declaration

```
// C#  
public int Second{get;}
```

### Property Value

A number that represents a second. Range of `Second` is (0 to 59).

### Exceptions

`OracleNullValueException` - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Value

This property specifies the date and time that is stored in the `OracleTimeStampLTZ` structure.

**Declaration**

```
// C#  
public DateTime Value{get;}
```

**Property Value**

A `DateTime`.

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Year

This property gets the year component of an `OracleTimeStampLTZ`.

**Declaration**

```
// C#  
public int Year{get;}
```

**Property Value**

A number that represents a year. The range of `Year` is (-4712 to 9999).

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## OracleTimeStampLTZ Methods

The OracleTimeStampLTZ methods are listed in [Table 14-126](#).

**Table 14-126 OracleTimeStampLTZ Methods**

| Methods                             | Description                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddDays</a>             | Adds the supplied number of days to the current instance                                                                   |
| <a href="#">AddHours</a>            | Adds the supplied number of hours to the current instance                                                                  |
| <a href="#">AddMilliseconds</a>     | Adds the supplied number of milliseconds to the current instance                                                           |
| <a href="#">AddMinutes</a>          | Adds the supplied number of minutes to the current instance                                                                |
| <a href="#">AddMonths</a>           | Adds the supplied number of months to the current instance                                                                 |
| <a href="#">AddNanoseconds</a>      | Adds the supplied number of nanoseconds to the current instance                                                            |
| <a href="#">AddSeconds</a>          | Adds the supplied number of seconds to the current instance                                                                |

## AddDays

This method adds the supplied number of days to the current instance.

**Declaration**

```
// C#  
public OracleTimeStampLTZ AddDays(double days);
```

**Parameters**

- *days*  
The supplied number of days. Range is  $(-1,000,000,000 < days < 1,000,000,000)$

**Return Value**

An OracleTimeStampLTZ.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)

## AddHours

This method adds the supplied number of hours to the current instance.

**Declaration**

```
// C#  
public OracleTimeStampLTZ AddHours(double hours);
```

**Parameters**

- *hours*  
The supplied number of hours. Range is  $(-24,000,000,000 < hours < 24,000,000,000)$ .

**Return Value**

An OracleTimeStampLTZ.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"

## AddMilliseconds

This method adds the supplied number of milliseconds to the current instance.

**Declaration**

```
// C#  
public OracleTimeStampLTZ AddMilliseconds(double milliseconds);
```

**Parameters**

- *milliseconds*

The supplied number of milliseconds. Range is  $(-8.64 * 10^{16} < \text{milliseconds} < 8.64 * 10^{16})$ .

**Return Value**

An OracleTimeStampLTZ.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"

- [OracleTimeStampLTZ Members](#)

## AddMinutes

This method adds the supplied number of minutes to the current instance.

### Declaration

```
// C#  
public OracleTimeStampLTZ AddMinutes(double minutes);
```

### Parameters

- *minutes*  
The supplied number of minutes. Range is  $(-1,440,000,000,000 < minutes < 1,440,000,000,000)$ .

### Return Value

An OracleTimeStampLTZ.

### Exceptions

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## AddMonths

This method adds the supplied number of months to the current instance.

### Declaration

```
// C#  
public OracleTimeStampLTZ AddMonths(long months);
```

### Parameters

- *months*  
The supplied number of months. Range is  $(-12,000,000,000 < months < 12,000,000,000)$ .

### Return Value

An OracleTimeStampLTZ.

### Exceptions

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## AddNanoseconds

This method adds the supplied number of nanoseconds to the current instance.

### Declaration

```
// C#  
public OracleTimeStampLTZ AddNanoseconds(long nanoseconds);
```

### Parameters

- *nanoseconds*  
The supplied number of nanoseconds.

### Return Value

An OracleTimeStampLTZ.

### Exceptions

OracleNullValueException - The current instance has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## AddSeconds

This method adds the supplied number of seconds to the current instance.

### Declaration

```
// C#  
public OracleTimeStampLTZ AddSeconds(double seconds);
```

### Parameters

- *seconds*  
The supplied number of seconds. Range is  $(-8.64 * 10^{13} < \text{seconds} < 8.64 * 10^{13})$ .

**Return Value**

An OracleTimeStampLTZ.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## AddYears

This method adds the supplied number of years to the current instance

**Declaration**

```
// C#  
public OracleTimeStampLTZ AddYears(int years);
```

**Parameters**

- *years*  
The supplied number of years. Range is (-999,999,999 <= *years* <= 999,999,999)

**Return Value**

An OracleTimeStampLTZ.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## CompareTo

This method compares the current `OracleTimeStampLTZ` instance to an object, and returns an integer that represents their relative values.

### Declaration

```
// C#  
public int CompareTo(object obj);
```

### Parameters

- *obj*  
The object being compared to the current `OracleTimeStampLTZ` instance.

### Return Value

The method returns a number that is:

- Less than zero: if the current `OracleTimeStampLTZ` instance value is less than that of *obj*.
- Zero: if the current `OracleTimeStampLTZ` instance and *obj* values are equal.
- Greater than zero: if the current `OracleTimeStampLTZ` instance value is greater than that of *obj*.

### Implements

`IComparable`

### Exceptions

`ArgumentException` - The *obj* parameter is not of type `OracleTimeStampLTZ`.

### Remarks

The following rules apply to the behavior of this method.

- The comparison must be between `OracleTimeStampLTZ`s. For example, comparing an `OracleTimeStampLTZ` instance with an `OracleBinary` instance is not allowed. When an `OracleTimeStampLTZ` is compared with a different type, an `ArgumentException` is thrown.
- Any `OracleTimeStampLTZ` that has a value is greater than an `OracleTimeStampLTZ` that has a null value.
- Two `OracleTimeStampLTZ`s that contain a null value are equal.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## Equals

Overrides Object

This method determines whether or not an object has the same date and time as the current OracleTimeStampLTZ instance.

### Declaration

```
// C#  
public override bool Equals(object obj);
```

### Parameters

- *obj*

The object being compared to the current OracleTimeStampLTZ instance.

### Return Value

Returns true if the *obj* is of type OracleTimeStampLTZ and represents the same date and time; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any OracleTimeStampLTZ that has a value is greater than an OracleTimeStampLTZ that has a null value.
- Two OracleTimeStampLTZs that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the OracleTimeStampLTZ instance.

### Declaration

```
// C#  
public override int GetHashCode();
```

### Return Value

A number that represents the hash code.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GetDaysBetween

This method subtracts an `OracleTimeStampLTZ` value from the current instance and returns an `OracleIntervalDS` that represents the difference.

### Declaration

```
// C#  
public OracleIntervalDS GetDaysBetween(OracleTimeStampLTZ value1);
```

### Parameters

- *value1*  
The `OracleTimeStampLTZ` value being subtracted.

### Return Value

An `OracleIntervalDS` that represents the interval between two `OracleTimeStampLTZ` values.

### Remarks

If either the current instance or the parameter has a null value, the returned `OracleIntervalDS` has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## GetYearsBetween

This method subtracts an `OracleTimeStampLTZ` value from the current instance and returns an `OracleIntervalYM` that represents the time interval.

### Declaration

```
// C#  
public OracleIntervalYM GetYearsBetween(OracleTimeStampLTZ value1);
```

### Parameters

- *value1*

The OracleTimeStampLTZ value being subtracted.

### Return Value

An OracleIntervalYM that represents the interval between two OracleTimeStampLTZ values.

### Remarks

If either the current instance or the parameter has a null value, the returned OracleIntervalYM has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## ToOracleDate

This method converts the current OracleTimeStampLTZ structure to an OracleDate structure.

### Declaration

```
// C#  
public OracleDate ToOracleDate();
```

### Return Value

The returned OracleDate structure contains the date and time in the current instance.

### Remarks

The precision of the OracleTimeStampLTZ value can be lost during the conversion.

If the current instance has a null value, the value of the returned OracleDate structure has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## ToOracleTimeStamp

This method converts the current OracleTimeStampLTZ structure to an OracleTimeStamp structure.

**Declaration**

```
// C#  
public OracleTimeStamp ToOracleTimeStamp();
```

**Return Value**

The returned `OracleTimeStamp` contains the date and time in the current instance.

**Remarks**

If the current instance has a null value, the value of the returned `OracleTimeStamp` structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## ToOracleTimeStampTZ

This method converts the current `OracleTimeStampLTZ` structure to an `OracleTimeStampTZ` structure.

**Declaration**

```
// C#  
public OracleTimeStampTZ ToOracleTimeStampTZ();
```

**Return Value**

The returned `OracleTimeStampTZ` contains the date and time of the current instance, with the time zone set to the `OracleGlobalization.TimeZone` from the thread.

**Remarks**

If the current instance has a null value, the value of the returned `OracleTimeStampTZ` structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## ToString

Overrides Object

This method converts the current OracleTimeStampLTZ structure to a string.

### Declaration

```
// C#  
public override string ToString();
```

### Return Value

A string that represents the same date and time as the current OracleTimeStampLTZ structure.

### Remarks

The returned value is a string representation of the OracleTimeStampLTZ in the format specified by the OracleGlobalization.TimeStampFormat property of the thread.

The names and abbreviations used for months and days are in the language specified by the DateLanguage and Calendar properties of the thread's OracleGlobalization object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Types;  
using Oracle.DataAccess.Client;  
  
class ToStringSample  
{  
    static void Main()  
    {  
        // Set the nls_timestamp_format for the OracleTimeStampLTZ(string)  
        // constructor  
        OracleGlobalization info = OracleGlobalization.GetClientInfo();  
        info.TimeStampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";  
        OracleGlobalization.SetThreadInfo(info);  
  
        // construct OracleTimeStampLTZ from a string using the format  
        // specified.  
        OracleTimeStampLTZ ts =  
            new OracleTimeStampLTZ("11-NOV-1999 11:02:33.444 AM");  
  
        // Set the nls_timestamp_format for the ToString() method  
        info.TimeStampFormat = "YYYY-MON-DD HH:MI:SS.FF AM";  
        OracleGlobalization.SetThreadInfo(info);  
  
        // Prints "1999-NOV-11 11:02:33.444000000 AM"  
        Console.WriteLine(ts.ToString());  
    }  
}
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

- ["Globalization Support "](#)

## ToUniversalTime

This method converts the current local time to Coordinated Universal Time (UTC).

### Declaration

```
// C#  
public OracleTimeStampTZ ToUniversalTime();
```

### Return Value

An `OracleTimeStampTZ` structure.

### Remarks

If the current instance has a null value, the value of the returned `OracleTimeStampTZ` structure has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampLTZ Structure](#)
- [OracleTimeStampLTZ Members](#)

## OracleTimeStampTZ Structure

The `OracleTimeStampTZ` structure represents the Oracle `TIMESTAMP WITH TIME ZONE` data type to be stored in or retrieved from a database. Each `OracleTimeStampTZ` stores the following information: year, month, day, hour, minute, second, nanosecond, and time zone.

### Class Inheritance

`System.Object`

`System.ValueType`

`Oracle.DataAccess.Types.OracleTimeStampTZ`

## Declaration

```
// C#
public struct OracleTimeStampTZ : IComparable, INullable, IXmlSerializable
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class OracleTimeStampTZSample
{
    static void Main()
    {
        // Set the nls parameters for the current thread
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimeZone = "US/Eastern";
        info.TimestampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
        info.TimestampTZFormat = "DD-MON-YYYY HH:MI:SS.FF AM TZR";
        OracleGlobalization.SetThreadInfo(info);

        // Create an OracleTimeStampTZ in US/Pacific time zone
        OracleTimeStampTZ tstz1=new OracleTimeStampTZ("11-NOV-1999 "+"
            "11:02:33.444 AM US/Pacific");

        // Note that ToOracleTimeStampTZ uses the thread's time zone region,
        // "US/Eastern"
        OracleTimeStamp ts = new OracleTimeStamp("11-NOV-1999 11:02:33.444 AM");
        OracleTimeStampTZ tstz2 = ts.ToOracleTimeStampTZ();

        // Calculate the difference between tstz1 and tstz2
        OracleIntervalDS idsDiff = tstz1.GetDaysBetween(tstz2);

        // Display information
        Console.WriteLine("tstz1.TimeZone = " + tstz1.TimeZone);

        // Prints "US/Pacific"
```

```

Console.WriteLine("tstz2.TimeZone = " + tstz2.TimeZone);

// Prints "US/Eastern"
Console.WriteLine("idsDiff.Hours = " + idsDiff.Hours); // Prints 3
Console.WriteLine("idsDiff.Minutes = " + idsDiff.Minutes); // Prints 0
}
}

```

## OracleTimeStampTZ Members

OracleTimeStampTZ members are listed in the following tables:

### OracleTimeStampTZ Constructors

OracleTimeStampTZ constructors are listed in [Table 14-127](#)

**Table 14-127 OracleTimeStampTZ Constructors**

| Constructor                                    | Description                                                             |
|------------------------------------------------|-------------------------------------------------------------------------|
| <a href="#">OracleTimeStampTZ Constructors</a> | Instantiates a new instance of OracleTimeStampTZ structure (Overloaded) |

### OracleTimeStampTZ Static Fields

The OracleTimeStampTZ static fields are listed in [Table 14-128](#).

**Table 14-128 OracleTimeStampTZ Static Fields**

| Field                    | Description                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an OracleTimeStampTZ structure in UTC, which is December 31, 999923:59:59.999999999 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an OracleTimeStampTZ structure in UTC, which is January 1, -4712 0:0:0              |

**Table 14-128 (Cont.) OracleTimeStampTZ Static Fields**

| Field                | Description                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an instance of the OracleTimeStampTZ structure |

**OracleTimeStampTZ Static Methods**

The OracleTimeStampTZ static methods are listed in [Table 14-129](#).

**Table 14-129 OracleTimeStampTZ Static Methods**

| Methods                            | Description                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleTimeStampTZ values are equal (Overloaded)                                  |
| <a href="#">GetSysDate</a>         | Gets an OracleTimeStampTZ structure that represents the current date and time                      |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleTimeStampTZ values is greater than the second                 |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleTimeStampTZ values is greater than or equal to the second     |
| <a href="#">LessThan</a>           | Determines if the first of two OracleTimeStampTZ values is less than the second                    |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleTimeStampTZ values is less than or equal to the second        |
| <a href="#">NotEquals</a>          | Determines if two OracleTimeStampTZ values are not equal                                           |
| <a href="#">Parse</a>              | Gets an OracleTimeStampTZ structure and sets its value for date and time using the supplied string |
| <a href="#">SetPrecision</a>       | Returns a new instance of an OracleTimeStampTZ with the specified fractional second precision      |

**OracleTimeStampTZ Static Operators**

The OracleTimeStampTZ static operators are listed in [Table 14-130](#).

**Table 14-130 OracleTimeStampTZ Static Operators**

| Operator                       | Description                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds the supplied instance value to the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure (Overloaded) |
| <a href="#">operator ==</a>    | Determines if two OracleTimeStampTZ values are equal                                                                          |
| <a href="#">operator &gt;</a>  | Determines if the first of two OracleTimeStampTZ values is greater than the second                                            |
| <a href="#">operator &gt;=</a> | Determines if the first of two OracleTimeStampTZ values is greater than or equal to the second                                |

**Table 14-130 (Cont.) OracleTimeStampTZ Static Operators**

| Operator                       | Description                                                                                                                          |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator !=</a>    | Determines if two OracleTimeStampTZ values are not equal                                                                             |
| <a href="#">operator &lt;</a>  | Determines if the first of two OracleTimeStampTZ values is less than the second                                                      |
| <a href="#">operator &lt;=</a> | Determines if the first of two OracleTimeStampTZ values is less than or equal to the second                                          |
| <a href="#">operator -</a>     | Subtracts the supplied instance value from the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure (Overloaded) |

**OracleTimeStampTZ Static Type Conversions**

The OracleTimeStampTZ static type conversions are listed in [Table 14-131](#).

**Table 14-131 OracleTimeStampTZ Static Type Conversions**

| Operator                                            | Description                                                               |
|-----------------------------------------------------|---------------------------------------------------------------------------|
| <a href="#">explicit operator OracleTimeStampTZ</a> | Converts an instance value to an OracleTimeStampTZ structure (Overloaded) |
| <a href="#">implicit operator OracleTimeStampTZ</a> | Converts an instance value to an OracleTimeStampTZ structure (Overloaded) |
| <a href="#">explicit operator DateTime</a>          | Converts an OracleTimeStampTZ value to a DateTime structure               |

**OracleTimeStampTZ Properties**

The OracleTimeStampTZ properties are listed in [Table 14-132](#).

**Table 14-132 OracleTimeStampTZ Properties**

| Properties                  | Description                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>     | Returns an array of bytes that represents an Oracle TIMESTAMP WITH TIME ZONE in Oracle internal format |
| <a href="#">Day</a>         | Specifies the day component of an OracleTimeStampTZ in the current time zone                           |
| <a href="#">IsNull</a>      | Indicates whether or not the current instance has a null value                                         |
| <a href="#">Hour</a>        | Specifies the hour component of an OracleTimeStampTZ in the current time zone                          |
| <a href="#">Millisecond</a> | Specifies the millisecond component of an OracleTimeStampTZ in the current time zone                   |
| <a href="#">Minute</a>      | Specifies the minute component of an OracleTimeStampTZ in the current time zone                        |
| <a href="#">Month</a>       | Specifies the month component of an OracleTimeStampTZ in the current time zone                         |

**Table 14-132 (Cont.) OracleTimeStampTZ Properties**

| Properties                 | Description                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------|
| <a href="#">Nanosecond</a> | Specifies the nanosecond component of an OracleTimeStampTZ in the current time zone                  |
| <a href="#">Second</a>     | Specifies the second component of an OracleTimeStampTZ in the current time zone                      |
| <a href="#">TimeZone</a>   | Returns the time zone of the OracleTimeStampTZ instance                                              |
| <a href="#">Value</a>      | Returns the date and time that is stored in the OracleTimeStampTZ structure in the current time zone |
| <a href="#">Year</a>       | Specifies the year component of an OracleTimeStampTZ                                                 |

**OracleTimeStampTZ Methods**

The OracleTimeStampTZ methods are listed in [Table 14-133](#).

**Table 14-133 OracleTimeStampTZ Methods**

| Methods                           | Description                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddDays</a>           | Adds the supplied number of days to the current instance                                                                   |
| <a href="#">AddHours</a>          | Adds the supplied number of hours to the current instance                                                                  |
| <a href="#">AddMilliseconds</a>   | Adds the supplied number of milliseconds to the current instance                                                           |
| <a href="#">AddMinutes</a>        | Adds the supplied number of minutes to the current instance                                                                |
| <a href="#">AddMonths</a>         | Adds the supplied number of months to the current instance                                                                 |
| <a href="#">AddNanoseconds</a>    | Adds the supplied number of nanoseconds to the current instance                                                            |
| <a href="#">AddSeconds</a>        | Adds the supplied number of seconds to the current instance                                                                |
| <a href="#">AddYears</a>          | Adds the supplied number of years to the current instance                                                                  |
| <a href="#">CompareTo</a>         | Compares the current OracleTimeStampTZ instance to an object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>            | Determines whether or not an object has the same date and time as the current OracleTimeStampTZ instance                   |
| <a href="#">GetDaysBetween</a>    | Subtracts an OracleTimeStampTZ from the current instance and returns an OracleIntervalDS that represents the time interval |
| <a href="#">GetHashCode</a>       | Returns a hash code for the OracleTimeStampTZ instance                                                                     |
| <a href="#">GetTimeZoneOffset</a> | Gets the time zone information in hours and minutes of the current OracleTimeStampTZ                                       |

**Table 14-133 (Cont.) OracleTimeStampTZ Methods**

| Methods                              | Description                                                                                                                |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GetYearsBetween</a>      | Subtracts an OracleTimeStampTZ from the current instance and returns an OracleIntervalYM that represents the time interval |
| GetType                              | Inherited from System.Object                                                                                               |
| <a href="#">ToLocalTime</a>          | Converts the current OracleTimeStampTZ instance to local time                                                              |
| <a href="#">ToOracleDate</a>         | Converts the current OracleTimeStampTZ structure to an OracleDate structure                                                |
| <a href="#">ToOracleTimeStampLTZ</a> | Converts the current OracleTimeStampTZ structure to an OracleTimeStampLTZ structure                                        |
| <a href="#">ToOracleTimeStamp</a>    | Converts the current OracleTimeStampTZ structure to an OracleTimeStamp structure                                           |
| <a href="#">ToString</a>             | Converts the current OracleTimeStampTZ structure to a string                                                               |
| <a href="#">ToUniversalTime</a>      | Converts the current datetime to Coordinated Universal Time (UTC)                                                          |

## OracleTimeStampTZ Constructors

The OracleTimeStampTZ constructors create new instances of the OracleTimeStampTZ structure.

### Overload List:

- [OracleTimeStampTZ\(DateTime\)](#)  
This constructor creates a new instance of the OracleTimeStampTZ structure and sets its value for date and time using the supplied DateTime value.
- [OracleTimeStampTZ\(DateTime, string\)](#)  
This constructor creates a new instance of the OracleTimeStampTZ structure and sets its value for date and time using the supplied DateTime value and the supplied time zone data.
- [OracleTimeStampTZ\(string\)](#)  
This constructor creates a new instance of the OracleTimeStampTZ structure and sets its value for date and time using the supplied string.
- [OracleTimeStampTZ\(int, int, int\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, and day.

- [OracleTimeStampTZ\(int, int, int, string\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, and time zone data.

- [OracleTimeStampTZ\(int, int, int, int, int, int\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, and second.

- [OracleTimeStampTZ\(int, int, int, int, int, int, string\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, and time zone data.

- [OracleTimeStampTZ\(int, int, int, int, int, int, double\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, and millisecond.

- [OracleTimeStampTZ\(int, int, int, int, int, int, double, string\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, millisecond, and time zone data.

- [OracleTimeStampTZ\(int, int, int, int, int, int, int\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, and nanosecond.

- [OracleTimeStampTZ\(int, int, int, int, int, int, int, string\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, nanosecond, and time zone data.

- [OracleTimeStampTZ\(byte \[\]\)](#)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value to the provided byte array, that represents the internal Oracle `TIMESTAMP WITH TIME ZONE` format.

#### ① See Also

## OracleTimeStampTZ(DateTime)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using the supplied `DateTime` value.

**Declaration**

```
// C#  
public OracleTimeStampTZ (DateTime dt);
```

**Parameters**

- *dt*  
The supplied DateTime value.

**Remarks**

The time zone is set to the `OracleGlobalization.TimeZone` of the thread.

**Exceptions**

`ArgumentException` - The *dt* parameter cannot be used to construct a valid `OracleTimeStampTZ`.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## OracleTimeStampTZ(DateTime, string)

This constructor creates a new instance of the `OracleTimeStampTZ` structure with the supplied `DateTime` value and the time zone data.

**Declaration**

```
// C#  
public OracleTimeStampTZ (DateTime value1, string timeZone);
```

**Parameters**

- *value1*  
The supplied DateTime value.
- *timeZone*  
The time zone data provided.

**Exceptions**

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ`.

**Remarks**

*timeZone* can be either an hour offset, for example, 7:00, or a valid time zone region name that is provided in `V$TIMEZONE_NAMES`, such as `US/Pacific`. Time zone abbreviations are not supported.

If time zone is null, the `OracleGlobalization.TimeZone` of the thread is used.

#### Note

PST is a time zone region name as well as a time zone abbreviation; therefore it is accepted by `OracleTimeStampTZ`.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## OracleTimeStampTZ(string)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using the supplied string.

### Declaration

```
// C#  
public OracleTimeStampTZ (string tsStr);
```

### Parameters

- *tsStr*  
A string that represents an Oracle `TIMESTAMP WITH TIME ZONE`.

### Exceptions

`ArgumentException` - The *tsStr* is an invalid string representation of an Oracle `TIMESTAMP WITH TIME ZONE` or the *tsStr* is not in the timestamp format specified by the `OracleGlobalization.TimeStampTZFormat` property of the thread.

`ArgumentNullException` - The *tsStr* value is null.

### Remarks

The names and abbreviations used for months and days are in the language specified by the `DateLanguage` and `Calendar` properties of the thread's `OracleGlobalization` object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class OracleTimeStampTZSample
```

```

{
    static void Main()
    {
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimeStampTZFormat = "DD-MON-YYYY HH:MI:SS.FF AM TZR";
        OracleGlobalization.SetThreadInfo(info);

        // construct OracleTimeStampTZ from a string using the format specified.
        OracleTimeStampTZ tstz = new OracleTimeStampTZ("11-NOV-1999" +
            "11:02:33.444 AM US/Pacific");

        // Set the nls_timestamp_tz_format for the ToString() method
        info.TimeStampTZFormat = "YYYY-MON-DD HH:MI:SS.FF AM TZR";
        OracleGlobalization.SetThreadInfo(info);

        // Prints "1999-NOV-11 11:02:33.444000000 AM US/Pacific"
        Console.WriteLine(tstz.ToString());
    }
}

```

## OracleTimeStampTZ(int, int, int)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, and day.

### Declaration

```
// C#
public OracleTimeStampTZ(int year, int month, int day);
```

### Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range for the month).

### Remarks

The time zone is set to the `OracleGlobalization.TimeZone` of the thread.

## OracleTimeStampTZ(int, int, int, string)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, and time zone data.

### Declaration

```
// C#
public OracleTimeStampTZ(int year, int month, int day,
    string timeZone);
```

### Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *timeZone*  
The time zone data provided.

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range for the month or the time zone is invalid).

## Remarks

timeZone can be either an hour offset, for example, 7:00, or a valid time zone region name that is provided in V\$TIMEZONE\_NAMES, such as US/Pacific. Time zone abbreviations are not supported.

If time zone is null, the OracleGlobalization.TimeZone of the thread is used.

### Note

PST is a time zone region name as well as a time zone abbreviation; therefore it is accepted by OracleTimeStampTZ.

## OracleTimeStampTZ(int, int, int, int, int, int)

This constructor creates a new instance of the OracleTimeStampTZ structure and sets its value for date and time using year, month, day, hour, minute, and second.

## Declaration

```
// C#
public OracleTimeStampTZ(int year, int month, int day, int hour,
    int minute, int second);
```

## Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range for the month).

### Remarks

The time zone is set to the `OracleGlobalization.TimeZone` of the thread.

## OracleTimeStampTZ(int, int, int, int, int, int, string)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, and time zone data.

### Declaration

```
// C#
public OracleTimeStampTZ (int year, int month, int day, int hour,
    int minute, int second, string timeZone);
```

### Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).
- *timeZone*  
The time zone data provided.

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range of the month or the time zone is invalid).

### Remarks

`timeZone` can be either an hour offset, for example, 7:00, or a valid time zone region name that is provided in `V$TIMEZONE_NAMES`, such as `US/Pacific`. Time zone abbreviations are not supported.

If time zone is null, the `OracleGlobalization.TimeZone` of the thread is used.

#### Note

PST is a time zone region name as well as a time zone abbreviation; therefore it is accepted by `OracleTimeStampTZ`.

## OracleTimeStampTZ(int, int, int, int, int, double)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, and millisecond.

### Declaration

```
// C#  
public OracleTimeStampTZ(int year, int month, int day, int hour,  
    int minute, int second, double millisecond);
```

### Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*

The hour provided. Range of *hour* is (0 to 23).

- *minute*

The minute provided. Range of *minute* is (0 to 59).

- *second*

The second provided. Range of *second* is (0 to 59).

- *millisecond*

The millisecond provided. Range of *millisecond* is (0 to 999.999999).

### Exceptions

**ArgumentOutOfRangeException** - The argument value for one or more of the parameters is out of the specified range.

**ArgumentException** - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range for the month).

### Remarks

The time zone is set to the `OracleGlobalization.TimeZone` of the thread.

## OracleTimeStampTZ(int, int, int, int, int, int, double, string)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, millisecond, and time zone data.

### Declaration

```
// C#
public OracleTimeStampTZ(int year, int month, int day, int hour,
    int minute, int second, double millisecond, string timeZone);
```

### Parameters

- *year*

The year provided. Range of *year* is (-4712 to 9999).

- *month*

The month provided. Range of *month* is (1 to 12).

- *day*

The day provided. Range of *day* is (1 to 31).

- *hour*

The hour provided. Range of *hour* is (0 to 23).

- *minute*

The minute provided. Range of *minute* is (0 to 59).

- *second*

The second provided. Range of *second* is (0 to 59).

- *millisecond*

The millisecond provided. Range of *millisecond* is (0 to 999.999999).

- *timeZone*

The time zone data provided.

### Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range for the month or the time zone is invalid).

### Remarks

*timeZone* can be either an hour offset, for example, 7:00, or a valid time zone region name that is provided in `V$TIMEZONE_NAMES`, such as `US/Pacific`. Time zone abbreviations are not supported.

If time zone is null, the `OracleGlobalization.TimeZone` of the thread is used.

#### Note

PST is a time zone region name as well as a time zone abbreviation; therefore it is accepted by `OracleTimeStampTZ`.

## OracleTimeStampTZ(int, int, int, int, int, int, int)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, and nanosecond.

## Declaration

```
// C#  
public OracleTimeStampTZ(int year, int month, int day, int hour,  
    int minute, int second, int nanosecond);
```

## Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).
- *nanosecond*  
The nanosecond provided. Range of *nanosecond* is (0 to 999999999).

## Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range for the month).

## Remarks

The time zone is set to the `OracleGlobalization.TimeZone` of the thread.

## OracleTimeStampTZ(int, int, int, int, int, int, string)

This constructor creates a new instance of the `OracleTimeStampTZ` structure and sets its value for date and time using year, month, day, hour, minute, second, nanosecond, and time zone data.

## Declaration

```
// C#  
public OracleTimeStampTZ(int year, int month, int day, int hour,  
    int minute, int second, int nanosecond, string timeZone);
```

## Parameters

- *year*  
The year provided. Range of *year* is (-4712 to 9999).
- *month*  
The month provided. Range of *month* is (1 to 12).
- *day*  
The day provided. Range of *day* is (1 to 31).
- *hour*  
The hour provided. Range of *hour* is (0 to 23).
- *minute*  
The minute provided. Range of *minute* is (0 to 59).
- *second*  
The second provided. Range of *second* is (0 to 59).
- *nanosecond*  
The nanosecond provided. Range of *nanosecond* is (0 to 999999999).
- *timeZone*  
The time zone data provided.

## Exceptions

`ArgumentOutOfRangeException` - The argument value for one or more of the parameters is out of the specified range.

`ArgumentException` - The argument values of the parameters cannot be used to construct a valid `OracleTimeStampTZ` (that is, the day is out of range for the month or the time zone is invalid).

## Remarks

*timeZone* can be either an hour offset, for example, 7:00, or a valid time zone region name that is provided in `V$TIMEZONE_NAMES`, such as `US/Pacific`. Time zone abbreviations are not supported.

If time zone is null, the `OracleGlobalization.TimeZone` of the thread is used.

### Note

PST is a time zone region name as well as a time zone abbreviation; therefore it is accepted by `OracleTimeStampTZ`.

OracleTimeStampTZ(byte [ ])

This constructor creates a new instance of the OracleTimeStampTZ structure and sets its value to the provided byte array, that represents the internal Oracle TIMESTAMP WITH TIME ZONE format.

Declaration

```
// C#
public OracleTimeStampLTZ (byte[] bytes);
```

Parameters

- *bytes*  
The provided byte array that represents an Oracle TIMESTAMP WITH TIME ZONE in Oracle internal format.

Exceptions

ArgumentException - *bytes* is not in internal Oracle TIMESTAMP WITH TIME ZONE format or *bytes* is not a valid Oracle TIMESTAMP WITH TIME ZONE.  
ArgumentNullException - *bytes* is null.

OracleTimeStampTZ Static Fields

The OracleTimeStampTZ static fields are listed in [Table 14-134](#).

Table 14-134 OracleTimeStampTZ Static Fields

| Field                    | Description                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <a href="#">MaxValue</a> | Represents the maximum valid date for an OracleTimeStampTZ structure in UTC, which is December 31, 999923:59:59.999999999 |
| <a href="#">MinValue</a> | Represents the minimum valid date for an OracleTimeStampTZ structure in UTC, which is January 1, -4712 0:0:0              |

**Table 14-134 (Cont.) OracleTimeStampTZ Static Fields**

| Field                | Description                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an instance of the OracleTimeStampTZ structure |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## MaxValue

This static field represents the maximum valid datetime time for an OracleTimeStampTZ structure in UTC, which is December 31, 999923:59:59.999999999.

**Declaration**

```
// C#  
public static readonly OracleTimeStampTZ MaxValue;
```

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## MinValue

This static field represents the minimum valid datetime for an OracleTimeStampTZ structure in UTC, which is January 1, -4712 0:0:0.

**Declaration**

```
// C#  
public static readonly OracleTimeStampTZ MinValue;
```

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Null

This static field represents a null value that can be assigned to an instance of the OracleTimeStampTZ structure.

### Declaration

```
// C#  
public static readonly OracleTimeStampTZ Null;
```

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## OracleTimeStampTZ Static Methods

The OracleTimeStampTZ static methods are listed in [Table 14-135](#).

**Table 14-135 OracleTimeStampTZ Static Methods**

| Methods                            | Description                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">Equals</a>             | Determines if two OracleTimeStampTZ values are equal (Overloaded)                                  |
| <a href="#">GetSysDate</a>         | Gets an OracleTimeStampTZ structure that represents the current date and time                      |
| <a href="#">GreaterThan</a>        | Determines if the first of two OracleTimeStampTZ values is greater than the second                 |
| <a href="#">GreaterThanOrEqual</a> | Determines if the first of two OracleTimeStampTZ values is greater than or equal to the second     |
| <a href="#">LessThan</a>           | Determines if the first of two OracleTimeStampTZ values is less than the second                    |
| <a href="#">LessThanOrEqual</a>    | Determines if the first of two OracleTimeStampTZ values is less than or equal to the second        |
| <a href="#">NotEquals</a>          | Determines if two OracleTimeStampTZ values are not equal                                           |
| <a href="#">Parse</a>              | Gets an OracleTimeStampTZ structure and sets its value for date and time using the supplied string |
| <a href="#">SetPrecision</a>       | Returns a new instance of an OracleTimeStampTZ with the specified fractional second precision      |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Equals

This static method determines if two `OracleTimeStampTZ` values are equal.

### Declaration

```
// C#  
public static bool Equals(OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

### Parameters

- *value1*  
The first `OracleTimeStampTZ`.
- *value2*  
The second `OracleTimeStampTZ`.

### Return Value

Returns true if two `OracleTimeStampTZ` values are equal. Returns false otherwise.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## GetSysDate

This static method gets an `OracleTimeStampTZ` structure that represents the current date and time.

**Declaration**

```
// C#  
public static OracleTimeStampTZ GetSysDate();
```

**Return Value**

An `OracleTimeStampTZ` structure that represents the current date and time.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## GreaterThan

This static method determines if the first of two `OracleTimeStampTZ` values is greater than the second.

**Declaration**

```
// C#  
public static bool GreaterThan(OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStampTZ`.
- *value2*  
The second `OracleTimeStampTZ`.

**Return Value**

Returns `true` if the first of two `OracleTimeStampTZ` values is greater than the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## GreaterThanOrEqual

This static method determines if the first of two `OracleTimeStampTZ` values is greater than or equal to the second.

### Declaration

```
// C#  
public static bool GreaterThanOrEqual(OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

### Parameters

- *value1*  
The first `OracleTimeStampTZ`.
- *value2*  
The second `OracleTimeStampTZ`.

### Return Value

Returns `true` if the first of two `OracleTimeStampTZ` values is greater than or equal to the second; otherwise, returns `false`.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## LessThan

This static method determines if the first of two `OracleTimeStampTZ` values is less than the second.

**Declaration**

```
// C#  
public static bool LessThan(OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampTZ.
- *value2*  
The second OracleTimeStampTZ.

**Return Value**

Returns true if the first of two OracleTimeStampTZ values is less than the second. Returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStampTZ that has a value is greater than an OracleTimeStampTZ that has a null value.
- Two OracleTimeStampTZs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## LessThanOrEqual

This static method determines if the first of two OracleTimeStampTZ values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool LessThanOrEqual(OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampTZ.
- *value2*  
The second OracleTimeStampTZ.

**Return Value**

Returns true if the first of two `OracleTimeStampTZ` values is less than or equal to the second. Returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## NotEquals

This static method determines if two `OracleTimeStampTZ` values are not equal.

**Declaration**

```
// C#
public static bool NotEquals(OracleTimeStampTZ value1,
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStampTZ`.
- *value2*  
The second `OracleTimeStampTZ`.

**Return Value**

Returns true if two `OracleTimeStampTZ` values are not equal. Returns false otherwise.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Parse

This static method returns an `OracleTimeStampTZ` structure and sets its value for date and time using the supplied string.

### Declaration

```
// C#  
public static OracleTimeStampTZ Parse(string tsStr);
```

### Parameters

- *tsStr*  
A string that represents an Oracle TIMESTAMP WITH TIME ZONE.

### Return Value

An `OracleTimeStampTZ` structure.

### Exceptions

`ArgumentException` - The *tsStr* is an invalid string representation of an Oracle TIMESTAMP WITH TIME ZONE or the *tsStr* is not in the timestamp format specified by the `OracleGlobalization.TimeStampTZFormat` property of the thread, which represents the Oracle `NLS_TIMESTAMP_TZ_FORMAT` parameter.

`ArgumentNullException` - The *tsStr* value is null.

### Remarks

The names and abbreviations used for months and days are in the language specified by the `DateLanguage` and `Calendar` properties of the thread's `OracleGlobalization` object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class ParseSample  
{  
    static void Main()  
    {  
        // Set the nls_timestamp_tz_format for the Parse() method  
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
```

```
info.TimeStampTZFormat = "DD-MON-YYYY HH:MI:SS.FF AM TZR";
OracleGlobalization.SetThreadInfo(info);

// construct OracleTimeStampTZ from a string using the format specified.
OracleTimeStampTZ tstz = OracleTimeStampTZ.Parse("11-NOV-1999 " +
    "11:02:33.444 AM US/Pacific");

// Set the nls_timestamp_tz_format for the ToString() method
info.TimeStampTZFormat = "YYYY-MON-DD HH:MI:SS.FF AM TZR";
OracleGlobalization.SetThreadInfo(info);

// Prints "1999-NOV-11 11:02:33.444000000 AM US/Pacific"
Console.WriteLine(tstz.ToString());
    }
}
```

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support"](#)

## SetPrecision

This static method returns a new instance of an `OracleTimeStampTZ` with the specified fractional second precision.

### Declaration

```
// C#
public static OracleTimeStampTZ SetPrecision(OracleTimeStampTZ value1,
    int fracSecPrecision);
```

### Parameters

- *value1*  
The provided `OracleTimeStampTZ` object.
- *fracSecPrecision*  
The fractional second precision provided. Range of fractional second precision is (0 to 9).

### Return Value

An `OracleTimeStampTZ` structure with the specified fractional second precision

### Exceptions

`ArgumentOutOfRangeException` - *fracSecPrecision* is out of the specified range.

**Remarks**

The value specified in the supplied *fracSecPrecision* is used to perform a rounding off operation on the supplied `OracleTimeStampTZ` value. Depending on this value, 0 or more trailing zeros are displayed in the string returned by `ToString()`.

**Example**

The `OracleTimeStampTZ` with a value of "December 31, 9999 23:59:59.99 US/Pacific" results in the string "December 31, 9999 23:59:59.99000 US/Pacific" when `SetPrecision()` is called with the fractional second precision set to 5.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## OracleTimeStampTZ Static Operators

The `OracleTimeStampTZ` static operators are listed in [Table 14-136](#).

**Table 14-136 OracleTimeStampTZ Static Operators**

| Operator                       | Description                                                                                                                                                    |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">operator +</a>     | Adds the supplied instance value to the supplied <code>OracleTimeStampTZ</code> and returns a new <code>OracleTimeStampTZ</code> structure (Overloaded)        |
| <a href="#">operator ==</a>    | Determines if two <code>OracleTimeStampTZ</code> values are equal                                                                                              |
| <a href="#">operator &gt;</a>  | Determines if the first of two <code>OracleTimeStampTZ</code> values is greater than the second                                                                |
| <a href="#">operator &gt;=</a> | Determines if the first of two <code>OracleTimeStampTZ</code> values is greater than or equal to the second                                                    |
| <a href="#">operator !=</a>    | Determines if two <code>OracleTimeStampTZ</code> values are not equal                                                                                          |
| <a href="#">operator &lt;</a>  | Determines if the first of two <code>OracleTimeStampTZ</code> values is less than the second                                                                   |
| <a href="#">operator &lt;=</a> | Determines if the first of two <code>OracleTimeStampTZ</code> values is less than or equal to the second                                                       |
| <a href="#">operator -</a>     | Subtracts the supplied instance value from the supplied <code>OracleTimeStampTZ</code> and returns a new <code>OracleTimeStampTZ</code> structure (Overloaded) |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator +

operator+ adds the supplied structure to the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure.

**Overload List:**

- [operator +\(OracleTimeStampTZ, OracleIntervalDS\)](#)  
This static operator adds the supplied OracleIntervalDS to the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure.
- [operator +\(OracleTimeStampTZ, OracleIntervalYM\)](#)  
This static operator adds the supplied OracleIntervalYM to the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure.
- [operator +\(OracleTimeStampTZ, TimeSpan\)](#)  
This static operator adds the supplied TimeSpan to the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator +(OracleTimeStampTZ, OracleIntervalDS)

This static operator adds the supplied OracleIntervalDS to the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure.

**Declaration**

```
// C#  
public static operator +(OracleTimeStampTZ value1,  
    OracleIntervalDS value2);
```

**Parameters**

- *value1*  
An OracleTimeStampTZ.
- *value2*

An `OracleIntervalDS`.

**Return Value**

An `OracleTimeStampTZ`.

**Remarks**

If either parameter has a null value, the returned `OracleTimeStampTZ` has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator +(OracleTimeStampTZ, OracleIntervalYM)

This static operator adds the supplied `OracleIntervalYM` to the supplied `OracleTimeStampTZ` and returns a new `OracleTimeStampTZ` structure.

**Declaration**

```
// C#  
public static operator +(OracleTimeStampTZ value1,  
    OracleIntervalYM value2);
```

**Parameters**

- *value1*  
An `OracleTimeStampTZ`.
- *value2*  
An `OracleIntervalYM`.

**Return Value**

An `OracleTimeStampTZ`.

**Remarks**

If either parameter has a null value, the returned `OracleTimeStampTZ` has a null value.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator +(OracleTimeStampTZ, TimeSpan)

This static operator adds the supplied TimeSpan to the supplied OracleTimeStampTZ and returns a new OracleTimeStampTZ structure.

### Declaration

```
// C#  
public static operator +(OracleTimeStampTZ value1, TimeSpan value2);
```

### Parameters

- *value1*  
An OracleTimeStampTZ.
- *value2*  
A TimeSpan.

### Return Value

An OracleTimeStampTZ.

### Remarks

If the OracleTimeStampTZ instance has a null value, the returned OracleTimeStampTZ has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator ==

This static operator determines if two OracleTimeStampTZ values are equal.

### Declaration

```
// C#  
public static bool operator ==(OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

### Parameters

- *value1*  
The first OracleTimeStampTZ.
- *value2*  
The second OracleTimeStampTZ.

**Return Value**

Returns true if they are equal; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStampTZ that has a value is greater than an OracleTimeStampTZ that has a null value.
- Two OracleTimeStampTZs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

**operator >**

This static operator determines if the first of two OracleTimeStampTZ values is greater than the second.

**Declaration**

```
// C#
public static bool operator > (OracleTimeStampTZ value1,
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampTZ.
- *value2*  
The second OracleTimeStampTZ.

**Return Value**

Returns true if the first OracleTimeStampTZ value is greater than the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStampTZ that has a value is greater than an OracleTimeStampTZ that has a null value.
- Two OracleTimeStampTZs that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator >=

This static operator determines if the first of two `OracleTimeStampTZ` values is greater than or equal to the second.

**Declaration**

```
// C#  
public static bool operator >= (OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStampTZ`.
- *value2*  
The second `OracleTimeStampTZ`.

**Return Value**

Returns `true` if the first `OracleTimeStampTZ` is greater than or equal to the second; otherwise, returns `false`.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator !=

This static operator determines if two `OracleTimeStampTZ` values are not equal.

**Declaration**

```
// C#  
public static bool operator != (OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampTZ.
- *value2*  
The second OracleTimeStampTZ.

**Return Value**

Returns true if two OracleTimeStampTZ values are not equal; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any OracleTimeStampTZ that has a value is greater than an OracleTimeStampTZ that has a null value.
- Two OracleTimeStampTZs that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

**operator <**

This static operator determines if the first of two OracleTimeStampTZ values is less than the second.

**Declaration**

```
// C#  
public static bool operator < (OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first OracleTimeStampTZ.
- *value2*  
The second OracleTimeStampTZ.

**Return Value**

Returns true if the first `OracleTimeStampTZ` is less than the second; otherwise returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

**operator <=**

This static operator determines if the first of two `OracleTimeStampTZ` values is less than or equal to the second.

**Declaration**

```
// C#  
public static bool operator <= (OracleTimeStampTZ value1,  
    OracleTimeStampTZ value2);
```

**Parameters**

- *value1*  
The first `OracleTimeStampTZ`.
- *value2*  
The second `OracleTimeStampTZ`.

**Return Value**

Returns true if the first `OracleTimeStampTZ` is less than or equal to the second; otherwise, returns false.

**Remarks**

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

## operator -

operator - subtracts the supplied value, from the supplied OracleTimeStampTZ value, and returns a new OracleTimeStampTZ structure.

**Overload List:**

- [operator - \(OracleTimeStampTZ, OracleIntervalDS\)](#)  
This static operator subtracts the supplied OracleIntervalDS value, from the supplied OracleTimeStampTZ value, and return a new OracleTimeStampTZ structure.
- [operator - \(OracleTimeStampTZ, OracleIntervalYM\)](#)  
This static operator subtracts the supplied OracleIntervalYM value, from the supplied OracleTimeStampTZ value, and returns a new OracleTimeStampTZ structure.
- [operator - \(OracleTimeStampTZ value1, TimeSpan value2\)](#)  
This static operator subtracts the supplied TimeSpan value, from the supplied OracleTimeStampTZ value, and returns a new OracleTimeStampTZ structure.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator - (OracleTimeStampTZ, OracleIntervalDS)

This static operator subtracts the supplied OracleIntervalDS value, from the supplied OracleTimeStampTZ value, and return a new OracleTimeStampTZ structure.

**Declaration**

```
// C#  
public static operator - (OracleTimeStampTZ value1,  
    OracleIntervalDS value2);
```

**Parameters**

- *value1*  
An OracleTimeStampTZ.
- *value2*

An `OracleIntervalDS`.

### Return Value

An `OracleTimeStampTZ` structure.

### Remarks

If either parameter has a null value, the returned `OracleTimeStampTZ` has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## operator - (OracleTimeStampTZ, OracleIntervalYM)

This static operator subtracts the supplied `OracleIntervalYM` value, from the supplied `OracleTimeStampTZ` value, and returns a new `OracleTimeStampTZ` structure.

### Declaration

```
// C#  
public static operator - (OracleTimeStampTZ value1,  
    OracleIntervalYM value2);
```

### Parameters

- *value1*  
An `OracleTimeStampTZ`.
- *value2*  
An `OracleIntervalYM`.

### Return Value

An `OracleTimeStampTZ` structure.

### Remarks

If either parameter has a null value, the returned `OracleTimeStampTZ` has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

operator - (OracleTimeStampTZ value1, TimeSpan value2)

This static operator subtracts the supplied TimeSpan value, from the supplied OracleTimeStampTZ value, and returns a new OracleTimeStampTZ structure.

Declaration

```
// C#
public static operator - (OracleTimeStampTZ value1, TimeSpan value2);
```

Parameters

- *value1*  
An OracleTimeStampTZ.
- *value2*  
A TimeSpan.

Return Value

An OracleTimeStampTZ structure.

Remarks

If the OracleTimeStampTZ instance has a null value, the returned OracleTimeStampTZ structure has a null value.

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

OracleTimeStampTZ Static Type Conversions

The OracleTimeStampTZ static type conversions are listed in [Table 14-137](#).

Table 14-137 OracleTimeStampTZ Static Type Conversions

| Operator                                            | Description                                                                          |
|-----------------------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">explicit operator OracleTimeStampTZ</a> | Converts an instance value to an OracleTimeStampTZ structure (Overloaded)            |
| <a href="#">implicit operator OracleTimeStampTZ</a> | Converts an instance value to an OracleTimeStampTZ structure (Overloaded)            |
| <a href="#">explicit operator DateTime</a>          | Converts an OracleTimeStampTZ value to a DateTime structure in the current time zone |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## explicit operator OracleTimeStampTZ

explicit operator OracleTimeStampTZ converts an instance value to an OracleTimeStampTZ structure.

**Overload List:**

- [explicit operator OracleTimeStampTZ\(OracleTimeStamp\)](#)  
This static type conversion operator converts an OracleTimeStamp value to an OracleTimeStampTZ structure.
- [explicit operator OracleTimeStampTZ\(OracleTimeStampLTZ\)](#)  
This static type conversion operator converts an OracleTimeStampLTZ value to an OracleTimeStampTZ structure.
- [explicit operator OracleTimeStampTZ\(string\)](#)  
This static type conversion operator converts the supplied string value to an OracleTimeStampTZ structure.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## explicit operator OracleTimeStampTZ(OracleTimeStamp)

This static type conversion operator converts an OracleTimeStamp value to an OracleTimeStampTZ structure.

**Declaration**

```
// C#  
public static explicit operator OracleTimeStampTZ(OracleTimeStamp value1);
```

**Parameters**

- *value1*  
An OracleTimeStamp.

**Return Value**

The returned `OracleTimeStampTZ` contains the date and time from the `OracleTimeStamp` and the time zone from the `OracleGlobalization.TimeZone` of the thread.

**Remarks**

The `OracleGlobalization.TimeZone` of the thread is used to convert from an `OracleTimeStamp` structure to an `OracleTimeStampTZ` structure.

If the `OracleTimeStamp` structure has a null value, the returned `OracleTimeStampTZ` structure also has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## explicit operator OracleTimeStampTZ(OracleTimeStampLTZ)

This static type conversion operator converts an `OracleTimeStampLTZ` value to an `OracleTimeStampTZ` structure.

**Declaration**

```
// C#  
public static explicit operator OracleTimeStampTZ(OracleTimeStampLTZ value1);
```

**Parameters**

- *value1*  
An `OracleTimeStampLTZ`.

**Return Value**

The returned `OracleTimeStampTZ` contains the date and time from the `OracleTimeStampLTZ` and the time zone from the `OracleGlobalization.TimeZone` of the thread.

**Remarks**

If the `OracleTimeStampLTZ` structure has a null value, the returned `OracleTimeStampTZ` structure also has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## explicit operator OracleTimeStampTZ(string)

This static type conversion operator converts the supplied string value to an OracleTimeStampTZ structure.

### Declaration

```
// C#  
public static explicit operator OracleTimeStampTZ(string tsStr);
```

### Parameters

- *tsStr*

A string representation of an Oracle TIMESTAMP WITH TIME ZONE.

### Return Value

An OracleTimeStampTZ value.

### Exceptions

ArgumentException - The *tsStr* is an invalid string representation of an Oracle TIMESTAMP WITH TIME ZONE, or the *tsStr* is not in the timestamp format specified by the thread's OracleGlobalization.TimestampTZFormat property, which represents the Oracle NLS\_TIMESTAMP\_TZ\_FORMAT parameter.

### Remarks

The names and abbreviations used for months and days are in the language specified by the DateLanguage and Calendar properties of the thread's OracleGlobalization object. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#  
  
using System;  
using Oracle.DataAccess.Client;  
using Oracle.DataAccess.Types;  
  
class OracleTimeStampTZSample  
{  
    static void Main()  
    {  
        // Set the nls_timestamp_tz_format for the explicit operator
```

```
// OracleTimeStampTZ(string)
OracleGlobalization info = OracleGlobalization.GetClientInfo();
info.TimeStampTZFormat = "DD-MON-YYYY HH:MI:SS.FF AM TZR";
OracleGlobalization.SetThreadInfo(info);

// construct OracleTimeStampTZ from a string using the format specified.
OracleTimeStampTZ tstz = new OracleTimeStampTZ("11-NOV-1999" +
    "11:02:33.444 AM US/Pacific");

// Set the nls_timestamp_tz_format for the ToString() method
info.TimeStampTZFormat = "YYYY-MON-DD HH:MI:SS.FF AM TZR";
OracleGlobalization.SetThreadInfo(info);
Console.WriteLine(tstz.ToString());
    }
}
```

- ["Globalization Support "](#)

## implicit operator OracleTimeStampTZ

implicit operator OracleTimeStampTZ converts a DateTime structure to an OracleTimeStampTZ structure.

#### Overload List:

- [implicit operator OracleTimeStampTZ\(OracleDate\)](#)  
This static type conversion operator converts an OracleDate value to an OracleTimeStampTZ structure.
- [implicit operator OracleTimeStampTZ\(DateTime\)](#)  
This static type conversion operator converts a DateTime structure to an OracleTimeStampTZ structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## implicit operator OracleTimeStampTZ(OracleDate)

This static type conversion operator converts an `OracleDate` value to an `OracleTimeStampTZ` structure.

### Declaration

```
// C#  
public static implicit operator OracleTimeStampTZ(OracleDate value1);
```

### Parameters

- *value1*  
An `OracleDate`.

### Return Value

The returned `OracleTimeStampTZ` contains the date and time from the `OracleDate` and the time zone from the `OracleGlobalization.TimeZone` of the thread.

### Remarks

The `OracleGlobalization.TimeZone` of the thread is used to convert from an `OracleDate` to an `OracleTimeStampTZ` structure. If the `OracleDate` structure has a null value, the returned `OracleTimeStampTZ` structure also has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## implicit operator OracleTimeStampTZ(DateTime)

This static type conversion operator converts a `DateTime` structure to an `OracleTimeStampTZ` structure.

### Declaration

```
// C#  
public static implicit operator OracleTimeStampTZ (DateTime value1);
```

### Parameters

- *value1*  
A `DateTime` structure.

### Return Value

The returned `OracleTimeStampTZ` contains the date and time from the `DateTime` and the time zone from the `OracleGlobalization.TimeZone` of the thread.

### Remarks

The `OracleGlobalization.TimeZone` of the thread is used to convert from a `DateTime` to an `OracleTimeStampTZ` structure.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## explicit operator DateTime

This static type conversion operator converts an `OracleTimeStampTZ` value to a `DateTime` structure and truncates the time zone information.

### Declaration

```
// C#  
public static explicit operator DateTime(OracleTimeStampTZ value1);
```

### Parameters

- *value1*  
An `OracleTimeStampTZ`.

### Return Value

A `DateTime` containing the date and time in the current instance, but with the time zone information in the current instance truncated.

### Exceptions

`OracleNullValueException` - The `OracleTimeStampTZ` structure has a null value.

### Remarks

The precision of the `OracleTimeStampTZ` value can be lost during the conversion, and the time zone information in the current instance is truncated

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)

## OracleTimeStampTZ Properties

The OracleTimeStampTZ properties are listed in [Table 14-138](#).

**Table 14-138 OracleTimeStampTZ Properties**

| Properties                  | Description                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">BinData</a>     | Returns an array of bytes that represents an Oracle TIMESTAMP WITH TIME ZONE in Oracle internal format |
| <a href="#">Day</a>         | Specifies the day component of an OracleTimeStampTZ in the current time zone                           |
| <a href="#">IsNull</a>      | Indicates whether or not the current instance has a null value                                         |
| <a href="#">Hour</a>        | Specifies the hour component of an OracleTimeStampTZ in the current time zone                          |
| <a href="#">Millisecond</a> | Specifies the millisecond component of an OracleTimeStampTZ in the current time zone                   |
| <a href="#">Minute</a>      | Specifies the minute component of an OracleTimeStampTZ in the current time zone                        |
| <a href="#">Month</a>       | Specifies the month component of an OracleTimeStampTZ in the current time zone                         |
| <a href="#">Nanosecond</a>  | Specifies the nanosecond component of an OracleTimeStampTZ in the current time zone                    |
| <a href="#">Second</a>      | Specifies the second component of an OracleTimeStampTZ in the current time zone                        |
| <a href="#">TimeZone</a>    | Returns the time zone of the OracleTimeStampTZ instance                                                |
| <a href="#">Value</a>       | Returns the date and time that is stored in the OracleTimeStampTZ structure in the current time zone   |
| <a href="#">Year</a>        | Specifies the year component of an OracleTimeStampTZ                                                   |

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## BinData

This property returns an array of bytes that represents an Oracle TIMESTAMP WITH TIME ZONE in Oracle internal format.

### Declaration

```
// C#  
public byte[] BinData {get;}
```

### Property Value

The provided byte array that represents an Oracle TIMESTAMP WITH TIME ZONE in Oracle internal format.

### Exceptions

OracleNullValueException - The current instance has a null value.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Day

This property specifies the day component of an OracleTimeStampTZ in the current time zone.

### Declaration

```
// C#  
public int Day{get;}
```

### Property Value

A number that represents the day. Range of Day is (1 to 31).

### Exceptions

OracleNullValueException - The current instance has a null value.

#### ① See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## IsNull

This property indicates whether or not the current instance has a null value.

### Declaration

```
// C#  
public bool IsNull{get;}
```

### Property Value

Returns true if the current instance has a null value. Otherwise, returns false.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Hour

This property specifies the hour component of an OracleTimeStampTZ in the current time zone.

### Declaration

```
// C#  
public int Hour{get;}
```

### Property Value

A number that represents the hour. Range of Hour is (0 to 23).

### Exceptions

OracleNullValueException - The current instance has a null value.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Millisecond

This property gets the millisecond component of an OracleTimeStampTZ in the current time zone.

**Declaration**

```
// C#  
public double Millisecond{get;}
```

**Property Value**

A number that represents a millisecond. Range of Millisecond is (0 to 999.999999)

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Minute

This property gets the minute component of an OracleTimeStampTZ in the current time zone.

**Declaration**

```
// C#  
public int Minute{get;}
```

**Property Value**

A number that represent a minute. Range of Minute is (0 to 59).

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Month

This property gets the month component of an OracleTimeStampTZ in the current time zone

**Declaration**

```
// C#  
public int Month{get;}
```

**Property Value**

A number that represents a month. Range of Month is (1 to 12).

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Nanosecond

This property gets the nanosecond component of an OracleTimeStampTZ in the current time zone.

**Declaration**

```
// C#  
public int Nanosecond{get;}
```

**Property Value**

A number that represents a nanosecond. Range of Nanosecond is (0 to 999999999).

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Second

This property gets the second component of an OracleTimeStampTZ in the current time zone.

**Declaration**

```
// C#  
public int Second{get;}
```

**Property Value**

A number that represents a second. Range of Second is (0 to 59).

## Exceptions

OracleNullValueException - The current instance has a null value.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## TimeZone

This property returns the time zone of the OracleTimeStampTZ instance.

### Declaration

```
// C#  
public string TimeZone{get;}
```

### Property Value

A string that represents the time zone.

### Remarks

If no time zone is specified in the constructor, this property is set to the thread's OracleGlobalization.TimeZone by default

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)
- ["OracleGlobalization Class"](#)
- ["Globalization Support "](#)

## Value

This property returns the date and time that is stored in the OracleTimeStampTZ structure in the current time zone.

### Declaration

```
// C#  
public DateTime Value{get;}
```

**Property Value**

A DateTime in the current time zone.

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

Year

This property sets the year component of an OracleTimeStampTZ in the current time zone.

**Declaration**

```
// C#
public int Year{get;}
```

**Property Value**

A number that represents a year. The range of Year is (-4712 to 9999).

**Exceptions**

OracleNullValueException - The current instance has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

OracleTimeStampTZ Methods

The OracleTimeStampTZ methods are listed in [Table 14-139](#).

**Table 14-139 OracleTimeStampTZ Methods**

| Methods                  | Description                                               |
|--------------------------|-----------------------------------------------------------|
| <a href="#">AddDays</a>  | Adds the supplied number of days to the current instance  |
| <a href="#">AddHours</a> | Adds the supplied number of hours to the current instance |

Table 14-139 (Cont.) OracleTimeStampTZ Methods

| Methods                              | Description                                                                                                                |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddMilliseconds</a>      | Adds the supplied number of milliseconds to the current instance                                                           |
| <a href="#">AddMinutes</a>           | Adds the supplied number of minutes to the current instance                                                                |
| <a href="#">AddMonths</a>            | Adds the supplied number of months to the current instance                                                                 |
| <a href="#">AddNanoseconds</a>       | Adds the supplied number of nanoseconds to the current instance                                                            |
| <a href="#">AddSeconds</a>           | Adds the supplied number of seconds to the current instance                                                                |
| <a href="#">AddYears</a>             | Adds the supplied number of years to the current instance                                                                  |
| <a href="#">CompareTo</a>            | Compares the current OracleTimeStampTZ instance to an object, and returns an integer that represents their relative values |
| <a href="#">Equals</a>               | Determines whether or not an object has the same date and time as the current OracleTimeStampTZ instance (Overloaded)      |
| <a href="#">GetDaysBetween</a>       | Subtracts an OracleTimeStampTZ from the current instance and returns an OracleIntervalDS that represents the time interval |
| <a href="#">GetHashCode</a>          | Returns a hash code for the OracleTimeStampTZ instance                                                                     |
| <a href="#">GetTimeZoneOffset</a>    | Gets the time zone information in hours and minutes of the current OracleTimeStampTZ                                       |
| <a href="#">GetYearsBetween</a>      | Subtracts an OracleTimeStampTZ from the current instance and returns an OracleIntervalYM that represents the time interval |
| GetType                              | Inherited from System.Object                                                                                               |
| <a href="#">ToLocalTime</a>          | Converts the current OracleTimeStampTZ instance to local time                                                              |
| <a href="#">ToOracleDate</a>         | Converts the current OracleTimeStampTZ structure to an OracleDate structure                                                |
| <a href="#">ToOracleTimeStampLTZ</a> | Converts the current OracleTimeStampTZ structure to an OracleTimeStampLTZ structure                                        |
| <a href="#">ToOracleTimeStamp</a>    | Converts the current OracleTimeStampTZ structure to an OracleTimeStamp structure                                           |
| <a href="#">ToString</a>             | Converts the current OracleTimeStampTZ structure to a string                                                               |
| <a href="#">ToUniversalTime</a>      | Converts the current datetime to Coordinated Universal Time (UTC)                                                          |

## AddDays

This method adds the supplied number of days to the current instance.

**Declaration**

```
// C#  
public OracleTimeStampTZ AddDays(double days);
```

**Parameters**

- *days*

The supplied number of days. Range is  $(-1,000,000,000 < days < 1,000,000,000)$

**Return Value**

An `OracleTimeStampTZ`.

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

`ArgumentOutOfRangeException` - The argument value is out of the specified range.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## AddHours

This method adds the supplied number of hours to the current instance.

**Declaration**

```
// C#  
public OracleTimeStampTZ AddHours(double hours);
```

**Parameters**

- *hours*

The supplied number of hours. Range is  $(-24,000,000,000 < hours < 24,000,000,000)$ .

**Return Value**

An `OracleTimeStampTZ`.

**Exceptions**

`OracleNullValueException` - The current instance has a null value.

`ArgumentOutOfRangeException` - The argument value is out of the specified range.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## AddMilliseconds

This method adds the supplied number of milliseconds to the current instance.

**Declaration**

```
// C#  
public OracleTimeStampTZ AddMilliseconds(double milliseconds);
```

**Parameters**

- *milliseconds*

The supplied number of milliseconds. Range is  $(-8.64 * 10^{16} < \text{milliseconds} < 8.64 * 10^{16})$ .

**Return Value**

An OracleTimeStampTZ.

**Exceptions**

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## AddMinutes

This method adds the supplied number of minutes to the current instance.

**Declaration**

```
// C#  
public OracleTimeStampTZ AddMinutes(double minutes);
```

**Parameters**

- *minutes*

The supplied number of minutes. Range is  $(-1,440,000,000,000 < minutes < 1,440,000,000,000)$ .

### Return Value

An OracleTimeStampTZ.

### Exceptions

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## AddMonths

This method adds the supplied number of months to the current instance.

### Declaration

```
// C#  
public OracleTimeStampTZ AddMonths(long months);
```

### Parameters

- *months*  
The supplied number of months. Range is  $(-12,000,000,000 < months < 12,000,000,000)$ .

### Return Value

An OracleTimeStampTZ.

### Exceptions

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

#### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## AddNanoseconds

This method adds the supplied number of nanoseconds to the current instance.

### Declaration

```
// C#  
public OracleTimeStampTZ AddNanoseconds(long nanoseconds);
```

### Parameters

- *nanoseconds*  
The supplied number of nanoseconds.

### Return Value

An `OracleTimeStampTZ`.

### Exceptions

`OracleNullValueException` - The current instance has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## AddSeconds

This method adds the supplied number of seconds to the current instance.

### Declaration

```
// C#  
public OracleTimeStampTZ AddSeconds(double seconds);
```

### Parameters

- *seconds*  
The supplied number of seconds. Range is  $(-8.64 * 10^{13} < \text{seconds} < 8.64 * 10^{13})$ .

### Return Value

An `OracleTimeStampTZ`.

### Exceptions

`OracleNullValueException` - The current instance has a null value.

`ArgumentOutOfRangeException` - The argument value is out of the specified range.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## AddYears

This method adds the supplied number of years to the current instance

### Declaration

```
// C#  
public OracleTimeStampTZ AddYears(int years);
```

### Parameters

- *years*  
The supplied number of years. Range is  $(-999,999,999 \leq \text{years} \leq 999,999,999)$ .

### Return Value

An OracleTimeStampTZ.

### Exceptions

OracleNullValueException - The current instance has a null value.

ArgumentOutOfRangeException - The argument value is out of the specified range.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## CompareTo

This method compares the current OracleTimeStampTZ instance to an object, and returns an integer that represents their relative values.

### Declaration

```
// C#  
public int CompareTo(object obj);
```

### Parameters

- *obj*  
The object being compared to the current OracleTimeStampTZ instance.

### Return Value

The method returns a number that is:

Less than zero: if the current `OracleTimeStampTZ` instance value is less than that of *obj*.

Zero: if the current `OracleTimeStampTZ` instance and *obj* values are equal.

Greater than zero: if the current `OracleTimeStampTZ` instance value is greater than that of *obj*.

### Implements

`Comparable`

### Exceptions

`ArgumentException` - The *obj* is not of type `OracleTimeStampTZ`.

### Remarks

The following rules apply to the behavior of this method.

- The comparison must be between `OracleTimeStampTZ`s. For example, comparing an `OracleTimeStampTZ` instance with an `OracleBinary` instance is not allowed. When an `OracleTimeStampTZ` is compared with a different type, an `ArgumentException` is thrown.
- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## Equals

Overrides `Object`

This method determines whether or not an object has the same date and time as the current `OracleTimeStampTZ` instance.

### Declaration

```
// C#  
public override bool Equals(object obj);
```

### Parameters

- *obj*

The object being compared to the current `OracleTimeStampTZ` instance.

### Return Value

Returns true if the *obj* is of type `OracleTimeStampTZ` and represents the same date and time; otherwise, returns false.

### Remarks

The following rules apply to the behavior of this method.

- Any `OracleTimeStampTZ` that has a value is greater than an `OracleTimeStampTZ` that has a null value.
- Two `OracleTimeStampTZ`s that contain a null value are equal.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## GetDaysBetween

This method subtracts an `OracleTimeStampTZ` value from the current instance and returns an `OracleIntervalDS` that represents the time interval.

### Declaration

```
// C#  
public OracleIntervalDS GetDaysBetween(OracleTimeStampTZ value1);
```

### Parameters

- *value1*  
The `OracleTimeStampTZ` value being subtracted.

### Return Value

An `OracleIntervalDS` that represents the interval between two `OracleTimeStampTZ` values.

### Remarks

If either the current instance or the parameter has a null value, the returned `OracleIntervalDS` has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## GetHashCode

Overrides Object

This method returns a hash code for the OracleTimeStampTZ instance.

### Declaration

```
// C#  
public override int GetHashCode();
```

### Return Value

A number that represents the hash code.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## GetTimeZoneOffset

This method gets the time zone portion in hours and minutes of the current OracleTimeStampTZ.

### Declaration

```
// C#  
public TimeSpan GetTimeZoneOffset();
```

### Return Value

A TimeSpan.

### Exceptions

OracleNullValueException - The current instance has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## GetYearsBetween

This method subtracts an OracleTimeStampTZ value from the current instance and returns an OracleIntervalYM that represents the time interval.

**Declaration**

```
// C#  
public OracleIntervalYM GetYearsBetween(OracleTimeStampTZ val);
```

**Parameters**

- `val`

The `OracleTimeStampTZ` value being subtracted.

**Return Value**

An `OracleIntervalYM` that represents the interval between two `OracleTimeStampTZ` values.

**Remarks**

If either the current instance or the parameter has a null value, the returned `OracleIntervalYM` has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## ToLocalTime

This method converts the current `OracleTimeStampTZ` instance to local time.

**Declaration**

```
// C#  
public OracleTimeStampLTZ ToLocalTime();
```

**Return Value**

An `OracleTimeStampLTZ` that contains the date and time, which is normalized to the client local time zone, in the current instance.

**Remarks**

If the current instance has a null value, the returned `OracleTimeStampLTZ` has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## ToOracleDate

This method converts the current `OracleTimeStampTZ` structure to an `OracleDate` structure.

### Declaration

```
// C#  
public OracleDate ToOracleDate();
```

### Return Value

The returned `OracleDate` contains the date and time in the current instance, but the time zone information in the current instance is truncated.

### Remarks

The precision of the `OracleTimeStampTZ` value can be lost during the conversion, and the time zone information in the current instance is truncated.

If the current instance has a null value, the value of the returned `OracleDate` structure has a null value.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## ToOracleTimeStampLTZ

This method converts the current `OracleTimeStampTZ` structure to an `OracleTimeStampLTZ` structure.

### Declaration

```
// C#  
public OracleTimeStampLTZ ToOracleTimeStampLTZ();
```

### Return Value

The returned `OracleTimeStampLTZ` structure contains the date and time, which is normalized to the client local time zone, in the current instance.

### Remarks

If the value of the current instance has a null value, the value of the returned `OracleTimeStampLTZ` structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## ToOracleTimeStamp

This method converts the current `OracleTimeStampTZ` structure to an `OracleTimeStamp` structure.

**Declaration**

```
// C#  
public OracleTimeStamp ToOracleTimeStamp();
```

**Return Value**

The returned `OracleTimeStamp` contains the date and time in the current instance, but the time zone information is truncated.

**Remarks**

If the value of the current instance has a null value, the value of the returned `OracleTimeStamp` structure has a null value.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## ToString

Overrides `Object`

This method converts the current `OracleTimeStampTZ` structure to a string.

**Declaration**

```
// C#  
public override string ToString();
```

**Return Value**

A string that represents the same date and time as the current `OracleTimeStampTZ` structure.

**Remarks**

The returned value is a string representation of an `OracleTimeStampTZ` in the format specified by the `OracleGlobalization.TimeStampTZFormat` property of the thread. The names and

abbreviations used for months and days are in the language specified by the `OracleGlobalization.DateLanguage` and the `OracleGlobalization.Calendar` properties of the thread. If any of the thread's globalization properties are set to null or an empty string, the client computer's settings are used.

### Example

```
// C#

using System;
using Oracle.DataAccess.Client;
using Oracle.DataAccess.Types;

class ToStringSample
{
    static void Main()
    {
        // Set the nls parameters for the current thread
        OracleGlobalization info = OracleGlobalization.GetClientInfo();
        info.TimeZone = "US/Eastern";
        info.TimestampFormat = "DD-MON-YYYY HH:MI:SS.FF AM";
        info.TimestampTZFormat = "DD-MON-YYYY HH:MI:SS.FF AM TZR";
        OracleGlobalization.SetThreadInfo(info);

        // Create an OracleTimeStampTZ in US/Pacific time zone
        OracleTimeStampTZ tstz1=new OracleTimeStampTZ("11-NOV-1999 "+"
            "11:02:33.444 AM US/Pacific");

        // Note that ToOracleTimeStampTZ uses the thread's time zone region,
        // "US/Eastern"
        OracleTimeStamp ts = new OracleTimeStamp("11-NOV-1999 11:02:33.444 AM");
        OracleTimeStampTZ tstz2 = ts.ToOracleTimeStampTZ();

        // Calculate the difference between tstz1 and tstz2
        OracleIntervalDS idsDiff = tstz1.GetDaysBetween(tstz2);

        // Prints "US/Pacific"
        Console.WriteLine("tstz1.TimeZone = " + tstz1.TimeZone);

        // Prints "US/Eastern"
        Console.WriteLine("tstz2.TimeZone = " + tstz2.TimeZone);

        // Prints 3
        Console.WriteLine("idsDiff.Hours = " + idsDiff.Hours);

        // Prints 0
        Console.WriteLine("idsDiff.Minutes = " + idsDiff.Minutes);
    }
}
```

- ["Globalization Support "](#)

## ToUniversalTime

This method converts the current datetime to Coordinated Universal Time (UTC).

### Declaration

```
// C#  
public OracleTimeStampTZ ToUniversalTime();
```

### Return Value

An `OracleTimeStampTZ` structure.

### Remarks

If the current instance has a null value, the value of the returned `OracleTimeStampTZ` structure has a null value.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTimeStampTZ Structure](#)
- [OracleTimeStampTZ Members](#)

## INullable Interface

The `INullable` interface is used to determine whether or not an ODP.NET type has a `NULL` value.

### Declaration

```
// C#  
public interface INullable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

- [INullable Interface Properties](#)

INullable Interface Members

INullable members are listed in the following tables.

INullable Interface Properties

INullable interface properties are listed in [Table 14-140](#).

Table 14-140 INullable Interface Properties

| Public Property        | Description                                                |
|------------------------|------------------------------------------------------------|
| <a href="#">IsNull</a> | Indicates whether or not the ODP.NET type has a NULL value |

See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [INullable Interface](#)

INullable Interface Properties

INullable interface properties are listed in [Table 14-140](#).

**Table 14-141 INullable Interface Properties**

| Public Property        | Description                                                |
|------------------------|------------------------------------------------------------|
| <a href="#">IsNull</a> | Indicates whether or not the ODP.NET type has a NULL value |

## IsNull

This property indicates whether or not the ODP.NET type has a NULL value.

### Declaration

```
// C#  
bool IsNull {get;}
```

### Property Value

Returns true if the ODP.NET type has a NULL value; otherwise, returns false.

# Oracle Data Provider for .NET Types Exceptions

This section covers the ODP.NET Types exceptions.

This chapter contains these topics:

- [OracleTypeException Class](#)
- [OracleNullValueException Class](#)
- [OracleTruncateException Class](#)

## OracleTypeException Class

The `OracleTypeException` is the base exception class for handling exceptions that occur in the ODP.NET Types classes.

### Class Inheritance

### Declaration

```
// C#
public class OracleTypeException : SystemException
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTypeException Members](#)
- [OracleTypeException Constructors](#)
- [OracleTypeException Static Methods](#)
- [OracleTypeException Properties](#)
- [OracleTypeException Methods](#)

## OracleTypeException Members

OracleTypeException members are listed in the following tables.

### OracleTypeException Constructors

The OracleTypeException constructors are listed in [Table 15-1](#).

**Table 15-1 OracleTypeException Constructor**

| Constructor                                      | Description                                                          |
|--------------------------------------------------|----------------------------------------------------------------------|
| <a href="#">OracleTypeException Constructors</a> | Creates a new instance of the OracleTypeException class (Overloaded) |

### OracleTypeException Static Methods

The OracleTypeException static methods are listed in [Table 15-2](#).

**Table 15-2 OracleTypeException Static Methods**

| Methods                | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

### OracleTypeException Properties

The OracleTypeException properties are listed in [Table 15-3](#).

**Table 15-3 OracleTypeException Properties**

| Properties                     | Description                                                      |
|--------------------------------|------------------------------------------------------------------|
| <a href="#">HelpLink</a>       | Inherited from System.SystemException.Exception                  |
| <a href="#">InnerException</a> | Inherited from System.SystemException.Exception                  |
| <a href="#">Message</a>        | Specifies the error messages that occur in the exception         |
| <a href="#">Number</a>         | Specifies the error number that occurs in the exception          |
| <a href="#">Source</a>         | Specifies the name of the data provider that generates the error |
| <a href="#">StackTrace</a>     | Inherited from System.SystemException.Exception                  |

**Table 15-3 (Cont.) OracleTypeException Properties**

| Properties | Description                                     |
|------------|-------------------------------------------------|
| TargetSite | Inherited from System.SystemException.Exception |

**OracleTypeException Methods**

The OracleTypeException methods are listed in [Table 15-4](#).

**Table 15-4 OracleTypeException Methods**

| Methods                  | Description                                        |
|--------------------------|----------------------------------------------------|
| Equals                   | Inherited from System.Object (Overloaded)          |
| GetBaseException         | Inherited from System.SystemException.Exception    |
| GetHashCode              | Inherited from System.Object                       |
| GetObjectData            | Inherited from System.SystemException.Exception    |
| GetType                  | Inherited from System.Object                       |
| <a href="#">ToString</a> | Returns the fully qualified name of this exception |

## OracleTypeException Constructors

The OracleTypeException constructors create new instances of the OracleTypeException class.

**Overload List:**

- [OracleTypeException\(string\)](#)  
This constructor creates a new instance of the OracleTypeException class with the specified error message, errMessage.
- [OracleTypeException\(SerializationInfo, StreamingContext\)](#)  
This constructor creates a new instance of the OracleTypeException class with the specified serialization information, si, and the specified streaming context, sc.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTypeException Class](#)
- [OracleTypeException Members](#)

## OracleTypeException(string)

This constructor creates a new instance of the `OracleTypeException` class with the specified error message, `errorMessage`.

**Declaration**

```
// C#  
public OracleTypeException (string errorMessage);
```

**Parameters**

- *errorMessage*  
The specified error message.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTypeException Class](#)
- [OracleTypeException Members](#)

## OracleTypeException(SerializationInfo, StreamingContext)

This constructor creates a new instance of the `OracleTypeException` class with the specified serialization information, `si`, and the specified streaming context, `sc`.

**Declaration**

```
// C#  
protected OracleTypeException (SerializationInfo si, StreamingContext sc);
```

**Parameters**

- *si*  
The specified serialization information.
- *sc*  
The specified streaming context.

## Message

Overrides Exception

This property specifies the error messages that occur in the exception.

### Declaration

```
// C#  
public override string Message {get;}
```

### Property Value

An error message.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTypeException Class](#)
- [OracleTypeException Members](#)

## Number

Overrides Exception

This property specifies the error number that occurs in the exception

### Declaration

```
// C#  
public override int Number {get;}
```

### Property Value

An error number

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTypeException Class](#)
- [OracleTypeException Members](#)

Source

Overrides Exception

This property specifies the name of the data provider that generates the error.

Declaration

```
// C#
public override string Source {get;}
```

Property Value

Oracle Data Provider for .NET.

See Also

OracleTypeException Methods

The OracleTypeException methods are listed in [Table 15-7](#).

Table 15-7 OracleTypeException Methods

| Methods                  | Description                                        |
|--------------------------|----------------------------------------------------|
| Equals                   | Inherited from System.Object (Overloaded)          |
| GetBaseException         | Inherited from System.SystemException.Exception    |
| GetHashCode              | Inherited from System.Object                       |
| GetObjectData            | Inherited from System.SystemException.Exception    |
| GetType                  | Inherited from System.Object                       |
| <a href="#">ToString</a> | Returns the fully qualified name of this exception |

See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleTypeException Class](#)
- [OracleTypeException Members](#)

ToString

Overrides Exception

This method returns the fully qualified name of this exception, the error message in the Message property, the InnerException.ToString() message, and the stack trace.

Declaration

```
// C#
public override string ToString();
```

Return Value

The fully qualified name of this exception.

- [OracleTypeException Class](#)
- [OracleTypeException Members](#)

# OracleNullValueException Class

The OracleNullValueException represents an exception that is thrown when trying to access an ODP.NET Types structure that has a null value.

Class Inheritance

Declaration

```
// C#
public sealed class OracleNullValueException : OracleTypeException
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

- [OracleNullValueException Methods](#)

## OracleNullValueException Members

OracleNullValueException members are listed in the following tables.

### OracleNullValueException Constructors

The OracleNullValueException constructors are listed in [Table 15-8](#).

**Table 15-8 OracleNullValueException Constructors**

| Constructor                                           | Description                                                               |
|-------------------------------------------------------|---------------------------------------------------------------------------|
| <a href="#">OracleNullValueException Constructors</a> | Creates a new instance of the OracleNullValueException class (Overloaded) |

### OracleNullValueException Static Methods

The OracleNullValueException static methods are listed in [Table 15-9](#).

**Table 15-9 OracleNullValueException Static Methods**

| Methods | Description                               |
|---------|-------------------------------------------|
| Equals  | Inherited from System.Object (Overloaded) |

### OracleNullValueException Properties

The OracleNullValueException properties are listed in [Table 15-10](#).

**Table 15-10 OracleNullValueException Properties**

| Properties     | Description                                     |
|----------------|-------------------------------------------------|
| HelpLink       | Inherited from System.SystemException.Exception |
| InnerException | Inherited from System.SystemException.Exception |

**Table 15-10 (Cont.) OracleNullValueException Properties**

| Properties | Description                                     |
|------------|-------------------------------------------------|
| Message    | Inherited from OracleTypeException              |
| Source     | Inherited from OracleTypeException              |
| StackTrace | Inherited from System.SystemException.Exception |
| TargetSite | Inherited from System.SystemException.Exception |

**OracleNullValueException Methods**

The OracleNullValueException methods are listed in [Table 15-11](#).

**Table 15-11 OracleNullValueException Methods**

| Methods          | Description                                     |
|------------------|-------------------------------------------------|
| Equals           | Inherited from System.Object (Overloaded)       |
| GetBaseException | Inherited from System.SystemException.Exception |
| GetHashCode      | Inherited from System.Object                    |
| GetObjectData    | Inherited from System.SystemException.Exception |
| GetType          | Inherited from System.Object                    |
| ToString         | Inherited from OracleTypeException              |

**See Also**

## OracleNullValueException Constructors

The OracleNullValueException constructors create new instances of the OracleNullValueException class.

**Overload List:**

- [OracleNullValueException\(\)](#)  
This constructor creates a new instance of the OracleNullValueException class with its default properties.
- [OracleNullValueException\(string\)](#)  
This constructor creates a new instance of the OracleNullValueException class with the specified error message, `errorMessage`.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleNullValueException Class](#)
- [OracleNullValueException Members](#)

## OracleNullValueException()

This constructor creates a new instance of the `OracleNullValueException` class with its default properties.

### Declaration

```
// C#  
public OracleNullValueException();
```

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleNullValueException Class](#)
- [OracleNullValueException Members](#)

## OracleNullValueException(string)

This constructor creates a new instance of the `OracleNullValueException` class with the specified error message, `errorMessage`.

### Declaration

```
// C#  
public OracleNullValueException (string errorMessage);
```

### Parameters

- *errorMessage*  
The specified error message.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleNullValueException Class](#)
- [OracleNullValueException Members](#)

## OracleNullValueException Static Methods

The OracleNullValueException static methods are listed in [Table 15-12](#).

**Table 15-12 OracleNullValueException Static Methods**

| Methods | Description                               |
|---------|-------------------------------------------|
| Equals  | Inherited from System.Object (Overloaded) |

### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleNullValueException Class](#)
- [OracleNullValueException Members](#)

## OracleNullValueException Properties

The OracleNullValueException properties are listed in [Table 15-13](#).

**Table 15-13 OracleNullValueException Properties**

| Properties     | Description                                     |
|----------------|-------------------------------------------------|
| HelpLink       | Inherited from System.SystemException.Exception |
| InnerException | Inherited from System.SystemException.Exception |
| Message        | Inherited from OracleTypeException              |
| Source         | Inherited from OracleTypeException              |
| StackTrace     | Inherited from System.SystemException.Exception |
| TargetSite     | Inherited from System.SystemException.Exception |

### See Also

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleNullValueException Class](#)
- [OracleNullValueException Members](#)

## OracleNullValueException Methods

The OracleNullValueException methods are listed in [Table 15-14](#).

**Table 15-14 OracleNullValueException Methods**

| Methods          | Description                                     |
|------------------|-------------------------------------------------|
| Equals           | Inherited from System.Object (Overloaded)       |
| GetBaseException | Inherited from System.SystemException.Exception |
| GetHashCode      | Inherited from System.Object                    |
| GetObjectData    | Inherited from System.SystemException.Exception |
| GetType          | Inherited from System.Object                    |
| ToString         | Inherited from OracleTypeException              |

## OracleTruncateException Class

The OracleTruncateException class represents an exception that is thrown when truncation in a ODP.NET Types class occurs.

### Class Inheritance

System.Object

System.Exception

System.SystemException

System.OracleTypeException

Oracle.DataAccess.Types.OracleTruncateException

### Declaration

```
// C#
public sealed class OracleTruncateException : OracleTypeException
```

### Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

- [OracleTruncateException Methods](#)

## OracleTruncateException Members

OracleTruncateException members are listed in the following tables.

### OracleTruncateException Constructors

The OracleTruncateException constructors are listed in [Table 15-15](#).

**Table 15-15 OracleTruncateException Constructors**

| Constructor                                          | Description                                                              |
|------------------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">OracleTruncateException Constructors</a> | Creates a new instance of the OracleTruncateException class (Overloaded) |

### OracleTruncateException Static Methods

The OracleTruncateException static methods are listed in [Table 15-16](#).

**Table 15-16 OracleTruncateException Static Methods**

| Methods | Description                               |
|---------|-------------------------------------------|
| Equals  | Inherited from System.Object (Overloaded) |

### OracleTruncateException Properties

The OracleTruncateException properties are listed in [Table 15-17](#).

**Table 15-17 OracleTruncateException Properties**

| Properties     | Description                                     |
|----------------|-------------------------------------------------|
| HelpLink       | Inherited from System.SystemException.Exception |
| InnerException | Inherited from System.SystemException.Exception |
| Message        | Inherited from OracleTypeException              |
| Source         | Inherited from OracleTypeException              |
| StackTrace     | Inherited from System.SystemException.Exception |
| TargetSite     | Inherited from System.SystemException.Exception |

## OracleTruncateException Methods

The OracleTruncateException methods are listed in [Table 15-18](#).

**Table 15-18 OracleTruncateException Methods**

| Methods          | Description                                     |
|------------------|-------------------------------------------------|
| Equals           | Inherited from System.Object (Overloaded)       |
| GetBaseException | Inherited from System.SystemException.Exception |
| GetHashCode      | Inherited from System.Object                    |
| GetObjectData    | Inherited from System.SystemException.Exception |
| GetType          | Inherited from System.Object                    |
| ToString         | Inherited from OracleTypeException              |

### See Also

# Oracle Data Provider for .NET UDT-Related Classes

This chapter describes the object-related classes and interfaces in the Oracle Data Provider for .NET that provide support for Oracle user-defined data types (UDT).

In ODAC Oracle Universal Installer, samples are provided in the `ORACLE_BASE\ORACLE_HOME\ODP.NET\Samples\UDT` directory.

## OracleCustomTypeMappingAttribute Class

The `OracleCustomTypeMappingAttribute` class is used to mark a custom type factory class or struct with information that is used by ODP.NET when a custom type is used to represent an Oracle UDT.

### Class Inheritance

`System.Object`

`System.Attribute`

`System.OracleCustomTypeMappingAttribute`

### Declaration

```
// C#  
[AttributeUsageAttribute(AttributeTargets.Class|AttributeTargets.Struct,  
    AllowMultiple=false, Inherited=true)]  
public sealed class OracleCustomTypeMappingAttribute : Attribute
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Remarks

The `OracleCustomTypeMapping` attribute must be specified on the custom type factory class to indicate the Oracle UDT that the corresponding custom type represents. The Oracle UDT may be specified in the form `schema_name.type_name`.

For each Oracle UDT that the application uses, there must be a unique custom type factory, as follows:

- Oracle Object Types  
The custom type factory must return a custom type that cannot be used to represent any other Oracle Object Type.
- Oracle Collection Types  
The custom type factory may return a custom type that can be used by other Oracle Collection Types. This is common when an array type is used to represent an Oracle Collection, that is, when an `int[]` is used to represent a collection of NUMBERS.

If the `OracleCustomTypeMappingAttribute` is not specified, then custom type mappings must be specified through an XML configuration file, for example, `app.config` for Windows applications or the `web.config` for web applications, and the `machine.config`

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OracleCustomTypeMappingAttribute Members

OracleCustomTypeMappingAttribute members are listed in the following tables.

### OracleCustomTypeMappingAttribute Constructors

OracleCustomTypeMappingAttribute constructors are listed in [Table 16-1](#).

**Table 16-1 OracleCustomTypeMappingAttribute Constructors**

| Constructor                                                   | Description                                                           |
|---------------------------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">OracleCustomTypeMappingAttribute Constructors</a> | Instantiates a new instance of OracleCustomTypeMappingAttribute class |

### OracleCustomTypeMappingAttribute Static Methods

OracleCustomTypeMappingAttribute static methods are listed in [Table 16-2](#).

**Table 16-2 OracleCustomTypeMappingAttribute Static Methods**

| Method              | Description                     |
|---------------------|---------------------------------|
| Equals              | Inherited from System.Attribute |
| GetCustomAttribute  | Inherited from System.Attribute |
| GetCustomAttributes | Inherited from System.Attribute |
| IsDefined           | Inherited from System.Attribute |
| ReferenceEquals     | Inherited from System.Attribute |

### OracleCustomTypeMappingAttribute Properties

OracleCustomTypeMappingAttribute properties are listed in [Table 16-3](#).

**Table 16-3 OracleCustomTypeMappingAttribute Properties**

| Property                    | Description                                                               |
|-----------------------------|---------------------------------------------------------------------------|
| <a href="#">UdtTypeName</a> | Specifies the Oracle user-defined type name that the custom class maps to |
| TypeId                      | Inherited from System.Attribute                                           |

### OracleCustomTypeMappingAttribute Methods

OracleCustomTypeMappingAttribute methods are listed in [Table 16-4](#).

**Table 16-4 OracleCustomTypeMappingAttribute Methods**

| Method      | Description                     |
|-------------|---------------------------------|
| Equals      | Inherited from System.Attribute |
| GetHashCode | Inherited from System.Attribute |
| GetType     | Inherited from System.Attribute |

**Table 16-4 (Cont.) OracleCustomTypeMappingAttribute Methods**

| Method             | Description                     |
|--------------------|---------------------------------|
| IsDefaultAttribute | Inherited from System.Attribute |
| Match              | Inherited from System.Attribute |
| ToString           | Inherited from System.Attribute |

## OracleCustomTypeMappingAttribute Constructors

OracleCustomTypeMappingAttribute constructors create new instances of the OracleCustomTypeMappingAttribute class.

**Overload List:**

- [OracleCustomTypeMappingAttribute\(string\)](#)

This constructor creates and initializes an OracleCustomTypeMappingAttribute using the specified Oracle user-defined type name.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleCustomTypeMappingAttribute Class](#)
- [OracleCustomTypeMappingAttribute Methods](#)

### OracleCustomTypeMappingAttribute(string)

This constructor creates and initializes an OracleCustomTypeMappingAttribute using the specified Oracle user-defined type name.

**Declaration**

```
// C#  
public OracleCustomTypeMappingAttribute(string udtTypeName)
```

**Parameters**

- *udtTypeName*

The Oracle user-defined type name that the custom class maps to.

## Remarks

The *udtTypeName* parameter is case-sensitive. The *udtTypeName* is specified in the form of *schema\_name.type\_name*.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleCustomTypeMappingAttribute Class](#)

## OracleCustomTypeMappingAttribute Static Methods

OracleCustomTypeMappingAttribute static methods are listed in [Table 16-5](#).

**Table 16-5 OracleCustomTypeMappingAttribute Static Methods**

| Method              | Description                     |
|---------------------|---------------------------------|
| Equals              | Inherited from System.Attribute |
| GetCustomAttribute  | Inherited from System.Attribute |
| GetCustomAttributes | Inherited from System.Attribute |
| IsDefined           | Inherited from System.Attribute |
| ReferenceEquals     | Inherited from System.Attribute |

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## OracleCustomTypeMappingAttribute Properties

OracleCustomTypeMappingAttribute properties are listed in [Table 16-6](#).

**Table 16-6 OracleCustomTypeMappingAttribute Properties**

| Property                    | Description                                                               |
|-----------------------------|---------------------------------------------------------------------------|
| <a href="#">UdtTypeName</a> | Specifies the Oracle user-defined type name that the custom class maps to |
| TypeId                      | Inherited from System.Attribute                                           |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleCustomTypeMappingAttribute Class](#)
- [OracleCustomTypeMappingAttribute Members](#)

## UdtTypeName

This property specifies the Oracle user-defined type name that the custom class maps to.

### Declaration

```
// C#  
public string UdtTypeName {get; set;}
```

### Property Value

A string that represents an Oracle user-defined type name.

### Remarks

UdtTypeName is case-sensitive. It is specified in the form of *schema\_name.type\_name*.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleCustomTypeMappingAttribute Class](#)

## OracleCustomTypeMappingAttribute Methods

OracleCustomTypeMappingAttribute methods are listed in [Table 16-7](#).

**Table 16-7 OracleCustomTypeMappingAttribute Methods**

| Method             | Description                     |
|--------------------|---------------------------------|
| Equals             | Inherited from System.Attribute |
| GetHashCode        | Inherited from System.Attribute |
| GetType            | Inherited from System.Attribute |
| IsDefaultAttribute | Inherited from System.Attribute |
| Match              | Inherited from System.Attribute |
| ToString           | Inherited from System.Attribute |

① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

# OracleObjectMappingAttribute Class

The OracleObjectMappingAttribute class marks custom class fields or properties with information that ODP.NET uses when a custom type represents an Oracle Object type.

### Class Inheritance

System.Object  
System.Attribute  
System.OracleObjectMappingAttribute

### Declaration

```
// C#  
[AttributeUsageAttribute(AttributeTargets.Field|AttributeTargets.Property,  
AllowMultiple=false, Inherited=true)]  
  
public sealed class OracleObjectMappingAttribute : Attribute
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Remarks

The OracleObjectMappingAttribute is specified on members of a custom type that represent an Oracle object type. This attribute must specify the name or zero-based index of the attribute in the Oracle object that the custom class field or property maps to. This also allows the custom type to declare field or property names which differ from the Oracle Object type.

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OracleObjectMappingAttribute Members

OracleObjectMappingAttribute members are listed in the following tables.

### OracleObjectMappingAttribute Constructors

OracleObjectMappingAttribute constructors are listed in [Table 16-8](#).

**Table 16-8 OracleObjectMappingAttribute Constructors**

| Constructor                                               | Description                                                                    |
|-----------------------------------------------------------|--------------------------------------------------------------------------------|
| <a href="#">OracleObjectMappingAttribute Constructors</a> | Instantiates a new instance of OracleObjectMappingAttribute class (Overloaded) |

### OracleObjectMappingAttribute Static Methods

OracleObjectMappingAttribute static methods are listed in [Table 16-9](#).

**Table 16-9 OracleObjectMappingAttribute Static Methods**

| Method              | Description                     |
|---------------------|---------------------------------|
| Equals              | Inherited from System.Attribute |
| GetCustomAttribute  | Inherited from System.Attribute |
| GetCustomAttributes | Inherited from System.Attribute |
| IsDefined           | Inherited from System.Attribute |
| ReferenceEquals     | Inherited from System.Attribute |

### OracleObjectMappingAttribute Properties

OracleObjectMappingAttribute properties are listed in [Table 16-10](#).

**Table 16-10 OracleObjectMappingAttribute Properties**

| Property                       | Description                                                               |
|--------------------------------|---------------------------------------------------------------------------|
| <a href="#">AttributeIndex</a> | Specifies the index of the Oracle Object attribute that must be retrieved |

**Table 16-10 (Cont.) OracleObjectMappingAttribute Properties**

| Property                      | Description                                                          |
|-------------------------------|----------------------------------------------------------------------|
| <a href="#">AttributeName</a> | Specifies the name of Oracle Object attribute that must be retrieved |
| TypeId                        | Inherited from System.Attribute                                      |

### OracleObjectMappingAttribute Methods

OracleObjectMappingAttribute methods are listed in [Table 16-11](#).

**Table 16-11 OracleObjectMappingAttribute Methods**

| Method             | Description                     |
|--------------------|---------------------------------|
| Equals             | Inherited from System.Attribute |
| GetHashCode        | Inherited from System.Attribute |
| GetType            | Inherited from System.Attribute |
| IsDefaultAttribute | Inherited from System.Attribute |
| Match              | Inherited from System.Attribute |
| ToString           | Inherited from System.Attribute |

## OracleObjectMappingAttribute Constructors

OracleObjectMappingAttribute constructors create new instances of the OracleObjectMappingAttribute class.

### Overload List:

- [OracleObjectMappingAttribute\(string\)](#)  
This constructor creates and initializes an OracleObjectMappingAttribute object with the specified Oracle Object attribute name.
- [OracleObjectMappingAttribute\(int\)](#)  
This constructor creates and initializes an OracleObjectMappingAttribute with the specified Oracle Object attribute index.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleObjectMappingAttribute Class](#)
- [OracleObjectMappingAttribute Members](#)

## OracleObjectMappingAttribute(string)

This constructor creates and initializes an `OracleObjectMappingAttribute` object with the specified Oracle Object attribute name.

**Declaration**

```
// C#  
public OracleObjectMappingAttribute(string attrName);
```

**Parameters**

- *attrName*

The name of the Oracle Object attribute to map to.

**Remarks**

The *attrName* parameter is case-sensitive.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleObjectMappingAttribute Class](#)
- [OracleObjectMappingAttribute Members](#)

## OracleObjectMappingAttribute(int)

This constructor creates and initializes an `OracleObjectMappingAttribute` object with the specified Oracle Object attribute index.

**Declaration**

```
// C#  
public OracleObjectMappingAttribute(int attrIndex);
```

**Parameters**

- *attrIndex*

The zero-based index of the Oracle Object attribute to map to.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleObjectMappingAttribute Class](#)
- [OracleObjectMappingAttribute Members](#)

## OracleObjectMappingAttribute Static Methods

OracleObjectMappingAttribute static methods are listed in [Table 16-12](#).

**Table 16-12 OracleObjectMappingAttribute Static Method**

| Method              | Description                     |
|---------------------|---------------------------------|
| Equals              | Inherited from System.Attribute |
| GetCustomAttribute  | Inherited from System.Attribute |
| GetCustomAttributes | Inherited from System.Attribute |
| IsDefined           | Inherited from System.Attribute |
| ReferenceEquals     | Inherited from System.Attribute |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleObjectMappingAttribute Class](#)
- [OracleObjectMappingAttribute Members](#)

## OracleObjectMappingAttribute Properties

OracleObjectMappingAttribute properties are listed in [Table 16-13](#).

**Table 16-13 OracleObjectMappingAttribute Properties**

| Property                       | Description                                                               |
|--------------------------------|---------------------------------------------------------------------------|
| <a href="#">AttributeIndex</a> | Specifies the index of the Oracle Object attribute that must be retrieved |
| <a href="#">AttributeName</a>  | Specifies the name of the Oracle Object attribute that must be retrieved  |
| TypeId                         | Inherited from System.Attribute                                           |

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleObjectMappingAttribute Class](#)
- [OracleObjectMappingAttribute Members](#)

## AttributeIndex

This property specifies the index of the Oracle Object attribute that must be retrieved.

### Declaration

```
// C#  
public int AttributeIndex {get;}
```

### Property Value

The zero-based index of an Oracle Object type attribute.

### Remarks

The AttributeIndex property specifies the index of the Oracle Object type attribute that the custom class field or property maps to. This allows the custom class to declare fields or property names that differ from the Oracle object.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleObjectMappingAttribute Class](#)
- [OracleObjectMappingAttribute Members](#)

## AttributeName

This property specifies the name of the Oracle Object attribute that must be retrieved.

### Declaration

```
// C#  
public string AttributeName {get;}
```

### Property Value

The name of an attribute of an Oracle Object type.

### Remarks

The AttributeName property specifies name of the attribute in the Oracle Object type that the custom class field or property maps to. This allows the custom class to declare field or property names that differ from the Oracle object.

The specified attribute name is case-sensitive.

OracleArrayMappingAttribute Class

The OracleArrayMappingAttribute class is required to mark a custom class field or property with information that ODP.NET uses when a custom type represents an Oracle Collection type.

Class Inheritance

System.Object  
    System.Attribute  
        System.OracleArrayMappingAttribute

Declaration

```
[AttributeUsageAttribute(AttributeTargets.Field|AttributeTargets.Property, AllowMultiple=false,
Inherited=true)]

// C#
public sealed class OracleArrayMappingAttribute : Attribute
```

## Requirements

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

## Remarks

An OracleArrayMappingAttribute object must be specified when a custom type represents an Oracle Collection. This attribute is applied only to the custom class member that stores the collection elements.

## Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## OracleArrayMappingAttribute Constructors

OracleArrayMappingAttribute constructors create new instances of the OracleArrayMappingAttribute class.

**Overload List:**

- [OracleArrayMappingAttribute\(\)](#)

This constructor creates and initializes an OracleArrayMappingAttribute object.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleArrayMappingAttribute Class](#)
- [OracleArrayMappingAttribute Members](#)

## OracleArrayMappingAttribute()

This constructor creates and initializes an OracleArrayMappingAttribute object.

**Declaration**

```
// C#  
public OracleArrayMappingAttribute();
```

**Remarks**

An OracleArrayMappingAttribute object must be applied when a custom class represents an Oracle Collection type, to specify the custom class field or property that stores the collection elements.

The OracleArrayMappingAttribute can be applied to only one field or property in the custom class.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleArrayMappingAttribute Class](#)
- [OracleArrayMappingAttribute Members](#)

## OracleArrayMappingAttribute Static Methods

OracleArrayMappingAttribute static methods are listed in [Table 16-19](#).

**Table 16-19 OracleArrayMappingAttribute Static Methods**

| Method              | Description                     |
|---------------------|---------------------------------|
| Equals              | Inherited from System.Attribute |
| GetCustomAttribute  | Inherited from System.Attribute |
| GetCustomAttributes | Inherited from System.Attribute |

**Table 16-19 (Cont.) OracleArrayMappingAttribute Static Methods**

| Method          | Description                     |
|-----------------|---------------------------------|
| IsDefined       | Inherited from System.Attribute |
| ReferenceEquals | Inherited from System.Attribute |

**See Also**

# IOracleCustomType Interface

IOracleCustomType is an interface for converting between a Custom Type and an Oracle Object or Collection Type.

Declaration

```
// C#
public interface IOracleCustomType
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## FromCustomObject(OracleConnection, IntPtr)

This interface method creates an Oracle Object or Collection by setting the attribute or element values respectively on the specified Oracle UDT.

### Declaration

```
// C#  
void FromCustomObject(OracleConnection con, IntPtr pUdt);
```

### Parameters

- *con*  
An OracleConnection instance.
- *pUdt*  
An opaque pointer to the Oracle Object or Collection to be created.

### Remarks

The FromCustomObject method is used to build an Oracle Object or Collection from a custom object by setting attribute or element values respectively through the OracleUdt.SetValue method.

The OracleUdt.SetValue method is invoked as follows:

- Oracle Object Type  
For a custom type that represents an Oracle Object Type, the OracleUdt.SetValue method must be invoked for each non-NULL attribute value that needs to be set.
- Oracle Collection Type  
For a custom type that represents an Oracle Collection Type, a single call to OracleUdt.SetValue method specifies the collection element values.

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [IOracleCustomType Interface](#)
- [IOracleCustomType Members](#)

## FromCustomObject(OracleConnection, object)

This interface method creates an Oracle Object or Collection by setting the attribute or element values respectively on the specified Oracle UDT.

### Declaration

```
// C#  
void FromCustomObject(OracleConnection con, object pUdt);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *pUdt*  
An object of Oracle Object or Collection to be created.

### Remarks

The `FromCustomObject` method is used to build an Oracle Object or Collection from a custom object by setting attribute or element values respectively through the `OracleUdt.SetValue` method.

The `OracleUdt.SetValue` method is invoked as follows:

- Oracle Object Type  
For a custom type that represents an Oracle Object Type, the `OracleUdt.SetValue` method must be invoked for each non-NULL attribute value that needs to be set.
- Oracle Collection Type  
For a custom type that represents an Oracle Collection Type, a single call to `OracleUdt.SetValue` method specifies the collection element values.

#### ① See Also

## ToCustomObject(OracleConnection, IntPtr)

This interface initializes a custom object using the specified Oracle UDT.

### Declaration

```
// C#  
void ToCustomObject (OracleConnection con, IntPtr pUdt);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *pUdt*  
An opaque pointer to the Oracle UDT.

### Remarks

The `ToCustomObject` method is used to initialize a custom object from the specified Oracle Object or Collection by retrieving attribute or element values respectively through the `OracleUdt.GetValue` method.

The `OracleUdt.GetValue` method is invoked as follows:

- **Oracle Object Type**  
For a custom type that represents an Oracle Object Type, the `OracleUdt.GetValue` method must be invoked for each attribute value to be retrieved.
- **For a custom type that represents an Oracle Collection Type**, a single call to `OracleUdt.GetValue` method retrieves the collection element values.

 **See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [IOracleCustomType Interface](#)
- [IOracleCustomType Members](#)

## ToCustomObject(OracleConnection, object)

This interface initializes a custom object using the specified Oracle UDT.

### Declaration

```
// C#  
void ToCustomObject (OracleConnection con, object pUdt);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *pUdt*  
An object of the Oracle UDT.

### Remarks

The `ToCustomObject` method is used to initialize a custom object from the specified Oracle Object or Collection by retrieving attribute or element values respectively through the `OracleUdt.GetValue` method.

The `OracleUdt.GetValue` method is invoked as follows:

- **Oracle Object Type**  
For a custom type that represents an Oracle Object Type, the `OracleUdt.GetValue` method must be invoked for each attribute value to be retrieved.
- **For a custom type that represents an Oracle Collection Type**, a single call to `OracleUdt.GetValue` method retrieves the collection element values.

# IOracleCustomTypeFactory Interface

The IOracleCustomTypeFactory interface is used by ODP.NET to create custom objects that represent Oracle Objects or Collections.

Declaration

```
// C#
public interface IOracleCustomTypeFactory
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## CreateObject

This interface method returns a new custom object to represent an Oracle Object or Collection.

**Declaration**

```
// C#  
IOracleCustomType CreateObject();
```

**Return Value**

An IOracleCustomType object.

**Remarks**

The CreateObject method is used to create a new instance of a custom object to represent an Oracle Object or Collection.

# IOracleArrayTypeFactory Interface

The IOracleArrayTypeFactory interface is used by ODP.NET to create arrays that represent Oracle Collections.

Declaration

```
// C#
public interface IOracleArrayTypeFactory
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

- [IOracleArrayTypeFactory Interface Methods](#)

# IOracleArrayTypeFactory Members

IOracleArrayTypeFactory members are listed in the following tables.

IOracleArrayTypeFactory Interface Methods

IOracleArrayTypeFactory interface methods are listed in [Table 16-26](#).

**Table 16-26 IOracleArrayTypeFactory Interface Methods**

| Public Method                     | Description                                                                                                                                   |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CreateArray</a>       | Returns a new array of the specified length to store Oracle Collection elements                                                               |
| <a href="#">CreateStatusArray</a> | Returns a newly allocated OracleUdtStatus array of the specified length that will be used to store the null status of the collection elements |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [IOracleArrayTypeFactory Interface](#)

## IOracleArrayTypeFactory Interface Methods

IOracleArrayTypeFactory Interface methods are listed in [Table 16-27](#).

**Table 16-27 IOracleArrayTypeFactory Interface Methods**

| Public Method                     | Description                                                                                                                                   |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CreateArray</a>       | Returns a new array of the specified length to store Oracle Collection elements                                                               |
| <a href="#">CreateStatusArray</a> | Returns a newly allocated OracleUdtStatus array of the specified length that will be used to store the null status of the collection elements |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [IOracleArrayTypeFactory Interface](#)
- [IOracleArrayTypeFactory Members](#)

## CreateArray

This interface method returns a new array of the specified length to store Oracle Collection elements.

**Declaration**

```
// C#  
Array CreateArray(int numElems);
```

**Parameters**

- *numElems*

The number of collection elements to be returned.

**Return Value**

A `System.Array` object.

**Remarks**

An Oracle Collection Type may be represented in either of the following ways:

- As an array of the appropriate type. The type must be able to represent a collection element.
- As a Custom Type that contains an array of the appropriate type.

In both cases, the `CreateArray` method creates an array of the specified length to store the collection elements.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [IOracleArrayTypeFactory Interface](#)
- [IOracleArrayTypeFactory Members](#)

## CreateStatusArray

This method returns a newly allocated `OracleUdtStatus` array of the specified length that will be used to store the null status of the collection elements.

**Declaration**

```
// C#  
Array CreateStatusArray(int numElems);
```

**Parameters**

- *numElems*

The number of collection elements to be returned.

**Return Value**

A multi-dimensional `OracleUdtStatus` array as a `System.Array`.

**Remarks**

An Oracle Collection Type can be represented in the following ways:

- As an array of the appropriate type. The type must be able to represent a collection element.
- As a Custom Type that contains an array of the appropriate type.

In both cases, the `CreateStatusArray` method creates an `OracleUdtStatus` array of the specified length that stores the null status of the collection elements.

# OracleUdt Class

The `OracleUdt` class defines static methods that are used when converting between Custom Types and Oracle UDTs and vice-versa.

**Class Inheritance**

System.Object  
    System.OracleUdt

**Declaration**

public sealed class OracleUdt

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**Thread Safety**

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

## GetValue

GetValue methods get the attributes or elements from the specified Oracle UDT.

**Overload List for ODP.NET, Unmanaged Driver:**

- [GetValue\(OracleConnection, IntPtr, string\)](#)  
This method gets the attributes or elements from the specified Oracle UDT, using the specified attribute name.
- [GetValue\(OracleConnection, IntPtr, int\)](#)  
This method gets the attribute or elements from the specified Oracle UDT, using the specified index.
- [GetValue\(OracleConnection, IntPtr, string, out object\)](#)  
This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.
- [GetValue\(OracleConnection, IntPtr, int, out object\)](#)  
This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.

**Overload List for ODP.NET, Managed Driver and ODP.NET Core:**

- [GetValue\(OracleConnection, object, string\)](#)  
This method gets the attributes or elements from the specified Oracle UDT, using the specified attribute name.
- [GetValue\(OracleConnection, object, int\)](#)  
This method gets the attribute or elements from the specified Oracle UDT, using the specified index.
- [GetValue\(OracleConnection, object, string, out object\)](#)  
This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.
- [GetValue\(OracleConnection, object, int, out object\)](#)  
This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.

## GetValue(OracleConnection, IntPtr, string)

This method gets the attributes or elements from the specified Oracle UDT, using the specified attribute name.

**Declaration**

```
public static object GetValue(OracleConnection con, IntPtr pUdt, string attrName);
```

**Parameters**

- *con*  
An OracleConnection instance.
- *pUdt*  
A pointer to an Oracle UDT.
- *attrName*  
The case-sensitive name of the attribute to be retrieved. Null is specified for retrieving collection elements from a Custom Type that represents an Oracle Collection.

**Return Value**

An object representing the returned attribute or collection elements.

**Exceptions**

ArgumentException - The specified name is not a valid attribute name.

**Remarks**

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type  
For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.
- Oracle Collection Type  
For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static `Null` property of the type is returned. For attributes that are represented as Nullable

types, for example, `System.String` and `System.Array` Types, null is returned, and for all other remaining built-in types such as `Int32` and `DateTime` `DBNull.Value` is returned.

## GetValue(OracleConnection, IntPtr, int)

This method gets the attribute or elements from the specified Oracle UDT, using the specified index.

### Declaration

```
// C#  
public static object GetValue(OracleConnection con, IntPtr pUdt, int attrIndex,);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *pUdt*  
A pointer to an Oracle UDT.
- *attrIndex*  
The zero-based index of the attribute to be retrieved. For retrieving collection elements from a Custom Type that represents an Oracle Collection, zero must be specified.

### Return Value

An object representing the returned attribute or collection elements.

### Exceptions

`ArgumentOutOfRangeException` - The specified index is not a valid attribute index.

### Remarks

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type  
For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.
- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static `Null` property of the type is returned. For attributes that are represented as Nullable types, for example, `System.String` and `System.Array` Types, null is returned, and for all other remaining built-in types such as `Int32` and `DateTime` `DBNull.Value` is returned.

## GetValue(OracleConnection, IntPtr, string, out object)

This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.

### Declaration

```
// C#  
public static object GetValue(OracleConnection con, IntPtr pUdt, string attrName,  
    out object statusArray);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *pUdt*  
An opaque pointer to an Oracle UDT.
- *attrName*  
The case-sensitive name of the attribute to be retrieved. Null must specified for retrieving collection elements from a Custom Type that represents an Oracle Collection.
- *statusArray*  
The `OracleUdtStatus` array which returns the null status for the retrieved collection elements.

### Return Value

An object representing the returned attribute or collection elements.

### Exceptions

`ArgumentException` - The specified name is not a valid attribute name.

## Remarks

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static `Null` property of the type is returned. For attributes that are represented as Nullable types, for example, `System.String` and `System.Array` Types, null is returned, and for all other remaining built-in types such as `Int32` and `DateTime` `DBNull.Value` is returned.

If the collection being returned is not NULL, the output *statusArray* parameter is populated with the null status for each of the collection elements.

## GetValue(OracleConnection, IntPtr, int, out object)

This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.

### Declaration

```
// C#
public static object GetValue(OracleConnection con, IntPtr pUdt, int attrIndex,
    out object statusArray);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *pUdt*  
An opaque pointer to an Oracle UDT.
- *attrIndex*

The zero-based index of the attribute to be retrieved. For retrieving collection elements from a Custom Type that represents an Oracle Collection, 0 is specified.

- *statusArray*

The `OracleUdtStatus` array which returns the null status for the retrieved collection elements.

### Return Value

An object representing the returned attribute or collection elements.

### Exceptions

`ArgumentOutOfRangeException` - The specified index is not a valid attribute index.

### Remarks

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static `Null` property of the type is returned. For attributes that are represented as Nullable types, for example, `System.String` and `System.Array` Types, null is returned, and for all other remaining built-in types such as `Int32` and `DateTime` `DBNull.Value` is returned.

If the collection being returned is not NULL, the output *statusArray* parameter is populated with the null status for each of the collection elements.

## GetValue(OracleConnection, object, string)

This method gets the attributes or elements from the specified Oracle UDT, using the specified attribute name.

## Declaration

```
public static object GetValue(OracleConnection con, object Udt, string attrName);
```

## Parameters

- *con*  
An `OracleConnection` instance.
- *Udt*  
An object of an Oracle UDT.
- *attrName*  
The case-sensitive name of the attribute to be retrieved. Null is specified for retrieving collection elements from a Custom Type that represents an Oracle Collection.

## Return Value

An object representing the returned attribute or collection elements.

## Exceptions

`ArgumentException` - The specified name is not a valid attribute name.

## Remarks

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the *con* and *Udt* parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type  
For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.
- Oracle Collection Type  
For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static `Null` property of the type is returned. For attributes that are represented as Nullable types, for example, `System.String` and `System.Array` Types, null is returned, and for all other remaining built-in types such as `Int32` and `DateTime` `DBNull.Value` is returned.

If the type of the member is mapped to a .NET Decimal, and `SuppressGetDecimalInvalidCastException` is set to true on `OracleConfiguration`, `OracleConnection`, `OracleDataAdapter`, or `OracleDataReader` associated with the UDT, then it returns a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal.

## GetValue(OracleConnection, object, int)

This method gets the attribute or elements from the specified Oracle UDT, using the specified index.

### Declaration

```
// C#  
public static object GetValue(OracleConnection con, object Udt, int attrIndex,);
```

### Parameters

- *con*  
An OracleConnection instance.
- *Udt*  
An Oracle UDT object.
- *attrIndex*  
The zero-based index of the attribute to be retrieved. For retrieving collection elements from a Custom Type that represents an Oracle Collection, zero must be specified.

### Return Value

An object representing the returned attribute or collection elements.

### Exceptions

ArgumentOutOfRangeException - The specified index is not a valid attribute index.

### Remarks

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the *con* and *Udt* parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type  
For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.
- Oracle Collection Type  
For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static Null property of the type is returned. For attributes that are represented as Nullable types, for example, System.String and System.Array Types, null is returned, and for all other remaining built-in types such as Int32 and DateTime DBNull.Value is returned.

If the type of the member is mapped to a .NET Decimal, and SuppressGetDecimalInvalidCastException is set to true on OracleConfiguration, OracleConnection, OracleDataAdapter, or OracleDataReader associated with the UDT, then it returns a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal.

## GetValue(OracleConnection, object, string, out object)

This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.

### Declaration

```
// C#  
public static object GetValue(OracleConnection con, object Udt, string attrName,  
    out object statusArray);
```

### Parameters

- *con*  
An OracleConnection instance.
- *pUdt*  
An Oracle UDT object.
- *attrName*  
The case-sensitive name of the attribute to be retrieved. Null must specified for retrieving collection elements from a Custom Type that represents an Oracle Collection.
- *statusArray*  
The OracleUdtStatus array which returns the null status for the retrieved collection elements.

### Return Value

An object representing the returned attribute or collection elements.

### Exceptions

ArgumentException - The specified name is not a valid attribute name.

## Remarks

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the `con` and `Udt` parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static `Null` property of the type is returned. For attributes that are represented as Nullable types, for example, `System.String` and `System.Array` Types, null is returned, and for all other remaining built-in types such as `Int32` and `DateTime` `DBNull.Value` is returned.

If the collection being returned is not NULL, the output `statusArray` parameter is populated with the null status for each of the collection elements.

If the type of the member is mapped to a .NET Decimal, and `SuppressGetDecimalInvalidCastException` is set to true on `OracleConfiguration`, `OracleConnection`, `OracleDataAdapter`, or `OracleDataReader` associated with the UDT, then it returns a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal.

## GetValue(OracleConnection, object, int, out object)

This method returns either the elements of the specified collection attribute of the specified Oracle Object or the elements of the specified Oracle Collection.

### Declaration

```
// C#
public static object GetValue(OracleConnection con, object Udt, int attrIndex,
    out object statusArray);
```

### Parameters

- `con`

An `OracleConnection` instance.

- *Udt*

An Oracle UDT object.

- *attrIndex*

The zero-based index of the attribute to be retrieved. For retrieving collection elements from a Custom Type that represents an Oracle Collection, 0 is specified.

- *statusArray*

The `OracleUdtStatus` array which returns the null status for the retrieved collection elements.

### Return Value

An object representing the returned attribute or collection elements.

### Exceptions

`ArgumentOutOfRangeException` - The specified index is not a valid attribute index.

### Remarks

The `IOracleCustomType.ToCustomObject` method invokes `OracleUdt.GetValue` method passing it the *con* and *Udt* parameters. The `OracleUdt.GetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type returned for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type returned is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

In the case of NULL attribute values, the appropriate null representation of the type is returned. For example, for attributes that are represented as Custom Types and Provider Specific Types, the static `Null` property of the type is returned. For attributes that are represented as Nullable types, for example, `System.String` and `System.Array` Types, null is returned, and for all other remaining built-in types such as `Int32` and `DateTime` `DBNull.Value` is returned.

If the collection being returned is not NULL, the output *statusArray* parameter is populated with the null status for each of the collection elements.

If the type of the member is mapped to a .NET Decimal, and `SuppressGetDecimalInvalidCastException` is set to true on `OracleConfiguration`, `OracleConnection`, `OracleDataAdapter`, or `OracleDataReader` associated with the UDT, then it returns a rounded-off 28 or 29 precision Oracle NUMBER value that can be represented as a .NET Decimal.

## IsDBNull

IsDBNull methods indicate whether or not the specified attribute being retrieved is NULL.

**Overload List for ODP.NET, Unmanaged Driver:**

- [IsDBNull\(OracleConnection, IntPtr, string\)](#)  
This method indicates whether or not the attribute being retrieved, specified by OracleConnection, pointer, and attribute name, is NULL.
- [IsDBNull\(OracleConnection, IntPtr, int\)](#)  
This method indicates whether or not the attribute being retrieved, specified by OracleConnection, pointer, and attribute index, is NULL.

**Overload List for ODP.NET, Managed Driver and ODP.NET Core :**

- [IsDBNull\(OracleConnection, object, string\)](#)  
This method indicates whether or not the attribute being retrieved, specified by OracleConnection, UDT, and attribute name, is NULL.
- [IsDBNull\(OracleConnection, object, int\)](#)  
This method indicates whether or not the attribute being retrieved, specified by OracleConnection, UDT, and attribute index, is NULL.

**① See Also**

## IsDBNull(OracleConnection, IntPtr, string)

This method indicates whether or not the attribute being retrieved, specified by OracleConnection, pointer, and attribute name, is NULL.

**Declaration**

```
// C#  
public static bool IsDBNull(OracleConnection con, IntPtr pUdt, string attrName);
```

**Parameters**

- *con*  
An `OracleConnection` instance.
- *pUdt*  
A pointer to an Oracle UDT.
- *attrName*  
The case-sensitive name of the attribute.

**Return Value**

True if the specified attribute is NULL; otherwise, false.

**Exceptions**

`ArgumentException` - The specified name is not a valid attribute name.

**Remarks**

This method is invoked from the `IOracleCustomType.ToCustomObject` method. The *con* and *pUdt* parameter is passed from the `IOracleCustomType.ToCustomObject` method to the `OracleUdt.IsDBNull` method. The *attrName* parameter is case-sensitive.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleUdt Class](#)
- [OracleUdt Members](#)

## IsDBNull(OracleConnection, IntPtr, int)

This method indicates whether or not the attribute being retrieved, specified by `OracleConnection`, pointer, and attribute index, is NULL.

**Declaration**

```
// C#  
public static bool IsDBNull(OracleConnection con, IntPtr pUdt, int attrIndex);
```

**Parameters**

- *con*  
An `OracleConnection` instance.

- *pUdt*  
An opaque pointer to an Oracle UDT.
- *attrIndex*  
The zero-based index of the attribute.

**Return Value**

True if the specified attribute is NULL; otherwise, false.

**Exceptions**

ArgumentOutOfRangeException - The specified index is not a valid attribute index

**Remarks**

This method is invoked from the `IOracleCustomType.ToCustomObject` method. The *con* and *pUdt* parameter is passed from the `IOracleCustomType.ToCustomObject` method to the `OracleUdt.IsDBNull` method.

**See Also**

- "[Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces](#)"
- [OracleUdt Class](#)

## IsDBNull(OracleConnection, object, string)

This method indicates whether or not the attribute being retrieved, specified by `OracleConnection`, UDT, and attribute name, is NULL.

**Declaration**

```
// C#  
public static bool IsDBNull(OracleConnection con, object Udt, string attrName);
```

**Parameters**

- *con*  
An `OracleConnection` instance.
- *Udt*  
An Oracle UDT.
- *attrName*  
The case-sensitive name of the attribute.

**Return Value**

True if the specified attribute is NULL; otherwise, false.

### Exceptions

`ArgumentException` - The specified name is not a valid attribute name.

### Remarks

This method is invoked from the `IOracleCustomType.ToCustomObject` method. The `con` and `Udt` parameter is passed from the `IOracleCustomType.ToCustomObject` method to the `OracleUdt.IsDBNull` method. The `attrName` parameter is case-sensitive.

## IsDBNull(OracleConnection, object, int)

This method indicates whether or not the attribute being retrieved, specified by `OracleConnection`, UDT, and attribute index, is NULL.

### Declaration

```
// C#  
public static bool IsDBNull(OracleConnection con, object Udt, int attrIndex);
```

### Parameters

- `con`  
An `OracleConnection` instance.
- `pUdt`  
An Oracle UDT object.
- `attrIndex`  
The zero-based index of the attribute.

### Return Value

True if the specified attribute is NULL; otherwise, false.

### Exceptions

`ArgumentOutOfRangeException` - The specified index is not a valid attribute index

### Remarks

This method is invoked from the `IOracleCustomType.ToCustomObject` method. The `con` and `Udt` parameter is passed from the `IOracleCustomType.ToCustomObject` method to the `OracleUdt.IsDBNull` method.

## SetValue

SetValue methods set the attributes or elements on the specified Oracle UDT.

**Overload List for ODP.NET, Unmanaged Driver:**

- [SetValue\(OracleConnection, IntPtr, string, object\)](#)  
This method sets the attribute or elements on the specified Oracle UDT, using the specified attribute name and value.
- [SetValue\(OracleConnection, IntPtr, int, object\)](#)  
This method sets the attribute or elements on the specified Oracle UDT, using the specified index and value.
- [SetValue\(OracleConnection, IntPtr, string, object, object\)](#)  
This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.
- [SetValue\(OracleConnection, IntPtr, int, object, object\)](#)  
This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.

**Overload List for ODP.NET, Managed Driver and ODP.NET Core**

- [SetValue\(OracleConnection, object, string, object\)](#)  
This method sets the attribute or elements on the specified Oracle UDT, using the specified attribute name and value.
- [SetValue\(OracleConnection, object, int, object\)](#)  
This method sets the attribute or elements on the specified Oracle UDT, using the specified index and value.
- [SetValue\(OracleConnection, object, string, object, object\)](#)  
This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.
- [SetValue\(OracleConnection, object, int, object, object\)](#)  
This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleUdt Class](#)
- [OracleUdt Members](#)

## SetValue(OracleConnection, IntPtr, string, object)

This method sets the attribute or elements on the specified Oracle UDT, using the specified attribute name and value.

### Declaration

```
// C#
public static void SetValue(OracleConnection con, IntPtr pUdt, string attrName,
    object value);
```

### Parameters

- *con*  
An OracleConnection instance.
- *pUdt*  
An opaque pointer to an Oracle UDT.
- *attrName*  
The name of the attribute to be set. Specify null for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.

### Exceptions

ArgumentException - The specified value is not of the appropriate type.

### Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type  
For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.
- Oracle Collection Type  
For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## SetValue(OracleConnection, IntPtr, int, object)

This method sets the attribute or elements on the specified Oracle UDT, using the specified index and value.

### Declaration

```
// C#  
public static void SetValue(OracleConnection con, IntPtr pUdt, int attrIndex, object  
value);
```

### Parameters

- *con*  
An OracleConnection instance.
- *pUdt*  
An opaque pointer to an Oracle UDT.
- *attrIndex*  
The index of the attribute to be set. Specify 0 for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.

### Exceptions

ArgumentException - The specified value is not of the appropriate type.

### Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type  
For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.
- Oracle Collection Type  
For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

## SetValue(OracleConnection, IntPtr, string, object, object)

This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.

### Declaration

```
// C#
public static void SetValue(OracleConnection con, IntPtr pUdt, string attrName,
    object value, object statusArray);
```

### Parameters

- *con*  
An OracleConnection instance.
- *pUdt*  
An opaque pointer to an Oracle UDT.
- *attrName*  
The name of the attribute to be set. Specify null for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.
- *statusArray*  
The null status for the collection elements.

### Exceptions

ArgumentException - The specified value is not of the appropriate type.

### Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type  
For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.
- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

## SetValue(OracleConnection, IntPtr, int, object, object)

This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.

### Declaration

```
// C#  
public static void SetValue(OracleConnection con, IntPtr pUdt, int attrIndex,  
    object value, object statusArray);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *pUdt*  
An opaque pointer to an Oracle UDT.
- *attrIndex*  
The index of the attribute to be set. Specify 0 for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.
- *statusArray*  
The null status for the collection elements.

### Exceptions

`ArgumentException` - The specified value is not of the appropriate type.

### Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *pUdt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

## SetValue(OracleConnection, object, string, object)

This method sets the attribute or elements on the specified Oracle UDT, using the specified attribute name and value.

### Declaration

```
// C#
public static void SetValue(OracleConnection con, object Udt, string attrName,
    object value);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *Udt*  
An Oracle UDT object.
- *attrName*  
The name of the attribute to be set. Specify null for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.

### Exceptions

`ArgumentException` - The specified value is not of the appropriate type.

### Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *Udt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

## SetValue(OracleConnection, object, int, object)

This method sets the attribute or elements on the specified Oracle UDT, using the specified index and value.

### Declaration

```
// C#
public static void SetValue(OracleConnection con, object Udt, int attrIndex, object value);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *Udt*  
An Oracle UDT object.
- *attrIndex*  
The index of the attribute to be set. Specify 0 for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.

### Exceptions

`ArgumentException` - The specified value is not of the appropriate type.

### Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *Udt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

## SetValue(OracleConnection, object, string, object, object)

This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.

### Declaration

```
// C#
public static void SetValue(OracleConnection con, object Udt, string attrName,
    object value, object statusArray);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *Udt*  
An Oracle UDT object.
- *attrName*  
The name of the attribute to be set. Specify null for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.
- *statusArray*  
The null status for the collection elements.

### Exceptions

`ArgumentException` - The specified value is not of the appropriate type.

## Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *Udt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute name is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

## SetValue(OracleConnection, object, int, object, object)

This method sets either the specified collection attribute of the specified Oracle Object or elements of the specified Oracle Collection, to the specified value using the supplied null status of the collection elements.

### Declaration

```
// C#
public static void SetValue(OracleConnection con, object Udt, int attrIndex,
    object value, object statusArray);
```

### Parameters

- *con*  
An `OracleConnection` instance.
- *Udt*  
An Oracle UDT object.
- *attrIndex*  
The index of the attribute to be set. Specify 0 for setting collection elements from a Custom Type that represents an Oracle Collection.
- *value*  
The attribute or collection value to be set.
- *statusArray*  
The null status for the collection elements.

### Exceptions

ArgumentException - The specified value is not of the appropriate type.

### Remarks

The `IOracleCustomType.FromCustomObject` method invokes `OracleUdt.SetValue` method passing it the *con* and *Udt* parameters. The `OracleUdt.SetValue` method returns these types of object:

- Oracle Object Type

For a Custom Type that represents an Oracle Object Type, the type accepted for a specified attribute index is the type of the member in the custom class or struct that is mapped to the attribute using the `OracleObjectMappingAttribute` object.

- Oracle Collection Type

For a Custom Type that represents an Oracle Collection Type, the type accepted is the type of the member in the custom class or struct to which the `OracleArrayMappingAttribute` object is applied.

## OracleRef Class

An `OracleRef` instance represents an Oracle REF, which references a persistent, standalone, referenceable object that resides in the database. The `OracleRef` object provides methods to insert, update, and delete the Oracle REF.

### Class Inheritance

`System.Object`

`System.MarshalByRefObject`

`Oracle.DataAccess.Types.OracleRef`

### Declaration

```
// C#  
public sealed class OracleRef : MarshalByRefObject, ICloneable, IDisposable,  
    INullable
```

Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

Remarks

If two or more OracleRef objects that refer to the same Oracle object in the database are retrieved through the same OracleConnection, then their operations on the referenced object must be synchronized.

OracleRef Members

OracleRef members are listed in the following tables.

OracleRef Constructors

OracleRef constructors are listed in [Table 16-30](#).

Table 16-30 OracleRef Constructors

| Constructor                            | Description                                                                                                                     |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleRef Constructors</a> | Instantiates a new instance of OracleRef class (Overloaded)<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |

## OracleRef Static Fields

OracleRef static methods are listed in [Table 16-31](#)

**Table 16-31 OracleRef Static Fields**

| Static Field         | Description                                                           |
|----------------------|-----------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an OracleRef instance |

## OracleRef Static Methods

OracleRef static methods are listed in [Table 16-32](#).

**Table 16-32 OracleRef Static Methods**

| Method                 | Description                               |
|------------------------|-------------------------------------------|
| <a href="#">Equals</a> | Inherited from System.Object (Overloaded) |

## OracleRef Instance Properties

OracleRef instance properties are listed in [Table 16-33](#).

**Table 16-33 OracleRef Instance Properties**

| Property                        | Description                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Connection</a>      | References the connection used by the OracleRef                                                                                                   |
| <a href="#">HasChanges</a>      | References the connection used by the OracleRef<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                               |
| <a href="#">IsLocked</a>        | Indicates whether or not the REF is locked                                                                                                        |
| <a href="#">IsNull</a>          | Indicates whether or not the Oracle REF is NULL                                                                                                   |
| <a href="#">ObjectTableName</a> | Returns the fully qualified object table name that is associated with the REF<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| <a href="#">Value</a>           | Returns a .NET representation of this Oracle REF                                                                                                  |

## OracleRef Instance Methods

OracleRef instance methods are listed in [Table 16-34](#).

**Table 16-34 OracleRef Instance Methods**

| Method                  | Description                                                                            |
|-------------------------|----------------------------------------------------------------------------------------|
| <a href="#">Clone</a>   | Clones the REF                                                                         |
| <a href="#">Delete</a>  | Deletes the referenced object from the database<br>See also <a href="#">Table 3-37</a> |
| <a href="#">Dispose</a> | Releases resources allocated for the OracleRef instance                                |
| <a href="#">Equals</a>  | Inherited from System.Object                                                           |

**Table 16-34 (Cont.) OracleRef Instance Methods**

| Method                                   | Description                                                                                                                                            |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Flush</a>                    | Flushes changes made on the REF object to the database<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                             |
| <a href="#">GetCustomObject</a>          | Returns the object that the specified REF references as a custom type (Overloaded)<br>See also <a href="#">Table 3-37</a>                              |
| <a href="#">GetCustomObjectForUpdate</a> | Returns the object that the specified REF references as a custom type (Overloaded)<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i> |
| GetHashCode                              | Inherited from System.Object                                                                                                                           |
| GetType                                  | Inherited from System.Object                                                                                                                           |
| <a href="#">IsEqual</a>                  | Compares two OracleRef objects                                                                                                                         |
| <a href="#">Lock</a>                     | Locks the REF in the database<br><i>Not Available in ODP.NET, Managed Driver and ODP.NET Core</i>                                                      |
| ToString                                 | Inherited from System.Object                                                                                                                           |
| <a href="#">Update</a>                   | Updates the object referenced by the specified REF in the database using the specified custom object<br>See also <a href="#">Table 3-37</a>            |

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)

## OracleRef Constructors

OracleRef constructors instantiate new instances of OracleRef class.

**Overload List:**

- [OracleRef\(OracleConnection, string\)](#)

This constructor creates an instance of the OracleRef class with a connection and a HEX string that represents an REF instance in the database.

*Not Available in ODP.NET, Managed Driver and ODP.NET Core*

- [OracleRef\(OracleConnection, string, string\)](#)

This constructor creates an instance of the OracleRef class using the specified OracleConnection object, user-defined type name, and an object table name

*Not Available in ODP.NET, Managed Driver and ODP.NET Core*

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## OracleRef(OracleConnection, string)

This constructor creates an instance of the `OracleRef` class with a connection and a HEX string that represents an REF instance in the database.

**Declaration**

```
// C#  
public OracleRef(OracleConnection con, string hexStr);
```

**Parameters**

- *con*  
An `OracleConnection` instance.
- *hexStr*  
A HEX string that represents an REF instance in the database.

**Exceptions**

`ArgumentException` - The HEX string does not represent a valid REF in the database.

`ArgumentNullException` - The connection or HEX string is null.

`InvalidOperationException` - The `OracleConnection` object is not open.

**Remarks**

When an `OracleRef` instance is created, it is referenced to a specific table in the database.

The connection must be opened explicitly by the application. `OracleRef` does not open the connection implicitly.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## OracleRef(OracleConnection, string, string)

This constructor creates an instance of the `OracleRef` class using the specified `OracleConnection` object, user-defined type name, and an object table name.

## Declaration

```
// C#  
public OracleRef(OracleConnection con, string udtTypeName, string objTabName);
```

## Parameters

- *con*  
An `OracleConnection` instance.
- *udtTypeName*  
A user-defined type name.
- *objTabName*  
An object table name.

## Exceptions

`ArgumentException` - The object type name or the object table name is not valid.

`ArgumentNullException` - The object type name or the table name is null.

`InvalidOperationException` - The `OracleConnection` object is not open.

## Remarks

When an `OracleRef` instance is created, this `OracleRef` instance is associated with the specific table in the database. In other words, it represents a persistent REF.

This constructor creates a reference to the object table. However, it does not cause any entries to be made in database tables until the object is flushed to the database, that is, until the `OracleRef.Flush` or the `OracleConnection.FlushCache` method is called on the `OracleRef` Connection. Therefore, any operation that attempts to operate on the database copy of the object before flushing the object, such as, lock the object or fetch the latest copy of the object from the database, results in an `OracleException`.

The connection must be opened explicitly by the application. `OracleRef` does not open the connection implicitly.

## OracleRef Static Fields

`OracleRef` static fields are listed in [Table 16-35](#).

Table 16-35 OracleRef Static Fields

| Static Field         | Description                                                           |
|----------------------|-----------------------------------------------------------------------|
| <a href="#">Null</a> | Represents a null value that can be assigned to an OracleRef instance |

 See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

Null

This static field represents a null value that can be assigned to an OracleRef instance.

Declaration

```
// C#  
public static readonly OracleRef Null;
```

### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## Connection

This instance property references the connection used by the OracleRef.

### Declaration

```
// C#  
public OracleConnection Connection{get;}
```

### Property Value

An OracleConnection object associated with the REF.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

Once the Dispose method is invoked, this property is set to null.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## HasChanges

This instance property indicates whether or not the object referenced by the Oracle REF in the object cache has any changes that can be flushed to the database.

### Declaration

```
// C#  
public bool HasChanges {get;}
```

### Property Value

Returns true if the object referenced by the Oracle REF in the object cache has any changes that can be flushed to the database; otherwise, returns false.

### Exceptions

ObjectDisposedException - The object is already disposed.

### Remarks

This property returns true if a copy of the referenced object in the object cache is updated or deleted.

If there is no copy of the referenced object in the object cache, the latest copy of the referenced object in the database is cached in the object cache and false is returned.

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## IsLocked

This instance property indicates whether or not the REF is locked.

### Declaration

```
// C#  
public bool IsLocked {get;}
```

**Property Value**

Returns true if the REF is locked; otherwise returns false.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## IsNull

This instance property indicates whether or not the Oracle REF is NULL.

**Declaration**

```
// C#  
public bool IsNull {get;}
```

**Property Value**

Returns true if the REF is NULL; otherwise, returns false.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

If the Oracle REF is NULL, this property returns true. Otherwise, it returns false.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## ObjectName

This instance property returns the fully-qualified object table name that is associated with the REF.

**Declaration**

```
// C#  
public string ObjectTableName{get;}
```

**Property Value**

A fully-qualified object table name that is associated with the REF.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

The object table name is in the form *schema\_Name.Table\_Name*.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## Value

This instance property returns a .NET representation of this Oracle REF.

**Declaration**

```
// C#  
public string Value{get;}
```

**Property Value**

A .NET representation of the Oracle REF.

**Exceptions**

ObjectDisposedException - The object is already disposed.

**Remarks**

This property returns a HEX string that represents the REF.

The returned string can be used to create a new OracleRef instance by using the OracleRef(OracleConnection, string) constructor.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## Clone

This instance method clones the REF.

### Declaration

```
// C#  
public OracleRef Clone();
```

**Return Value**

A clone of the current instance.

**Implements**

ICloneable

**Exceptions**

InvalidOperationException - The associated connection is not open.

**See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## Delete

This method deletes the referenced object from the database.

**Declaration**

```
// C# - managed and core ODP.NET  
public void Delete();
```

```
// C# - unmanaged ODP.NET  
public void Delete(bool bFlush);
```

**Parameters**

- *bFlush*  
A bool that specifies whether or not the REF is flushed immediately.

**Remarks**

This method marks the specified REF for deletion.

In managed ODP.NET and ODP.NET Core, Delete() has the same behavior as unmanaged ODP.NET Delete(true).

Depending on whether the value of *bFlush* is set to true or false, the following occurs:

- True  
The object referenced by the specified REF is deleted immediately from the database.  
Before flushing objects, it is required that the application has explicitly started a transaction by executing the BeginTransaction method on the OracleConnection object. This is because if the object being flushed has not already been locked by the application, an exclusive lock is obtained implicitly for the object. The lock is only released when the transaction commits or rollbacks.
- False

The object referenced by the REF is not deleted immediately from the database, but only when a subsequent Flush method is invoked for the specified REF or the FlushCache method is invoked on the OracleRef or the FlushCache method is invoked on the OracleRef connection.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)
- OracleConnection ["FlushCache"](#)

## Dispose

This instance method releases resources allocated for the OracleRef instance.

#### Declaration

```
// C#  
public void Dispose();
```

#### Implements

IDisposable

#### Remarks

The object cannot be reused after it is disposed. Although some properties can still be accessed, their values may not be up-to-date.

#### See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## Flush

This instance method flushes changes made on the REF object to the database, such as updates or deletes.

#### Declaration

```
// C#  
public void Flush();
```

#### Exceptions

InvalidOperationException - The associated connection is not open.

### Remarks

Before flushing objects, it is required that the application has explicitly started a transaction by executing the `BeginTransaction` method on the `OracleConnection` object. This is because if the object being flushed has not already been locked by the application, an exclusive lock is obtained implicitly for the object. The lock is only released when the transaction commits or rollbacks.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)

## GetCustomObject

`GetCustomObject` methods return the object that the specified REF references as a custom type.

### Overload List

- [GetCustomObject\(OracleUdtFetchOption\)](#)  
This method returns the object that the specified REF references as a custom type using the specified fetch option.
- [GetCustomObject\(OracleUdtFetchOption, int\)](#)  
This method returns the object that the specified REF references as a custom type using the specified fetch option and depth level.

*Not supported in ODP.NET, Managed Driver and ODP.NET Core.*

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## GetCustomObject(OracleUdtFetchOption)

This method returns the object that the specified REF references, as a custom type, using the specified fetch option.

### Declaration

```
// C# - managed and core ODP.NET
public object GetCustomObject();
```

```
// C# - unmanaged ODP.NET  
public object GetCustomObject(OracleUdtFetchOption fetchOption);
```

### Parameters

- *fetchOption*  
An `OracleUdtFetchOption` value.

### Return Value

A custom object that represents the object that the specified REF references.

### Exceptions

`InvalidOperationException` - The specified connection is not open, or a valid custom type has not been registered for the type of the referenced object.

### Remarks

This method returns a custom type determined by the UDT mappings on the specified connection.

The connection must be opened explicitly by the application. This method does not open the connection implicitly.

Managed ODP.NET and ODP.NET Core always retrieves the object from the database as it does not have an object cache.

The application can use the `OracleUdtFetchOption` method to control the copy of the Object that is returned according to the specified option:

- `OracleUdtFetchOption.Cache` option  
If this option is specified, and there is a copy of the referenced object in the object cache, it is returned immediately. If no cached copy exists, the latest copy of the referenced object in the database is cached in the object cache and returned.
- `OracleUdtFetchOption.Server` option  
If this option is specified, the latest copy of the referenced object from the database is cached in the object cache and returned. If a copy of the referenced object already exists in the cache, the latest copy overwrites the existing one.
- `OracleUdtFetchOption.TransactionCache` option  
If this option is specified, and a copy of the referenced object is cached in the current transaction, the copy is returned. Otherwise, the latest copy of the referenced object from the database is cached in the object cache and returned. If a copy of the referenced object already exists in the cache, the latest copy overwrites the existing one.  
  
Note that if a cached copy of the referenced object was modified before the current transaction began, that is, if the `OracleRef.HasChanges` property returns `true`, then the `Recent` option returns the cached copy of the referenced object. Outside of a transaction, the `Recent` option behaves like the `Any` option.

## GetCustomObject(OracleUdtFetchOption, int)

This method returns the object that the specified REF references, as a custom type, using the specified fetch option and depth level.

### Declaration

```
// C#  
public object GetCustomObject(OracleUdtFetchOption fetchOption, int depthLevel);
```

### Parameters

- *fetchOption*  
An `OracleUdtFetchOption` value.
- *depthLevel*  
The number of levels to be fetched for nested REF attributes.

### Return Value

A custom object that represents the object that the specified REF references.

### Exceptions

`InvalidOperationException` - The specified connection is not open, or a valid custom type has not been registered for the type of the referenced object.

### Remarks

This method returns a custom type determined by the UDT mappings on the specified connection.

If the object that the REF references contains nested REF attributes, the *depthLevel* can be specified to optimize the subsequent object retrieval. The value of *depthLevel* determines the number of levels that are optimized.

For example, if the *depthLevel* is specified as two, the optimization is applied to all top-level nested REF attributes in the object being fetched and also to all nested REF attributes within the objects referenced by the top-level nested REF attributes.

The connection must be opened explicitly by the application. This method does not open the connection implicitly.

The application can use the `OracleUdtFetchOption` method to control the copy of the Object that is returned according to the specified option:

- `OracleUdtFetchOption.Cache` option

If this option is specified, and there is a copy of the referenced object in the object cache, it is returned immediately. If no cached copy exists, the latest copy of the referenced object in the database is cached in the object cache and returned.

- `OracleUdtFetchOption.Server` option

If this option is specified, the latest copy of the referenced object from the database is cached in the object cache and returned. If a copy of the referenced object already exists in the cache, the latest copy overwrites the existing one.

- `OracleUdtFetchOption.TransactionCache` option

If this option is specified, and a copy of the referenced object is cached in the current transaction, the copy is returned. Otherwise, the latest copy of the referenced object from the database is cached in the object cache and returned. If a copy of the referenced object already exists in the cache, the latest copy overwrites the existing one.

Note that if a cached copy of the referenced object was modified before the current transaction began, that is, if the `OracleRef.HasChanges` property returns `true`, then the `Recent` option returns the cached copy of the referenced object. Outside of a transaction, the `Recent` option behaves like the `Any` option.

## GetCustomObjectForUpdate

`GetCustomObjectForUpdate` methods return the object that the specified REF references as a custom type.

- [GetCustomObjectForUpdate\(bool\)](#)

This method locks the specified REF in the database and returns the object that the specified REF references as a custom type using the specified wait option.

*Not supported in ODP.NET, Managed Driver and ODP.NET Core.*

- [GetCustomObjectForUpdate\(bool, int\)](#)

This method locks the specified REF in the database and returns the object that the specified REF references as a custom type using the specified wait option and depth level.

*Not supported in ODP.NET, Managed Driver and ODP.NET Core.*

### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## GetCustomObjectForUpdate(bool)

This method locks the specified REF in the database and returns the object that the specified REF references, as a custom type, using the specified wait option.

### Declaration

```
// C#  
public object GetCustomObjectForUpdate(bool bWait);
```

### Parameters

- *bWait*

Specifies if the REF is to be locked with the no-wait option. If wait is set to true, this method invocation does not return until the REF is locked.

### Return Value

A custom object that represents the object that the specified REF references.

### Exceptions

*InvalidOperationException* - The specified connection is not open, or a valid custom type has not been registered for type of the referenced object.

*OracleException* - *bWait* is set to false, and the lock cannot be acquired.

### Remarks

This method returns the latest copy of the referenced object, as a custom type, determined by the custom types registered on the *OracleRef* connection.

To be able to release the lock on the REF appropriately after flushing the REF using the *Flush* method on the *OracleRef* or *FlushCache* method on the *OracleConnection*, the application must commit or rollback the transaction. Therefore, it is required that, before invoking this method, a transaction is explicitly started by executing the *BeginTransaction* method on the *OracleConnection* object.

This method makes a network round-trip to lock the REF in the database. After this call, programmers can modify the associated row object exclusively. Then a call to the *Flush* method on the *OracleRef* or *FlushCache* method on the *OracleConnection* flushes the changes to the database.

If true is passed, this method blocks until the lock can be acquired. If false is passed, this method immediately returns. If the lock cannot be acquired, an *OracleException* is thrown.

The connection must be opened explicitly by the application. This method does not open the connection implicitly.

**① See Also**

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## GetCustomObjectForUpdate(bool, int)

This method locks the specified REF in the database and returns the object that the specified REF references, as a custom type, using the specified wait option and depth level

### Declaration

```
public object GetCustomObjectForUpdate(bool bWait, int depthLevel);
```

### Parameters

- *bWait*  
A boolean value that specifies if the REF is to be locked with the no-wait option. If wait is set to true, this method invocation does not return until the REF is locked.
- *depthLevel*  
The number of levels to be fetched for nested REF attributes.

### Return Value

A custom object that represents the object that the specified REF references.

### Exceptions

`InvalidOperationException` - The specified connection is not open, or a valid custom type has not been registered for type of the referenced object.

`OracleException` - *bWait* is set to false, and the lock cannot be acquired.

### Remarks

This method returns the latest copy of the referenced object, as a custom type, determined by the custom types registered on the `OracleRef` connection.

To be able to release the lock on the REF appropriately after flushing the REF using the `Flush` method on the `OracleRef` or `FlushCache` method on the `OracleConnection`, the application must commit or rollback the transaction. Therefore, it is required that, before invoking this method, a transaction is explicitly started by executing the `BeginTransaction` method on the `OracleConnection` object.

This method makes a network round-trip to lock the REF in the database. After this call, programmers can modify the associated row object exclusively. Then a call to the `Flush` method on the `OracleRef` or `FlushCache` method on the `OracleConnection` flushes the changes to the database.

If `true` is passed, this method blocks until the lock can be acquired. If `false` is passed, this method immediately returns. If the lock cannot be acquired, an `OracleException` is thrown.

If the object that the REF references contains nested REF attributes, the *depthLevel* can be specified to optimize the subsequent object retrieval. The value of *depthLevel* determines the number of levels that are optimized.

For example, if the *depthLevel* is specified as 2, the optimization is applied to all top-level nested REF attributes in the object being fetched and also to all nested REF attributes within the objects referenced by the top-level nested REF attributes.

The connection must be opened explicitly by the application. This method does not open the connection implicitly.

## IsEqual

This instance method compares two OracleRef objects.

#### Declaration

```
// C#  
public bool IsEqual(OracleRef oraRef);
```

#### Parameters

- *oraRef*  
The provided OracleRef object.

#### Return Value

bool

#### Remarks

This instance method returns true if the OracleRef instance and the OracleRef parameter both reference the same object. Otherwise, it returns false.

#### ① See Also

- ["Oracle.DataAccess.Types and Oracle.ManagedDataAccess.Types Namespaces"](#)
- [OracleRef Class](#)
- [OracleRef Members](#)

## Lock

This instance method locks the REF in the database.

## Declaration

```
// C#  
public bool Lock(bool bWait);
```

## Parameters

- *bWait*

Specifies if the lock is set to the no-wait option. If *bWait* is set to `true`, the method invocation does not return until the REF is locked.

## Return Value

A boolean value that indicates whether or not the lock has been acquired.

## Exceptions

`InvalidOperationException` - The associated connection is not open.

`ObjectDisposedException` - The object is already disposed.

## Remarks

In order for the application to release the lock on the REF appropriately after the `Flush` invocation on the `OracleRef` or `FlushCache` methods, the application must commit or rollback the transaction. Therefore, it is required that, before invoking a lock on an `OracleRef` object, a transaction is explicitly started by executing the `BeginTransaction` method on the `OracleConnection` object.

This instance method makes a network round-trip to lock the REF in the database. After this call, programmers can modify the attribute values of the associated row object exclusively. Then a call to the `Flush` instance method on the `OracleRef` or `FlushCache` method on the `OracleConnection` flushes the changes to the database.

If `true` is passed, this method blocks, that is, does not return, until the lock is acquired. Consequently, the return value is always `true`.

If `false` is passed, this method immediately returns. The return value indicates `true` if the lock is acquired, and `false` if it is not.

## Update

This method updates the object referenced by the specified REF in the database using the specified custom object.

## Declaration

```
// C# - managed and core ODP.NET
public void Update(object customObject);

// C# - unmanaged ODP.NET
public void Update(object customObject, bool bFlush);
```

## Parameters

- *customObject*  
The custom object used to update the referenced object.
- *bFlush*  
A boolean that specifies if the changes must be flushed immediately. If *bFlush* is set to true, this method invocation flushes the changes immediately.

## Exceptions

`InvalidOperationException` - The specified connection is not open or the custom object does not map to the type of referenced object.

## Remarks

This method marks the specified REF for update. In managed ODP.NET and ODP.NET Core, `Update(customObject)` has the same behavior as unmanaged ODP.NET `Update(customObject, true)`. Depending on whether the value of *bFlush* is set to true or false, the following occurs:

- **True**  
The object referenced by the specified REF is updated immediately in the database.  
Before flushing objects, it is required that the application has explicitly started a transaction by executing the `BeginTransaction` method on the `OracleConnection` object. This is because if the object being flushed has not already been locked by the application, an exclusive lock is obtained implicitly for the object. The lock is only released when the transaction commits or rollbacks.
- **False**  
The object referenced by the REF is not updated immediately in the database, but only when a subsequent `Flush` method is invoked for the specified REF or the `FlushCache` method is invoked for the specified connection.

The connection must be opened explicitly by the application. This method does not open the connection implicitly.

## OracleUdtFetchOption Enumeration

OracleUdtFetchOption enumeration values specify how to retrieve a copy of the referenceable object.

[Table 16-39](#) lists all the OracleUdtFetchOption enumeration values with a description of each enumerated value.

**Table 16-39 OracleUdtFetchOption Enumeration Values**

| Member Name      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cache            | If there is a copy of the referenced object in the object cache, it is returned immediately. If no cached copy exists, the latest copy of the referenced object in the database is cached in the object cache and returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server           | The latest copy of the referenced object from the database is cached in the object cache and returned. If a copy of the referenced object already exists in the cache, the latest copy overwrites the existing one.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TransactionCache | <p>If a copy of the referenced object is cached in the current transaction, the copy is returned. Otherwise, the latest copy of the referenced object from the database is cached in the object cache and returned. If a copy of the referenced object already exists in the cache, the latest copy overwrites the existing one.</p> <p>Note that if a cached copy of the referenced object was modified before the current transaction began, that is, if the <code>OracleRef.HasChanges</code> property returns <code>true</code>, then the <code>Recent</code> option returns the cached copy of the referenced object. Outside of a transaction, the <code>Recent</code> option behaves like the <code>Any</code> option.</p> |

## OracleUdtStatus Enumeration

OracleUdtStatus enumeration values specify the status of an object attribute or collection element. An object attribute or a collection element can be a valid value or a null value.

[Table 16-40](#) lists all the OracleUdtStatus enumeration values with a description of each enumerated value:

**Table 16-40 OracleUdtStatus Enumeration Values**

| Member Name | Description                                                       |
|-------------|-------------------------------------------------------------------|
| Null        | Indicates that an object attribute or collection element is NULL. |

Table 16-40 (Cont.) OracleUdtStatus Enumeration Values

| Member Name | Description                                                                            |
|-------------|----------------------------------------------------------------------------------------|
| NotNull     | Indicates that a non-NULL value exists for the object attribute or collection element. |

# Oracle Data Provider for .NET Bulk Copy Classes

This chapter describes Oracle Data Provider for .NET support for Bulk Copy operations.

**Note**

Oracle Data Provider for .NET bulk copy operations do not support loading of UDT type columns.

This chapter includes the following topics:

- [OracleBulkCopy Class](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyOptions Enumeration](#)
- [OracleRowsCopiedEventHandler Delegate](#)
- [OracleRowsCopiedEventArgs Class](#)

## OracleBulkCopy Class

An OracleBulkCopy object efficiently bulk loads or copies data into an Oracle table from another data source.

**Class Inheritance**

System.Object  
    System.OracleBulkCopy

**Declaration**

```
// C#
public sealed class OracleBulkCopy : IDisposable
```

**Requirements**

| Provider  | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------|---------------------------------|---------------------------------|
| Assembly  | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.DataAccess.Client  | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

The OracleBulkCopy class can be used to write data to Oracle database tables only. However, the data source is not limited to Oracle databases; any data source can be used, as long as the data can be loaded to a DataTable instance or read with an IDataReader instance.

Bulk copy of string data to destination number column is currently not supported.

## OracleBulkCopy Members

OracleBulkCopy members are listed in the following tables.

### OracleBulkCopy Constructors

OracleBulkCopy constructors are listed in [Table 17-1](#).

**Table 17-1 OracleBulkCopy Constructors**

| Constructor                                 | Description                                                                  |
|---------------------------------------------|------------------------------------------------------------------------------|
| <a href="#">OracleBulkCopy Constructors</a> | OracleBulkCopy constructors create new instances of the OracleBulkCopy class |

### OracleBulkCopy Properties

OracleBulkCopy properties are listed in [Table 17-2](#).

**Table 17-2 OracleBulkCopy Properties**

| Property                                 | Description                                                                                                                |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">BatchSize</a>                | Specifies the number of rows to be sent as a batch to the database                                                         |
| <a href="#">BulkCopyOptions</a>          | Specifies the <code>OracleBulkCopyOptions</code> enumeration value that determines the behavior of the bulk copy operation |
| <a href="#">BulkCopyTimeout</a>          | Specifies the number of seconds allowed for the bulk copy operation to complete before it is aborted                       |
| <a href="#">ColumnMappings</a>           | Specifies the column mappings between the data source and destination table                                                |
| <a href="#">Connection</a>               | Specifies the <code>OracleConnection</code> object that the Oracle database uses to perform the bulk copy operation        |
| <a href="#">DestinationPartitionName</a> | Specifies the database partition that the data is loaded into                                                              |
| <a href="#">DestinationSchemaName</a>    | Specifies the database schema that the data is loaded into                                                                 |
| <a href="#">DestinationTableName</a>     | Specifies the database table that the data is loaded in                                                                    |
| <a href="#">NotifyAfter</a>              | Defines the number of rows to be processed before a notification event is generated                                        |

### OracleBulkCopy Public Methods

OracleBulkCopy public methods are listed in [Table 17-3](#).

**Table 17-3 OracleBulkCopy Public Methods**

| Method                        | Description                                              |
|-------------------------------|----------------------------------------------------------|
| <a href="#">Close</a>         | Closes the <code>OracleBulkCopy</code> instance          |
| <a href="#">Dispose</a>       | Releases any resources or memory allocated by the object |
| <a href="#">WriteToServer</a> | Copies rows to a destination table                       |

### OracleBulkCopy Events

OracleBulkCopy events are listed in [Table 17-4](#).

**Table 17-4 OracleBulkCopy Events**

| Event                            | Description                                                                                                                  |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleRowsCopied</a> | Triggered every time the number of rows specified by the <code>OracleBulkCopy.NotifyAfter</code> property has been processed |

## OracleBulkCopy Constructors

OracleBulkCopy constructors create new instances of the OracleBulkCopy class.

### Overload List:

- [OracleBulkCopy\(OracleConnection\)](#)  
This constructor instantiates a new instance of OracleBulkCopy class using the specified connection and default value for OracleBulkCopyOptions.
- [OracleBulkCopy\(string\)](#)  
This constructor instantiates a new instance of OracleBulkCopy based on the supplied *connectionString* and default value for OracleBulkCopyOptions.
- [OracleBulkCopy\(OracleConnection, OracleBulkCopyOptions\)](#)  
This constructor instantiates a new instance of OracleBulkCopy using the specified connection object and OracleBulkCopyOptions value.
- [OracleBulkCopy\(string, OracleBulkCopyOptions\)](#)  
This constructor instantiates a new instance of OracleConnection based on the supplied *connectionString* and OracleBulkCopyOptions value.

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## OracleBulkCopy(OracleConnection)

This constructor instantiates a new instance of OracleBulkCopy class using the specified connection and default OracleBulkCopyOptions enumeration values.

### Declaration

```
// C#  
public OracleBulkCopy(OracleConnection connection);
```

### Parameters

- *connection*  
The open instance of OracleConnection that performs the bulk copy operation.

### Exceptions

ArgumentNullException - The connection parameter is null.

InvalidOperationException - The connection is not in the open state.

### Remarks

The connection object passed to this constructor must be open. It remains open after the `OracleBulkCopy` instance is closed.

This constructor uses the default enumeration value `OracleBulkCopyOptions.Default`.

The `Connection` property is set to the supplied connection.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)
- ["OracleBulkCopyOptions Enumeration"](#)

## OracleBulkCopy(string)

This constructor instantiates a new instance of the `OracleBulkCopy` class by first creating an `OracleConnection` object based on the supplied *connectionString*, then initializing the new `OracleBulkCopy` object with the `OracleConnection` object and `OracleBulkCopyOptions` default value.

### Declaration

```
// C#  
public OracleBulkCopy(string connectionString);
```

### Parameters

- *connectionString*

The connection information used to connect to the Oracle database and perform the bulk copy operation.

### Exception

`ArgumentNullException` - The *connectionString* parameter is null.

`ArgumentException` - The *connectionString* parameter is empty.

### Remarks

The `WriteToServer` method opens the connection, if it is not already opened. The connection is automatically closed when the `OracleBulkCopy` instance is closed.

This constructor uses the default enumeration value `OracleBulkCopyOptions.Default`.

The `Connection` property is set to the `OracleConnection` object initialized using the supplied *connectionString*.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)
- ["OracleBulkCopyOptions Enumeration"](#)

## OracleBulkCopy(OracleConnection, OracleBulkCopyOptions)

This constructor instantiates a new instance of `OracleBulkCopy` using the specified connection object and `OracleBulkCopyOptions` value.

### Declaration

```
// C#  
public OracleBulkCopy(OracleConnection connection, OracleBulkCopyOptions  
    copyOptions);
```

### Parameters

- *connection*  
The open instance of an `OracleConnection` object that performs the bulk copy operation.
- *copyOptions*  
The combination of `OracleBulkCopyOptions` enumeration values that determine the behavior of the `OracleBulkCopy` object.

### Exceptions

`ArgumentNullException` - The *connection* parameter is null.

`InvalidOperationException` - The connection is not in the open state.

### Remarks

The connection passed to this constructor must be open. It remains open after the `OracleBulkCopy` instance is closed.

The `Connection` property is set to the supplied connection.

### ① See Also

- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)
- ["OracleBulkCopyOptions Enumeration"](#)

## OracleBulkCopy(string, OracleBulkCopyOptions)

This constructor instantiates a new instance of the `OracleBulkCopy` class by first creating an `OracleConnection` object based on the supplied *connectionString*, then initializing the new `OracleBulkCopy` object with the `OracleConnection` object and the supplied `OracleBulkCopyOptions` enumeration values.

### Declaration

```
// C#  
public OracleBulkCopy(string connectionString, OracleBulkCopyOptions copyOptions);
```

### Parameters

- *connectionString*  
The connection information used to connect to the Oracle database to perform the bulk copy operation.
- *copyOptions*  
The combination of `OracleBulkCopyOptions` enumeration values that determine the behavior of the bulk copy operation.

### Exceptions

`ArgumentNullException` - The *connectionString* is null.

`ArgumentException` - The *connectionString* parameter is empty.

### Remarks

The constructor uses the new instance of the `OracleConnection` class to initialize a new instance of the `OracleBulkCopy` class. The `OracleBulkCopy` instance behaves according to options supplied in the *copyOptions* parameter.

The connection is automatically closed when the `OracleBulkCopy` instance is closed.

The `Connection` property is set to an `OracleConnection` object initialized using the supplied *connectionString*.

## OracleBulkCopy Properties

`OracleBulkCopy` properties are listed in [Table 17-5](#).

**Table 17-5 OracleBulkCopy Properties**

| Property                                 | Description                                                                                                                |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">BatchSize</a>                | Specifies the number of rows to be sent as a batch to the database                                                         |
| <a href="#">BulkCopyOptions</a>          | Specifies the <code>OracleBulkCopyOptions</code> enumeration value that determines the behavior of the bulk copy operation |
| <a href="#">BulkCopyTimeout</a>          | Specifies the number of seconds allowed for the bulk copy operation to complete before it is aborted                       |
| <a href="#">ColumnMappings</a>           | Specifies the column mappings between the data source and destination table                                                |
| <a href="#">Connection</a>               | Specifies the <code>OracleConnection</code> object that the Oracle database uses to perform the bulk copy operation        |
| <a href="#">DestinationPartitionName</a> | Specifies the database partition that the data is loaded into                                                              |
| <a href="#">DestinationSchemaName</a>    | Specifies the database schema that the data is loaded into                                                                 |
| <a href="#">DestinationTableName</a>     | Specifies the database table that the data is loaded in                                                                    |
| <a href="#">NotifyAfter</a>              | Defines the number of rows to be processed before a notification event is generated                                        |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## BatchSize

This property specifies the number of rows to be sent as a batch to the database.

**Declaration**

```
// C#  
public int BatchSize {get; set;}
```

**Property Value**

An integer value for the number of rows to be sent to the database as a batch.

**Exceptions**

`ArgumentOutOfRangeException` - The batch size is less than zero.

**Remarks**

The default value is zero, indicating that the rows are not sent to the database in batches. The entire set of rows are sent in one single batch.

A large batch size reduces database round trips, but it can also consume large amounts of client side memory. Excessive memory consumption slows down overall machine performance

and leads to errors if the process runs out of accessible memory. It is recommended that client side memory is not consumed in excess. This can be done by reducing the batch size.

A batch is complete when BatchSize number of rows have been processed or there are no more rows to send to the database.

- If BatchSize > 0 and the UseInternalTransaction bulk copy option is specified, each batch of the bulk copy operation occurs within a transaction. If the connection used to perform the bulk copy operation is already part of a transaction, an `InvalidOperationException` exception is raised.
- If BatchSize > 0 and the UseInternalTransaction option is not specified, rows are sent to the database in batches of size BatchSize, but no transaction-related action is taken.

The BatchSize property can be set at any time. If a bulk copy is already in progress, the current batch size is determined by the previous batch size. Subsequent batches use the new batch size.

If the BatchSize property is initially zero and changes while a `WriteToServer` operation is in progress, that operation loads the data as a single batch. Any subsequent `WriteToServer` operations on the same `OracleBulkCopy` instance use the new BatchSize.

- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)
- ["OracleBulkCopyOptions Enumeration"](#)

## BulkCopyOptions

This property specifies the `OracleBulkCopyOptions` enumeration value that determines the behavior of the bulk copy option.

### Declaration

```
// C#  
public OracleBulkCopyOptions BulkCopyOptions {get; set;}
```

### Property Value

The `OracleBulkCopyOptions` enumeration object that defines the behavior of the bulk copy operation.

### Exceptions

`ArgumentNullException` - The bulk copy options set is null.

### Remarks

The default value of this property is `OracleBulkCopyOptions.Default` value. This property can be used to change the bulk copy options between the batches of a bulk copy operation.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)
- ["OracleBulkCopyOptions Enumeration"](#)

## BulkCopyTimeout

This property specifies the number of seconds allowed for the bulk copy operation to complete before it is aborted.

### Declaration

```
// C#  
public int BulkCopyTimeout {get; set;}
```

### Property Value

An integer value for the number of seconds after which the bulk copy operation times out.

### Exceptions

ArgumentOutOfRangeException - The timeout value is set to less than zero.

### Remarks

The default value is 30 seconds.

If BatchSize>0, rows that were sent to the database in the previous batches remain committed. The rows that are processed in the current batch are not sent to the database. If BatchSize=0, no rows are sent to the database.

## ColumnMappings

This property specifies the column mappings between the data source and destination table.

### Declaration

```
// C#  
public OracleBulkCopyColumnMappingCollection ColumnMappings {get;}
```

### Property Value

The `OracleBulkCopyColumnMappingCollection` object that defines the column mapping between the source and destination table.

### Remarks

The `ColumnMappings` collection is unnecessary if the data source and the destination table have the same number of columns, and the ordinal position of each source column matches the ordinal position of the corresponding destination column. However, if the column counts differ, or the ordinal positions are not consistent, the `ColumnMappings` collection must be used to ensure that data is copied into the correct columns.

During the execution of a bulk copy operation, this collection can be accessed, but it cannot be changed.

By default, this property specifies an empty collection of column mappings.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## Connection

This property specifies the `OracleConnection` object that the Oracle database uses to perform the bulk copy operation.

### Declaration

```
// C#  
public OracleConnection Connection {get; }
```

### Property Value

The `OracleConnection` object used for the bulk copy operations.

### Remarks

This property gets the connection constructed by the `OracleBulkCopy`, if the `OracleBulkCopy` object is initialized using a connection string.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## DestinationPartitionName

This property specifies the database partition that the data is loaded into.

### Declaration

```
// C#  
public string DestinationPartitionName {get; set;}
```

### Property Value

A string value that identifies the destination partition name.

### Remarks

If `DestinationPartitionName` is modified while a `WriteToServer` operation is running, the change does not affect the current operation. The new `DestinationPartitionName` value is used the next time a `WriteToServer` method is called.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## DestinationSchemaName

This property specifies the database schema that the data is loaded into.

### Declaration

```
// C#  
public string DestinationSchemaName {get; set;}
```

### Property Value

A string value that identifies the destination schema name.

### Remarks

By default, this property is set to the schema or the user associated with the connection used by the `OracleBulkCopy` object. This default can be modified by setting this property to a different destination schema or user name.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## DestinationTableName

This property specifies the database table that the data is loaded into.

### Declaration

```
// C#  
public string DestinationTableName {get; set;}
```

### Property Value

A string value that identifies the destination table name.

### Exceptions

`ArgumentNullException` - The destination table name set is null.

`ArgumentException` - The destination table name is empty.

### Remarks

If `DestinationTableName` is modified while a `WriteToServer` operation is running, the change does not affect the current operation. The new `DestinationTableName` value is used the next time a `WriteToServer` method is called.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## NotifyAfter

This property defines the number of rows to be processed before a notification event is generated.

### Declaration

```
// C#  
public int NotifyAfter {get; set;}
```

### Property Value

An integer value that specifies the number of rows to be processed before the notification event is raised.

### Exceptions

`ArgumentOutOfRangeException` - The property value is set to a number less than zero.

### Remarks

The default value for this property is zero, to specify that no notifications events are to be generated.

This property can be retrieved in user interface components to display the progress of a bulk copy operation. The `NotifyAfter` property can be set at anytime, even during a bulk copy operation. The changes take effect for the next notification and any subsequent operations on the same instance. By ADO.NET design, this property is intended to measure the progress of a bulk copy operation, not when all rows have been processed. To be alerted when all rows have been processed, use `OracleBulkCopyOptions.NotifyAllRowProcessed`.

## OracleBulkCopy Public Methods

OracleBulkCopy methods are listed in [Table 17-6](#).

**Table 17-6 OracleBulkCopy Public Methods**

| Method                        | Description                                              |
|-------------------------------|----------------------------------------------------------|
| <a href="#">Close</a>         | Closes the OracleBulkCopy instance                       |
| <a href="#">Dispose</a>       | Releases any resources or memory allocated by the object |
| <a href="#">WriteToServer</a> | Copies rows to a destination table                       |

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## Close

This method closes the OracleBulkCopy instance.

### Declaration

```
// C#  
public void Close();
```

### Exceptions

`InvalidOperationException` - The Close method was called from a `OracleRowsCopied` event.

### Remarks

After the Close method is called on a OracleBulkCopy object, no other operation can succeed. Calls to the WriteToServer method throw an `InvalidOperationException`. The Close method

closes the connection if the connection was opened by the `OracleBulkCopy` object, that is, if the `OracleBulkCopy` object was created by a constructor that takes a connection string.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## Dispose

This method releases any resources or memory allocated by the object.

#### Declaration

```
// C#  
public void Dispose();
```

#### Implements

`IDisposable`

#### Remarks

After the `Dispose` method is called on the `OracleBulkCopy` object, no other operation can succeed. The connection is closed if the connection was opened by the `OracleBulkCopy` object, that is, if a constructor that takes a connection string created the `OracleBulkCopy` object.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## WriteToServer

`WriteToServer` copies rows to a destination table.

#### Overload List:

- [WriteToServer\(DataRow\[\]\)](#)

This method copies all rows from the supplied `DataRow` array to a destination table specified by the `DestinationTableName` property of the `OracleBulkCopy` object.

- [WriteToServer\(DataTable\)](#)

This method copies all rows in the supplied `DataTable` to a destination table specified by the `DestinationTableName` property of the `OracleBulkCopy` object.

- [WriteToServer\(IDataReader\)](#)

This method copies all rows in the supplied `IDataReader` to a destination table specified by the `DestinationTableName` property of the `OracleBulkCopy` object.

- [WriteToServer\(DataTable, DataRowState\)](#)

This method copies rows that match the supplied row state in the supplied `DataTable` to a destination table specified by the `DestinationTableName` property of the `OracleBulkCopy` object.

- [WriteToServer\(OracleRefCursor\)](#)

This method copies all rows from the specified `OracleRefCursor` to a destination table specified by the `DestinationTableName` property of the `OracleBulkCopy` object.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## WriteToServer(DataRow[])

This method copies all rows from the supplied `DataRow` array to a destination table specified by the `DestinationTableName` property of the `OracleBulkCopy` object.

### Declaration

```
// C#  
public void WriteToServer(DataRow[] rows);
```

### Parameters

- *rows*

An array of `DataRow` objects to be copied to the destination table.

### Exceptions

`ArgumentNullException` - The *rows* parameter is null.

`InvalidOperationException` - The connection is not in an open state.

### Remarks

The `ColumnMappings` collection maps from the `DataRow` columns to the destination database table.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## WriteToServer(DataTable)

This method copies all rows in the supplied DataTable to a destination table specified by the DestinationTableName property of the OracleBulkCopy object.

### Declaration

```
// C#  
public void WriteToServer(DataTable table);
```

### Parameters

- *table*

The source DataTable containing rows to be copied to the destination table.

### Exceptions

ArgumentNullException - The *table* parameter is null.

InvalidOperationException - The connection is not in an open state.

### Remarks

All rows in the DataTable are copied to the destination table except those that have been deleted.

The ColumnMappings collection maps from the DataTable columns to the destination database table.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## WriteToServer(IDataReader)

This method copies all rows in the supplied IDataReader to a destination table specified by the DestinationTableName property of the OracleBulkCopy object.

### Declaration

```
// C#  
public void WriteToServer(IDataReader reader);
```

### Parameters

- *reader*  
A *IDataReader* instance containing rows to be copied to the destination table.

### Exceptions

*ArgumentNullException* - The *reader* parameter is null.

*InvalidOperationException* - The connection is not in an open state.

### Remarks

The bulk copy operation starts with the next available row of the data reader. Typically, the *reader* returned by a call to the *ExecuteReader* method is passed to the *WriteToServer* method so that the next row becomes the first row. To copy multiple result sets, the application must call *NextResult* on the *reader* and then call the *WriteToServer* method again.

This *WriteToServer* method changes the state of the reader as it calls *reader.Read* internally to get the source rows. Thus, at the end of the *WriteToServer* operation, the *reader* is at the end of the result set.

The *ColumnMappings* collection maps from the data reader columns to the destination database table.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## WriteToServer(DataTable, DataRowState)

This method copies rows that match the supplied row state in the supplied *DataTable* to a destination table specified by the *DestinationTableName* property of the *OracleBulkCopy* object.

### Declaration

```
// C#  
public void WriteToServer(DataTable table, DataRowState rowState);
```

### Parameters

- *table*  
A *DataTable* containing rows to be copied to the destination table.
- *rowState*  
The *DataRowState* enumeration value. Only rows matching the row state are copied to the destination.

### Exceptions

ArgumentNullException - The *table* or *rowState* parameter is null.

InvalidOperationException - The connection is not in an open state.

### Remarks

Only rows in the DataTable that are in the state indicated in the *rowState* argument and have not been deleted are copied to the destination table.

The ColumnMappings collection maps from the DataTable columns to the destination database table.

DataRowState.Deleted is not supported and the behavior would be that all the rows except the deleted ones are copied.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## WriteToServer(OracleRefCursor)

This method copies all rows from the specified OracleRefCursor to a destination table specified by the DestinationTableName property of the OracleBulkCopy object.

### Declaration

```
// C#  
public void WriteToServer(OracleRefCursor refCursor);
```

### Parameters

- *refCursor*  
An OracleRefCursor object containing rows to be copied to the destination table.

### Exceptions

ArgumentNullException - The *refCursor* parameter is null

InvalidOperationException - The connection is not in an open state.

### Remarks

The ColumnMappings collection maps from the OracleRefCursor columns to the destination database table.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## OracleBulkCopy Events

OracleBulkCopy events are listed in [Table 17-7](#).

**Table 17-7 OracleBulkCopy Events**

| Event                            | Description                                                                                                                  |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleRowsCopied</a> | Triggered every time the number of rows specified by the <code>OracleBulkCopy.NotifyAfter</code> property has been processed |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopy Class](#)
- [OracleBulkCopy Members](#)

## OracleRowsCopied

This event is triggered every time the number of rows specified by the `OracleBulkCopy.NotifyAfter` property has been processed.

### Declaration

```
// C#  
public event OracleRowsCopiedEventHandler OracleRowsCopied;
```

### Exceptions

`InvalidOperationException` - The `Close` method is called inside this event.

### Remarks

This event is raised when the number of rows specified by the `NotifyAfter` property has been processed. It does not imply that the rows have been sent to the database or committed.

To cancel the operation from this event, use the `Abort` property of `OracleRowsCopiedEventArgs` class.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

# OracleBulkCopyColumnMapping Class

The OracleBulkCopyColumnMapping class defines the mapping between a column in the data source and a column in the destination database table.

### Class Inheritance

System.Object  
    System.OracleBulkCopyColumnMapping

### Declaration

```
// C#  
public sealed class OracleBulkCopyColumnMapping
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

Column mappings define the mapping between data source and the target table.

It is not necessary to specify column mappings for all the columns in the data source. If a ColumnMapping is not specified, then, by default, columns are mapped based on the ordinal position. This succeeds only if the source and destination table schema match. If there is a mismatch, an InvalidOperationException is thrown.

All the mappings in a mapping collection must be by name or ordinal position.

**Note**

Oracle Data Provider for .NET makes one or more round-trips to the database to determine the column name if the mapping is specified by ordinal position. To avoid this performance overhead, specify the mapping by column name.

**Example**

```
// C#
```

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Members](#)
- [OracleBulkCopyColumnMapping Constructors](#)
- [OracleBulkCopyColumnMapping Methods](#)
- [OracleBulkCopyColumnMapping Properties](#)

## OracleBulkCopyColumnMapping Members

OracleBulkCopyColumnMapping members are listed in the following tables.

**OracleBulkCopyColumnMapping Constructors**

The OracleBulkCopyColumnMapping constructors are listed in [Table 17-8](#).

**Table 17-8 OracleBulkCopyColumnMapping Constructors**

| Constructor                                              | Description                                                         |
|----------------------------------------------------------|---------------------------------------------------------------------|
| <a href="#">OracleBulkCopyColumnMapping Constructors</a> | Instantiates new instances of the OracleBulkCopyColumnMapping class |

**OracleBulkCopyColumnMapping Methods**

The OracleBulkCopyColumnMapping method is listed in [Table 17-9](#).

**Table 17-9 OracleBulkCopyColumnMapping Method**

| Constructor               | Description                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a> | Compares the current instance to the supplied object and returns an integer that represents their relative values |

**OracleBulkCopyColumnMapping Properties**

The OracleBulkCopyColumnMapping properties are listed in [Table 17-10](#).

**Table 17-10 OracleBulkCopyColumnMapping Properties**

| Property                           | Description                                                                      |
|------------------------------------|----------------------------------------------------------------------------------|
| <a href="#">DestinationColumn</a>  | Specifies the column name of the destination table that is being mapped          |
| <a href="#">DestinationOrdinal</a> | Specifies the column ordinal value of the destination table that is being mapped |
| <a href="#">SourceColumn</a>       | Specifies the column name of the data source that is being mapped                |
| <a href="#">SourceOrdinal</a>      | Specifies the column ordinal value of the data source that is being mapped       |

**See Also**

- "[Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)"

## OracleBulkCopyColumnMapping Constructors

OracleBulkCopyColumnMapping constructors instantiates new instances of the OracleBulkCopyColumnMapping class.

**Overload List:**

- [OracleBulkCopyColumnMapping\(\)](#)  
This constructor instantiates a new instance of the OracleBulkCopyColumnMapping class
- [OracleBulkCopyColumnMapping\(int, int\)](#)  
This constructor instantiates a new instance of the OracleBulkCopyColumnMapping class using the provided source column ordinal and destination column ordinal.
- [OracleBulkCopyColumnMapping\(int, string\)](#)  
This constructor instantiates a new instance of the OracleBulkCopyColumnMapping class using the provided source column ordinal and destination column name.
- [OracleBulkCopyColumnMapping\(string, int\)](#)  
This constructor instantiates a new instance of the OracleBulkCopyColumnMapping class using the provided source column name and destination column ordinal.
- [OracleBulkCopyColumnMapping\(string, string\)](#)  
This constructor instantiates a new instance of the OracleBulkCopyColumnMapping class using the provided source column name and destination column name.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## OracleBulkCopyColumnMapping()

This constructor instantiates a new instance of the `OracleBulkCopyColumnMapping` class.

### Declaration

```
// C#  
public OracleBulkCopyColumnMapping();
```

### Remarks

Applications that use this constructor must define the source for the mapping using the `SourceColumn` or `SourceOrdinal` property, and must define the destination for the mapping using the `DestinationColumn` or `DestinationOrdinal` property.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## OracleBulkCopyColumnMapping(int, int)

This constructor instantiates a new instance of the `OracleBulkCopyColumnMapping` class using the provided source and destination column ordinal positions.

### Declaration

```
// C#  
public OracleBulkCopyColumnMapping(int sourceColumnOrdinal,  
    int destinationOrdinal);
```

### Parameters

- *sourceColumnOrdinal*  
The ordinal position of the source column within the data source.
- *destinationOrdinal*  
The ordinal position of the destination column within the destination table.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## OracleBulkCopyColumnMapping(int, string)

This constructor instantiates a new instance of the `OracleBulkCopyColumnMapping` class using the provided source column ordinal and destination column name.

**Declaration**

```
// C#  
public OracleBulkCopyColumnMapping(int sourceColumnOrdinal,  
    string destinationColumn);
```

**Parameters**

- *sourceColumnOrdinal*  
The ordinal position of the source column within the data source.
- *destinationColumn*  
The name of the destination column within the destination table.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## OracleBulkCopyColumnMapping(string, int)

This constructor instantiates a new instance of the `OracleBulkCopyColumnMapping` class using the provided source column name and destination column ordinal.

**Declaration**

```
// C#  
public OracleBulkCopyColumnMapping(string sourceColumn, int destinationOrdinal);
```

**Parameters**

- *sourceColumn*  
The name of the source column within the data source.
- *destinationOrdinal*  
The ordinal position of the destination column within the destination table.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## OracleBulkCopyColumnMapping(string, string)

This constructor instantiates a new instance of the `OracleBulkCopyColumnMapping` class using the provided source and destination column names.

**Declaration**

```
// C#
public OracleBulkCopyColumnMapping(string sourceColumn, string destinationColumn);
```

**Parameters**

- *sourceColumn*  
The name of the source column within the data source.
- *destinationColumn*  
The name of the destination column within the destination table.

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## OracleBulkCopyColumnMapping Methods

The `OracleBulkCopyColumnMapping` method is listed in [Table 17-11](#).

**Table 17-11 OracleBulkCopyColumnMapping Method**

| Property                  | Description                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">CompareTo</a> | Compares the current instance to the supplied object and returns an integer that represents their relative values |

① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

CompareTo

This method compares the current instance to the supplied object and returns an integer that represents their relative values.

Declaration

```
// C#
public int CompareTo(object obj);
```

Parameters

obj - The supplied instance.

Return Value

Less than zero: if the value of the current instance is less than obj.  
Zero: if the value of the current instance is equal to obj.  
Greater than zero: if the value of the current instance is greater than obj.

Implements

IComparable

- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

OracleBulkCopyColumnMapping Properties

The OracleBulkCopyColumnMapping properties are listed in [Table 17-12](#).

Table 17-12 OracleBulkCopyColumnMapping Properties

| Property                           | Description                                                                      |
|------------------------------------|----------------------------------------------------------------------------------|
| <a href="#">DestinationColumn</a>  | Specifies the column name of the destination table that is being mapped          |
| <a href="#">DestinationOrdinal</a> | Specifies the column ordinal value of the destination table that is being mapped |

**Table 17-12 (Cont.) OracleBulkCopyColumnMapping Properties**

| Property                      | Description                                                                |
|-------------------------------|----------------------------------------------------------------------------|
| <a href="#">SourceColumn</a>  | Specifies the column name of the data source that is being mapped          |
| <a href="#">SourceOrdinal</a> | Specifies the column ordinal value of the data source that is being mapped |

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## DestinationColumn

This property specifies the column name of the destination table that is being mapped.

**Declaration**

```
// C#  
public string DestinationColumn {get; set;}
```

**Property Value**

A string value that represents the destination column name of the mapping.

**Remarks**

The DestinationColumn and DestinationOrdinal properties are mutually exclusive. The last value set takes precedence.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## DestinationOrdinal

This property specifies the column ordinal value of the destination table that is being mapped.

**Declaration**

```
// C#  
public int DestinationOrdinal {get; set;}
```

**Property Value**

An integer value that represents the destination column ordinal of the mapping.

**Exceptions**

`IndexOutOfRangeException` - The destination ordinal is invalid.

**Remarks**

The `DestinationOrdinal` and `DestinationColumn` properties are mutually exclusive. The last value set takes precedence.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMapping Class](#)
- [OracleBulkCopyColumnMapping Members](#)

## SourceColumn

This property specifies the column name of the data source that is being mapped.

**Declaration**

```
// C#  
public string SourceColumn {get; set;}
```

**Property Value**

A string value that represents the source column name of the mapping.

**Remarks**

The `SourceColumn` and `SourceOrdinal` properties are mutually exclusive. The last value set takes precedence.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## SourceOrdinal

This property specifies the column ordinal value of the data source that is being mapped.

Declaration

```
// C#
public int SourceOrdinal {get; set;}
```

Property Value

An integer value that represents the source column ordinal of the mapping.

Exceptions

IndexOutOfRangeException - The source ordinal is invalid.

Remarks

The SourceOrdinal and SourceColumn properties are mutually exclusive. The last value set takes precedence.

# OracleBulkCopyColumnMappingCollection Class

The OracleBulkCopyColumnMappingCollection class represents a collection of OracleBulkCopyColumnMapping objects that are used to map columns in the data source to columns in a destination table.

Class Inheritance

```
System.Object
    System.CollectionBase
        System.OracleBulkCopyColumnMappingCollection
```

Declaration

```
// C#
public sealed class OracleBulkCopyColumnMappingCollection : CollectionBase
```

Requirements

| Provider  | ODP.NET, Unmanaged Driver | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------|---------------------------------|---------------------------------|
| Assembly  | Oracle.DataAccess.dll     | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.DataAccess.Client  | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

Column mappings define the mapping between data source and the target table.

It is not necessary to specify column mappings for all the columns in the data source. If a ColumnMapping is not specified, then, by default, columns are mapped based on the ordinal position. This succeeds only if the source and destination table schema match. If there is a mismatch, an `InvalidOperationException` is thrown.

All the mappings in a mapping collection must be by name or ordinal position.

#### Note

Oracle Data Provider for .NET makes one or more round-trips to the database to determine the column name if the mapping is specified by ordinal position. To avoid this performance overhead, specify the mapping by column name.

### Example

```
// C#
```

## OracleBulkCopyColumnMappingCollection Members

OracleBulkCopyColumnMappingCollection members are listed in the following tables.

### OracleBulkCopyColumnMappingCollection Properties

The OracleBulkCopyColumnMappingCollection properties are listed in [Table 17-13](#).

**Table 17-13 OracleBulkCopyColumnMappingCollection Properties**

| Property                    | Description                                                                          |
|-----------------------------|--------------------------------------------------------------------------------------|
| <a href="#">Item[index]</a> | Gets or sets the OracleBulkCopyColumnMappingCollection object at the specified index |

**OracleBulkCopyColumnMappingCollection Public Methods**

The OracleBulkCopyColumnMappingCollection public methods are listed in [Table 17-14](#).

**Table 17-14 OracleBulkCopyColumnMappingCollection Public Methods**

| Public Method            | Description                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>      | Adds objects to the collection                                                                                                                   |
| <a href="#">Clear</a>    | Clears the contents of the collection                                                                                                            |
| <a href="#">Contains</a> | Returns a value indicating whether or not a specified OracleBulkCopyColumnMapping object exists in the collection                                |
| <a href="#">CopyTo</a>   | Copies the elements of the OracleBulkCopyColumnMappingCollection to an array of OracleBulkCopyColumnMapping items, starting at a specified index |
| <a href="#">IndexOf</a>  | Returns the index of the specified OracleBulkCopyColumnMapping object                                                                            |
| <a href="#">Insert</a>   | Inserts a new OracleBulkCopyColumnMapping object in the collection, at the index specified.                                                      |
| <a href="#">Remove</a>   | Removes the specified OracleBulkCopyColumnMapping element from the OracleBulkCopyColumnMappingCollection.                                        |
| <a href="#">RemoveAt</a> | Removes the mapping from the collection at the specified index.                                                                                  |

## OracleBulkCopyColumnMappingCollection Properties

The OracleBulkCopyColumnMappingCollection properties are listed in [Table 17-15](#).

**Table 17-15 OracleBulkCopyColumnMappingCollection Properties**

| Property                    | Description                                                                          |
|-----------------------------|--------------------------------------------------------------------------------------|
| <a href="#">Item[index]</a> | Gets or sets the OracleBulkCopyColumnMappingCollection object at the specified index |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Item[index]

This property gets or sets the OracleBulkCopyColumnMapping object at the specified index.

**Declaration**

```
// C#
public OracleBulkCopyColumnMapping this[int index] {get;set;}
```

**Parameters**

- *index*

The zero-based index of the OracleBulkCopyColumnMapping being set or retrieved.

**Property Value**

An OracleBulkCopyColumnMapping object at the specified index.

**Exceptions**

IndexOutOfRangeException - The specified index does not exist.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)

## OracleBulkCopyColumnMappingCollection Public Methods

The OracleBulkCopyColumnMappingCollection public methods are listed in [Table 17-16](#).

**Table 17-16 OracleBulkCopyColumnMappingCollection Public Methods**

| Public Method            | Description                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>      | Adds objects to the collection                                                                                    |
| <a href="#">Clear</a>    | Clears the contents of the collection                                                                             |
| <a href="#">Contains</a> | Returns a value indicating whether or not a specified OracleBulkCopyColumnMapping object exists in the collection |

**Table 17-16 (Cont.) OracleBulkCopyColumnMappingCollection Public Methods**

| Public Method            | Description                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CopyTo</a>   | Copies the elements of the OracleBulkCopyColumnMappingCollection to an array of OracleBulkCopyColumnMapping items, starting at a specified index |
| <a href="#">IndexOf</a>  | Returns the index of the specified OracleBulkCopyColumnMapping object                                                                            |
| <a href="#">Insert</a>   | Inserts a new OracleBulkCopyColumnMapping object in the collection, at the index specified.                                                      |
| <a href="#">Remove</a>   | Removes the specified OracleBulkCopyColumnMapping element from the OracleBulkCopyColumnMappingCollection.                                        |
| <a href="#">RemoveAt</a> | Removes the mapping from the collection at the specified index.                                                                                  |

**See Also**

## Add

Add methods add objects to the collection.

**Overload List:**

- [Add\(OracleBulkCopyColumnMapping\)](#)  
This method adds the supplied OracleBulkCopyColumnMapping object to the collection.
- [Add\(int, int\)](#)  
This method creates and adds an OracleBulkCopyColumnMapping object to the collection using the supplied source and destination column ordinal positions.
- [Add\(int, string\)](#)  
This method creates and adds an OracleBulkCopyColumnMapping object to the collection using the supplied source column ordinal and destination column name.
- [Add\(string, int\)](#)  
This method creates and adds an OracleBulkCopyColumnMapping object to the collection using the supplied source column name and destination column ordinal.
- [Add\(string, string\)](#)  
This method creates and adds an OracleBulkCopyColumnMapping object to the collection using the supplied source and destination column names.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Add(OracleBulkCopyColumnMapping)

This method adds the supplied `OracleBulkCopyColumnMapping` object to the collection.

**Declaration**

```
// C#  
public OracleBulkCopyColumnMapping Add(OracleBulkCopyColumnMapping  
    bulkCopyColumnMapping);
```

**Parameters**

- *bulkCopyColumnMapping*

The `OracleBulkCopyColumnMapping` object that describes the mapping to be added to the collection.

**Exceptions**

`InvalidOperationException` - The bulk copy operation is in progress.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Add(int, int)

This method creates and adds an `OracleBulkCopyColumnMapping` object to the collection using the supplied source and destination column ordinal positions.

**Declaration**

```
// C#  
public OracleBulkCopyColumnMapping Add(int sourceColumnIndex,  
    int destinationColumnIndex);
```

**Parameters**

- *sourceColumnIndex*  
The ordinal position of the source column within the data source.
- *destinationColumnIndex*

The ordinal position of the destination column within the destination table.

### Exceptions

InvalidOperationException - The bulk copy operation is in progress.

### Return Value

The newly created OracleBulkCopyColumnMapping object that was added to the collection.

### Remarks

It is not necessary to specify column mappings for all the columns in the data source. If a ColumnMapping is not specified, then, by default, columns are mapped based on the ordinal position. This succeeds only if the source and destination table schema match. If there is a mismatch, an InvalidOperationException is thrown.

All the mappings in a mapping collection must be by name or ordinal position.

#### Note

Oracle Data Provider for .NET makes one or more round-trips to the database to determine the column name if the mapping is specified by ordinal position. To avoid this performance overhead, specify the mapping by column name.

#### See Also

- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Add(int, string)

This method creates and adds an OracleBulkCopyColumnMapping object to the collection using the supplied source column ordinal and destination column name.

### Declaration

```
// C#  
public OracleBulkCopyColumnMapping Add(int sourceColumnIndex,  
    string destinationColumn);
```

### Parameters

- *sourceColumnIndex*  
The ordinal position of the source column within the data source.
- *destinationColumn*  
The name of the destination column within the destination table.

### Exceptions

InvalidOperationException - The bulk copy operation is in progress.

### Return Value

The newly created OracleBulkCopyColumnMapping object that was added to the collection.

### Remarks

It is not necessary to specify column mappings for all the columns in the data source. If a ColumnMapping is not specified, then, by default, columns are mapped based on the ordinal position. This succeeds only if the source and destination table schema match. If there is a mismatch, an InvalidOperationException is thrown.

All the mappings in a mapping collection must be by name or ordinal position.

#### Note

Oracle Data Provider for .NET makes one or more round trips to the database to determine the column names if the mapping is specified by ordinal resulting in a performance overhead. Therefore, it is recommended to specify the mapping by column names.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)

## Add(string, int)

This method creates and adds an OracleBulkCopyColumnMapping object to the collection using the supplied source column name and destination column ordinal.

### Declaration

```
// C#  
public OracleBulkCopyColumnMapping Add(string sourceColumn,  
    int destinationColumnIndex);
```

### Parameters

- *sourceColumn*  
The name of the source column within the data source.
- *destinationColumnIndex*  
The ordinal position of the destination column within the destination table.

### Return Value

The newly created `OracleBulkCopyColumnMapping` object that was added to the collection.

### Exceptions

`InvalidOperationException` - The bulk copy operation is in progress.

### Remarks

It is not necessary to specify column mappings for all the columns in the data source. If a `ColumnMapping` is not specified, then, by default, columns are mapped based on the ordinal position. This succeeds only if the source and destination table schema match. If there is a mismatch, an `InvalidOperationException` is thrown.

All the mappings in a mapping collection must be by name or ordinal position.

#### Note

Oracle Data Provider for .NET makes one or more round trips to the database to determine the column names if the mapping is specified by ordinal resulting in a performance overhead. Therefore, it is recommended to specify the mapping by column names.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Add(string, string)

This method creates and adds an `OracleBulkCopyColumnMapping` object to the collection using the supplied source and destination column names.

### Declaration

```
// C#
public OracleBulkCopyColumnMapping Add(string sourceColumn,
    string destinationColumn);
```

### Parameters

- *sourceColumn*  
The name of the source column within the data source.
- *destinationColumn*  
The name of the destination column within the destination table.

### Exceptions

InvalidOperationException - The bulk copy operation is in progress.

### Return Value

The newly created OracleBulkCopyColumnMapping object that was added to the collection.

### Remarks

It is not necessary to specify column mappings for all the columns in the data source. If a ColumnMapping is not specified, then, by default, columns are mapped based on the ordinal position. This succeeds only if the source and destination table schema match. If there is a mismatch, an InvalidOperationException is thrown.

All the mappings in a mapping collection must be by name or ordinal position.

#### Note

Oracle Data Provider for .NET makes one or more round-trips to the database to determine the column name if the mapping is specified by ordinal position. To avoid this performance overhead, specify the mapping by column name.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Clear

This method clears the contents of the collection.

### Declaration

```
// C#  
public void Clear();
```

### Exceptions

InvalidOperationException - The bulk copy operation is in progress.

### Remarks

The Clear method is most commonly used when an application uses a single OracleBulkCopy instance to process more than one bulk copy operation. If column mappings are created for one bulk copy operation, the OracleBulkCopyColumnMappingCollection must be cleared after the WriteToServer method invocation and before the next bulk copy is processed.

It is usually more efficient to perform several bulk copies using the same OracleBulkCopy instance than to use a separate OracleBulkCopy for each operation.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Contains

This method returns a value indicating whether or not a specified OracleBulkCopyColumnMapping object exists in the collection.

### Declaration

```
// C#  
public bool Contains(OracleBulkCopyColumnMapping value);
```

### Parameters

- *value*  
A valid OracleBulkCopyColumnMapping object.

### Return Value

Returns true if the specified mapping exists in the collection; otherwise, returns false.

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## CopyTo

This method copies the elements of the OracleBulkCopyColumnMappingCollection to an array of OracleBulkCopyColumnMapping items, starting at a specified index.

### Declaration

```
// C#  
public void CopyTo(OracleBulkCopyColumnMapping[] array, int index);
```

### Parameters

- *array*  
The one-dimensional OracleBulkCopyColumnMapping array that is the destination for the elements copied from the OracleBulkCopyColumnMappingCollection object. The array must have zero-based indexing.
- *index*

The zero-based array index at which copying begins.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## IndexOf

This method returns the index of the specified `OracleBulkCopyColumnMapping` object.

### Declaration

```
// C#  
public int IndexOf(OracleBulkCopyColumnMapping value);
```

### Parameters

- *value*  
The `OracleBulkCopyColumnMapping` object that is being returned.

### Return Value

The zero-based index of the column mapping or -1 if the column mapping is not found in the collection.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Insert

This method inserts a new `OracleBulkCopyColumnMapping` object in the collection, at the index specified.

### Declaration

```
// C#  
public void Insert(int index, OracleBulkCopyColumnMapping value);
```

### Parameters

- *index*  
The integer value of the location within the `OracleBulkCopyColumnMappingCollection` at which the new `OracleBulkCopyColumnMapping` is inserted.

- *value*

The `OracleBulkCopyColumnMapping` object to be inserted in the collection.

### Exceptions

`InvalidOperationException` - The bulk copy operation is in progress.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## Remove

This method removes the specified `OracleBulkCopyColumnMapping` element from the `OracleBulkCopyColumnMappingCollection`.

### Declaration

```
// C#  
public void Remove(OracleBulkCopyColumnMapping value);
```

### Parameters

- *value*

The `OracleBulkCopyColumnMapping` object to be removed from the collection.

### Exceptions

`InvalidOperationException` - The bulk copy operation is in progress.

### Remarks

The `Remove` method is most commonly used when a single `OracleBulkCopy` instance processes more than one bulk copy operation. If column mappings are created for one bulk copy operation, mappings that no longer apply must be removed after the `WriteToServer` method invocation and before mappings are defined for the next bulk copy. The `Clear` method can clear the entire collection, and the `Remove` and the `RemoveAt` methods can remove mappings individually.

It is usually more efficient to perform several bulk copies using the same `OracleBulkCopy` instance than to use a separate `OracleBulkCopy` for each operation.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleBulkCopyColumnMappingCollection Class](#)
- [OracleBulkCopyColumnMappingCollection Members](#)

## RemoveAt

This method removes the mapping from the collection at the specified index.

### Declaration

```
// C#  
public void RemoveAt(int index);
```

### Parameters

- *index*  
The zero-based index of the `OracleBulkCopyColumnMapping` object to be removed from the collection.

### Exceptions

`InvalidOperationException` - The bulk copy operation is in progress.

### Remarks

The `RemoveAt` method is most commonly used when a single `OracleBulkCopy` instance is used to process more than one bulk copy operation. If column mappings are created for one bulk copy operation, mappings that no longer apply must be removed after the `WriteToServer` method invocation and before the mappings for the next bulk copy are defined. The `Clear` method can clear the entire collection, and the `Remove` and the `RemoveAt` methods can remove mappings individually.

It is usually more efficient to perform several bulk copies using the same `OracleBulkCopy` instance than to use a separate `OracleBulkCopy` for each operation.

## OracleBulkCopyOptions Enumeration

The `OracleBulkCopyOptions` enumeration specifies the values that can be combined with an instance of the `OracleBulkCopy` class and used as options to determine its behavior and the behavior of the `WriteToServer` methods for that instance.

[Table 17-17](#) lists all the `OracleBulkCopyOptions` enumeration values with a description of each enumerated value.

**Table 17-17 OracleBulkCopyOptions Enumeration Members**

| Member Name | Description                                                     |
|-------------|-----------------------------------------------------------------|
| Default     | Indicates that the default value for all options are to be used |

Table 17-17 (Cont.) OracleBulkCopyOptions Enumeration Members

| Member Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EnforceIndexChecks     | <p>Indicates when a direct path load results in an index-related error, the load is aborted. No rows are loaded, and indexes remain unchanged. When this option is not specified and a direct path load results in an index becoming unusable, the rows are loaded and the index is left in an unusable state.</p> <p>Oracle database primary key and unique constraints are enforced using unique indexes, which means the database automatically creates unique indexes on columns specified as primary key or unique. Therefore, this option only affects primary key and unique constraints.</p> <p>This option behavior is similar to the NO_INDEX_ERRORS parameter in SQL *LOADER.</p> <p>This member is supported with managed ODP.NET and ODP.NET Core 23.8 and higher.</p> <div data-bbox="980 779 1468 1035"> <p><b>Note</b></p> <p>While using ODP.NET bulk copy, the check and not null constraints are automatically enforced, whereas the foreign key constraint is never enforced.</p> </div>                                                                                                                                                                                                                                                                                                                                                     |
| NotifyAllRowsProcessed | <p>Indicates when bulk copy has processed all the rows by sending a notification. This member can be used in conjunction with OracleBulkCopy.NotifyAfter or by itself. NotifyAfter sends notifications after a specific number of rows have been bulk copied. It only sends an alert when the entire bulk copy operation is completed if the NotifyAfter value is a multiple of the total rows copied.</p> <p>For example, let's say you set NotifyAfter=5 without enabling NotifyAllRowsProcessed. When you bulk copy 15 rows, you will receive three alerts: once after 5 rows, once after 10, and once after 15. If you bulk 12 rows instead, then you would receive only two alerts: once after 5 rows and once after 10 rows. If you had also enabled NotifyAllRowsProcessed in both scenarios, then you would receive three alerts in both instances and always after the bulk copy operation completes processing the 15 rows.</p> <p>NotifyAllRowsProcessed will send a notification when all the rows are processed regardless of NotifyAfter's value.</p> <p>By design, NotifyAfter is intended to measure bulk copy progress. NotifyAllRowsProcessed is intended to indicate when bulk copy has processed all the rows.</p> <p>This member is supported with managed ODP.NET and ODP.NET Core only starting with versions 23.5, 21.15, and 19.24.</p> |

Table 17-17 (Cont.) OracleBulkCopyOptions Enumeration Members

| Member Name            | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UseInternalTransaction | Indicates that each batch of the bulk copy operation occurs within a transaction. If the connection used to perform the bulk copy operation is already part of a transaction, an <code>InvalidOperationException</code> exception is raised.<br><br>If this member is not specified, <code>BatchSize</code> number of rows are sent to the database, without any transaction-related activity. |

**Note**

All bulk copy operations are agnostic of any local or distributed transaction created by the application.

**Requirements**

| Provider              | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|-----------------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| <b>Assembly</b>       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| <b>Namespace</b>      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| <b>.NET (Core)</b>    | -                                       | -                                       | See <a href="#">System Requirements</a> |

**Sample Code: NotifyAllRowsProcessed**

```
// Set up the bulk copy object so that it will notify the app when all rows have been
// copied.
using (OracleBulkCopy bulkCopy = new OracleBulkCopy(destinationConnection,
OracleBulkCopyOption.NotifyAllRowsProcessed))
{
    bulkCopy.DestinationTableName = "BLOGS";

    try
    {
        // Write rows from the source to the destination.
        bulkCopy.NotifyAfter = 5;
        // OnSqlRowsCopied is the event handler delegate whenever NotifyAfter or
        // NotifyAllRowsProcessed sends a notification. OnSqlRowsCopied's implementation is
        // not included in this code sample.
        bulkCopy.OracleRowsCopied += new OracleRowsCopiedEventHandler(OnSqlRowsCopied);
        bulkCopy.WriteToServer(reader);
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.Message);
    }
}
```

```
}
finally
{
    // Close the OracleDataReader. The OracleBulkCopy object is automatically closed at
    the end of the using block.
    reader.Close();
}
}
```

## OracleRowsCopiedEventHandler Delegate

The OracleRowsCopiedEventHandler delegate represents the method that handles the OracleRowsCopied event of an OracleBulkCopy object.

### Declaration

```
// C#
public delegate void OracleRowsCopiedEventHandler (object sender,
    OracleRowsCopiedEventArgs EventArgs);
```

### Requirements

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Parameters

- *sender*  
The source of the event.
- *EventArgs*  
The OracleRowsCopiedEventArgs object that contains the event data.

### Remarks

Event callbacks can be registered through this event delegate for applications that wish to be notified every time the number of rows specified by the OracleBulkCopy.NotifyAfter property has been processed.

If the event handler calls the `OracleBulkCopy.Close` method, an exception is generated, and the `OracleBulkCopy` object state does not change.

The event handler can also set the `OracleRowsCopiedEventArgs.Abort` property to `true` to indicate that the bulk copy operation must be aborted. If the bulk copy operation is part of an external transaction, an exception is generated and the transaction is not rolled back. The application is responsible for either committing or rolling back the external transaction.

If there is no external transaction, the internal transaction for the current batch of rows is automatically rolled back. However the previous batches of imported rows are unaffected, as their transactions have already been committed.

# OracleRowsCopiedEventArgs Class

The `OracleRowsCopiedEventArgs` class represents the set of arguments passed as part of event data for the `OracleRowsCopied` event.

**Class Inheritance**

System.Object  
    System.EventArgs  
        System.OracleRowsCopiedEventArgs

**Declaration**

```
// C#  
public class OracleRowsCopiedEventArgs : EventArgs
```

**Requirements**

| Provider       | ODP.NET, Unmanaged Driver               | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.DataAccess.dll                   | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.DataAccess.Client                | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | -                                       | See <a href="#">System Requirements</a> |

### Thread Safety

All public static methods are thread-safe, although instance methods do not guarantee thread safety.

### Remarks

Each time the number of rows represented by the `OracleBulkCopy.NotifyAfter` property is processed, the `OracleBulkCopy.RowsCopied` event is raised, providing an `OracleRowsCopiedEventArgs` object that stores the event data.

## OracleRowsCopiedEventArgs Members

`OracleRowsCopiedEventArgs` members are listed in the following tables.

### OracleRowsCopiedEventArgs Constructors

`OracleRowsCopiedEventArgs` constructors are listed in [Table 17-18](#).

**Table 17-18 OracleRowsCopiedEventArgs Constructors**

| Constructor                                              | Description                                                                                                      |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <a href="#">OracleRowsCopiedEventArgs Constructors</a> . | <code>OracleRowsCopiedEventArgs</code> creates new instances of the <code>OracleRowsCopiedEventArgs</code> class |

### OracleRowsCopiedEventArgs Properties

`OracleRowsCopiedEventArgs` properties are listed in [Table 17-19](#).

**Table 17-19 OracleRowsCopiedEventArgs Properties**

| Property                   | Description                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">Abort</a>      | Retrieves or sets a value that indicates whether or not the bulk copy operation is aborted         |
| <a href="#">RowsCopied</a> | Retrieves a value that represents the number of rows copied during the current bulk copy operation |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRowsCopiedEventArgs Class](#)

## OracleRowsCopiedEventArgs Constructors

OracleRowsCopiedEventArgs creates new instances of the OracleRowsCopiedEventArgs class.

**Overload List:**

- [OracleRowsCopiedEventArgs\(long\)](#)

This constructor creates a new instance of the OracleRowsCopiedEventArgs object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRowsCopiedEventArgs Class](#)
- [OracleRowsCopiedEventArgs Members](#)

## OracleRowsCopiedEventArgs(long)

This constructor creates a new instance of the OracleRowsCopiedEventArgs object.

**Declaration**

```
// C#  
public OracleRowsCopiedEventArgs(long rowsCopied);
```

**Parameters**

- *rowsCopied*

An Int64 value that indicates the number of rows copied during the current bulk copy operation.

**Remarks**

The value in the *rowsCopied* parameter is reset by each call to a WriteToServer method.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRowsCopiedEventArgs Class](#)
- [OracleRowsCopiedEventArgs Members](#)

# OracleRowsCopiedEventArgs Properties

OracleRowsCopiedEventArgs properties are listed in [Table 17-20](#).

**Table 17-20 OracleRowsCopiedEventArgs Properties**

| Property                   | Description                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">Abort</a>      | Retrieves or sets a value that indicates whether or not the bulk copy operation is aborted         |
| <a href="#">RowsCopied</a> | Retrieves a value that represents the number of rows copied during the current bulk copy operation |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleRowsCopiedEventArgs Class](#)
- [OracleRowsCopiedEventArgs Members](#)

## Abort

This property retrieves or sets a value that indicates whether or not the bulk copy operation is aborted.

**Declaration**

```
// C#
public bool Abort{get; set;}
```

**Property Value**

Returns true if the bulk copy operation is to be aborted; otherwise, returns false.

**Remarks**

Set the Abort property to true to cancel the bulk copy operation.

If the Close method is called from OracleRowsCopied, an exception is generated, and the OracleBulkCopy object state does not change.

If the application does not create a transaction, the internal transaction corresponding to the current batch is automatically rolled back. However, changes related to previous batches within the bulk copy operation are retained, because the transactions in those batches are committed. This case is applicable only when UseInternalTransaction bulk copy option is chosen.

- [OracleRowsCopiedEventArgs Class](#)
- [OracleRowsCopiedEventArgs Members](#)

## RowsCopied

This property retrieves a value that represents the number of rows copied during the current bulk copy operation.

### Declaration

```
// C#  
public long RowsCopied {get;}
```

### Property Value

An Int64 value that returns the number of rows copied.

### Remarks

The value in the RowsCopied property is reset by each call to a WriteToServer method.

# Oracle Data Provider for .NET OpenTelemetry and Metrics Classes

This chapter describes ODP.NET OpenTelemetry classes and objects. OracleDataProviderInstrumentationOptions Class is available through ODP.NET Core and managed ODP.NET. AddOracleDataProviderInstrumentation extension method is available through Oracle.ManagedDataAccess.OpenTelemetry NuGet package, which can be used with ODP.NET Core and managed ODP.NET.

```
public static TracerProviderBuilder AddOracleDataProviderInstrumentation(this
TracerProviderBuilder
builder, Action<OracleDataProviderInstrumentationOptions>
configureInstrumentationOptions = null)
```

Client applications call this extension method to enable OpenTelemetry instrumentation in ODP.NET.

This method accepts options to enable or disable different instrumentation types.

- [OracleDataProviderInstrumentationOptions Class](#)
- [AddOracleDataProviderInstrumentation](#) extension method

## OracleDataProviderInstrumentationOptions Class

OracleDataProviderInstrumentationOptions class is available through the Oracle.ManagedDataAccess and Oracle.ManagedDataAccess.Core NuGet package.

This option class provides options passed to the AddOracleDataProviderInstrumentation extension method for enabling or disabling ODP.NET instrumentation types and tags.

### Declaration

```
// C#
public class OracleDataProviderInstrumentationOptions
```

### Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

## OracleDataProviderInstrumentationOptions Properties

OracleDataProviderInstrumentationOptions properties are listed in [Table 18-1](#).

**Table 18-1 OracleDataProviderInstrumentationOptions Properties**

| Method                                             | Description                                                                                                                                                                                                                             |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddDBInfoToDisplayName</a>             | Indicates whether or not to record Host, Port and database name with Displayname                                                                                                                                                        |
| <a href="#">EnableConnectionLevelAttributes</a>    | Indicates whether or not to instrument connection level attributes, such as peer.service, db.name, password less connection string, db.user and so on                                                                                   |
| <a href="#">EnableDBRoundTripTracing</a>           | Allows creating child spans that encapsulate the database roundtrips for parent spans in public APIs like <code>OracleCommand.ExecuteNonQuery()</code> , <code>OracleDataReader.Read()</code> , and <code>OracleDataAdapter.Fill</code> |
| <a href="#">EnableOpenCloseTracing</a>             | Indicates whether to record database soft and hard connection/disconnection instrumentation or not                                                                                                                                      |
| <a href="#">EnableSqlIdTracing</a>                 | Enables SQL identifier instrumentation of each executed SQL statement                                                                                                                                                                   |
| <a href="#">InstrumentOracleDataReaderRead</a>     | Indicates whether or not to instrument <code>OracleDataReader.Read</code> method calls                                                                                                                                                  |
| <a href="#">RecordException</a>                    | Indicates whether or not to record exception details in instrumentation                                                                                                                                                                 |
| <a href="#">RequireApplicationRootSpanCreation</a> | Controls whether ODP.NET instruments only those operations that are associated with root spans created by the application or not                                                                                                        |
| <a href="#">SetDbStatementForStoredProcedure</a>   | Indicates whether or not to instrument stored procedure and function names when the command type is for a stored procedure ( <code>CommandType.StoredProcedure</code> )                                                                 |
| <a href="#">SetDbStatementForText</a>              | Indicates whether or not to instrument SQL queries when command type is of Text type ( <code>CommandType.Text</code> )                                                                                                                  |

### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)

## AddDBInfoToDisplayName

This property indicates whether or not to add Host, Port and database name to Displayname.  
Example: Displayname <DB Host/IP>:<DB Port>:<DB Name>

**Declaration**

```
// C#  
public bool AddDBInfoToDisplayName { get; set; }
```

**Return Value**

A bool.

**Remarks**

Default value is false.

**Note**

If EnableConnectionLevelAttributes is set to false, then Host, Port, and database name information will not be added to DisplayName.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## EnableConnectionLevelAttributes

This property indicates whether or not to instrument connection level attributes, such as peer.service, db.name, password less connection string, db.user and so on.

**Declaration**

```
// C#  
public bool EnableConnectionLevelAttributes { get; set; }
```

**Return Value**

A bool.

**Remarks**

Default value is false.

When enabled, the db.odp.connection.id OpenTelemetry attribute publishes a unique identifier for each connection. This attribute can be used to diagnose and trace a specific connection's behavior. The identifier can be prefixed with an ODP.NET connection ID when the ConnectionIdPrefix property in OracleConnection or OracleCommand is set to an ID value.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## EnableDBRoundTripTracing

This property allows creating child spans that encapsulate the database roundtrips for parent spans in public APIs like `OracleCommand.ExecuteNonQuery()`, `OracleDataReader.Read()`, and `OracleDataAdapter.Fill`.

**Declaration**

```
// C#  
public bool EnableDBRoundTripTracing { get; set; }
```

**Return Value**

A bool.

**Remarks**

Default value is true.

This property enables instrumentation of database round-trips for the following public APIs:

- `OracleCommand.ExecuteNonQuery()`
- `OracleCommand.ExecuteReader` (All overloads)
- `OracleCommand.ExecuteScalar()`
- `OracleCommand.ExecuteScalarAsync` (All overloads)
- `OracleCommand.ExecuteStream()`
- `OracleCommand.ExecuteToStream(Stream outputStream)`
- `OracleCommand.ExecuteXmlReader()`
- `OracleCommand.ExecuteNonQueryAsync` (All overloads)
- `OracleCommand.ExecuteReaderAsync` (All overloads)
- `OracleCommand.ExecuteScalarAsync(CancellationToken cancellationToken)`
- `OracleCommand.ExecuteXmlReaderAsync` (All overloads)
- `OracleConnection.Open()`
- `OracleConnection.OpenAsync` (All overloads)
- `OracleConnection.Close()`
- `OracleDataReader.Read()`
- `OracleDataReader.ReadAsync` (All overloads)
- `OracleDataAdapter.Fill` (All overloads)

`Open()`, `OpenAsync()`, and `Close()` instrumentation requires the [EnableOpenCloseTracing](#) enum to be set to any valid value except `EnableOpenCloseTracing.None`.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## EnableOpenCloseTracing

This property indicates whether to record database soft and hard connection/disconnection instrumentation or not.

**Declaration**

```
// C#  
public EnableOpenCloseTracing EnableOpenCloseTracing { get; set; }
```

**Return Value**

EnableOpenCloseTracing enum values

**Remarks**

Default value is EnableOpenCloseTracing.None.

This option takes following EnableOpenCloseTracing enum values:

- EnableOpenCloseTracing.None: No open/close instrumentation
- EnableOpenCloseTracing.HardOpenCloseOnly: Hard open/close instrumentation only
- EnableOpenCloseTracing.AllOpenClose: All open/close (soft + hard) instrumentation

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## EnableSqlIdTracing

This property enables SQL identifier instrumentation of each executed SQL statement.

**Declaration**

```
// C#  
public bool EnableSqlIdTracing { get; set; }
```

**Return Value**

A bool.

**Remarks**

Default value is false.

This SQL identifier allows you to uniquely identify the SQL being executed through an identifier. The property's value is equivalent to the Oracle Database's statement SQL identifier (SQL\_ID) so that the SQL execution can be matched between ODP.NET and server.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## InstrumentOracleDataReaderRead

This property indicates whether to instrument OracleDataReader Read method calls.

**Declaration**

```
// C#  
public bool InstrumentOracleDataReaderRead { get; set; }
```

**Return Value**

A bool.

**Remarks**

Default value is false.

**Note**

If EnableDBRoundTripTracing is set to false, then OracleDataReader Read() database round trips will not be instrumented.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## RecordException

This property indicates whether or not to record exception details in instrumentation.

**Declaration**

```
// C#  
public bool RecordException { get; set; }
```

**Return Value**

A bool.

**Remarks**

Default value is false.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## RequireApplicationRootSpanCreation

This property controls whether ODP.NET instruments only those operations that are associated with root spans created by the application or not.

**Declaration**

```
// C#  
public bool RequireApplicationRootSpanCreation { get; set; }
```

**Return Value**

A bool

**Remarks**

Default value is false.

When a new activity/span is created, it becomes child of current (in progress) activity/span automatically. But if there is no span in progress and a new span is created, then it will become Root/parentless/orphan span.

Similarly, if the user application creates a span before calling ODP.NET instrumented methods, the span created by the user application becomes root span and all span created by ODP.NET become children of it.

If user application did not create a root span and call ODP.NET instrumented methods, the multiple parentless/orphan spans will be created because of no parent linking. These spans are hard to visualize and analyze.

Parentless/Orphan span are also generated by server/database round trip calls happening from background threads. parentless/orphan spans do not add much value in most scenarios because of missing parent linking. Using this option user/client can control parentless/orphan span tracing as per their needs.

By default, instrumentation of parentless/orphan span is enabled.

This means application need not create any activity before calling ODP.NET instrumented methods. But if the user sets this option to true, then the user application must create a root activity, otherwise no ODP.NET spans will be generated.

- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## SetDbStatementForStoredProcedure

This property indicates whether or not to instrument stored procedure and function names when the command type is for a stored procedure (CommandType.StoredProcedure).

### Declaration

```
// C#  
public bool SetDbStatementForStoredProcedure { get; set; }
```

### Return Value

A bool.

### Remarks

Default value is true.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## SetDbStatementForText

This property indicates whether or not to instrument SQL queries when command type is of Text type (CommandType.Text).

### Declaration

```
// C#  
public bool SetDbStatementForText { get; set; }
```

### Return Value

A bool.

### Remarks

Default value is false.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## AddOracleDataProviderInstrumentation

Client applications call this extension method to enable OpenTelemetry instrumentation in ODP.NET. Certain tags and attributes are enabled/disabled based on the options provided.

**Declaration**

```
// C#
public static TracerProviderBuilder AddOracleDataProviderInstrumentation
(this TracerProviderBuilder builder, Action<OracleDataProviderInstrumentationOptions>
configureInstrumentationOptions = null)
```

**Remarks**

If no options are passed default options will be used.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OracleDataProviderInstrumentationOptions Class](#)
- [OracleDataProviderInstrumentationOptions Properties](#)

## OraclePoolNameCollection Class

This class represents the pool names collection corresponding to each unique connection string.

Namespace: `Oracle.ManagedDataAccess.Client`

Assembly: `Oracle.ManagedDataAccess`

**Declaration**

```
// C#
public sealed class OraclePoolNameCollection
```

**Inheritance**

Object -> `OraclePoolNameCollection`

**Thread Safety**

This class is a thread-safe class.

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

Remarks

Connection strings combined with application names and process identifiers can be very long and hard to distinguish with many that look similar when using .NET Metrics or Windows Performance Counters. This collection class allows applications to set an arbitrary string to easily identify which pool is being monitored.

Constructor

Internal OraclePoolNameCollection() – This class is instantiated internally.

① See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OraclePoolNameCollection Methods](#)

OraclePoolNameCollection Methods

OraclePoolNameCollection methods are listed in OraclePoolNameCollection Methods.

Table 18-2 OraclePoolNameCollection Methods

| Method                              | Description                                                                 |
|-------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">Add(string, string)</a> | Add an element with pool name as the key and connection string as the value |
| <a href="#">Remove(string)</a>      | Removes the element with the specified key from the collection              |

① Note

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OraclePoolNameCollection Class](#)

## Add(string, string)

This method adds an element with pool name as the key and connection string as the value.

### Definition

```
C#  
public void Add(string poolName, string passwordLessConnectionString)
```

### Parameters

- poolName (string) – name to identify pool with
- passwordLessConnectionString (string) – connection string without password field

### Exceptions

NullReferenceException – If either or both poolName and passwordLessConnectionString are null.

#### See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OraclePoolNameCollection Class](#)
- [OraclePoolNameCollection Methods](#)

## Remove(string)

This method removes the element with the specified key from the collection.

### Definition

```
C#  
public void Remove(string poolName)
```

### Parameters

- poolName (string) – name of the pool to remove

### Exceptions

NullReferenceException – If poolName is null.

#### See Also

- [Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces](#)
- [OraclePoolNameCollection Class](#)

# Oracle Data Provider for .NET Oracle Identity and Access Management Classes

This chapter describes Oracle Identity and Access Management (IAM) single sign-on classes and objects. They are available through the `Oracle.ManagedDataAccess.Oci` NuGet package, which can be used with ODP.NET Core and managed ODP.NET.

- [OciTokenAuthentication Class](#)

① **See Also**

- [UseOciTokenAuthentication](#)
- [OciConfigurationFile](#)
- [OciProfile](#)

## OciTokenAuthentication Class

This class accepts configuration parameters for OCI IAM SSO integration with ODP.NET. The class is part of the `Oracle.ManagedDataAccess.Oci` NuGet package. Applications provide the OCI IAM values in the class properties to connect. Once ODP.NET initiates opening the connection, the class instance is marked as read-only to prevent further modification during the pool's lifetime.

If customers use the same instance for another connection open, this new connection will be opened in the same connection pool as the earlier opened connection.

All the `OciTokenAuthentication` class properties should not be set to null nor empty values. Those null/empty values will be ignored, though no error is thrown.

### Class Inheritance

`OracleInternal.Common.AbstractTokenAuthentication`

### Declaration

```
// C#
public sealed class OciTokenAuthentication : AbstractTokenAuthentication
```

### Requirements

| Provider  | ODP.NET, Managed Driver         | ODP.NET Core                    |
|-----------|---------------------------------|---------------------------------|
| Assembly  | Oracle.ManagedDataAccess.dll    | Oracle.ManagedDataAccess.dll    |
| Namespace | Oracle.ManagedDataAccess.Client | Oracle.ManagedDataAccess.Client |

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

#### ① See Also

- [OciTokenAuthentication Members](#)
- [OciTokenAuthentication Constructor\(\)](#)
- [OciTokenAuthentication Properties](#)

## OciTokenAuthentication Members

OciTokenAuthentication members are listed in the following tables.

### OciTokenAuthentication Constructors

OciTokenAuthentication constructors are listed in [Table 19-1](#).

**Table 19-1 OciTokenAuthentication Constructors**

| Constructor                                          | Description                                                      |
|------------------------------------------------------|------------------------------------------------------------------|
| <a href="#">OciTokenAuthentication Constructor()</a> | Instantiates an empty object of the OciTokenAuthentication class |

### OciTokenAuthentication Properties

OciTokenAuthentication properties are listed in [Table 19-2](#).

**Table 19-2 OciTokenAuthentication Properties**

| Property                          | Description                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Compartment</a>       | Sets the database compartment's Oracle Cloud ID (OCID).                                      |
| <a href="#">ConfigurationFile</a> | Sets the configuration file location where the OCI token authentication values can be found. |
| <a href="#">Database</a>          | Sets the database Oracle Cloud ID (OCID).                                                    |
| <a href="#">Profile</a>           | Sets the OCI profile to use from the token authentication configuration file.                |

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)

## OciTokenAuthentication Constructor()

This constructor instantiates an empty object of the `OciTokenAuthentication` class.

### Declaration

```
// C#  
public OciTokenAuthentication();
```

### Remarks

This constructor without parameters is invoked in the processing of object initializers. Parameters should be set individually as per the selected OCI IAM SSO authentication flow.

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OciTokenAuthentication Class](#)
- [OciTokenAuthentication Members](#)

## OciTokenAuthentication Properties

`OciTokenAuthentication` properties are listed in [Table 19-3](#).

**Table 19-3 OciTokenAuthentication Properties**

| Property                          | Description                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Compartment</a>       | Sets the database compartment's Oracle Cloud ID (OCID).                                      |
| <a href="#">ConfigurationFile</a> | Sets the configuration file location where the OCI token authentication values can be found. |
| <a href="#">Database</a>          | Sets the database Oracle Cloud ID (OCID).                                                    |
| <a href="#">Profile</a>           | Sets the OCI profile to use from the token authentication configuration file.                |

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OciTokenAuthentication Class](#)
- [OciTokenAuthentication Members](#)

## Compartment

This property sets the database compartment's Oracle Cloud ID (OCID).

### Declaration

```
// C#  
public string Compartment { set; }
```

### Exceptions

An `InvalidOperationException` will be raised if the application tries to modify an `ociTokenAuthenticationConfiguration` object by setting this property once a connection has opened using that configuration object.

### Remarks

This parameter is applicable to the OCI API key, OCI interactive, OCI instance principal, and OCI delegation token authentication flows only and is optional. This property becomes mandatory if the `OciDatabase` property is set.

There is no default value for this parameter. If it is not set, ODP.NET requests access to all the databases within the OCI IAM user's tenancy.

### Sample Code

```
OracleConnection conn = new OracleConnection(constr);  
conn.TokenAuthentication = OracleTokenAuth.OciInstancePrincipal;  
OciTokenAuthentication tokenconfig = new OciTokenAuthentication{  
    Compartment = "<COMPARTMENT OCID>",  
    Database = "<DATABASE OCID>"  
}  
conn.UseOciTokenAuthentication(tokenConfig);  
conn.Open();  
conn.Close();
```

#### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OciTokenAuthentication Class](#)
- [OciTokenAuthentication Members](#)

## ConfigurationFile

This property sets the configuration file location where the OCI token authentication values can be found.

### Declaration

```
// C#  
public string ConfigurationFile { set; }
```

### Exceptions

An `InvalidOperationException` will be raised if the application tries to modify an `ociTokenAuthenticationConfiguration` object by setting this property once a connection has opened using that configuration object.

## Remarks

This parameter is applicable to the OCI API key and OCI interactive authentication flows only and is optional.

Whenever this parameter is provided, the entire directory path including the configuration file name should be specified. ODP.NET does not use the standard file name if it is missing. Example of setting configuration file is C:\Users\admin\.oci\config. Skipping the file name config from the path like C:\Users\admin\.oci\, will throw an error.

If this parameter is not set, then ODP.NET uses the OCI configuration file in the default location: C:/<user-profile>/.oci/config. If the parameter is not set and the default configuration file is not found, then the user is prompted on the console to provide a region id for the OCI interactive authentication flow. A list of possible region ids will be displayed to the user. In the case of the OCI API key flow, the user will see an error.

On Windows, the Oracle HOME and USERPROFILE environment variables are used for the default directory location if they are set. Otherwise, Oracle HOMEPATH and HOMEDRIVE environment variables are used.

## Sample Code

```
OracleConnection conn = new OracleConnection(constr);
conn.TokenAuthentication = OracleTokenAuth.OciApiKey;
OciTokenAuthentication tokenconfig = new OciTokenAuthentication{
    ConfigurationFile = "<CONFIGURATION FILE>",
    Profile = "<PROFILE>",
    Compartment = "<COMPARTMENT OCID>",
    Database = "<DATABASE OCID>"
}
conn.UseOciTokenAuthentication(tokenConfig);
conn.Open();
conn.Close();
```

### See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OciTokenAuthentication Class](#)
- [OciTokenAuthentication Members](#)

## Database

This property sets the database Oracle Cloud ID (OCID).

### Declaration

```
// C#
public string Database { get; set; }
```

### Exceptions

An `InvalidOperationException` will be raised if the application tries to modify an `ociTokenAuthenticationConfiguration` object by setting this property once a connection has opened using that configuration object.

### Remarks

This parameter is applicable to the OCI API key, OCI interactive, OCI instance principal, and OCI delegation token authentication flows only and is optional.

There is no default value for this parameter. If it is not set, ODP.NET requests access to all the compartment's databases specified by the `OciCompartment` property. If `OciCompartment` property is also not set, then ODP.NET requests access to all the databases within the OCI IAM user's tenancy.

### Sample Code

```
OracleConnection conn = new OracleConnection(constr);
conn.TokenAuthentication = OracleTokenAuth.OciDelegationToken;
OciTokenAuthentication tokenconfig = new OciTokenAuthentication{
    Compartment = "<COMPARTMENT OCID>",
    Database = "<DATABASE OCID>"
}
conn.UseOciTokenAuthentication(tokenConfig);
conn.Open();
conn.Close();
```

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [OciTokenAuthentication Class](#)
- [OciTokenAuthentication Members](#)

## Profile

This property sets the OCI profile to use from the token authentication configuration file.

### Declaration

```
// C#
public string Profile { set; }
```

### Exceptions

An `InvalidOperationException` will be raised if the application tries to modify an `ociTokenAuthenticationConfiguration` object by setting this property once a connection has opened using that configuration object.

### Remarks

This parameter is applicable to the OCI API key and OCI interactive authentication flows only and is optional.

ODP.NET uses the DEFAULT profile if no profile value is set.

### Sample Code

```
OracleConnection conn = new OracleConnection(constr);
conn.TokenAuthentication = OracleTokenAuth.OciInteractive;
```

```
OciTokenAuthentication tokenconfig = new OciTokenAuthentication{  
    ConfigurationFile = "<CONFIGURATION FILE>",  
    Profile = "<PROFILE>",  
    Compartment = "<COMPARTMENT OCID>",  
    Database = "<DATABASE OCID>"  
}  
conn.UseOciTokenAuthentication(tokenConfig);  
conn.Open();  
conn.Close();
```

# Oracle Data Provider for .NET Microsoft Entra ID Classes

This chapter describes the Microsoft Entra ID single sign-on classes and objects. They are available through the `Oracle.ManagedDataAccess.Azure` NuGet package. Microsoft Entra ID was formerly named Azure Active Directory.

- [AzureTokenAuthentication Class](#)

## AzureTokenAuthentication Class

This class accepts configuration parameters for Microsoft Entra ID SSO integration with ODP.NET. The class is part of the `Oracle.ManagedDataAccess.Azure` NuGet package. Applications provide the Microsoft Entra ID values in the class properties to connect. Once ODP.NET initiates opening the connection, the class instance is marked as read-only to prevent further modification during the pool's lifetime.

If customers use same instance for another connection open, this new connection will be opened in the same connection pool as the earlier opened connection.

### Class Inheritance

`System.Object`

`System.Object.AbstractTokenAuthentication`

`Oracle.ManagedDataAccess.Azure.AzureTokenAuthentication`

### Declaration

```
// C#
public class AzureTokenAuthentication : AbstractTokenAuthentication
```

### Requirements

| Provider              | ODP.NET, Managed Driver                      | ODP.NET Core                                 |
|-----------------------|----------------------------------------------|----------------------------------------------|
| <b>Assembly</b>       | <code>Oracle.ManagedDataAccess.dll</code>    | <code>Oracle.ManagedDataAccess.dll</code>    |
| <b>Namespace</b>      | <code>Oracle.ManagedDataAccess.Client</code> | <code>Oracle.ManagedDataAccess.Client</code> |
| <b>.NET Framework</b> | See <a href="#">System Requirements</a>      | -                                            |
| <b>.NET (Core)</b>    | -                                            | See <a href="#">System Requirements</a>      |

## AzureTokenAuthentication Members

AzureTokenAuthentication members are listed in the following tables.

### AzureTokenAuthentication Constructors

AzureTokenAuthentication constructors are listed in [Table 20-1](#).

**Table 20-1 AzureTokenAuthentication Constructors**

| Constructor                                      | Description                                                                                           |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">AzureTokenAuthentication()</a>       | Instantiates an empty object of the AzureTokenAuthentication class                                    |
| <a href="#">AzureTokenAuthentication(string)</a> | Instantiates an empty object of the AzureTokenAuthentication class with a database application id URI |

### AzureTokenAuthentication Properties

AzureTokenAuthentication properties are listed in [Table 20-2](#).

**Table 20-2 AzureTokenAuthentication Properties**

| Property                                  | Description                                                                                                                                                           |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DatabaseApplicationIdUri</a>  | Sets the database application URI identifier, which is the protected resource identifier on Microsoft Entra ID for which client application requests the access token |
| <a href="#">ClientId</a>                  | Sets the client identifier, which is Microsoft Entra ID registered application identifier                                                                             |
| <a href="#">TenantId</a>                  | Sets the Azure tenant identifier under which applications (client app or database) are registered                                                                     |
| <a href="#">RedirectUri</a>               | Sets the reply URL where the authorization server sends the user once the app has been successfully authorized and granted an authorization code or access token      |
| <a href="#">ClientSecret</a>              | Sets the Azure resource credential                                                                                                                                    |
| <a href="#">ClientCertificate</a>         | This property sets the Azure resource digital certificate.                                                                                                            |
| <a href="#">ClientCertificatePassword</a> | Sets the Azure client certificate password                                                                                                                            |
| <a href="#">CustomDeviceCodeCallback</a>  | Sets a delegate/callback to the application providing them the Azure SDK DeviceCodeInfo object.                                                                       |

## AzureTokenAuthentication Constructors

AzureTokenAuthentication constructors instantiate new instances of AzureTokenAuthentication class.

**Overload List:**

- [AzureTokenAuthentication\(\)](#)  
This constructor instantiates an empty object of the AzureTokenAuthentication class.
- [AzureTokenAuthentication\(string\)](#)  
This constructor instantiates an empty object of the AzureTokenAuthentication class with a database application id URI.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## AzureTokenAuthentication()

This constructor instantiates an empty object of the AzureTokenAuthentication class.

**Declaration**

```
// C#  
public AzureTokenAuthentication();
```

**Remarks**

This constructor without parameters is invoked in the processing of object initializers. Parameters should be set individually as per the selected Microsoft Entra ID authentication flow.

**See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## AzureTokenAuthentication(string)

This constructor instantiates an empty object of the AzureTokenAuthentication class with a database application id URI.

### Declaration

```
// C#  
public AzureTokenAuthentication(string databaseApplicationIdUri);
```

### Parameters

**databaseApplicationIdUri** – The database application id URI configured in the database app registration on Microsoft Entra ID.

### Exceptions

ArgumentException if databaseApplicationIdUri is null, empty, or has only whitespaces.

### Remarks

The database application id URI is a mandatory parameter for all Microsoft Entra ID authentication flows. Other parameters should be set individually as per the selected authentication flow.

## AzureTokenAuthentication Properties

AzureTokenAuthentication properties are listed in [Table 20-3](#).

**Table 20-3 AzureTokenAuthentication Properties**

| Property                                 | Description                                                                                                                                                           |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DatabaseApplicationIdUri</a> | Sets the database application URI identifier, which is the protected resource identifier on Microsoft Entra ID for which client application requests the access token |
| <a href="#">ClientId</a>                 | Sets the client identifier, which is Microsoft Entra ID registered application identifier                                                                             |
| <a href="#">TenantId</a>                 | Sets the Azure tenant identifier under which applications (client app or database) are registered                                                                     |
| <a href="#">RedirectUri</a>              | Sets the reply URL where the authorization server sends the user once the app has been successfully authorized and granted an authorization code or access token      |
| <a href="#">ClientSecret</a>             | Sets the Azure resource credential                                                                                                                                    |
| <a href="#">ClientCertificate</a>        | This property sets the Azure resource digital certificate.                                                                                                            |

Table 20-3 (Cont.) AzureTokenAuthentication Properties

| Property                                  | Description                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------|
| <a href="#">ClientCertificatePassword</a> | Sets the Azure client certificate password                                                      |
| <a href="#">CustomDeviceCodeCallback</a>  | Sets a delegate/callback to the application providing them the Azure SDK DeviceCodeInfo object. |

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## DatabaseApplicationIdUri

This property sets the database application URI identifier, which is the protected resource identifier on Microsoft Entra ID for which client application requests the access token.

**Declaration**

```
// C#  
public string DatabaseApplicationIdUri { set; }
```

**Exceptions**

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## ClientId

This property sets the client identifier, which is Microsoft Entra ID registered application identifier.

**Declaration**

```
// C#  
public string ClientId { set; }
```

**Exceptions**

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## TenantId

This property sets the Azure tenant identifier under which applications (client app or database) are registered.

**Declaration**

```
// C#  
public string TenantId { set; }
```

**Exceptions**

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## RedirectUri

This property sets the reply URL where the authorization server sends the user once the app has been successfully authorized and granted an authorization code or access token.

**Declaration**

```
// C#  
public string RedirectUri { set; }
```

**Exceptions**

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

**Remarks**

This property is used with Azure interactive authentication.

This property has "http://localhost" as the default value if not provided by the user.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## ClientSecret

This property sets the Azure resource credential.

**Declaration**

```
// C#  
public SecureString ClientSecret { set; }
```

**Exceptions**

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## ClientCertificate

This property sets the Azure resource digital certificate.

**Declaration**

```
// C#  
public string ClientCertificate { set; }
```

**Exceptions**

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

**① See Also**

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## ClientCertificatePassword

This property sets the Azure client certificate password.

### Declaration

```
// C#  
public SecureString ClientCertificatePassword { set; }
```

### Exceptions

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

#### ① See Also

- ["Oracle.DataAccess.Client and Oracle.ManagedDataAccess.Client Namespaces"](#)
- [AzureTokenAuthentication Class](#)
- [AzureTokenAuthentication Members](#)

## CustomDeviceCodeCallback

This property sets a delegate/callback to the application providing them the Azure SDK DeviceCodeInfo object.

### Declaration

```
// C#  
public Func<DeviceCodeInfo, Task> CustomDeviceCodeCallback { set; }
```

### Exceptions

InvalidOperationException – if application tries to set this property once a connection is already opened using its encapsulating object.

### Remarks

This property is used with Azure device code authentication flow.

This property facilitates ODP.NET applications to receive display device code, URL, and other device code parameters. The DeviceCodeInfo object encapsulates these parameters for Azure use. Applications may choose to display these details if needed in the application user interface.

If this property is not set when using Azure device code authentication, then ODP.NET displays the device code and URL on the application console.

# Oracle Database Vector Store Connector for Semantic Kernel Classes

Semantic Kernel is a lightweight, open-source development kit that lets you easily build AI agents and integrate the latest AI models into your C#, Python, or Java codebase. It serves as an efficient middleware that enables rapid delivery of enterprise-grade solutions. Semantic Kernel supports vector databases for storing information to enable large language models (LLMs) to generate more relevant and coherent responses.

.NET provides vector store abstractions as a common API set for adding and retrieving data from vector stores. Semantic Kernel uses these APIs for vector manipulation, but they can also be used by generic .NET vectors or any other framework that incorporates vectors. The Oracle Database Vector Store Connector for Semantic Kernel implements the .NET vector API set for adding data, retrieving data, and performing vector search in the Oracle database. Thus, it can support .NET vector and Semantic Kernel applications. This chapter describes the connector classes.

ODP.NET Core or managed ODP.NET provides connector data access. The `Oracle.VectorData` NuGet package is required to use the connector.

## OracleCollection Class

An `OracleCollection` object implements the `Microsoft.Extensions.VectorData.VectorStoreCollection` interface. It is used to search and manage records, and to create or delete the collection.

In an Oracle database, a named collection is mapped to an Oracle database table, and the table definition is also defined based on the provided key type and the data model. A collection record is mapped to a database row of an Oracle database table.

Class Inheritance

System.Object  
    Microsoft.Extensions.VectorData.VectorStoreCollection  
        Oracle.VectorData.OracleCollection

Declaration

```
// C#  
public class OracleCollection :  
Microsoft.Extensions.VectorData.VectorStoreCollection
```

Thread Safety

All public methods are thread-safe, unless stated otherwise.

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

OracleCollection Constructors

The OracleCollection constructors create new instances of the OracleCollection class with the provided data source or connection string and the collection name.

Overload List:

- [OracleCollection<TKey, TRecord>\(OracleDataSource, string, OracleCollectionOptions?\)](#)  
This constructor instantiates a new instance of OracleCollection class using the provided data source and collection name. It is available to use only in a .NET Core environment.
- [OracleCollection<TKey, TRecord>\(string, string, OracleCollectionOptions?\)](#)  
This constructor creates a new instance of the OracleCollection class using the provided connection string and collection name.

**① See Also**

- [OracleCollection Class](#)
- [OracleCollection Properties](#)
- [OracleCollection Public Methods](#)

## OracleCollection<TKey, TRecord>(OracleDataSource, string, OracleCollectionOptions?)

Instantiates a new instance of OracleCollection class using the provided data source and collection name.

**Declaration**

```
// C#
OracleCollection<TKey, TRecord>(OracleDataSource dataSource, string
collectionName, OracleCollectionOptions? options = default)
```

**Parameters**

- **dataSource**  
The data source which can be used to obtain open database connections.
- **collectionName**  
Name of the collection
- **options**  
Optional vector collection configuration options.

**Exceptions**

- **ArgumentNullException:** The provided dataSource or name parameter is null.
- **ArgumentException:**
  - The provided collectionName parameter is null, an empty string or contains white spaces only.
  - The provided collectionName is not compliant with Oracle name standard.
  - The definition provided in OracleCollectionOptions.Definition cannot be mapped to an Oracle type based on the default/custom type mapping.

**① See Also**

- [OracleDataSource Class](#)
- [OracleCollectionOptions Class](#)

## OracleCollection<TKey, TRecord>(string, string, OracleCollectionOptions?)

Instantiates a new instance of OracleCollection class using the provided connection string and collection name.

### Declaration

```
// C#  
OracleCollection<TKey, TRecord>(string connectionString, string  
collectionName, OracleCollectionOptions? options = default)
```

### Parameters

- **string**  
The connection string which can be used to obtain database connections.
- **collectionName**  
Name of the collection
- **options**  
Optional vector collection configuration options.

### Exceptions

- **ArgumentNullException:** The provided dataSource or name parameter is null.
- **ArgumentException:**
  - The provided collectionName parameter is null, an empty string or contains white spaces only.
  - The provided collectionName is not compliant with Oracle name standard.
  - The definition provided in OracleCollectionOptions.Definition cannot be mapped to an Oracle type based on the default/custom type mapping.

## OracleCollection Properties

OracleCollection properties are listed in [Table 21-1](#).

**Table 21-1 OracleCollection Properties**

| Property             | Description                                                                       |
|----------------------|-----------------------------------------------------------------------------------|
| <a href="#">Name</a> | This property specifies the name of this collection/table in the Oracle database. |

**① See Also**

- [OracleCollection Class](#)
- [OracleCollection Constructors](#)
- [OracleCollection Public Methods](#)

## Name

This property specifies the name of this collection/table in the Oracle database.

### Declaration

```
// C#  
public string Name { get; }
```

### Property Value

The string specifying the name of the collection. The collection name is the name given by the application when the `OracleCollection` instance is created.

### Implements

`Microsoft.Extensions.VectorData.VectorStoreCollection`

## OracleCollection Public Methods

`OracleCollection` public methods are listed in [Table 21-2](#).

**Table 21-2 OracleCollection Public Methods**

| Public Method                                | Description                                                                                                                                                          |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CollectionExistsAsync</a>        | Checks whether the collection exists in the vector store.                                                                                                            |
| <a href="#">DeleteAsync</a>                  | Deletes a single record or a batch of records from the vector store. It does not guarantee that the collection exists.                                               |
| <a href="#">Dispose</a>                      | Releases any resources or memory held by the object.                                                                                                                 |
| <a href="#">EnsureCollectionExistsAsync</a>  | Ensures the existence of the collection. Creates the collection in the vector store if it does not exist.                                                            |
| <a href="#">EnsureCollectionDeletedAsync</a> | Deletes the collection from the vector store if it exists.                                                                                                           |
| <a href="#">GetAsync</a>                     | Retrieves a single record or a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found. |
| <a href="#">GetService</a>                   | Retrieves an object of a specified service type from the collection or vector store.                                                                                 |
| <a href="#">SearchAsync</a>                  | Searches the vector store for records that are similar to input data.                                                                                                |

Table 21-2 (Cont.) OracleCollection Public Methods

| Public Method               | Description                                                                                                                                                                                                       |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">UpsertAsync</a> | Updates or inserts a record or a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created. |

 **See Also**

- [OracleCollection Class](#)
- [OracleCollection Constructors](#)
- [OracleCollection Properties](#)

## CollectionExistsAsync

This method checks if a collection exists in the vector store.

**Declaration**

```
// C#
public async Task<bool> CollectionExistsAsync(CancellationTok
cancellationToken = default)
```

**Parameters**

- `cancellationToken`  
The cancellation token.

**Return Value**

A task representing the asynchronous operation. The task result contains a boolean indicating whether the collection exists in the database. True if exists, else false.

**Implements**

Microsoft.Extensions.VectorData.VectorStore

## DeleteAsync

DeleteAsync methods delete a single record or a batch of records from the vector store. It does not guarantee that the collection exists.

**Overload List**

- [DeleteAsync\(TKey key, CancellationTok](#)  
This method deletes a record from the vector store. It does not guarantee that the collection exists.
- [DeleteAsync\(IEnumerable<TKey> keys, CancellationTok](#)  
This method deletes a batch of records from the vector store. It does not guarantee that the collection exists.

## DeleteAsync(TKey key, CancellationToken)

This method deletes a record from the vector store. It does not guarantee that the collection exists.

### Declaration

```
// C#  
public async Task DeleteAsync(<TKey> key, CancellationToken cancellationToken  
= default);
```

### Parameters

- **key**  
The unique key associated with the record to delete.
- **cancellationToken**  
The cancellation token.

### Return Value

A task representing the asynchronous operation that completes when the record is deleted.

### Implements

Microsoft.Extensions.VectorData.VectorStoreCollection

### Exceptions

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

## DeleteAsync(IEnumerable<TKey> keys, CancellationToken)

This method deletes a batch of records from the vector store. It does not guarantee that the collection exists.

### Declaration

```
// C#  
public async Task DeleteAsync(IEnumerable<Tkey> keys, CancellationToken  
cancellationToken = default)
```

### Parameters

- **keys**  
The unique keys associated with the records to delete.
- **cancellationToken**  
The cancellation token.

### Return Value

A task representing the asynchronous operation when the records are deleted.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**Remarks**

If a record is not found, it is ignored, and the batch operation succeeds. However, if a record cannot be deleted for any reason, the operation throws an error. Since some records may have already been deleted while others have not, the entire operation needs to be retried.

## Dispose

This method releases any resources or memory allocated by the object.

**Declaration**

```
// C#  
public void Dispose()
```

**Implements**

System.IDisposable

**Thread Safety**

This method is not thread-safe.

## EnsureCollectionDeletedAsync

This method deletes the collection from the vector store if it exists.

**Declaration**

```
// C#  
public async Task EnsureCollectionDeleteAsync(CancellationTokens  
cancellationTokens = default)
```

**Parameters**

- `cancellationTokens`  
The cancellation token.

**Return Value**

A task representing the asynchronous operation that completes when the collection has been deleted from the database.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

## EnsureCollectionExistsAsync

This method ensures the existence of the collection. It creates the collection in the vector store if it does not exist.

### Declaration

```
// C#  
public async Task EnsureCollectionExistsAsync(CancellationTokens  
cancellationTokens = default)
```

### Parameters

- `cancellationTokens`  
The cancellation token.

### Return Value

A task representing the asynchronous operation that completes when the collection has been created in the database.

### Implements

Microsoft.Extensions.VectorData.VectorStoreCollection

## GetAsync

GetAsync methods retrieve a single record or a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.

### Overload List

- [GetAsync\(TKey, RecordRetrieveOptions?, CancellationTokens\)](#)  
This method retrieves a single record from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.
- [GetAsync\(IEnumerable<TKey>, RecordRetrieveOptions?, CancellationTokens\)](#)  
This method retrieves a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.
- [GetAsync\(Expression<Func<TRecord, bool>>, int, FilteredRecordRetrieveOptions<TRecord>?, CancellationTokens\)](#)  
This method retrieves from the vector store records matching a filter expression. It does not guarantee the existence of the collection.

## GetAsync(TKey, RecordRetrieveOptions?, CancellationTokens)

This method retrieves a single record from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.

### Declaration

```
// C#  
public async Task<TRecord> GetAsync(TKey key, RecordRetrieveOptions? options  
= null, CancellationTokens cancellationTokens = default);
```

**Parameters**

- **key**  
The unique ID associated with the record to retrieve.
- **options**  
Optional options for retrieving the records.
- **cancellationToken**  
The cancellation token.

**Return Value**

Task<TRecord?> object representing the record if found, or null if not found.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**See Also**

- [RecordRetrievalOptions](#)

## GetAsync(IEnumerable<TKey>, RecordRetrieveOptions?, CancellationToken)

This method retrieves a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.

**Declaration**

```
// C#  
public async IAsyncEnumerable<TRecord?> GetAsync(IEnumerable<TKey> keys,  
RecordRetrieveOptions? options = null, CancellationToken cancellationToken =  
default);
```

**Parameters**

- **key**  
The unique IDs associated with the records to retrieve.
- **options**  
Optional options for retrieving the records.
- **cancellationToken**  
The cancellation token.

**Return Value**

IAsyncEnumerable<TRecord?> object representing the result set of found records.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**① See Also**

- [RecordRetrievalOptions](#)

## GetAsync(Expression<Func<TRecord, bool>>, int, FilteredRecordRetrievalOptions<TRecord>?, CancellationToken)

This method retrieves from the vector store records matching a filter expression. It does not guarantee the existence of the collection.

**Declaration**

```
// C#
public async IEnumerable<TRecord?> GetAsync( Expression<Func<TRecord,
bool>> filter, int top, FilteredRecordRetrievalOptions<TRecord>? options =
null, CancellationToken cancellationToken = default);
```

**Parameter**

- filter  
Predicate for filtering the records.
- top  
Maximum number of results to return.
- options  
Optional options for retrieving the records.
- cancellationToken  
The cancellation token.

**Return Value**

IAsyncEnumerable<TRecord?> object representing the records matching the provided predicate.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**Remarks**

The filter cannot compare the following unsupported columns types:

- BFile
- Blob
- Clob
- Json
- NClob
- Vector
- Vector\_Binary
- Vector\_Float32
- Vector\_Float64
- Vector\_Int8
- XmlType

**① See Also**

- [FilteredRecordRetrievalOptions<TRecord> Class](#)

## GetService

This method retrieves an object of a specified service type from the vector store.

**Declaration**

```
// C#  
public object? GetService(Type serviceType, object? serviceKey = null);
```

**Parameters**

- serviceType  
The type of an object to retrieve. Supported ServiceType: VectorStoreCollectionMetaData, OracleCollection or OracleDataSource (.NET Core only).
- serviceKey  
An optional key that can be used to identify the target service.

**Return Value**

An Object of a specified service type, otherwise null.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

## SearchAsync

This method searches the vector store for records that are similar to input data.

### Declaration

```
// C#  
public async IEnumerable<VectorSearchResult<TRecord>>  
SearchAsync<TInput>(TInput searchValue, int top,  
VectorSearchOptions<TRecord>? options = null, CancellationToken  
cancellation_token = default) where TInput : notnull;
```

### Parameters

- **TInput**  
The type of the input value to perform the similarity search.
- **searchValue**  
Input value for similarity search. For more information, see the Remarks section.
- **top**  
The maximum number of results to return.
- **options**  
The options that control search behavior.
- **cancellation\_token**  
The cancellation token.

### Return Value

`IEnumerable<VectorSearchResult<TRecord>>` records found by the vector search, including their result scores.

### Implements

`Microsoft.Extensions.VectorData.IVectorSearchable`

### Exceptions

- **VectorStoreException**: The command fails to execute for any reason other than the absence of a record.
- **NotSupportedException**: The database is not a 26ai or later database that does not have vector data type support.

### Remarks

The types supported for the `searchValue` parameter vary based on the provider being used and the embedding generation configured.

A string or [DataContent](#)(for images, sound...) if an appropriate [IEmbeddingGenerator](#) has been configured that accepts that type as input. For example, register an [IEmbeddingGenerator](#) that accepts string as input in your dependency injection container, and then pass in a string argument to this method; the argument will be automatically passed to the [IEmbeddingGenerator](#) to generate the embedding and perform the search.

Some databases support generating embeddings at the database side. In this case, you can pass in a string or [DataContent](#) without configuring an [IEmbeddingGenerator](#) with

[Microsoft.Extensions.VectorData..](#) The provider will simply send your argument to the database as-is for embedding generation.

Arbitrary .NET types can also be passed in as long as an appropriate [IEmbeddingGenerator](#) has been configured; for example, you can create your own [IEmbeddingGenerator](#) that accepts your own custom types as input, and uses another [IEmbeddingGenerator](#) to generate embedding from multiple properties.

For .NET types beyond string and [DataContent](#) , you must use the generic [VectorStoreVectorProperty](#) in your record definition.

To work with embeddings directly, pass in the .NET data types that the connector accepts for Vector data type.

If you are using [IEmbeddingGenerator](#) directly in your code, that type returns an [Embedding](#) (for example, `Embedding`), which can also be passed in directly, as long as the provider supports the specific embedding type. However, consider registering your [IEmbeddingGenerator](#) with the provider instead and pass in the input type (for example, `string`).

## UpsertAsync

`UpsertAsync` methods update or insert a record or a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

### Overload List

- [UpsertAsync\(TRecord, CancellationToken\)](#)  
This method updates or inserts a record into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.
- [UpsertAsync\(IEnumerable<TRecord>, CancellationToken\)](#)  
This method updates or inserts a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

## UpsertAsync(TRecord, CancellationToken)

This method updates or inserts a record into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

### Declaration

```
// C#
public async Task UpsertAsync(TRecord record, CancellationToken
cancellationTokn = default);
```

**Parameters**

- record  
The record to update or insert.
- cancellationToken  
The cancellation token.

**Return Value**

Task representing the asynchronous operation when the records are updated or inserted.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

## UpsertAsync(IEnumerable<TRecord>, CancellationToken)

This method updates or inserts a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

**Declaration**

```
// C#  
public async Task UpsertAsync(IEnumerable<TRecord> records, CancellationToken  
cancellationToken = default);
```

**Parameters**

- records  
The records to update or insert.
- cancellationToken  
The cancellation token.

**Return Value**

Task representing the asynchronous operation when the records are updated or inserted.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**Remarks**

All records are upserted when succeed or none when fails.

# OracleCollectionOptions Class

The OracleCollectionOptions object encapsulates configuration options for creating an instance of the OracleCollection class. While creating the collection, these options control aspects like schema assignment, custom collection definitions, and embedding generator assignment.

### Class Inheritance

```
System.Object
    Microsoft.Extensions.VectorData.VectorStoreCollectionOptions
        Oracle.VectorData.OracleCollectionOptions
```

### Declaration

```
// C#
public class OracleCollectionOptions :
    Microsoft.Extensions.VectorData.VectorStoreCollectionOptions
```

### Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

 See Also

- [OracleCollectionOptions Constructor](#)
- [OracleCollectionOptions Properties](#)

## OracleCollectionOptions Constructor

Instantiates a new instance of the OracleCollectionOptions class for configuring collection-level options.

### Declaration

```
// C#
public OracleCollectionOptions()
```

① See Also

- [OracleCollectionOptions Class](#)
- [OracleCollectionOptions Properties](#)

# OracleCollectionOptions Properties

OracleCollectionOptions properties are listed in [Table 21-3](#).

**Table 21-3 OracleCollectionOptions Properties**

| Property                           | Description                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">EmbeddingGenerator</a> | This property specifies the default embedding generator to use for generating vector embeddings when working with the collection. |
| <a href="#">Schema</a>             | This property specifies the database schema name under which collections are created by default.                                  |
| <a href="#">Definition</a>         | This property specifies an optional record definition, describing the schema of the record type.                                  |

① See Also

- [OracleCollectionOptions Class](#)
- [OracleCollectionOptions Constructor](#)

# EmbeddingGenerator

This property specifies the default embedding generator to use for generating vector embeddings when working with the collection.

**Declaration**

```
// C#
public IEmbeddingGenerator? EmbeddingGenerator { get; set; }
```

**Property Value**

The default embedding generator to use for generating vector embeddings when working with the vector store.

**Implements**

Inherited from `Microsoft.Extensions.VectorData.VectorStoreCollectionOptions`

**Remarks**

When embedding is specified, the collection uses the EmbeddingGenerator to generate embeddings. The default property value is null. When the embedding generator is provided, the collection automatically generates the embedding during both upsert and search operations, eliminating the need for the application to generate and provide the embedding.

## Schema

This property specifies the database schema name under which collections are created.

### Declaration

```
// C#  
public string? Schema { get; set; }
```

### Property Value

The string specifying the name of the database schema.

### Remarks

When Schema is specified, the collections under this vector store are created under the schema. The default schema value is null. When null, the collections are created under the connected user's schema.

## Definition

This property specifies an optional record definition, describing the schema of the record type.

### Declaration

```
// C#  
public VectorStoreCollectionDefinition? Definition { get; set; }
```

### Property Value

An optional record Definition, describing the schema of the record type.

### Implements

Inherited from `Microsoft.Extensions.VectorData.VectorStoreCollectionOptions`

### Remarks

If not provided, schema is auto-inferred from the record model class. In this case, the record model properties needs to be annotated with the appropriate attributes to indicate their usage.

#### See Also

- [Defining your storage schema using a record definition](#)
- [VectorStoreCollectionDefinition Class](#)

## OracleDynamicCollection Class

An `OracleDynamicCollection` object implements `Microsoft.Extensions.VectorData.VectorStoreCollection` interface. It is used to search and manage records, and to create or delete the collection itself.

The definition of the named collection is based on the application-provided key type and a generic data model, Dictionary<object, object?>. In an Oracle database, a named collection is mapped to an Oracle database table, and the table definition is defined based on the provided key type and the provided record definition.

An OracleDynamicCollection can be used without requiring an application to provide a data model. Records can be managed or processed using the generic Dictionary<string, object?> class.

**Class Inheritance**

```
System.Object
    Microsoft.Extensions.VectorData.VectorStoreCollection
        Oracle.VectorData.OracleCollection
            Oracle.VectorData.OracleDynamicCollection
```

**Declaration**

```
// C#
public class OracleDynamicCollection : OracleCollection <object,
Dictionary<string, object?>>
```

**Thread Safety**

All public methods are thread-safe, unless stated otherwise.

**Requirements**

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

**See Also**

# OracleDynamicCollection Constructors

The OracleDynamicCollection constructors create new instances of the OracleDynamicCollection class with the provided data source or connection string and the collection name.

**Overload List:**

- [OracleDynamicCollection\(OracleDataSource, string, OracleCollectionOptions\)](#)  
This constructor instantiates a new instance of OracleDynamicCollection class using the provided data source and collection name
- [OracleDynamicCollection\(string, string, OracleCollectionOptions\)](#)  
This constructor instantiates a new instance of OracleDynamicCollection class using the provided connection string and collection name.

**See Also**

- [OracleDynamicCollection Class](#)
- [OracleDynamicCollection Properties](#)
- [OracleDynamicCollection Public Methods](#)

## OracleDynamicCollection(OracleDataSource, string, OracleCollectionOptions)

Instantiates a new instance of OracleDynamicCollection class using the provided data source and collection name.

**Declaration**

```
// C#
OracleDynamicCollection (OracleDataSource dataSource, string collectionName,
OracleCollectionOptions options)
```

**Parameters**

- **dataSource**  
The data source which can be used to obtain open database connections.
- **collectionName**  
Name of the collection
- **options**  
Vector collection configuration options.

**Exceptions**

- **ArgumentNullException:** The provided dataSource or name parameter is null.
- **ArgumentException:**
  - The provided collectionName parameter is null, an empty string or contains white spaces only.
  - The provided collectionName is not compliant with Oracle name standard.
  - The definition provided in OracleCollectionOptions.Definition is null or cannot be mapped to an Oracle type based on the default/custom type mapping.

**① See Also**

- [OracleDataSource Class](#)
- [GetDynamicCollection\(string, VectorStoreCollectionDefinition\)](#)
- [OracleCollectionOptions Class](#)

## OracleDynamicCollection(string, string, OracleCollectionOptions)

Instantiates a new instance of OracleDynamicCollection class using the provided connection string and collection name.

**Declaration**

```
// C#
OracleDynamicCollection(string connectionString, string collectionName,
OracleCollectionOptions options)
```

**Parameters**

- `string`  
The connection string which can be used to obtain database connections.
- `collectionName`  
Name of the collection
- `options`  
Vector collection configuration options.

**Exceptions**

- `ArgumentNullException`: The provided dataSource or name parameter is null.
- `ArgumentException`:
  - The provided collectionName parameter is null, an empty string or contains white spaces only.
  - The provided collectionName is not compliant with Oracle name standard.
  - The definition provided in `OracleCollectionOptions.Definition` is null or cannot be mapped to an Oracle type based on the default/custom type mapping.

**① See Also**

- [OracleDataSource Class](#)
- [GetDynamicCollection\(string, VectorStoreCollectionDefinition\)](#)

## OracleDynamicCollection Properties

OracleDynamicCollection properties are listed in [Table 21-4](#) .

**Table 21-4 OracleDynamicCollection Properties**

| Property             | Description                                                                       |
|----------------------|-----------------------------------------------------------------------------------|
| <a href="#">Name</a> | This property specifies the name of this collection/table in the Oracle database. |

### See Also

- [OracleDynamicCollection Class](#)
- [OracleDynamicCollection Constructors](#)
- [OracleDynamicCollection Public Methods](#)

## Name

This property specifies the name of this collection/table in the Oracle database.

### Declaration

```
// C#  
public string Name { get; }
```

### Property Value

The string specifying the name of the collection. The collection name is the name given by the application when the OracleDynamicCollection instance is created.

### Implements

Microsoft.Extensions.VectorData.VectorStoreCollection

## OracleDynamicCollection Public Methods

OracleDynamicCollection public methods are listed in [Table 21-5](#).

**Table 21-5 OracleDynamicCollection Public Methods**

| Public Method                         | Description                                                                                                            |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CollectionExistsAsync</a> | Checks whether the collection exists in the vector store.                                                              |
| <a href="#">DeleteAsync</a>           | Deletes a single record or a batch of records from the vector store. It does not guarantee that the collection exists. |
| <a href="#">Dispose</a>               | Releases any resources or memory held by the object.                                                                   |

Table 21-5 (Cont.) OracleDynamicCollection Public Methods

| Public Method                                | Description                                                                                                                                                                                                       |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">EnsureCollectionExistsAsync</a>  | Ensures the existence of the collection. Creates the collection in the vector store if it does not exist.                                                                                                         |
| <a href="#">EnsureCollectionDeletedAsync</a> | Deletes the collection from the vector store if it exists.                                                                                                                                                        |
| <a href="#">#unique_2988</a>                 | Retrieves a single record or a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.                                              |
| <a href="#">GetService</a>                   | Retrieves an object of a specified service type from the collection or vector store.                                                                                                                              |
| <a href="#">SearchAsync</a>                  | Searches the vector store for records that are similar to input data.                                                                                                                                             |
| <a href="#">UpsertAsync</a>                  | Updates or inserts a record or a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created. |

## GetAsync

GetAsync methods retrieve a single record or a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.

### Overload List

- [GetAsync\(Object, RecordRetrieveOptions?, CancellationToken\)](#)  
This method retrieves a single record from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.
- [GetAsync\(IEnumerable<Object>, RecordRetrieveOptions?, CancellationToken\)](#)  
This method retrieve a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.
- [GetAsync\(Expression<Func<Dictionary<string, object?>, bool>>, int, <Dictionary<string, object?>>?, CancellationToken\)](#)  
This method retrieves from the vector store records matching a filter expression. It does not guarantee the existence of the collection.

## CollectionExistsAsync

This method checks if a collection exists in the vector store.

**Declaration**

```
// C#  
public async Task<bool> CollectionExistsAsync(CancellationTok  
cancellationToken = default)
```

**Parameters**

- `cancellationToken`  
The cancellation token.

**Return Value**

A task representing the asynchronous operation. The task result contains a boolean indicating whether the collection exists in the database. True if exists, else false.

**Implements**

Microsoft.Extensions.VectorData.VectorStore

## DeleteAsync

DeleteAsync methods delete a single record or a batch of records from the vector store. It does not guarantee that the collection exists.

**Overload List**

- [DeleteAsync\(Object key, CancellationTok](#)  
This method deletes a record from the vector store. It does not guarantee that the collection exists.
- [DeleteAsync\(IEnumerable<Object> keys, CancellationTok](#)  
This method deletes a batch of records from the vector store. It does not guarantee that the collection exists.

## DeleteAsync(Object key, CancellationTok

This method deletes a record from the vector store. It does not guarantee that the collection exists.

**Declaration**

```
// C#  
public async Task DeleteAsync(Object key, CancellationTok  
= default);
```

**Parameters**

- `key`  
The unique key associated with the record to delete.
- `cancellationToken`  
The cancellation token.

**Return Value**

A task representing the asynchronous operation that completes when the record is deleted.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**Remarks**

Unlike OracleCollection, OracleDynamicCollection uses Object as TKey, and Dictionary<string, object?> as TRecord. Please make sure to use the correct parameter types.

## DeleteAsync(IEnumerable<Object> keys, CancellationToken)

This method deletes a batch of records from the vector store. It does not guarantee that the collection exists.

**Declaration**

```
// C#
public async Task DeleteAsync(IEnumerable<Object> keys, CancellationToken
cancellationTokn = default);
```

**Parameters**

- **keys**  
The unique keys associated with the records to delete.
- **cancellationTokn**  
The cancellation token.

**Return Value**

A task representing the asynchronous operation when the records are deleted.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**Remarks**

If a record is not found, it is ignored, and the batch operation succeeds. However, if a record cannot be deleted for any reason, the operation throws an error. Since some records may have already been deleted while others have not, the entire operation needs to be retried.

Unlike OracleCollection, OracleDynamicCollection uses Object as TKey, and Dictionary<string, object?> as TRecord. Please make sure to use the correct parameter types: IEnumerable<Object> for keys.

## Dispose

This method releases any resources or memory allocated by the object.

### Declaration

```
// C#  
public void Dispose()
```

### Implements

System.IDisposable

### Thread Safety

This method is not thread-safe.

## EnsureCollectionDeletedAsync

This method deletes the collection from the vector store if it exists.

### Declaration

```
// C#  
public async Task EnsureCollectionDeleteAsync(CancellationTokentoken = default)
```

### Parameters

- cancellationTokentoken  
The cancellation token.

### Return Value

A task representing the asynchronous operation that completes when the collection has been deleted from the database.

### Implements

Microsoft.Extensions.VectorData.VectorStoreCollection

## EnsureCollectionExistsAsync

This method ensures the existence of the collection. It creates the collection in the vector store if it does not exist.

### Declaration

```
// C#  
public async Task EnsureCollectionExistsAsync(CancellationTokentoken = default)
```

**Parameters**

- `cancellationToken`  
The cancellation token.

**Return Value**

A task representing the asynchronous operation that completes when the collection has been created in the database.

**Implements**

`Microsoft.Extensions.VectorData.VectorStoreCollection`

## GetAsync(Object, RecordRetrieveOptions?, CancellationToken)

This method retrieves a single record from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.

**Declaration**

```
// C#  
public async Task<Dictionary<string, object?>> GetAsync(Object key,  
RecordRetrieveOptions? options = null, CancellationToken cancellationToken =  
default);
```

**Parameters**

- `key`  
The unique ID associated with the record to retrieve.
- `options`  
Optional options for retrieving the record.
- `cancellationToken`  
The cancellation token.

**Return Value**

`Task<Dictionary<string, object?>>` representing the record if found, or null if not found.

**Implements**

`Microsoft.Extensions.VectorData.VectorStoreCollection`

**Exceptions**

`VectorStoreException`: The command fails to execute for any reason other than the absence of a record.

**Remarks**

Unlike `OracleCollection`, `OracleDynamicCollection` uses `Object` as `TKey`, and `Dictionary<string, object?>` as `TRecord`. Please make sure to use the correct parameter types.

**① See Also**

- [RecordRetrievalOptions](#)

## GetAsync(IEnumerable<Object>, RecordRetrieveOptions?, CancellationToken)

This method retrieves a batch of records from the vector store. It does not guarantee that the collection exists and returns null if the record is not found.

### Declaration

```
// C#
public async IEnumerable<Dictionary<string, object?>>
GetAsync(IEnumerable<Object> keys, RecordRetrieveOptions? options = null,
CancellationToken cancellationToken = default);
```

### Parameters

- **key**  
The unique IDs associated with the records to retrieve.
- **options**  
Optional options for retrieving the records.
- **cancellationToken**  
The cancellation token.

### Return Value

`IAsyncEnumerable<Dictionary<string, object?>` object representing the result set of found records.

### Implements

`Microsoft.Extensions.VectorData.VectorStoreCollection`

### Exceptions

`VectorStoreException`: The command fails to execute for any reason other than the absence of a record.

### Remarks

Unlike `OracleCollection`, `OracleDynamicCollection` uses `Object` as `TKey`, and `Dictionary<string, object?>` as `TRecord`. Please make sure to use the correct parameter types: `IEnumerable<Object>` for keys.

**① See Also**

- [RecordRetrievalOptions](#)

GetAsync(Expression<Func<Dictionary<string, object?>, bool>>, int,<Dictionary<string, object?>>?, CancellationToken )

This method retrieves from the vector store records matching a filter expression. It does not guarantee the existence of the collection.

#### Declaration

```
// C#
public async IEnumerable<Dictionary<string, object?>>
    GetAsync(Expression<Func<Dictionary<string, object?>, bool>> filter, int top,
        FilteredRecordRetrievalOptions<Dictionary<string, object?>>? options = null,
        CancellationToken cancellationToken = default);
```

#### Parameter

- filter  
Predicate for filtering the records.
- top  
Maximum number of results to return.
- options  
Optional options for retrieving the records.
- cancellationToken  
The cancellation token.

#### Return Value

IAsyncEnumerable<Dictionary<string, object?>> object representing the records matching the provided predicate.

#### Implements

Microsoft.Extensions.VectorData.VectorStoreCollection

#### Exceptions

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

#### Remarks

The filter cannot compare the following unsupported columns types:

- BFile
- Blob
- Clob
- Json
- NClob
- Vector
- Vector\_Binary

- Vector\_Float32
- Vector\_Float64
- Vector\_Int8
- XmlType

Unlike OracleCollection, OracleDynamicCollection uses Object as TKey, and Dictionary<string, object?> as TRecord. Ensure to use the correct parameter types for the filter and options: Dictionary<string, object?>.

#### ① See Also

- [FilteredRecordRetrievalOptions<TRecord> Class](#)

## GetService

This method retrieves an object of a specified service type from the vector store.

### Declaration

```
// C#  
public object? GetService(Type serviceType, object? serviceKey = null);
```

### Parameters

- serviceType  
The type of an object to retrieve. Supported ServiceType: VectorStoreCollectionMetaData, OracleCollection or OracleDataSource (.NET Core only).
- serviceKey  
An optional key that can be used to identify the target service.

### Return Value

An object of a specified service type, otherwise null.

### Implements

Microsoft.Extensions.VectorData.VectorStoreCollection

## SearchAsync

This method searches the vector store for records that are similar to input data.

### Declaration

```
// C#  
public async IEnumerable<VectorSearchResult<Dictionary<string, object?>>> SearchAsync<TInput>(TInput searchValue, int top, VectorSearchOptions<Dictionary<string, object?>>? options = null, CancellationToken cancellationToken = default) where TInput : notnull;
```

### Parameters

- **TInput**  
The type of the input value to perform the similarity search.
- **searchValue**  
Input value for similarity search. For more information, see the Remarks section.
- **top**  
The maximum number of results to return.
- **options**  
The options that control search behavior.
- **cancellationToken**  
The cancellation token.

### Return Value

`IAsyncEnumerable<VectorSearchResult<Dictionary<string, object?>>` records found by the vector search, including their result scores.

### Implements

`Microsoft.Extensions.VectorData.IVectorSearchable`

### Exceptions

- **VectorStoreException**: The command fails to execute for any reason other than the absence of a record.
- **NotSupportedException**: The database is not a 26ai or later database that does not have vector data type support.

### Remarks

The types supported for the `searchValue` parameter vary based on the provider being used and the embedding generation configured.

A string or [DataContent](#) (for images, sound...) if an appropriate [IEmbeddingGenerator](#) has been configured that accepts that type as input. For example, register an [IEmbeddingGenerator](#) that accepts string as input in your dependency injection container, and then pass in a string argument to this method; the argument will be automatically passed to the [IEmbeddingGenerator](#) to generate the embedding and perform the search.

Some databases support generating embeddings at the database side. In this case, you can pass in a string or [DataContent](#) without configuring an [IEmbeddingGenerator](#) with [Microsoft.Extensions.VectorData..](#) The provider will simply send your argument to the database as-is for embedding generation.

Arbitrary .NET types can also be passed in as long as an appropriate [IEmbeddingGenerator](#) has been configured; for example, you can create your own [IEmbeddingGenerator](#) that accepts your own custom types as input, and uses another [IEmbeddingGenerator](#) to generate embedding from multiple properties.

For .NET types beyond string and [DataContent](#), you must use the generic [VectorStoreVectorProperty](#) in your record definition.

To work with embeddings directly, pass in the .NET data types that the connector accepts for Vector data type.

If you are using [IEmbeddingGenerator](#) directly in your code, that type returns an [Embedding](#) (for example, `Embedding`), which can also be passed in directly, as long as the provider supports the specific embedding type. However, consider registering your [IEmbeddingGenerator](#) with the provider instead and pass in the input type (for example, `string`).

Unlike `OracleCollection`, `OracleDynamicCollection` uses `Object` as `TKey`, and `Dictionary<string, object?>` as `TRecord`. Ensure to use the correct parameter types for options: `Dictionary<string, object?>`.

## UpsertAsync

`UpsertAsync` methods update or insert a record or a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

### Overload List

- [UpsertAsync\(Dictionary<string, object?>, CancellationToken\)](#)  
This method updates or inserts a record into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.
- [UpsertAsync\(IEnumerable<Dictionary<string, object?>>, CancellationToken\)](#)  
This method updates or inserts a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

## UpsertAsync(Dictionary<string, object?>, CancellationToken)

This method updates or inserts a record into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

### Declaration

```
// C#
public async Task UpsertAsync(Dictionary<string, object?> record,
    CancellationToken cancellationToken = default);
```

### Parameters

- `record`  
The record to update or insert.
- `cancellationToken`  
The cancellation token.

### Return Value

Task representing the asynchronous operation when the records are updated or inserted.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**Remarks**

Unlike OracleCollection, OracleDynamicCollection uses Object as TKey, and Dictionary<string, object?> as TRecord. Please make sure to use the correct parameter types, Dictionary<string, object?>, for record.

## UpsertAsync(IEnumerable<Dictionary<string, object?>>, CancellationToken)

This method updates or inserts a batch of records into the vector store. It does not guarantee the existence of the collection. If the record already exists, it is updated; if it does not exist, it is created.

**Declaration**

```
// C#  
public async Task UpsertAsync(IEnumerable<Dictionary<string, object?>>  
records, CancellationToken cancellationToken = default);
```

**Parameters**

- records  
The records to update or insert.
- cancellationToken  
The cancellation token.

**Return Value**

Task representing the asynchronous operation when the records are updated or inserted.

**Implements**

Microsoft.Extensions.VectorData.VectorStoreCollection

**Exceptions**

VectorStoreException: The command fails to execute for any reason other than the absence of a record.

**Remarks**

All records are upserted when succeed or none when fails.

Unlike OracleCollection, OracleDynamicCollection uses Object as TKey, and Dictionary<string, object?> as TRecord. Please make sure to use the correct parameter types, IEnumerable<Dictionary<string, object?>> for records.

# OracleServiceCollectionExtensions Class

OracleServiceCollectionExtensions class is for extension methods to register OracleVectorStore or OracleCollection instances on an IServiceCollection. It extends the .NET IServiceCollection class through dependency injection to provide the application a service to register either OracleVectorStore or OracleCollection services.

**Class Inheritance**

System.Object  
    Microsoft.Extensions.DependencyInjection.OracleServiceCollectionExtensions

**Declaration**

```
// C#  
public static class OracleServiceCollectionExtensions
```

**Thread Safety**

All public methods are thread-safe, unless stated otherwise.

**Requirements**

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

## OracleServiceCollectionExtensions Static Methods

OracleServiceCollectionExtensions static methods are listed in [Table 21-6](#).

**Table 21-6 OracleServiceCollectionExtensions Static Methods**

| Public Method                            | Description                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddKeyedOracleCollection</a> | Registers a keyed OracleCollection as VectorStoreCollection, with the specified connection string and service lifetime. |

**Table 21-6 (Cont.) OracleServiceCollectionExtensions Static Methods**

| Public Method                             | Description                                                                                                        |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <a href="#">AddKeyedOracleVectorStore</a> | Registers a keyed OracleVectorStore as VectorStore, with the specified connection string and service lifetime.     |
| <a href="#">AddOracleCollection</a>       | Registers an OracleCollection as VectorStoreCollection, with the specified connection string and service lifetime. |
| <a href="#">AddOracleVectorStore</a>      | Registers an OracleVectorStore as VectorStore, with the specified connection string and service lifetime.          |

**See Also**

- [OracleServiceCollectionExtensions Class](#)

## AddKeyedOracleCollection

AddKeyedOracleCollection methods register a keyed OracleCollection as VectorStoreCollection.

**Overload List**

- [AddKeyedOracleCollection<TKey, TRecord>\(IServiceCollection, object?, string, Func<IServiceProvider, string>, Func<IServiceProvider, OracleVectorCollectionOptions>?, ServiceLifetime \)](#)  
This method registers a keyed OracleCollection as VectorStoreCollection, with the specified connection string provider and service lifetime.
- [AddKeyedOracleCollection<TKey, TRecord>\(IServiceCollection, object?, string, string, OracleCollectionOptions?, ServiceLifetime\)](#)  
This method registers a keyed OracleCollection as VectorStoreCollection, with the specified connection string and service lifetime.

**AddKeyedOracleCollection<TKey, TRecord>(IServiceCollection, object?, string, Func<IServiceProvider, string>, Func<IServiceProvider, OracleVectorCollectionOptions>?, ServiceLifetime )**

This method registers a keyed OracleCollection<TKey, TRecord> as VectorStoreCollection, with the specified connection string provider and service lifetime.

**Declaration**

```
// C#
public static IServiceCollection AddKeyedOracleCollection<TKey, TRecord>(this
IServiceCollection services, object? serviceKey, string name,
Func<IServiceProvider, string> connectionStringProvider,
Func<IServiceProvider, OracleVectorCollectionOptions>? optionsProvider =
```

```
null, ServiceLifetime lifetime = ServiceLifetime.Singleton) where TKey :  
notnull where TRecord : class
```

### Parameters

- **TKey**  
The key type of `OracleCollection<TKey, TRecord>`.
- **TRecord**  
The record type of `OracleCollection<TKey, TRecord>`.
- **services**  
The `IServiceCollection` to register the `VectorStore` on.
- **serviceKey**  
The key to associate with the vector collection.
- **name**  
The name of the collection.
- **connectionStringProvider**  
The connection string provider.
- **optionsProvider**  
The optional options provider to further configure the vector store.
- **lifetime**  
The service lifetime for the store. Defaults to `ServiceLifetime.Singleton`.

### Return Value

Returns the service collection.

### Exceptions

`InvalidArgumentException`:

- The provided `connectionStringProvider` or `services` parameter is null.
- The provided `name` parameter is null or empty.

## AddKeyedOracleCollection<TKey, TRecord>(IServiceCollection, object?, string, string, OracleCollectionOptions?, ServiceLifetime)

This method registers a keyed `OracleCollection<TKey, TRecord>` as `VectorStoreCollection`, with the specified connection string and service lifetime.

### Declaration

```
// C#  
public static IServiceCollection AddKeyedOracleCollection<TKey, TRecord>(this  
IServiceCollection services, object? serviceKey, string name, string  
connectionString, OracleCollectionOptions? options = default, ServiceLifetime  
lifetime = ServiceLifetime.Singleton) where TKey : notnull where TRecord :  
class
```

### Parameters

- **services**

The IServiceCollection to register the VectorStore on.

- **serviceKey**  
The key to associate with the vector collection.
- **name**  
The name of the collection.
- **connectionString**  
The connection string.
- **optionsProvider**  
The optional options provider to further configure the vector store.
- **lifetime**  
The service lifetime for the store. Defaults to ServiceLifetime.Singleton.

### Return Value

Returns the service collection.

## AddKeyedOracleVectorStore

AddKeyedOracleVectorStore methods register a keyed OracleVectorStore as VectorStore.

### Overload List

- [AddKeyedOracleVectorStore\(IServiceCollection, object?, Func<IServiceProvider, string>, Func<IServiceProvider, OracleVectorStoreOptions>?, ServiceLifetime\)](#)  
This method registers a keyed OracleVectorStore as VectorStore, with the specified connection string provider and service lifetime.
- [AddKeyedOracleVectorStore\(IServiceCollection, object?, string, OracleVectorStoreOptions?, ServiceLifetime\)](#)  
This method registers a keyed OracleVectorStore as VectorStore, with the specified connection string and service lifetime.

## AddKeyedOracleVectorStore(IServiceCollection, object?, Func<IServiceProvider, string>, Func<IServiceProvider, OracleVectorStoreOptions>?, ServiceLifetime)

This method registers a keyed OracleVectorStore as VectorStore, with the specified connection string provider and service lifetime.

### Declaration

```
// C#
public static IServiceCollection AddKeyedOracleVectorStore(this
IServiceCollection services, object? serviceKey, Func<IServiceProvider,
string> connectionStringProvider, Func<IServiceProvider,
OracleVectorStoreOptions>? optionsProvider = null, ServiceLifetime lifetime =
ServiceLifeTime.Singleton)
```

### Parameters

- **services**  
The IServiceCollection to register the VectorStore on.
- **serviceKey**

The key to associate with the vector store.

- `connectionStringProvider`  
The connection string provider.
- `optionsProvider`  
The optional options provider to further configure the vector store.
- `lifetime`  
The service lifetime for the store. Defaults to `ServiceLifetime.Singleton`.

### Return Value

Returns the service collection.

### Exceptions

`InvalidArgumentException`: The provided `connectionStringProvider` or `services` parameters is null.

## AddKeyedOracleVectorStore(IServiceCollection, object?, string, OracleVectorStoreOptions?, ServiceLifetime)

This method registers a keyed `OracleVectorStore` as `VectorStore`, with the specified connection string and service lifetime.

### Declaration

```
// C#  
public static IServiceCollection AddKeyedOracleVectorStore(this  
IServiceCollection services, object? serviceKey, string  
connectionString, OracleVectorStoreOptions? options = null, ServiceLifetime  
lifetime = ServiceLifetime.Singleton)
```

### Parameters

- `services`  
The `IServiceCollection` to register the `VectorStore` on.
- `serviceKey`  
The key to associate with the vector store.
- `connectionString`  
The connection string.
- `options`  
Options to further configure the vector store.
- `lifetime`  
The service lifetime for the store. Defaults to `ServiceLifetime.Singleton`.

### Return Value

Returns the service collection.

## AddOracleCollection

`AddOracleCollection` methods register an `OracleCollection` as `VectorStoreCollection`.

### Overload List

- [AddOracleCollection<TKey, TRecord>\(IServiceCollection, string, Func<IServiceProvider, string>, Func<IServiceProvider, OracleCollectionsOptions>?, ServiceLifetime\)](#)  
This method registers an OracleCollection as VectorStoreCollection, with the specified connection string and service lifetime.
- [AddOracleCollection<TKey, TRecord>\(IServiceCollection, string, string, OracleCollectionOptions?, ServiceLifetime\)](#)  
This method registers an OracleCollection as VectorStoreCollection, with the specified connection string and service lifetime.
- [AddOracleCollection<TKey, TRecord>\(this IServiceCollection, string, OracleCollectionOptions?, ServiceLifetime\)](#)  
This method registers an OracleCollection as VectorStoreCollection, with the OracleDataSource retrieved from the IServiceCollection.

AddOracleCollection<TKey, TRecord>(IServiceCollection, string, Func<IServiceProvider, string>, Func<IServiceProvider, OracleCollectionsOptions>?, ServiceLifetime)

This method registers an OracleCollection as VectorStoreCollection, with the specified connection string provider and service lifetime.

### Declaration

```
// C#
public static IServiceCollection AddOracleCollection<TKey, TRecord>(this
IServiceCollection services, string name, Func<IServiceProvider, string>
connectionStringProvider, Func<IServiceProvider, OracleCollectionsOptions>?
optionsProvider = null, ServiceLifetime lifetime = ServiceLifeTime.Singleton)
where TKey : notnull where TRecord : class
```

### Parameters

- services  
The IServiceCollection to register the VectorStore on.
- name  
The name of the collection.
- connectionStringProvider  
The connection string provider.
- optionsProvider  
The optional options provider to further configure the vector store.
- lifetime  
The service lifetime for the store. Defaults to ServiceLifetime.Singleton.

### Return Value

Returns the service collection.

### Exceptions

InvalidArgumentException:

- The provided connectionStringProvider or services parameter is null.
- The provided name parameter is null or empty.

## AddOracleCollection<TKey, TRecord>(IServiceCollection, string, string, OracleCollectionOptions?, ServiceLifetime)

This method registers an OracleCollection as VectorStoreCollection, with the specified connection string and service lifetime.

### Declaration

```
// C#  
public static IServiceCollection AddOracleCollection<TKey, TRecord>(this  
IServiceCollection services, string name, string  
connectionString, OracleCollectionOptions? options = default, ServiceLifetime  
lifetime = ServiceLifetime.Singleton) where TKey : notnull where TRecord : class
```

### Parameters

- services  
The IServiceCollection to register the VectorStore on.
- name  
The name of the collection.
- connectionString  
The connection string.
- options  
Options to further configure the vector store.
- lifetime  
The service lifetime for the store. Defaults to ServiceLifetime.Singleton.

### Return Value

Returns the service collection.

### Exceptions

InvalidArgumentException

- The provided services parameter is null.
- The provided connectionString or name parameter is null or empty.

## AddOracleCollection<TKey, TRecord>(this IServiceCollection, string, OracleCollectionOptions?, ServiceLifetime)

This method registers an OracleCollection as VectorStoreCollection, with the OracleDataSource retrieved from the IServiceCollection.

### Declaration

```
// C#  
public static IServiceCollection AddOracleCollection(this IServiceCollection
```

```
services, string name, OracleCollectionsOptions? options = null,
ServiceLifetime lifetime = ServiceLifeTime.Singleton) where TKey : notnull
where TRecord : class;
```

### Parameters

- **services**  
The IServiceCollection to register the VectorStore on.
- **name**  
The name of the collection.
- **options**  
Options to further configure the vector store.
- **lifetime**  
The service lifetime for the store. Defaults to ServiceLifetime.Singleton.

### Return Value

Returns the service collection.

### Exceptions

InvalidArgumentException:

- The provided services parameter is null.
- The provided name parameter is null or empty.

InvalidOperationException: The service collection does not contain an OracleDataSource.

## AddOracleVectorStore

AddOracleVectorStore methods register an OracleVectorStore as VectorStore.

### Overload List

- [AddOracleVectorStore\(IServiceCollection, Func<IServiceProvider, string>, Func<IServiceProvider, OracleVectorStoreOptions>?, ServiceLifetime\)](#)  
This method registers an OracleVectorStore as VectorStore, with the specified connection string and service lifetime.
- [AddOracleVectorStore\(IServiceCollection, string, OracleVectorStoreOptions?, ServiceLifetime\)](#)  
This method registers an OracleVectorStore as VectorStore, with the specified connection string and service lifetime.
- [AddOracleVectorStore\(this IServiceCollection, OracleVectorStoreOptions?, ServiceLifetime\)](#)  
This method registers an OracleVectorStore as VectorStore, with the OracleDataSource retrieved from the IServiceCollection.

## AddOracleVectorStore(this IServiceCollection, OracleVectorStoreOptions?, ServiceLifetime)

This method registers an OracleVectorStore as VectorStore, with the OracleDataSource retrieved from the IServiceCollection.

**Declaration**

```
// C#  
public static IServiceCollection AddOracleVectorStore(this IServiceCollection  
services, OracleVectorStoreOptions? options = null, ServiceLifetime lifetime  
= ServiceLifetime.Singleton);
```

**Parameters**

- **services**  
The IServiceCollection to register the VectorStore on.
- **options**  
Options to further configure the vector store.
- **lifetime**  
The service lifetime for the store. Defaults to ServiceLifetime.Singleton.

**Return Value**

Returns the service collection.

**Exceptions**

InvalidArgumentException: The provided services parameter is null.

InvalidOperationException: The service collection does not contain an OracleDataSource.

## AddOracleVectorStore(IServiceCollection, string, OracleVectorStoreOptions?, ServiceLifetime)

This method registers an OracleVectorStore as VectorStore, with the specified connection string and service lifetime.

**Declaration**

```
// C#  
public static IServiceCollection AddOracleVectorStore(this IServiceCollection  
services, string connectionString, OracleVectorStoreOptions? options =  
null, ServiceLifetime lifetime = ServiceLifetime.Singleton)
```

**Parameters**

- **services**  
The IServiceCollection to register the VectorStore on.
- **connectionString**  
The connection string.
- **options**  
Options to further configure the vector store.
- **lifetime**  
The service lifetime for the store. Defaults to ServiceLifetime.Singleton.

**Return Value**

Returns the service collection.

**Exceptions**

InvalidArgumentException

- The provided services parameter is null.
- The provided connectionString parameter is null or empty string.

## AddOracleVectorStore(IServiceCollection, Func<IServiceProvider, string>, Func<IServiceProvider, OracleVectorStoreOptions>?, ServiceLifetime)

This method registers an OracleVectorStore as VectorStore, with the specified connection string provider and service lifetime.

**Declaration**

```
// C#
public static IServiceCollection AddOracleVectorStore(this IServiceCollection
services, Func<IServiceProvider, string> connectionStringProvider,
Func<IServiceProvider, OracleVectorStoreOptions>? optionsProvider = null,
ServiceLifetime lifetime = ServiceLifetime.Singleton)
```

**Parameters**

- services  
The IServiceCollection to register the VectorStore on.
- connectionStringProvider  
The connection string provider.
- optionsProvider  
Options provider to further configure the vector store.
- lifetime  
The service lifetime for the store. Defaults to ServiceLifetime.Singleton.

**Return Value**

Returns the service collection.

**Exceptions**

InvalidArgumentException: The provided connectionStringProvider or services parameter is null.

## OracleVectorStore Class

An OracleVectorStore object implements the Microsoft.Extensions.VectorData.VectorStore interface. It represents a database connection and provides access to a database. It is primarily used for creating, deleting and getting a collection (table).

Class Inheritance

System.Object  
    Microsoft.Extensions.VectorData.VectorStore  
        Oracle.VectorData.OracleVectorStore

Declaration

```
// C#
public sealed class OracleVectorStore :
Microsoft.Extensions.VectorData.VectorStore
```

Thread Safety

All public methods are thread-safe, unless stated otherwise.

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |
| Namespace      | Oracle.ManagedDataAccess.Client         | Oracle.ManagedDataAccess.Client         |
| .NET Framework | See <a href="#">System Requirements</a> | -                                       |
| .NET (Core)    | -                                       | See <a href="#">System Requirements</a> |

OracleVectorStore Constructors

OracleVectorStore constructors instantiate a new instance of OracleVectorStore class using either the provided data source or a connection string.

Overload List:

- [OracleVectorStore\(OracleDataSource, OracleVectorStoreOptions?\)](#)  
This constructor creates an instance of the OracleVectorStore class using the provided data source. It is applicable only to .NET Core 8.0 or above versions.
- [OracleVectorStore\(string connectionString, OracleVectorStoreOptions?\)](#)  
This constructor creates an instance of the OracleVectorStore class using the provided database connection string.

**① See Also**

- [OracleVectorStore Class](#)
- [OracleVectorStore Public Methods](#)

## OracleVectorStore(OracleDataSource, OracleVectorStoreOptions?)

Instantiates a new instance of `OracleVectorStore` class using the provided data source.

**Declaration**

```
// C#
OracleVectorStore(OracleDataSource dataSource, OracleVectorStoreOptions?
options = default)
```

**Parameters**

- *dataSource*  
The data source that can be used to obtain open database connections.
- *options*  
Optional vector store configuration options.

**① Note**

When these options are specified, the collections created within the vector store inherit these options.

**Remarks**

The vector store is created based on the following connector defined values in `Microsoft.Extensions.VectorData.VectorStore.VectorStoreMetaData` class:

- `VectorStoreSystemName`: "Oracle"
- `VectorStoreName`: The name of the database that the vector store is connected to. This value is auto-populated from `OracleConnection.DatabaseName`.

**Exceptions**

`ArgumentNullException`: The provided `dataSource` parameter is null.

**① See Also**

- [OracleDataSource Class](#)

## OracleVectorStore(string connectionString, OracleVectorStoreOptions?)

Instantiates a new instance of `OracleVectorStore` class using the provided database connection string.

## Declaration

```
// C#  
OracleVectorStore(string connectionString, OracleVectorStoreOptions? options  
= default)
```

## Parameters

- *connectionString*  
The connection string which can be used to obtain database connections.
- *options*  
Optional vector store configuration options.

### Note

When these options are specified, the collections created within the vector store inherit these options.

## Remarks

The vector store is created based on the following connector defined values in `Microsoft.Extensions.VectorData.VectorStore.VectorStoreMetaData`:

- `VectorStoreSystemName`: "Oracle"
- `VectorStoreName`: The database name that the vector store is connected to. This value is auto-populated from `OracleConnection.DatabaseName`.

## Exceptions

- `ArgumentNullException`: The provided `connectionString` parameter is null.
- `ArgumentException`: The provided `connectionString` parameter is empty or whitespace.

# OracleVectorStore Public Methods

OracleVectorStore public methods are listed in [Table 21-7](#).

**Table 21-7 OracleVectorStore Public Methods**

| Public Method                                | Description                                          |
|----------------------------------------------|------------------------------------------------------|
| <a href="#">CollectionExistsAsync</a>        | Checks if a collection exists in the vector store.   |
| <a href="#">Dispose</a>                      | Releases any resources or memory held by the object. |
| <a href="#">EnsureCollectionDeletedAsync</a> | Deletes a specified collection.                      |

**Table 21-7 (Cont.) OracleVectorStore Public Methods**

| Public Method                                                                 | Description                                                            |
|-------------------------------------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">GetCollection(string, VectorStoreCollectionDefinition?)</a>       | Creates a vector store collection using its name.                      |
| <a href="#">GetDynamicCollection(string, VectorStoreCollectionDefinition)</a> | Creates a vector store collection using its name.                      |
| <a href="#">GetService</a>                                                    | Retrieves an object of a specified service type from the vector store. |
| <a href="#">ListCollectionNamesAsync</a>                                      | Retrieves the names of all the collections in the vector store.        |

**See Also**

## CollectionExistsAsync

This method checks if a collection exists in the vector store.

**Declaration**

```
// C#  
public Task<bool> CollectionExistsAsync(string name, CancellationToken  
cancellationTok = default)
```

**Parameters**

- `name`  
The name of the collection.
- `cancellationTok`  
The cancellation token.

**Return Value**

A task representing the asynchronous operation. The task result contains a boolean indicating whether the collection exists in the database. True if exists, else false.

**Implements**

Microsoft.Extensions.VectorData.VectorStore

## Dispose

This method releases any resources or memory allocated by the object.

**Declaration**

```
// C#  
public void Dispose()
```

**Implements**

System.IDisposable

**Thread Safety**

This method is not thread-safe.

## EnsureCollectionDeletedAsync

This method deletes a specified collection.

**Declaration**

```
// C#  
public Task EnsureCollectionDeletedAsync(string name, CancellationToken  
cancellationTok = default)
```

**Parameters**

- name  
The name of the collection.
- cancellationTok  
The cancellation token.

**Return Value**

A task representing the asynchronous operation that completes when the collection has been deleted from the database.

**Implements**

Microsoft.Extensions.VectorData.VectorStore

## GetCollection(string, VectorStoreCollectionDefinition?)

This method creates a vector store collection using its name.

**Declaration**

```
// C#  
public VectorStoreCollection<TKey, TRecord> GetCollection(string  
collectionName, VectorStoreCollectionDefinition? definition = null)where  
TKey : notnullwhere TRecord : notnull
```

**Parameters**

- TKey  
The data type of the record key.

- **TRecord**  
The record data model to use for adding, updating, and retrieving data from the collection.
- **collectionName**  
The name of the collection.
- **definition**  
The schema of the record type.

### Return Value

A new `OracleCollection<TKey, TRecord>` instance for managing records in the collection.

### Implements

`Microsoft.Extensions.VectorData.VectorStore`

### Exceptions

`ArgumentException`:

- The provided `collectionName` parameter is null, an empty string or contains white spaces only.
- The provided `collectionName` is not compliant with Oracle name standard.
- The provided `TKey` and `TRecord` cannot be mapped to an Oracle type based on the default/custom type mapping.

### Remarks

To successfully request a collection, either must be annotated with attributes that define the schema of the record type, or must be provided.

The `OracleCollection` instance is created for application to operate on a collection. However, the collection is not created in the database. To create a collection in the database, use `OracleCollection.EnsureCollectionExistsAsync()`.

#### See Also

`Microsoft.Extensions.VectorData.VectorStoreKeyAttribute`,  
`VectorStoreDataAttribute`, `VectorStoreVectorAttribute` classes.

## GetDynamicCollection(string, VectorStoreCollectionDefinition)

This method creates a vector store collection using its name.

### Declaration

```
// C#
public VectorStoreCollection<object, Dictionary<string, object?>>
GetDynamicCollection(string collectionName, VectorStoreRecordDefinition
definition)
```

### Parameters

- `collectionName`

Name of the collection to retrieve.

- **definition**  
The schema of the record type.

### Return Value

A new `OracleDynamicCollection` instance for managing the records in the collection.

### Implements

`Microsoft.Extensions.VectorData.VectorStore`

### Exceptions

`ArgumentException`:

- The provided `collectionName` parameter is null, an empty string or contains white spaces only.
- The provided `collectionName` is not compliant with Oracle name standard.

### Remarks

The `OracleDynamicCollection` instance is created for application to operate on a collection. However, the collection is not created in the database. To create a collection in the database, use `OracleCollection.EnsureCollectionExistsAsync()`.

The provided collection name is treated as case-sensitive and should not be a fully qualified name(like `.`) as the Schema is referred based on the `OracleVectorStoreOptions`.

#### See Also

`Microsoft.Extensions.VectorData.VectorStoreCollectionDefinition` class.

## GetService

This method retrieves an object of a specified service type from the vector store.

### Declaration

```
// C#  
public object? GetService(Type serviceType, object? serviceKey = null);
```

### Parameters

- **serviceType**  
The type of an object to retrieve. Supported `ServiceType`: `VectorStoreMetaData`, `OracleVectorStore` or `OracleDataSource` (.NET Core only).
- **serviceKey**  
An optional key that can be used to identify the target service.

### Return Value

An object of a specified service type, otherwise null.

Implements

Microsoft.Extensions.VectorData.VectorStore

ListCollectionNamesAsync

This method retrieves the names of all the collections in the vector store.

Declaration

```
// C#
public async IEnumerable<string>
ListCollectionNamesAsync(CancellationToken cancellationToken = default)
```

Parameters

- `cancellationToken`  
The cancellation token.

Return Value

The list of all the collection names in the vector store.

Implements

Microsoft.Extensions.VectorData.VectorStore

OracleVectorStoreOptions Class

An `OracleVectorStoreOptions` object encapsulates configuration options for creating and managing an instance of the `OracleVectorStore` class. It lets you to specify the database schema and the default embedding generator to use for vector operations.

Class Inheritance

System.Object  
    Oracle.VectorData.OracleVectorStoreOptions

Declaration

```
// C#
public sealed class OracleVectorStoreOptions
```

Requirements

| Provider       | ODP.NET, Managed Driver                 | ODP.NET Core                            |
|----------------|-----------------------------------------|-----------------------------------------|
| Assembly       | Oracle.ManagedDataAccess.dll            | Oracle.ManagedDataAccess.dll            |

- [OracleVectorStoreOptions Constructor](#)
- [OracleVectorStoreOptions Properties](#)

# OracleVectorStoreOptions Constructor

Instantiates a new instance of the OracleVectorStoreOptions class.

Declaration

```
// C#
public OracleVectorStoreOptions()
```

① See Also

- [OracleVectorStoreOptions Class](#)
- [OracleVectorStoreOptions Properties](#)

# OracleVectorStoreOptions Properties

OracleVectorStoreOptions properties are listed in [Table 21-8](#).

Table 21-8 OracleVectorStoreOptions Properties

| Property                           | Description                                                                                                                         |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">EmbeddingGenerator</a> | This property specifies the default embedding generator to use for generating vector embeddings when working with the vector store. |
| <a href="#">Schema</a>             | This property specifies the database schema name under which collections are created by default.                                    |

① See Also

- [OracleVectorStoreOptions Class](#)
- [OracleVectorStoreOptions Constructor](#)

# EmbeddingGenerator

This property specifies the default embedding generator to use for generating vector embeddings when working with the vector store.

**Declaration**

```
// C#  
public IEmbeddingGenerator? EmbeddingGenerator { get; set; }
```

**Property Value**

The default embedding generator to use for generating vector embeddings when working with the vector store.

**Remarks**

When embedding is specified, the collections under this vector store uses the `EmbeddingGenerator` to generate embeddings. The default property value is null. When the embedding generator is provided, the vector store automatically generates the embedding during both upsert and search operations, eliminating the need for the application to generate and provide the embedding.

## Schema

This property specifies the database schema name under which collections are created.

**Declaration**

```
// C#  
public string? Schema { get; set; }
```

**Property Value**

The string specifying the name of the database schema.

**Remarks**

When Schema is specified, the collections under this vector store are created under the schema. The default schema value is null. When null, the collections are created under the connected user's schema.

# A

## Oracle Schema Collections

ODP.NET provides standard metadata collections as well as various Oracle database-specific metadata collections that can be retrieved through the `OracleConnection.GetSchema` API.

### See Also

- ["Schema Discovery"](#)
- ["GetSchema"](#)

This appendix contains the following topics:

- [Common Schema Collections](#)
- [ODP.NET-Specific Schema Collection](#)

## Common Schema Collections

The common schema collections are available for all .NET Framework managed providers. ODP.NET supports the same common schema collections.

- [MetaDataCollections](#)
- [DataSourceInformation](#)
- [DataTypes](#)
- [Restrictions](#)
- [ReservedWords](#)

### See Also

"Common Schema Collections" in the [MSDN Library](#)

## MetaDataCollections

[Table A-1](#) is a list of metadata collections that is available from the data source, such as tables, columns, indexes, and stored procedures.

**Table A-1   MetaDataCollections**

| Column Name    | Data Type | Description                                                                           |
|----------------|-----------|---------------------------------------------------------------------------------------|
| CollectionName | string    | The name of the collection passed to the <code>GetSchema</code> method for retrieval. |

**Table A-1 (Cont.) MetaDataCollections**

| Column Name             | Data Type | Description                                                       |
|-------------------------|-----------|-------------------------------------------------------------------|
| NumberOfRestrictions    | int       | Number of restrictions specified for the named collection.        |
| NumberOfIdentifierParts | int       | Number of parts in the composite identifier/database object name. |

## DataSourceInformation

[Table A-2](#) lists DataSourceInformation information which may include these columns and possibly others.

**Table A-2 DataSource Information**

| Columns                             | Data Type       | Description                                                                                                                                                                       |
|-------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CompositeIdentifierSeparatorPattern | string          | Separator for multipart names: @   \ .                                                                                                                                            |
| DataSourceProductName               | string          | Database name: Oracle                                                                                                                                                             |
| DataSourceProductVersion            | string          | Database version. Note that this is the version of the database instance currently being accessed by DbConnection.                                                                |
| DataSourceProductVersionNormalized  | string          | A normalized DataSource version for easier comparison between different versions. For example:<br>DataSource Version: 10.2.0.1.0<br>Normalized DataSource Version: 10.02.00.01.00 |
| GroupByBehavior                     | GroupByBehavior | An enumeration that indicates the relationship between the columns in a GROUP BY clause and the non-aggregated columns in a select list.                                          |
| IdentifierPattern                   | string          | Format for a valid identifier.                                                                                                                                                    |
| IdentifierCase                      | IdentifierCase  | An enumeration that specifies whether or not to treat non-quoted identifiers as case sensitive.                                                                                   |
| OrderByColumnsInSelect              | bool            | A boolean that indicates whether or not the select list must contain the columns in an ORDER BY clause.                                                                           |
| ParameterMarkerFormat               | string          | A string indicating whether or not parameter markers begin with a special character.                                                                                              |
| ParameterMarkerPattern              | string          | The format of a parameter marker.                                                                                                                                                 |
| ParameterNameMaxLength              | int             | Maximum length of a parameter.                                                                                                                                                    |
| ParameterNamePattern                | string          | The format for a valid parameter name.                                                                                                                                            |
| QuotedIdentifierPattern             | string          | The format of a quoted identifier.                                                                                                                                                |
| QuotedIdentifierCase                | IdentifierCase  | An enumeration that specifies whether or not to treat quote identifiers as case sensitive.                                                                                        |
| StringLiteralPattern                | string          | The format for a string literal.                                                                                                                                                  |

Table A-2 (Cont.) DataSource Information

| Columns                | Data Type              | Description                                                                              |
|------------------------|------------------------|------------------------------------------------------------------------------------------|
| SupportedJoinOperators | SupportedJoinOperators | An enumeration indicating the types of SQL join statements supported by the data source. |

## DataTypes

[Table A-3](#) lists DataTypes Collection information which may include these columns and possibly others.

### Note

As an example, the description column includes complete information for the `TIMESTAMP WITH LOCAL TIME ZONE` data type.

Table A-3 Data Types

| ColumnName          | Data Type | Description                                                                                                                            |
|---------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| TypeName            | string    | The provider-specific data type name.<br>Example: <code>TIMESTAMP WITH LOCAL TIME ZONE</code>                                          |
| ProviderDbType      | int       | The provider-specific type value.<br>Example: 124                                                                                      |
| ColumnSize          | long      | The length of a non-numeric column or parameter.<br>Example: 27                                                                        |
| CreateFormat        | string    | A format string that indicates how to add this column to a DDL statement.<br>Example: <code>TIMESTAMP({0}) WITH LOCAL TIME ZONE</code> |
| CreateParameters    | string    | The parameters specified to create a column of this data type.<br>Example: 8                                                           |
| DataType            | string    | The .NET type for the data type.<br>Example: <code>System.DateTime</code>                                                              |
| IsAutoIncrementable | bool      | A boolean value that indicates whether or not this data type can be auto-incremented.<br>Example: false                                |

**Table A-3 (Cont.) Data Types**

| ColumnName            | Data Type | Description                                                                                                                                              |
|-----------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| IsBestMatch           | bool      | A boolean value that indicates whether or not this data type is the best match to values in the DataType column.<br>Example: false                       |
| IsCaseSensitive       | bool      | A boolean value that indicates whether or not this data type is case-sensitive.<br>Example: false                                                        |
| IsFixedLength         | bool      | A boolean value that indicates whether or not this data type has a fixed length.<br>Example: true                                                        |
| IsFixedPrecisionScale | bool      | A boolean value that indicates whether or not this data type has a fixed precision and scale.<br>Example: false                                          |
| IsLong                | bool      | A boolean value that indicates whether or not this data type contains very long data.<br>Example: false                                                  |
| IsNullable            | bool      | A boolean value that indicates whether or not this data type is nullable.<br>Example: true                                                               |
| IsSearchable          | bool      | A boolean value that indicates whether or not the data type can be used in a WHERE clause with any operator, except the LIKE predicate.<br>Example: true |
| IsSearchableWithLike  | bool      | A boolean value that indicates whether or not this data type can be used with the LIKE predicate.<br>Example: false                                      |
| IsUnsigned            | bool      | A boolean value that indicates whether or not the data type is unsigned.                                                                                 |
| MaximumScale          | short     | The maximum number of digits allowed to the right of the decimal point.                                                                                  |
| MinimumScale          | short     | The minimum number of digits allowed to the right of the decimal point.                                                                                  |

**Table A-3 (Cont.) Data Types**

| ColumnName         | Data Type | Description                                                                                                                                                                                    |
|--------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IsConcurrencyType  | bool      | A boolean value that indicates whether or not the database updates the data type every time the row is changed and the value of the column differs from all previous values.<br>Example: false |
| MinimumVersion     | String    | The earliest version of the database that can be used.<br>Example:09.00.00.00.00                                                                                                               |
| IsLiteralSupported | bool      | A boolean value that indicates whether or not the data type can be expressed as a literal.<br>Example: true                                                                                    |
| LiteralPrefix      | string    | The prefix of a specified literal.<br>Example: TO_TIMESTAMP_TZ( '                                                                                                                              |
| LiteralSuffix      | string    | The suffix of a specified literal.<br>Example: ', 'YYYY-MM-DD HH24:MI:SS.FF')                                                                                                                  |

## Restrictions

[Table A-4](#) lists Restrictions, including the following columns.

**Table A-4 Restrictions**

| ColumnName        | Data Type | Description                                              |
|-------------------|-----------|----------------------------------------------------------|
| CollectionName    | string    | The collection that the restrictions apply to.           |
| RestrictionName   | string    | The restriction name.                                    |
| RestrictionNumber | int       | A number that indicates the location of the restriction. |

## ReservedWords

The ReservedWords collection exposes information about the words that are reserved by the database currently connected to ODP.NET.

[Table A-5](#) lists the ReservedWords Collection.

**Table A-5 ReservedWords**

| ColumnName   | Data Type | Description                      |
|--------------|-----------|----------------------------------|
| ReservedWord | string    | Provider-specific reserved words |

# ODP.NET-Specific Schema Collection

Oracle Data Provider for .NET supports both the common schema collections described previously and the following Oracle-specific schema collections:

- [Tables](#)
- [Columns](#)
- [Views](#)
- [XMLSchema](#)
- [Users](#)
- [Synonyms](#)
- [Sequences](#)
- [Functions](#)
- [Procedures](#)
- [ProcedureParameters](#)
- [Arguments](#)
- [Packages](#)
- [PackageBodies](#)
- [JavaClasses](#)
- [Indexes](#)
- [IndexColumns](#)
- [PrimaryKeys](#)
- [ForeignKeys](#)
- [ForeignKeyColumns](#)
- [UniqueKeys](#)

## Tables

[Table A-6](#) lists the column name, data type, and description of the Tables Schema Schema Collection.

**Table A-6 Tables**

| Column Name | Data Type | Description                                 |
|-------------|-----------|---------------------------------------------|
| OWNER       | String    | Owner of the Table.                         |
| TABLE_NAME  | String    | Name of the Table.                          |
| TYPE        | String    | Type of Table, for example, System or User. |

## Columns

[Table A-7](#) lists the column name, data type, and description of the Columns Schema Collection .

**Table A-7 Columns**

| ColumnName    | Data Type | Description                                                                                                  |
|---------------|-----------|--------------------------------------------------------------------------------------------------------------|
| OWNER         | String    | Owner of the table or view.                                                                                  |
| TABLE_NAME    | String    | Name of the table or view.                                                                                   |
| COLUMN_NAME   | String    | Name of the column.                                                                                          |
| ID            | Decimal   | Sequence number of the column as created.                                                                    |
| DATATYPE      | String    | Data type of the column.                                                                                     |
| LENGTH        | Decimal   | Length of the column in bytes.                                                                               |
| PRECISION     | Decimal   | Decimal precision for NUMBER data type; binary precision for FLOAT data type, null for all other data types. |
| Scale         | Decimal   | Digits to right of decimal point in a number.                                                                |
| NULLABLE      | String    | Specifies whether or not a column allows NULLs.                                                              |
| CHAR_USED     | String    | Indicates whether the column uses BYTE length semantics (B) or CHAR length semantics (C).                    |
| LengthInChars | Decimal   | Length of the column in characters.<br>This value only applies to CHAR, VARCHAR2, NCHAR, and NVARCHAR2.      |

## Views

[Table A-8](#) lists the column name, data type, and description of the Views Schema Collection.

**Table A-8 Views**

| Column Name      | Data Type | Description                                         |
|------------------|-----------|-----------------------------------------------------|
| OWNER            | String    | Owner of the view.                                  |
| VIEW_NAME        | String    | Name of the view.                                   |
| TEXT_LENGTH      | Decimal   | Length of the view text.                            |
| TEXT             | String    | View text.                                          |
| TYPE_TEXT_LENGTH | Decimal   | Length of the type clause of the typed view.        |
| TYPE_TEXT        | String    | Type clause of the typed view.                      |
| OID_TEXT_LENGTH  | Decimal   | Length of the WITH OID clause of the typed view.    |
| OID_TEXT         | String    | WITH OID clause of the typed view.                  |
| VIEW_TYPE_OWNER  | String    | Owner of the view type if the view is a typed view. |
| VIEW_TYPE        | String    | Type of the view if the view is a typed view.       |
| SUPERVIEW_NAME   | String    | Name of the superview.<br>(Oracle9i or later)       |

## XMLSchema

[Table A-9](#) lists the column name, data type and description of the XMLSchema Schema Collection.

**Note**

This collection is only available with Oracle Database 10g and later.

**Table A-9 XMLSchema**

| Column Name     | Data Type | Description                                                     |
|-----------------|-----------|-----------------------------------------------------------------|
| OWNER           | String    | Owner of the XML schema.                                        |
| SCHEMA_URL      | String    | Schema URL of the XML schema.                                   |
| LOCAL           | String    | Indicates whether the XML schema is local (YES) or global (NO). |
| SCHEMA          | String    | XML schema document.                                            |
| INT_OBJNAME     | String    | Internal database object name for the schema.                   |
| QUAL_SCHEMA_URL | String    | Fully qualified schema URL.                                     |
| HIER_TYPE       | String    | Hierarchy type for the schema.                                  |

## Users

[Table A-10](#) lists the column name, data type and description of the Users Schema Collection.

**Table A-10 Users**

| Column Name | Data Type | Description            |
|-------------|-----------|------------------------|
| NAME        | String    | Name of the user.      |
| ID          | Decimal   | ID number of the user. |
| CREATEDATE  | DateTime  | User creation date.    |

## Synonyms

[Table A-11](#) lists the column name, data type and description of the Synonyms Schema Collection.

**Table A-11 Synonyms**

| Column Name  | Data Type | Description                                                                                                                                                                                                                         |
|--------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER        | String    | Owner of the synonym.                                                                                                                                                                                                               |
| SYNONYM_NAME | String    | Name of the synonym.                                                                                                                                                                                                                |
| TABLE_OWNER  | String    | Owner of the object referenced by the synonym. Although the column is called TABLE_OWNER, the object owned is not necessarily a table. It can be any general object such as a view, sequence, stored procedure, synonym, and so on. |

**Table A-11 (Cont.) Synonyms**

| Column Name | Data Type | Description                                                                                                                                                                                                                              |
|-------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLE_NAME  | String    | Name of the object referenced by the synonym. Although the column is called TABLE_NAME, the object does not necessarily have to be a table. It can be any general object such as a view, sequence, stored procedure, synonym, and so on. |
| DB_LINK     | String    | Name of the database link referenced, if any.                                                                                                                                                                                            |

## Sequences

[Table A-12](#) lists the column name, data type, and description of the Sequences Schema Collection.

**Table A-12 Sequences**

| Column Name    | Data Type | Description                                                                                                                                                                                                                    |
|----------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEQUENCE_OWNER | String    | Name of the owner of the sequence.                                                                                                                                                                                             |
| SEQUENCE_NAME  | String    | Sequence name.                                                                                                                                                                                                                 |
| MIN_VALUE      | Decimal   | Minimum value of the sequence.                                                                                                                                                                                                 |
| MAX_VALUE      | Decimal   | Maximum value of the sequence.                                                                                                                                                                                                 |
| INCREMENT_BY   | Decimal   | Value by which sequence is incremented.                                                                                                                                                                                        |
| CYCLE_FLAG     | String    | Indicates if sequence wraps around on reaching limit.                                                                                                                                                                          |
| ORDER_FLAG     | String    | Indicates if sequence numbers are generated in order.                                                                                                                                                                          |
| CACHE_SIZE     | Decimal   | Number of sequence numbers to cache.                                                                                                                                                                                           |
| LAST_NUMBER    | Decimal   | Last sequence number written to disk. If a sequence uses caching, the number written to disk is the last number placed in the sequence cache. This number is likely to be greater than the last sequence number that was used. |

## Functions

[Table A-13](#) lists the column name, data type, and description of the Functions Schema Collection.

**Table A-13 Functions**

| Column Name    | Data Type | Description                                                         |
|----------------|-----------|---------------------------------------------------------------------|
| OWNER          | String    | Owner of the function.                                              |
| OBJECT_NAME    | String    | Name of the function.                                               |
| SUBOBJECT_NAME | String    | Name of the subobject (for example, partition).                     |
| OBJECT_ID      | Decimal   | Dictionary object number of the function.                           |
| DATA_OBJECT_ID | Decimal   | Dictionary object number of the segment that contains the function. |
| CREATED        | DateTime  | Timestamp for the creation of the function.                         |

**Table A-13 (Cont.) Functions**

| Column Name   | Data Type | Description                                                                                                            |
|---------------|-----------|------------------------------------------------------------------------------------------------------------------------|
| LAST_DDL_TIME | DateTime  | Timestamp for the last modification of the function resulting from a DDL statement (including grants and revokes).     |
| TIMESTAMP     | String    | Timestamp for the specification of the function (character data).                                                      |
| STATUS        | String    | Status of the function (VALID, INVALID, or N/A).                                                                       |
| TEMPORARY     | String    | Whether or not the function is temporary (the current session can see only data that it placed in this object itself). |
| GENERATED     | String    | Indicates whether the name of this function is system generated (Y) or not (N).                                        |
| SECONDARY     | String    | Whether or not this is a secondary object created by the ODCIIndexCreate method of the Oracle Data Cartridge (Y   N).  |

## Procedures

[Table A-14](#) lists the column name, data type, and description of the Procedures Schema Collection.

**Table A-14 Procedures**

| Column Name    | Data Type | Description                                                                                                             |
|----------------|-----------|-------------------------------------------------------------------------------------------------------------------------|
| OWNER          | String    | Owner of the procedure.                                                                                                 |
| OBJECT_NAME    | String    | Name of the procedure.                                                                                                  |
| SUBOBJECT_NAME | String    | Name of the subobject (for example, partition).                                                                         |
| OBJECT_ID      | Decimal   | Dictionary object number of the procedure.                                                                              |
| DATA_OBJECT_ID | Decimal   | Dictionary object number of the segment that contains the procedure.                                                    |
| CREATED        | DateTime  | Timestamp for the creation of the procedure.                                                                            |
| LAST_DDL_TIME  | Decimal   | Timestamp for the last modification of the procedure resulting from a DDL statement (including grants and revokes).     |
| TIMESTAMP      | String    | Timestamp for the specification of the procedure (character data).                                                      |
| STATUS         | String    | Status of the procedure (VALID, INVALID, or N/A).                                                                       |
| TEMPORARY      | String    | Whether or not the procedure is temporary (the current session can see only data that it placed in this object itself). |
| GENERATED      | String    | Indicates whether the name of this procedure is system generated (Y) or not (N).                                        |
| SECONDARY      | String    | Whether or not this is a secondary object created by the ODCIIndexCreate method of the Oracle Data Cartridge (Y   N).   |

## ProcedureParameters

[Table A-15](#) lists the column name, data type and description of the ProcedureParameters Schema Collection.

**Table A-15 ProcedureParameters**

| Column Name        | Data Type | Description                                                                                                                                                                     |
|--------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER              | String    | Owner of the object.                                                                                                                                                            |
| OBJECT_NAME        | String    | Name of the procedure or function.                                                                                                                                              |
| PACKAGE_NAME       | String    | Name of the package.                                                                                                                                                            |
| OBJECT_ID          | Decimal   | Object number of the object.                                                                                                                                                    |
| OVERLOAD           | String    | Indicates the <i>n</i> th overloading ordered by its appearance in the source; otherwise, it is NULL.                                                                           |
| SUBPROGRAM_ID      | Decimal   | Subprogram id for the procedure or function                                                                                                                                     |
| ARGUMENT_NAME      | String    | If the argument is a scalar type, then the argument name is the name of the argument. A null argument name is used to denote a function return value.                           |
| POSITION           | Decimal   | If DATA_LEVEL is zero, then this column holds the position of this item in the argument list, or zero for a function return value.                                              |
| SEQUENCE           | Decimal   | Defines the sequential order of the argument. Argument sequence starts from 1.                                                                                                  |
| DATA_LEVEL         | Decimal   | Nesting depth of the argument for composite types.                                                                                                                              |
| DATA_TYPE          | String    | Data type of the argument.                                                                                                                                                      |
| DEFAULT_VALUE      | String    | Default value for the argument.                                                                                                                                                 |
| DEFAULT_LENGTH     | Decimal   | Length of the default value for the argument.                                                                                                                                   |
| IN_OUT             | String    | Direction of the argument: [IN] [OUT] [IN/OUT].                                                                                                                                 |
| DATA_LENGTH        | Decimal   | Length of the column (in bytes).                                                                                                                                                |
| DATA_PRECISION     | Decimal   | Length in decimal digits (NUMBER) or binary digits (FLOAT).                                                                                                                     |
| DATA_SCALE         | Decimal   | Digits to the right of the decimal point in a number.                                                                                                                           |
| RADIX              | Decimal   | Argument radix for a number.                                                                                                                                                    |
| CHARACTER_SET_NAME | String    | Character set name for the argument.                                                                                                                                            |
| TYPE_OWNER         | String    | Owner of the type of the argument.                                                                                                                                              |
| TYPE_NAME          | String    | Name of the type of the argument. If the type is a package local type (that is, it is declared in a package specification), then this column displays the name of the package.  |
| TYPE_SUBNAME       | String    | Displays the name of the type declared in the package identified in the TYPE_NAME column.<br>Relevant only for package local types.                                             |
| TYPE_LINK          | String    | Displays the database link that refers to the remote package.<br>Relevant only for package local types when the package identified in the TYPE_NAME column is a remote package. |

**Table A-15 (Cont.) ProcedureParameters**

| Column Name | Data Type | Description                                                                             |
|-------------|-----------|-----------------------------------------------------------------------------------------|
| PLS_TYPE    | String    | For numeric arguments, the name of the PL/SQL type of the argument. Otherwise, Null.    |
| CHAR_LENGTH | Decimal   | Character limit for string data types.                                                  |
| CHAR_USED   | String    | Indicates whether the byte limit (B) or character limit (C) is official for the string. |

## Arguments

[Table A-16](#) lists the column name, data type, and description of the Arguments Schema Collection.

**Table A-16 Arguments**

| Column Name    | Data Type | Description                                                                                                                                           |
|----------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER          | String    | Owner of the object.                                                                                                                                  |
| PACKAGE_NAME   | String    | Name of the package.                                                                                                                                  |
| OBJECT_NAME    | String    | Name of the procedure or function.                                                                                                                    |
| ARGUMENT_NAME  | String    | If the argument is a scalar type, then the argument name is the name of the argument. A null argument name is used to denote a function return value. |
| POSITION       | Decimal   | If DATA_LEVEL is zero, then this column holds the position of this item in the argument list, or zero for a function return value.                    |
| SEQUENCE       | Decimal   | Defines the sequential order of the argument. Argument sequence starts from 1.                                                                        |
| DEFAULT_VALUE  | String    | Default value for the argument.                                                                                                                       |
| DEFAULT_LENGTH | Decimal   | Length of the default value for the argument.                                                                                                         |
| IN_OUT         | String    | Direction of the argument: [IN] [OUT] [IN/OUT].                                                                                                       |
| DATA_LENGTH    | Decimal   | Length of the column (in bytes).                                                                                                                      |
| DATA_PRECISION | Decimal   | Length in decimal digits (NUMBER) or binary digits (FLOAT).                                                                                           |
| DATA_SCALE     | Decimal   | Digits to the right of the decimal point in a number.                                                                                                 |
| DATA_TYPE      | String    | Data type of the argument.                                                                                                                            |
| CHAR_USED      | String    | Indicates whether the column uses BYTE length semantics (B) or CHAR length semantics (C).                                                             |

## Packages

[Table A-17](#) lists the column name, data type, and description of the Packages Schema Collection.

**Table A-17 Packages**

| Column Name    | Data Type | Description                                                                                                           |
|----------------|-----------|-----------------------------------------------------------------------------------------------------------------------|
| OWNER          | String    | Owner of the package.                                                                                                 |
| OBJECT_NAME    | String    | Name of the package.                                                                                                  |
| SUBOBJECT_NAME | String    | Name of the subobject (for example, partition).                                                                       |
| OBJECT_ID      | Decimal   | Dictionary object number of the package.                                                                              |
| DATA_OBJECT_ID | Decimal   | Dictionary object number of the segment that contains the package.                                                    |
| CREATED        | DateTime  | Timestamp for the creation of the package.                                                                            |
| LAST_DDL_TIME  | DateTime  | Timestamp for the last modification of the package resulting from a DDL statement (including grants and revokes).     |
| TIMESTAMP      | String    | Timestamp for the specification of the package (character data).                                                      |
| STATUS         | String    | Status of the package (VALID, INVALID, or N/A).                                                                       |
| TEMPORARY      | String    | Whether or not the package is temporary (the current session can see only data that it placed in this object itself). |
| GENERATED      | String    | Indicates whether the name of this package was system generated (Y) or not (N).                                       |
| SECONDARY      | String    | Whether or not this is a secondary object created by the ODCIIndexCreate method of the Oracle Data Cartridge (Y   N). |

## PackageBodies

[Table A-18](#) lists the column name, data type, and description of the PackageBodies Schema Collection.

**Table A-18 PackageBodies**

| Column Name    | Data Type | Description                                                                                                            |
|----------------|-----------|------------------------------------------------------------------------------------------------------------------------|
| OWNER          | String    | Owner of the package body.                                                                                             |
| OBJECT_NAME    | String    | Name of the package body.                                                                                              |
| SUBOBJECT_NAME | String    | Name of the subobject (for example, partition).                                                                        |
| OBJECT_ID      | Decimal   | Dictionary object number of the package body.                                                                          |
| DATA_OBJECT_ID | Decimal   | Dictionary object number of the segment that contains the package body.                                                |
| CREATED        | DateTime  | Timestamp for the creation of the package body.                                                                        |
| LAST_DDL_TIME  | DateTime  | Timestamp for the last modification of the package body resulting from a DDL statement (including grants and revokes). |
| TIMESTAMP      | String    | Timestamp for the specification of the package body (character data).                                                  |
| STATUS         | String    | Status of the package body (VALID, INVALID, or N/A).                                                                   |

**Table A-18 (Cont.) PackageBodies**

| Column Name | Data Type | Description                                                                                                           |
|-------------|-----------|-----------------------------------------------------------------------------------------------------------------------|
| TEMPORARY   | String    | Whether the package body is temporary (the current session can see only data that it placed in this object itself).   |
| GENERATED   | String    | Indicates whether the name of this package body is system generated (Y) or not (N).                                   |
| SECONDARY   | String    | Whether or not this is a secondary object created by the ODCIIndexCreate method of the Oracle Data Cartridge (Y   N). |

## JavaClasses

[Table A-19](#) lists the column name, data type, and description of the JavaClasses Schema Collection.

**Table A-19 JavaClasses**

| Column Name   | Data Type | Description                                                                                  |
|---------------|-----------|----------------------------------------------------------------------------------------------|
| OWNER         | String    | Owner of the Java class.                                                                     |
| NAME          | String    | Name of the Java class.                                                                      |
| MAJOR         | Decimal   | Major version number of the Java class, as defined in the JVM specification.                 |
| MINOR         | Decimal   | Minor version number of the Java class, as defined in the JVM specification.                 |
| KIND          | String    | Indicates whether the stored object is a Java class (CLASS) or a Java interface (INTERFACE). |
| ACCESSIBILITY | String    | Accessibility of the Java class.                                                             |
| IS_INNER      | String    | Indicates whether this Java class is an inner class (YES) or not (NO).                       |
| IS_ABSTRACT   | String    | Indicates whether this Java class is an abstract class (YES) or not (NO).                    |
| IS_FINAL      | String    | Indicates whether this Java class is a final class (YES) or not (NO).                        |
| IS_DEBUG      | String    | Indicates whether this Java class contains debug information (YES) or not (NO).              |
| SOURCE        | String    | Source designation of the Java class.                                                        |
| SUPER         | String    | Super class of this Java class.                                                              |
| OUTER         | String    | Outer class of this Java class if this Java class is an inner class.                         |

## Indexes

[Table A-20](#) lists the column name, data type, and description of the Indexes Schema Collection.

**Table A-20 Indexes**

| Column Name     | Data Type | Description                                                                                                                                                                                 |
|-----------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER           | String    | Owner of the index.                                                                                                                                                                         |
| INDEX_NAME      | String    | Name of the index.                                                                                                                                                                          |
| INDEX_TYPE      | String    | Type of the index: <ul style="list-style-type: none"> <li>NORMAL</li> <li>BITMAP</li> <li>FUNCTION-BASED NORMAL</li> <li>FUNCTION-BASED BITMAP</li> <li>DOMAIN</li> </ul>                   |
| TABLE_OWNER     | String    | Owner of the indexed object.                                                                                                                                                                |
| TABLE_NAME      | String    | Name of the indexed object.                                                                                                                                                                 |
| TABLE_TYPE      | String    | Type of the indexed object (for example, TABLE or CLUSTER).                                                                                                                                 |
| UNIQUENESS      | String    | Indicates whether the index is UNIQUE or NONUNIQUE.                                                                                                                                         |
| COMPRESSION     | String    | Indicates whether index compression is enabled (ENABLED) or not (DISABLED).                                                                                                                 |
| PREFIX_LENGTH   | Decimal   | Number of columns in the prefix of the compression key.                                                                                                                                     |
| TABLESPACE_NAME | String    | Name of the tablespace containing the index.                                                                                                                                                |
| INI_TRANS       | Decimal   | Initial number of transactions.                                                                                                                                                             |
| MAX_TRANS       | Decimal   | Maximum number of transactions.                                                                                                                                                             |
| INITIAL_EXTENT  | Decimal   | Size of the initial extent.                                                                                                                                                                 |
| NEXT_EXTENT     | Decimal   | Size of secondary extents.                                                                                                                                                                  |
| MIN_EXTENTS     | Decimal   | Minimum number of extents allowed in the segment.                                                                                                                                           |
| MAX_EXTENTS     | Decimal   | Maximum number of extents allowed in the segment.                                                                                                                                           |
| PCT_INCREASE    | Decimal   | Percentage increase in extent size.                                                                                                                                                         |
| PCT_THRESHOLD   | Decimal   | Threshold percentage of block space allowed per index entry.                                                                                                                                |
| INCLUDE_COLUMN  | Decimal   | Column ID of the last column to be included in index-organized table primary key (non-overflow) index. This column maps to the COLUMN_ID column of the *_TAB_COLUMNS data dictionary views. |
| FREELISTS       | Decimal   | Number of process freelists allocated to this segment.                                                                                                                                      |
| FREELIST_GROUPS | Decimal   | Number of freelist groups allocated to this segment.                                                                                                                                        |
| PCT_FREE        | Decimal   | Minimum percentage of free space in a block.                                                                                                                                                |
| LOGGING         | String    | Logging information.                                                                                                                                                                        |
| BLEVEL          | Decimal   | B*-Tree level: depth of the index from its root block to its leaf blocks. A depth of 0 indicates that the root block and leaf block are the same.                                           |
| LEAF_BLOCKS     | Decimal   | Number of leaf blocks in the index.                                                                                                                                                         |
| DISTINCT_KEYS   | Decimal   | Number of distinct indexed values. For indexes that enforce UNIQUE and PRIMARY KEY constraints, this value is the same as the number of rows in the table (USER_TABLES.NUM_ROWS).           |

**Table A-20 (Cont.) Indexes**

| Column Name             | Data Type | Description                                                                                                                                                                                                                                                |
|-------------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AVG_LEAF_BLOCKS_PER_KEY | Decimal   | Average number of leaf blocks in which each distinct value in the index appears, rounded to the nearest integer. For indexes that enforce UNIQUE and PRIMARY KEY constraints, this value is always 1.                                                      |
| AVG_DATA_BLOCKS_PER_KEY | Decimal   | Average number of data blocks in the table that are pointed to by a distinct value in the index, rounded to the nearest integer. This statistic is the average number of data blocks that contain rows that contain a given value for the indexed columns. |
| CLUSTERING_FACTOR       | Decimal   | Indicates the amount of order of the rows in the table based on the values of the index.                                                                                                                                                                   |
| STATUS                  | String    | Indicates whether a nonpartitioned index is VALID or UNUSABLE.                                                                                                                                                                                             |
| NUM_ROWS                | Decimal   | Number of rows in the index.                                                                                                                                                                                                                               |
| SAMPLE_SIZE             | Decimal   | Size of the sample used to analyze the index.                                                                                                                                                                                                              |
| LAST_ANALYZED           | Date      | Date on which this index was most recently analyzed.                                                                                                                                                                                                       |
| DEGREE                  | String    | Number of threads per instance for scanning the index.                                                                                                                                                                                                     |
| INSTANCES               | String    | Number of instances across which the indexes to be scanned.                                                                                                                                                                                                |
| PARTITIONED             | String    | Indicates whether the index is partitioned (YES) or not (NO).                                                                                                                                                                                              |
| TEMPORARY               | String    | Indicates whether or not the index is on a temporary table.                                                                                                                                                                                                |
| GENERATED               | String    | Indicates whether the name of the index is system generated (Y) or not (N).                                                                                                                                                                                |
| SECONDARY               | String    | Indicates whether the index is a secondary object created by the ODCIIndexCreate method of the Oracle Data Cartridge (Y) or not (N).                                                                                                                       |
| BUFFER_POOL             | String    | Name of the default buffer pool to be used for the index blocks.                                                                                                                                                                                           |
| USER_STATS              | String    | Indicates whether statistics were entered directly by the user (YES) or not (NO).                                                                                                                                                                          |
| DURATION                | String    | Indicates the duration of a temporary table.                                                                                                                                                                                                               |
| PCT_DIRECT_ACCESS       | Decimal   | For a secondary index on an index-organized table, the percentage of rows with VALID guess.                                                                                                                                                                |
| ITYP_OWNER              | String    | For a domain index, the owner of the index type.                                                                                                                                                                                                           |
| ITYP_NAME               | String    | For a domain index, the name of the index type.                                                                                                                                                                                                            |
| PARAMETERS              | String    | For a domain index, the parameter string.                                                                                                                                                                                                                  |
| GLOBAL_STATS            | String    | For partitioned indexes, indicates whether statistics are collected by analyzing the index as a whole (YES) or estimated from statistics on underlying index partitions and subpartitions (NO).                                                            |

**Table A-20 (Cont.) Indexes**

| Column Name             | Data Type | Description                                                                                                                                                                                                                                     |
|-------------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DOMIDX_STATUS           | String    | Status of the domain index: <ul style="list-style-type: none"> <li>• NULL - Index is not a domain index.</li> <li>• VALID - Index is a valid domain index.</li> <li>• IDXTYP_INVLD - Indextype of the domain index is invalid.</li> </ul>       |
| DOMIDX_OPSTATUS         | String    | Status of the operation on the domain index: <ul style="list-style-type: none"> <li>• NULL - Index is not a domain index.</li> <li>• VALID - Operation performed without errors.</li> <li>• FAILED - Operation failed with an error.</li> </ul> |
| FUNCIDX_STATUS          | String    | Status of a function-based index: <ul style="list-style-type: none"> <li>• NULL - Index is not a function-based index.</li> <li>• ENABLED - Function-based index is enabled.</li> <li>• DISABLED - Function-based index is disabled.</li> </ul> |
| JOIN_INDEX              | String    | Indicates whether the index is a join index (YES) or not (NO).                                                                                                                                                                                  |
| IOT_REDUNDANT_PKEY_ELIM | String    | Indicates whether redundant primary key columns are eliminated from secondary indexes on index-organized tables (YES) or not (NO).                                                                                                              |
| DROPPED                 | String    | Indicates whether the index has been dropped and is in the recycle bin (YES) or not (NO); null for partitioned tables.                                                                                                                          |

## IndexColumns

[Table A-21](#) lists the column name, data type, and description of the IndexColumns Schema Collection.

**Table A-21 IndexColumns**

| Column Name     | Data Type | Description                                                    |
|-----------------|-----------|----------------------------------------------------------------|
| INDEX_OWNER     | String    | Owner of the index.                                            |
| INDEX_NAME      | String    | Name of the index.                                             |
| TABLE_OWNER     | String    | Owner of the table or cluster.                                 |
| TABLE_NAME      | String    | Name of the table or cluster.                                  |
| COLUMN_NAME     | String    | Column name or attribute of object type column.                |
| COLUMN_POSITION | Decimal   | Position of column or attribute within the index.              |
| COLUMN_LENGTH   | Decimal   | Indexed length of the column.                                  |
| DESCEND         | String    | Whether the column is sorted in descending order (Y/N).        |
| CHAR_LENGTH     | Decimal   | Maximum codepoint length of the column.<br>(Oracle9i or later) |

## PrimaryKeys

[Table A-22](#) lists the column name, data type, and description of the PrimaryKeys Schema Collection.

**Table A-22 PrimaryKeys**

| Column Name       | Data Type | Description                                                                                                                                                                                                          |
|-------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER             | String    | Owner of the constraint definition.                                                                                                                                                                                  |
| CONSTRAINT_NAME   | String    | Name of the constraint definition.                                                                                                                                                                                   |
| TABLE_NAME        | String    | Name associated with the table (or view) with constraint definition.                                                                                                                                                 |
| SEARCH_CONDITION  | String    | Text of search condition for a check constraint.                                                                                                                                                                     |
| R_OWNER           | String    | Owner of table referred to in a referential constraint.                                                                                                                                                              |
| R_CONSTRAINT_NAME | String    | Name of the unique constraint definition for referenced table.                                                                                                                                                       |
| DELETE_RULE       | String    | Delete rule for a referential constraint (CASCADE or NO ACTION).                                                                                                                                                     |
| STATUS            | String    | Enforcement status of constraint (ENABLED or DISABLED).                                                                                                                                                              |
| DEFERRABLE        | String    | Whether or not the constraint is deferrable.                                                                                                                                                                         |
| VALIDATED         | String    | Whether all data obeys the constraint (VALIDATED or NOT VALIDATED).                                                                                                                                                  |
| GENERATED         | String    | Whether the name of the constraint is user or system generated.                                                                                                                                                      |
| BAD               | String    | Indicates that this constraint specifies a century in an ambiguous manner. (Yes  No)<br><br>To avoid errors resulting from this ambiguity, rewrite the constraint using the TO_DATE function with a four-digit year. |
| RELY              | String    | Whether an enabled constraint is enforced or unenforced.                                                                                                                                                             |
| LAST_CHANGE       | DateTime  | When the constraint was last enabled or disabled.                                                                                                                                                                    |
| INDEX_OWNER       | String    | Name of the user owning the index.<br>(Oracle9i or later)                                                                                                                                                            |
| INDEX_NAME        | String    | Name of the index (only shown for unique and primary-key constraints).<br>(Oracle9i or later)                                                                                                                        |

## ForeignKeys

[Table A-23](#) lists the column name, data type, and description of the ForeignKeys Schema Collection.

**Table A-23 ForeignKeys**

| Column Name                 | Data Type | Description                                                          |
|-----------------------------|-----------|----------------------------------------------------------------------|
| PRIMARY_KEY_CONSTRAINT_NAME | String    | Name of the constraint definition.                                   |
| PRIMARY_KEY_OWNER           | String    | Owner of the constraint definition.                                  |
| PRIMARY_KEY_TABLE_NAME      | String    | Name associated with the table (or view) with constraint definition. |

**Table A-23 (Cont.) ForeignKeys**

| Column Name                    | Data Type | Description                                                                |
|--------------------------------|-----------|----------------------------------------------------------------------------|
| FOREIGN_KEY_OWNER              | String    | Owner of the constraint definition.                                        |
| FOREIGN_KEY_CONSTR<br>INT_NAME | String    | Name of the constraint definition.                                         |
| FOREIGN_KEY_TABLE_N<br>AME     | String    | Name associated with the table (or view) with constraint definition.       |
| SEARCH_CONDITION               | String    | Text of search condition for a check constraint                            |
| R_OWNER                        | String    | Owner of table referred to, in a referential constraint.                   |
| R_CONSTRAINT_NAME              | String    | Name of the unique constraint definition for referenced table.             |
| DELETE_RULE                    | String    | Delete rule for a referential constraint (CASCADE or NO ACTION).           |
| STATUS                         | String    | Enforcement status of constraint (ENABLED or DISABLED).                    |
| VALIDATED                      | String    | Whether or not all data obeys the constraint (VALIDATED or NOT VALIDATED). |
| GENERATED                      | String    | Whether the name of the constraint is user or system generated.            |
| RELY                           | String    | Whether an enabled constraint is enforced or unenforced.                   |
| LAST_CHANGE                    | DateTime  | When the constraint was last enabled or disabled.                          |
| INDEX_OWNER                    | String    | Name of the user owning the index.<br>(Oracle9i or later)                  |
| INDEX_NAME                     | String    | Name of the index.<br>(Oracle9i or later)                                  |

## ForeignKeyColumns

[Table A-24](#) lists the column name, data type, and description of the ForeignKeyColumns Schema Collection.

**Table A-24 ForeignKeyColumns**

| Column Name     | Data Type | Description                                                                                       |
|-----------------|-----------|---------------------------------------------------------------------------------------------------|
| OWNER           | String    | Owner of the constraint definition.                                                               |
| CONSTRAINT_NAME | String    | Name of the constraint definition.                                                                |
| TABLE_NAME      | String    | Name of the table with constraint definition.                                                     |
| COLUMN_NAME     | String    | Name of the column or attribute of the object type column specified in the constraint definition. |
| POSITION        | String    | Original position of column or attribute in the definition of the object.                         |

## UniqueKeys

[Table A-25](#) lists the column name, data type, and description of the UniqueKeys Schema Collection.

**Table A-25 UniqueKeys**

| Column Name       | Data Type | Description                                                                                                                                                                                                          |
|-------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER             | String    | Owner of the constraint definition.                                                                                                                                                                                  |
| CONSTRAINT_NAME   | String    | Name of the constraint definition.                                                                                                                                                                                   |
| TABLE_NAME        | String    | Name associated with the table (or view) with constraint definition.                                                                                                                                                 |
| SEARCH_CONDITION  | String    | Text of search condition for a check constraint.                                                                                                                                                                     |
| R_OWNER           | String    | Owner of table referred to in a referential constraint.                                                                                                                                                              |
| R_CONSTRAINT_NAME | String    | Name of the unique constraint definition for referenced table.                                                                                                                                                       |
| DELETE_RULE       | String    | Delete rule for a referential constraint (CASCADE or NO ACTION).                                                                                                                                                     |
| STATUS            | String    | Enforcement status of constraint (ENABLED or DISABLED).                                                                                                                                                              |
| DEFERRABLE        | String    | Whether or not the constraint is deferrable.                                                                                                                                                                         |
| VALIDATED         | String    | Whether all data obeys the constraint (VALIDATED or NOT VALIDATED).                                                                                                                                                  |
| GENERATED         | String    | Whether the name of the constraint is user or system generated.                                                                                                                                                      |
| BAD               | String    | Indicates that this constraint specifies a century in an ambiguous manner. (Yes  No)<br><br>To avoid errors resulting from this ambiguity, rewrite the constraint using the TO_DATE function with a four-digit year. |
| RELY              | String    | Whether an enabled constraint is enforced or not.                                                                                                                                                                    |
| LAST_CHANGE       | String    | When the constraint was last enabled or disabled.                                                                                                                                                                    |
| INDEX_OWNER       | String    | Name of the user owning the index.<br>(Oracle9i or later)                                                                                                                                                            |
| INDEX_NAME        | String    | Name of the index (only shown for unique and primary-key constraints).<br>(Oracle9i or later)                                                                                                                        |

# B

## Mapping LINQ Canonical Functions and Oracle Functions

This appendix lists the Entity Framework canonical functions and the corresponding ODP.NET provider functions to which they map.

### Aggregate Canonical Functions

**Table B-1 Mapping of Aggregate Canonical Functions and Oracle Functions**

| Canonical Function             | Oracle Function             |
|--------------------------------|-----------------------------|
| Avg ( <i>expression</i> )      | AVG( <i>expression</i> )    |
| BigCount ( <i>expression</i> ) | COUNT( <i>expression</i> )  |
| Count ( <i>expression</i> )    | COUNT( <i>expression</i> )  |
| Max ( <i>expression</i> )      | MAX( <i>expression</i> )    |
| Min ( <i>expression</i> )      | MIN( <i>expression</i> )    |
| StDev ( <i>expression</i> )    | STDDEV( <i>expression</i> ) |
| StDevP( <i>expression</i> )    | STDEVP( <i>expression</i> ) |
| Sum ( <i>expression</i> )      | SUM ( <i>expression</i> )   |
| Var( <i>expression</i> )       | VAR( <i>expression</i> )    |
| VarP( <i>expression</i> )      | VARP( <i>expression</i> )   |

### Math Canonical Functions

**Table B-2 Mapping of Math Canonical Functions and Oracle Functions**

| Canonical Function                       | Oracle Function                         |
|------------------------------------------|-----------------------------------------|
| Abs ( <i>value</i> )                     | ABS ( <i>value</i> )                    |
| Ceiling ( <i>value</i> )                 | CEIL( <i>value</i> )                    |
| Floor ( <i>value</i> )                   | FLOOR( <i>value</i> )                   |
| Power( <i>value</i> , <i>exponent</i> )  | POWER( <i>value</i> , <i>exponent</i> ) |
| Round ( <i>value</i> )                   | ROUND( <i>value</i> )                   |
| Round ( <i>value</i> , <i>digits</i> )   | ROUND( <i>value</i> , <i>digits</i> )   |
| Truncate( <i>value</i> , <i>digits</i> ) | TRUNC( <i>value</i> , <i>digits</i> )   |

## String Canonical Functions

**Table B-3 Mapping of String Canonical Functions and Oracle Functions**

| Canonical Function                                                                                                | Oracle Function                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Concat ( <i>string1</i> , <i>string2</i> )                                                                        | CONCAT( <i>string1</i> , <i>string2</i> )<br>or<br>( ( <i>string1</i> )    ( <i>string2</i> ))                                                    |
| Contains( <i>string</i> , <i>target</i> )                                                                         | INSTR( <i>string</i> , <i>target</i> )                                                                                                            |
| EndsWith( <i>string</i> , <i>target</i> )                                                                         | INSTR(REVERSE( <i>string</i> ), REVERSE( <i>target</i> ))                                                                                         |
| Comparison operators<br>( <i>&lt;</i> , <i>&lt;=</i> , <i>&gt;</i> , <i>&gt;=</i> , <i>&lt;&gt;</i> , <i>!=</i> ) | Comparison operators<br>( <i>&lt;</i> , <i>&lt;=</i> , <i>&gt;</i> , <i>&gt;=</i> , <i>&lt;&gt;</i> , <i>!=</i> )                                 |
| IndexOf( <i>target</i> , <i>string</i> )                                                                          | INSTR( <i>string2</i> , <i>target</i> )                                                                                                           |
| Left ( <i>string1</i> , <i>length</i> )                                                                           | SUBSTR( <i>string1</i> , <i>length</i> )                                                                                                          |
| Length ( <i>string</i> )                                                                                          | LENGTH( <i>string</i> )                                                                                                                           |

| Canonical Function | Oracle Function |
|--------------------|-----------------|
| NewGuid()          | SYS_GUID        |

# Glossary

## **assembly**

Assembly is Microsoft's term for the module that is created when a DLL or .EXE is compiled by a .NET compiler.

## **BFILES**

External binary files that exist outside the database tablespaces residing in the operating system. BFILES are referenced from the database semantics, and are also known as external LOBs.

## **Binary Large Object (BLOB)**

A large object data type whose content consists of binary data. Additionally, this data is considered raw as its structure is not recognized by the database.

## **Character Large Object (CLOB)**

The LOB data type whose value is composed of character data corresponding to the database character set. A CLOB may be indexed and searched by the Oracle Text search engine.

## **data provider**

As the term is used with Oracle Data Provider for .NET, a data provider is the connected component in the ADO.NET model and transfers data between a data source and the DataSet.

## **DataSet**

A DataSet is an in-memory copy of database data. The DataSet exists in memory without an active connection to the database.

## **dirty writes**

Dirty writes means writing uncommitted or dirty data.

**DDL**

DDL refers to data definition language, which includes statements defining or changing data structure.

**DOM**

Document Object Model (DOM) is an application program interface (API) for HTML and XML documents. It defines the logical structure of documents and the way that a document is accessed and manipulated.

**Extensible Stylesheet Language Transformation (XSLT)**

The XSL W3C standard specification that defines a transformation language to convert one XML document into another.

**flush**

Flush or flushing refers to recording changes (that is, sending modified data) to the database.

**Global Assembly Cache (GAC)**

A cache for .NET assemblies.

**goodness**

The degree of load in the Oracle database. The lighter load is better and vice versa.

**instantiate**

A term used in object-based languages such as C# to refer to the creation of an object of a specific class.

**invalidation message**

The content of a change notification which indicates that the cache is now invalid

**Large Object (LOB)**

The class of SQL data type that is further divided into internal LOBs and external LOBs. Internal LOBs include BLOBs, CLOBs, and NLOBs while external LOBs include BFILEs.

**Microsoft .NET Framework Class Library**

The Microsoft .NET Framework Class Library provides the classes for the .NET framework model.

**namespace**

- .NET:

A namespace is naming device for grouping related types. More than one namespace can be contained in an assembly.

- XML Documents:

A namespace describes a set of related element names or attributes within an XML document.

**National Character Large Object (NCLOB)**

The LOB data type whose value is composed of character data corresponding to the database national character set.

**Oracle Net Services**

The Oracle client/server communication software that offers transparent operation to Oracle tools or databases over any type of network protocol and operating system.

**OracleDataReader**

An OracleDataReader is a read-only, forward-only result set.

**Oracle XML DB**

Oracle XML DB is the name for a distinct group of technologies related to high-performance XML storage and retrieval that are available within the Oracle database. Oracle XML DB is not a separate server.

Oracle XML DB is based on the W3C XML data model.

**PL/SQL**

The Oracle procedural language extension to SQL.

**primary key**

The column or set of columns included in the definition of a table's PRIMARY KEY constraint.

**reference semantics**

Reference semantics indicates that assignment is to a reference (an address such as a pointer) rather than to a value. See [value semantics](#).

**REF**

A data type that encapsulates references to row objects of a specified object type.

**result set**

The output of a SQL query, consisting of one or more rows of data.

**Safe Type Mapping**

Safe Type Mapping allows the `OracleDataAdapter` to populate a `DataSet` with .NET type representations of Oracle data without any data or precision loss.

**savepoint**

A point in the workspace to which operations can be rolled back.

**stored procedure**

A stored procedure is a PL/SQL block that Oracle stores in the database and can be executed from an application.

**Transparent Application Failover (TAF)**

Transparent Application Failover is a runtime failover for high-availability environments. It enables client applications to automatically reconnect to the database if the connection fails. This reconnect happens automatically from within the Oracle Call Interface (OCI) library.

**Unicode**

Unicode is a universal encoded character set that enables information from any language to be stored using a single character set.

**URL**

URL (Universal Resource Locator).

**value semantics**

Value semantics indicates that assignment copies the value, not the reference or address (such as a pointer). See [reference semantics](#).

**XPath**

XML Path Language (XPath), based on a W3C recommendation, is a language for addressing parts of an XML document. It is designed to be used by both XSLT and XPointer. It can be used as a searching or query language as well as in hypertext linking.
