Oracle® Fusion Middleware

Developing Portals with Oracle WebCenter Portal and Oracle JDeveloper

11*g* Release 1 (11.1.1.9.0)

E27739-08

October 2015

Documentation for developers that explains how to build and deploy Portal Framework applications, portlets, portal assets, and custom portal components using Oracle WebCenter Portal and Oracle JDeveloper.

Oracle Fusion Middleware Developing Portals with Oracle WebCenter Portal and Oracle JDeveloper, 11*g* Release 1 (11.1.1.9.0)

E27739-08

Primary Author: Peter Jacobsen

Contributing Authors: Ingrid Snedecor, Joan Carter, Savita Thakur, Sue Highmoor, Shahana Mitra, Will Harris

Contents

3 Working Productively in Teams

4 Preparing Your Application for WebCenter Portal Tools and Services

6 Creating WebCenter Portal Framework Applications

7 Deploying and Testing Your Portal Framework Application

8 Understanding the WebCenter Portal Framework Application Life Cycle

9 Introduction to Portal Resource Management

10 Developing a Navigation Model

11 Developing Page Templates

12 Developing Page Styles and Task Flow Styles

13 Developing Skins

14 Developing Resource Catalogs

15 Creating Pages and Adding Resources

Part III Customizing Your Application and Extending Customization Options

16 Using WebCenter Portal Composer

17 Enabling Runtime Creation and Management of Pages

18 Enabling Runtime Editing of Pages Using Composer

19 Extending Runtime Editing Capabilities Using Composer

20 Performing Advanced Composer Configurations

21 Performing Composer-Specific MDS Configurations

22 Modifying Default Security Behavior of Composer Components

23 Customizing WebCenter Portal Tools and Services Task Flows

Part IV Integrating and Publishing Content

24 Introduction to Integrating and Publishing Content

25 Configuring Content Repository Connections

26 Working with Content Data Controls

27 Creating Content Presenter Display Templates

28 Integrating Documents

29 Adding Content Task Flows and Document Components to a Portal Page

30 Integrating Wikis and Blogs

31 Content Management REST API

Part V Enabling Communication and Collaboration

32 Integrating Announcements

33 Integrating Discussions

34 Integrating Instant Messaging and Presence

35 Integrating Mail

36 Integrating Polls

Part VI Working with People Connections

37 Introducing the People Connections Service

38 Basic Configuration for the People Connections Service

39 People Connections Task Flow Binding Parameters

40 Using People Connections Data Controls and Java APIs

41 Integrating Worklists

42 Using the People Connections REST APIs

Part VII Helping Users Find Content

43 Integrating Links

44 Integrating Tags

45 Integrating Search

46 Integrating the Activity Graph

47 Integrating Analytics

Part VIII Helping Users Keep Track

48 Integrating Events

49 Integrating Lists

50 Integrating Notifications

51 Integrating Recent Activities

52 Integrating RSS

Part IX Extending WebCenter Portal and Portal Framework Applications

53 Using Oracle WebCenter Portal REST APIs

54 Integrating Other Oracle Applications

55 Developing Components for WebCenter Portal Using JDeveloper

Part X Working with Portlets and Pagelets

57 Introduction to Portlets

58 Creating Portlets from JSF Applications Using the Oracle JSF Portlet Bridge

59 Building Standards-Based Java Portlets Using JSR 286

60 Building Java Portlets Using the Oracle PDK-Java

61 Deploying Portlet Producers

62 Creating Pagelets with Pagelet Producer

63 Consuming Portlets

64 Creating Portlets with OmniPortlet

65 Creating Content-Based Portlets with Web Clipping

Part XI Delivering Personalized Content

66 Personalizing Oracle WebCenter Portal Applications

67 Implementing Custom Data Providers: Introduction

68 Implementing Custom Function Providers: Introduction

69 Function Provider Reference

70 Using the Property Service

71 Property Service REST APIs

72 Conductor API Reference

73 Cache Management for Personalization

Part XII Completing Your WebCenter Portal Application

74 Securing Your WebCenter Portal Framework Application

75 Building Multilanguage Portals

Part XIII Appendixes

A WebCenter Portal Files

B Composer Component Properties and Files

C Resource Catalog Properties and Files

D Guidelines for Creating Task Flows to Be Used in Composer-Enabled Pages

E Using ADF JavaScript Partitioning for Performance

F Reuse of Oracle Portal Components

G Expression Language Expressions

I WebCenter Portal Accessibility Features

Preface

This guide explains how to build portal applications and custom components using WebCenter Portal Framework and JDeveloper, and provides in-depth information for all of the following tasks:

- How to set up and prepare your development environment for portal development, including iterative and round-trip development.
- How to build, deploy, and manage a Portal Framework application.
- How to secure, administer, monitor, and maintain a Portal Framework application and all of its associated components.
- How to develop custom navigation user interfaces for a portal.
- How to prepare an application for, configure, and integrate Oracle WebCenter Portal services.
- How to integrate content into a Portal Framework application.
- How to deliver personalized content to a Portal Framework application.
- How to plan, build, deploy, and manage portlets for a Portal Framework application.

> **Note:** For the portable document format (PDF) version of this manual, when a URL breaks onto two lines, the full URL data is not sent to the browser when you click it. To get to the correct target of any URL included in the PDF, copy and paste the URL into your browser's address field. In the HTML version of this manual, you can click a link to directly display its target in your browser.

Audience

This manual is written for all of the following developers:

- The developer who wants to build a WebCenter Portal Framework application or integrate Oracle WebCenter Portal functionality to their application.
- The component developer, who wants to build portlets from Oracle WebCenter Portal services.

This guide also assumes that the audience has already read the *Fusion Developer's Guide for Oracle Application Development Framework* and is familiar with the following technologies:

- Java

- Oracle JDeveloper
- JavaServer Faces
- Oracle Application Development Framework (Oracle ADF) (purpose, basic architecture, basic development skills)
- Oracle ADF Faces components
- Oracle WebLogic Server

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at `http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc`.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit `http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info` or visit `http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs` if you are hearing impaired.

Related Documents

For more information, see the following documents in the Oracle Fusion Middleware 11*g* Release 1 (11.1.1.9.0) documentation set or on Oracle Technology Network (OTN) at `http://www.oracle.com/technology/index.html`.

- *Administering Oracle WebCenter Portal*
- *Building Portals with Oracle WebCenter Portal*
- *Using Oracle WebCenter Portal*
- *Error Messages Reference*
- *Fusion Developer's Guide for Oracle Application Development Framework*

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
`monospace`	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

What's New?

The following topics introduce the new and changed features in Oracle WebCenter Portal 11*g* Release 1, and provide pointers to additional information:

- System Requirements and Specifications
- New and Changed Features for 11g Release 1 (11.1.1.9.0)
- New and Changed Features for 11g Release 1 (11.1.1.8.3)
- New and Changed Features for 11g Release 1 (11.1.1.8.0)

System Requirements and Specifications

For system and platform-specific information for Oracle Fusion Middleware products for 11*g* Release 1, refer to *Oracle Fusion Middleware System Requirements and Specifications*. That guide describes how to find out what is certified and how to verify the requirements of the certification. Your system administrator performs these tasks prior to installing Oracle WebCenter Portal.

New and Changed Features for 11*g* Release 1 (11.1.1.9.0)

WebCenter Portal 11*g* Release 1 (11.1.1.9.0) includes the following new and changed features:

- Support for running WebCenter Portal on cloud technologies:
  - Portal on-premise: WebCenter Portal deployment in a customer data center.
  - Oracle Private Cloud: provisioning and running WebCenter Portal on Oracle MWaaS; that is, using Oracle EM Cloud Control.
  - Oracle Public Cloud: provisioning and running WebCenter Portal on Oracle Java Cloud Service (JCS).
- Support for migration of the WebCenter Portal and Portal Framework application content from the Folders_g folder service to the FrameworkFolders folder service. See the "Migrating Folders_g to FrameworkFolders" appendix in *Administering Oracle WebCenter Portal*.
- Support for upgrading a pre-11.1.1.8.0 portal to the current release. See the "Upgrading a Pre-11.1.1.8.0 Portal" section in *Building Portals with Oracle WebCenter Portal*.
- Addition of the `childCreation` property for the `Show Detail Frame` component to specify when the children (contents) of the `Show Detail Frame` component are created, thus reducing processing time. See `childCreation` in Table B–7, " Attributes of a Show Detail Frame Component".

- Support for image renditions in Content Presenter display templates. See Section 27.3.6, "Using Image Renditions in Content Presenter Display Templates.".

New and Changed Features for 11*g* Release 1 (11.1.1.8.3)

WebCenter Portal 11*g* Release 1 (11.1.1.8.3) included the following new and changed features:

- Support for four new page templates that provide efficiency and performance enhancements over the existing page templates. See "New Page Templates."
- Support for the FrameworkFolders component that provides a scalable, high-performing folder service from Oracle WebCenter Content as an alternative to Folders_g. See "FrameworkFolders Support."

New Page Templates

Four new page templates provide efficiency and performance improvements over the existing page templates. The files included are:

- Four *page templates*: Skyros Side Navigation v2, Skyros Side Navigation (Stretch) v2, Skyros Top Navigation v2, and Skyros Top Navigation (Stretch) v2
- One *skin*: Skyros v2

  This is the preferred skin for the new page templates. Do not attempt to use the new Skyros v2 skin with existing page templates. Likewise, do not attempt to use the new page templates with the existing skins.
- Two *task flows*: Portal Side Navigation and Portal Top Navigation

  These task flows implement the navigation in the page templates, either in a side pane or as tabs along the top of a portal. The styling of the navigation in these task flows relies on the CSS in the skin file available in this patch. If you want to use these task flows in a page template that uses a different skin, be aware that the navigation may not look as expected due to CSS mismatches in the skin. However, if you copy and paste the navigation sections from the new Skyros v2 skin source code into your skin source code, you can achieve the expected results.

With WebCenter Portal 11*g* Release 1 (11.1.1.9.0), these files are pre-installed, and you will see them on the **Shared Assets** page, which is available if you have the permissions of the `Administrator` or `Application Specialist` role:

Asset Type	File Names

Page Templates	`pageTemplate_Skyros_Side_Navigation_Stretch_v2.ear`
	`pageTemplate_Skyros_Side_Navigation_v2.ear`
	`pageTemplate_Skyros_Top_Navigation_Stretch_v2.ear`
	`pageTemplate_Skyros_Top_Navigation_v2.ear`

Skins	`skin_Skyros_v2_Skin.ear`
Task Flows	`taskFlow_Portal_Side_Navigation.ear` `taskFlow_Portal_Top_Navigation.ear`

Perform the following steps to use the new page templates:

1. To set a new default page template for pages in the Home portal and all new portals (when the portal's template does not specify that a particular page

template must be used), see the "Choosing a Default Page Template" section in *Administering Oracle WebCenter Portal*.

2. To change the page template used by an individual portal, see the "Changing the Page Template for a Portal" section in *Building Portals with Oracle WebCenter Portal*.
3. To change the preferred skin used by a page template, see the "Setting the Preferred Skin for a Page Template" section in *Building Portals with Oracle WebCenter Portal*.

For more information, see the "Working with Page Templates" chapter in *Building Portals with Oracle WebCenter Portal* and Chapter 11, "Developing Page Templates."

FrameworkFolders Support

Previously, Oracle WebCenter Portal supported only Folders_g. WebCenter Portal 11*g* Release 1 (11.1.1.8.3) enables *new* installations of Oracle WebCenter Portal to be integrated with FrameworkFolders. Existing installations of Oracle WebCenter Portal patched to 11*g* Release 1 (11.1.1.8.3) *must* continue to use Folders_g.

The FrameworkFolders component provides a scalable hierarchical folder interface for accessing and organizing repository content, and is the recommended enterprise folder service for Content Server.

New and Changed Features for 11*g* Release 1 (11.1.1.8.0)

WebCenter Portal 11*g* Release 1 (11.1.1.8.0) included the following new and changed features:

- Terminology changes:

Prior Releases	11*g* Release 1 (11.1.1.8.0)
WebCenter Portal: Spaces	WebCenter Portal
space	portal
space template	portal template
resource	asset

- End-User Experience
  - Updated profile user interface that includes improved organization of profile information, click to edit, and clear profile photo functionality. See the "Managing Your Profile" chapter in *Using Oracle WebCenter Portal*. Additional documentation for the rich user profile is referenced under Portal Builder, Administration, and Development Environment.
  - Improved search experience (supported with Oracle SES 11.2.2.2) that includes faceted search and document thumbnails. See the "Searching for Information" chapter in *Using Oracle WebCenter Portal*.
- Portal Builder
  - Simplified portal creation that includes in-place page creation. See the "Creating and Building a New Portal" chapter in *Building Portals with Oracle WebCenter Portal*.
  - Redesigned portal edit and administration user interface (Portal Builder) that consolidates tasks into fewer steps. See the "Editing a Portal" and

"Administering a Portal" chapters in *Building Portals with Oracle WebCenter Portal*.

  - Simplified page creation and editing: Web (for editing) and Data (for managing) views, inline resource catalog (with support for component drag-and-drop onto a page), and Select view. See the "Working with Portal Pages" chapter in *Building Portals with Oracle WebCenter Portal*.
  - Automatic update of portal navigation as new pages are created. See the "Creating a Page or Subpage in an Existing Portal" section in *Building Portals with Oracle WebCenter Portal*.
  - "Lazy provisioning" of tools—WebCenter Portal configures the back-end server at first use of a tool rather than at portal creation to speed the successful creation of a new portal. See the "About Creating a New Portal" section in *Building Portals with Oracle WebCenter Portal*.
  - Hierarchical page support (subpages). See the "Creating Pages or Subpages in a Portal" section in *Building Portals with Oracle WebCenter Portal*.
  - Updated profile user interface that includes improved organization of profile information, click to edit, and clear profile photo functionality; new component properties for improved control of people connections and activity graph components. See the "Adding Activity Graphs and Recommendations to a Portal," "Adding Connections to a Portal," and "Adding Profiles to aPortal" chapters in *Building Portals with Oracle WebCenter Portal*. Additional documentation for the rich user profile is referenced under End-User Experience, Administration, and Development Environment.
  - Device Settings that control how your portal pages render on different devices, such smart phones, tablets, and desktop browsers. Page variants can be created to target and optimally render a portal on specific groups of devices like iOS phones, iOS tablets, and others. See the "Administering Device Settings in a Portal" section, the "Managing Device Groups for a Portal" chapter, and the "Creating a Page Variant for a Device Group" section in *Building Portals with Oracle WebCenter Portal*. Additional documentation for mobile support is referenced under Administration and Development Environment.
  - Responsive Content Presenter templates that provide an example of how you can use Content Presenter and CSS3 media queries to produce a responsive layout that adjusts to the width of the browser (for example, on smart phones, tablets, and desktop browsers). See the "Using Responsive Templates" section in *Building Portals with Oracle WebCenter Portal*. Additional documentation for mobile support is referenced under Development Environment.

- Development Environment
  - Updated profile user interface that includes improved organization of profile information, click to edit, and clear profile photo functionality; new component properties for improved control of people connections and activity graph components. See Chapter 37, "Introducing the People Connections Service," Chapter 39, "People Connections Task Flow Binding Parameters," and Chapter 46, "Integrating the Activity Graph." Additional documentation for the rich user profile is referenced under End-User Experience, Portal Builder, and Administration.
  - Developers can use Expression Language (EL) to retrieve information about Device Settings. Device Settings control how your portal pages render on different devices including smart phones, tablets, and desktop browsers. See

Section G.15, "EL Expressions Related to Device Settings." Additional documentation for mobile support is referenced under Portal Builder and Administration.

  - Responsive Content Presenter templates that provide an example of how you can use Content Presenter and CSS3 media queries to produce a responsive layout that adjusts to the width of the browser (for example, on phones, tablets, or personal computers). See Section 27.3.4, "Using Responsive Templates" and Section 27.3.5, "Extending Responsive Templates." Additional documentation for mobile support is referenced under Portal Builder.
  - Simplified custom shared library development and deployment. WebCenter Portal provides a new JDeveloper template that enables you to build custom components, such as task flows, data controls, and managed beans and deploy them in shared libraries directly to the WebCenter Portal server. See Chapter 55, "Developing Components for WebCenter Portal Using JDeveloper."

- Administration
  - Simplified WebCenter Portal administration that includes a power user oriented experience with familiar concepts for legacy WebCenter Portal customers. See the "Managing Portals in Portal Builder Administration" part in *Administering Oracle WebCenter Portal*.
  - New profile configuration settings that include properties to specify whether to show the new or legacy profile user interface and to specify profile synchronization settings. See the "Managing People Connections" chapter in *Administering Oracle WebCenter Portal*. Additional documentation for the rich user profile is referenced under End-User Experience, Portal Builder, and Development Environment.
  - Device Settings that control how your portal pages render on different devices, such as smart phones, tablets, and desktop browsers. Page variants can be created to target and optimally render a portal on specific groups of devices like iOS phones, iOS tablets, and others. See the "Deploying Devices and Device Groups" section, the "Creating a Page Variant of a System Page for Device Groups" section, and the "Administering Device Settings" chapter in *Administering Oracle WebCenter Portal*. Additional documentation for mobile support is referenced under Portal Builder and Development Environment.
  - Impersonation, which allows a privileged user to impersonate another user for the purposes of verifying the other user's experience in WebCenter Portal and troubleshooting unexpected results. See the "Managing Impersonation" chapter in *Administering Oracle WebCenter Portal*.
  - Improved portal lifecycle tools that enable export/import and backup/recovery of one or more portals with minimal downtime. See the "Deploying Portals, Templates, Assets, and Extensions" and "Managing WebCenter Portal Backup, Recovery, and Cloning" chapters in *Administering Oracle WebCenter Portal*.
  - Integrated Oracle WebCenter Portal's Pagelet Producer user interface within WebCenter Portal's administrative user interface to make system administrators aware of the existence of Pagelet Producer pagelets and to allow them to make these pagelets available to end users. Integrating the UIs also provides Pagelet Producer developers to easily navigate from WebCenter Portal where they see the pagelets to the Pagelet Producer Admin UI so they can create new or edit existing pagelets. See the "Managing the Pagelet Producer" chapter in *Administering Oracle WebCenter Portal*.

  - New page performance analyzer that shows you how long individual components take to display on a portal page, as well as the overall time taken to display a page. This new tool is useful to developers who are performing first level performance analysis, customers who build their own pages, and any user who customizes pages in WebCenter Portal. See the "How to Identify Slow Page Components" section in *Administering Oracle WebCenter Portal*.

- Restructured documentation library according to personas and their roles in WebCenter Portal:

  - *Developing Portals with Oracle WebCenter Portal and Oracle JDeveloper* (this guide) covers information needed by a *developer* who primarily works with JDeveloper to provide support for both portals and WebCenter Portal Framework applications.

  - *Using Oracle WebCenter Portal* covers information needed by a *knowledge worker* who typically uses WebCenter Portal to contribute and review content, participate in social interactions, and leverage the Home portal to manage her own documents and profile.

  - *Building Portals with Oracle WebCenter Portal* covers information needed by an *application specialist* who works in Portal Builder to create and administer portals, their structure (hierarchy of pages, navigation, security), and their content (components on a page, layout, behavior, and so on).

  - *Administering Oracle WebCenter Portal* covers information needed by a *system administrator* who fields requests from IT employees and business users to set up new machines; clone or back up existing applications systems and databases; install patches, packages, and applications; and perform other administration-related tasks.

  For more information, see "Who's Who."

Who's Who

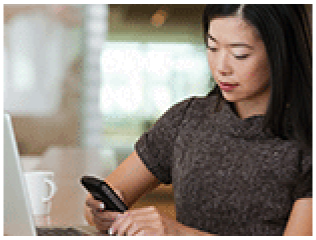
The WebCenter Portal documentation is organized so that the tasks in a particular guide address a specific user *persona*. Each persona is associated with a set of skills required to work with WebCenter Portal, from basic to advanced. For example, this guide is aimed at the *Developer* persona.

This preface introduces you to the WebCenter Portal personas and describes the ways in which they might interact with WebCenter Portal. Each persona is assigned a default role provided out-of-the-box with WebCenter Portal. The default roles are given a unique set of permissions appropriate for the work that each persona will typically do. Note that you can modify these default roles or configure new roles to meet the unique needs of your organization.

The people who interact with WebCenter Portal typically work together as a team that is comprised of the following personas:

- Knowledge Worker
- Application Specialist
- Web Developer
- Developer
- System Administrator

Knowledge Worker



Karen is a *knowledge worker* who typically uses WebCenter Portal to contribute and review content, participate in social interactions, and leverage the Home portal to manage her own documents and profile.

At the application level, Karen has permissions such as those granted to the default `Authenticated-User` role, which may be customized for the specific needs of the organization. At the portal level, the portal `Moderator` will likely assign Karen the `Viewer` or `Participant` role, or a custom role that offers a similar set of permissions.

For more information about roles and permissions, see the "About Roles and Permissions for a Portal" section in *Building Portals with Oracle WebCenter Portal*.

Knowledge Worker Tasks in WebCenter Portal

Tasks that are typical of a knowledge worker like Karen include:

- Connecting to and collaborating with other WebCenter Portal users by sharing information, files, and links; and by interacting through instant messaging, mail, message boards, discussions, wikis, and blogs
- Uploading, sharing, and managing documents stored in WebCenter Content
- Joining a team or project portal
- Keeping up with changes in WebCenter Portal by receiving notifications when content is updated, exploring recommendations from other users, viewing the activities of the portals she is a member of and users she's connected to, viewing announcements, taking polls, and monitoring WebCenter Portal RSS feeds
- Staying organized through the use of favorites, notes, calendars, lists, links to portal objects, and tags
- Viewing and responding to worklist items

As Karen becomes more familiar with the functionality available in WebCenter Portal, she may begin to perform more advanced tasks, such as creating portals. As a more advanced knowledge worker, her role may evolve to overlap with application specialist tasks.

Information targeted for knowledge workers like Karen is in *Using Oracle WebCenter Portal*. Advanced tasks that overlap with those of an application specialist are covered in *Building Portals with Oracle WebCenter Portal*.

Application Specialist

Ari is an *application specialist* who works in Portal Builder to create and administer portals, their structure (hierarchy of pages, navigation, security), and their content (components on a page, layout, behavior, and so on). In a typical project, Ari coordinates the efforts of Karen (knowledge worker), Wendy (web developer), and Dave (developer).

At the application level, Ari has permissions such as those granted to the default `Application Specialist` role, which may be customized for the specific needs of the organization. In a portal that Ari creates, he performs actions available to the `Moderator` role to manage the portal.

For more information about roles and permissions, see the "About Roles and Permissions for a Portal" section in *Building Portals with Oracle WebCenter Portal*.

Application Specialist Tasks in WebCenter Portal

Tasks that are typical of an application specialist like Ari include:

- Planning and creating new portals
- Editing and administering the portals he owns
- Creating and building portal pages using the page editor (Composer) and the resource catalog to add and configure page components
- Creating and managing portal assets, tools, and services
- Managing shared assets and portal templates across all portals

Information targeted for application specialists like Ari is in *Building Portals with Oracle WebCenter Portal*. To work with his personal view of the Home portal, Ari will also refer to *Using Oracle WebCenter Portal*.

Web Developer

Wendy is a *web developer* who focuses on delivering a consistent, branded look and feel to all portals. Wendy provides graphics designs and HTML markup from which Ari (application specialist in Portal Builder) or Dave (developer in JDeveloper) can create content or page style templates, skins, and so on. Once these assets are created, Ari can leverage them to create portal pages. Wendy typically does not interact with WebCenter Portal directly.

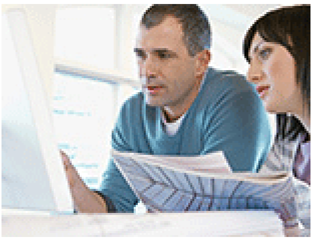
Web Developer Tasks in WebCenter Portal

Tasks that are typical of a web developer like Wendy include:

- Developing a corporate portal look and feel
- Designing new portal page templates

Information targeted for web developers like Wendy is in the "Creating a Look and Feel for Portals" chapter in *Building Portals with Oracle WebCenter Portal*.

Developer



Dave is a *developer* who provides support for both portals and WebCenter Portal Framework applications:

- **Portals (Portal Builder)**

Dave is primarily responsible for developing components (such as task flows, page templates, and content templates), which are published and leveraged by Ari (the application specialist). Dave primarily works with JDeveloper and leverages the WebCenter Portal Extension/WebCenter Portal Service Extension projects.

- **Framework Applications**

  Dave primarily works with JDeveloper to develop WebCenter Portal Framework applications. Once he has developed the application, he can package it as an EAR file and deploy it on the application server. In a typical environment, Dave would have JDeveloper configured with a SCM system and be working within a team with automated build and deploy processes.

Developer Tasks

Tasks that are typical of a developer like Dave include:

- Building and maintaining WebCenter Portal Framework applications
- Developing custom assets, like page templates and navigation components for portals in WebCenter Portal
- Developing Java portlets
- Developing and deploying task flows, managed beans, and other custom components
- Developing custom personalization components
- Maintaining the source control system
- Maintaining a build system

Information targeted for developers like Dave is in *Developing Portals with Oracle WebCenter Portal and Oracle JDeveloper*.

System Administrator

Syed is a *system administrator* who fields requests from IT employees and business users to set up new machines; clone or back up existing applications systems and databases; install patches, packages, and applications; and perform other administration-related tasks. As the system administrator, Syed works with other tools such as Fusion Middleware Control and command line tools. He leverages Enterprise Manager to configure portal settings, and also configures integrations such as WebCenter Content and other Fusion Middleware products and Oracle applications.

In WebCenter Portal's Portal Builder, he has permissions such as those granted to the default `Administrator` role, which provides exclusive access to administer and set global options for all portals (including the Home portal).

For more information about application level roles and permissions, see the "About Application Roles and Permissions" section in *Administering Oracle WebCenter Portal*.

System Administrator Tasks

Tasks that are typical of a system administrator like Syed include:

- Uses Portal Builder administration to administer all portals (including import and export of portals) and security site-wide
- Uses Portal Builder administration to manage site-wide system pages, business role pages, and personal pages
- Uses Portal Framework application administration console to manage application-wide preferences, manage users and roles, manage assets, configure the content repository, create polls, register producers and external applications
- Leads security, taxonomy, metadata, workflow, governance
- Uses the management console for administrative functions
- Executes command line utilities for administrative functions
- Installs and configures production versions of developers' efforts
- Performs patching of the production versions and the operating system
- Creates clones and backups of the production versions
- Performs restores of production versions
- Monitors the operating system for issues with the production version
- Deploys and redeploys applications

Information targeted for system administrators like Syed is in *Administering Oracle WebCenter Portal* and *WebLogic Scripting Tool Command Reference*.

Part I

Getting Started

Part I contains the following chapters:

- Chapter 1, "Introduction to Oracle WebCenter Portal for Developers"
- Chapter 2, "Setting Up Your Development Environment"
- Chapter 3, "Working Productively in Teams"
- Chapter 4, "Preparing Your Application for WebCenter Portal Tools and Services"

1 Introduction to Oracle WebCenter Portal for Developers

This guide is the primary resource for developers using JDeveloper to create Portal Framework applications, portlets, and custom portal components.

This chapter includes the following topics:

- Section 1.1, "What Is the Purpose of this Guide?"
- Section 1.2, "What Is My Role as a WebCenter Portal Developer?"

1.1 What Is the Purpose of this Guide?

This developer's guide discusses developing Portal Framework applications, portlets, and custom portal components using Oracle JDeveloper. Many of the tasks described in this guide involve activities that require Java, CSS, Application Development Framework (ADF), Expression Language (EL), and related experience.

Major activities described in this guide include:

Setting Up Your Environment

See chapters on setting up your environment and your team environment in Part I, "Getting Started."

Building Portals with WebCenter Portal Framework

A WebCenter Portal Framework application is a standard ADF web application that includes portal features, like navigation, pages, page templates, content, and more. The chapters in Part II, "Building WebCenter Portal Framework Applications" explain how to create Framework applications and develop assets like skins, templates, and navigation components.

Several parts of this guide contain chapters devoted to working with portal pages, content, look and feel, collaborative features, and so on.

- Part III, "Customizing Your Application and Extending Customization Options" discusses creating, customizing, and editing portal pages and customizing task flows used in your portal.
- Part IV, "Integrating and Publishing Content" explains how to integrate content into your portal by connecting to content repositories and working with content display components, like Content Presenter. The part also includes chapters on integrating wikis and blogs into the portal.
- Part IV, "Integrating and Publishing Content" explains how to integrate content into your portal by connecting to content repositories and working with content

display components, like Content Presenter. The part also includes chapters on integrating wikis and blogs into the portal.

- Part V, "Enabling Communication and Collaboration" discusses integrating features like discussions, mail, and presence into the portal.
- Part VI, "Working with People Connections" explains how to integrate people connections features into the portal. People connections provide social networking tools for use in enhancing connection and communication within a project team and throughout an enterprise. It does this through a set of features that include Activity Stream, Connections, Feedback, Message Board, Profile, and Publisher.
- Part VII, "Helping Users Find Content" discusses how to add links, tags, search, and activity tracking to the portal.
- Part VIII, "Helping Users Keep Track" discusses adding features like analytics, lists, notifications, and related features to the portal.

Developing Custom Components and Extending WebCenter Portal

WebCenter Portal Framework applications can be integrated with other applications, like Seibel, Oracle E-Business Suite, and PeopleSoft. You can use JDeveloper to create custom components, like task flows and managed beans, that can be deployed to the Portal Server and used in Portal Builder. These topics are covered in the chapters of Part IX, "Extending WebCenter Portal and Portal Framework Applications."

Working with Portlets and Pagelets

Portlets provide a means of presenting data from multiple sources in a meaningful and related way. Portlets can display excerpts of other web sites, generate summaries of key information, perform searches, and access assembled collections of information from a variety of data sources. Because several different portlets can be placed on a single page, users benefit from a single-source experience even though, in reality, the content may be derived from multiple sources. See the chapters of Part X, "Working with Portlets and Pagelets," for detailed information.

Pagelets are sub-components of a Web page accessed through Pagelet Producer that can be injected into any proxied application. Any application on a Pagelet Producer resource that returns markup can be registered as a pagelet, which can then be displayed in a portal or Framework application, or any other Web application. See the chapters of Part X, "Working with Portlets and Pagelets," for detailed information.

Delivering Personalized Content

Personalization delivers targeted content based on both user and application context for Portal Framework applications, and WebCenter Portal pages using Expression Language (EL) expressions. See Part XI, "Delivering Personalized Content."

Securing Your Portal

The security chapter describes security mechanisms and features provided in a Framework application, and how you can use Oracle ADF Security to handle authentication and authorization. See Part XII, "Completing Your WebCenter Portal Application." This part also includes guidlines for creating multi-language portals.

1.2 What Is My Role as a WebCenter Portal Developer?

In some cases, a portal requires custom components that do not exist out-of-the-box or cannot easily be created with the browser-based Portal Builder. For example, design requirements might call for page templates, page styles, and skins that are branded and organized in a precise way. In this case, you may need to use ADF Faces and CSS to achieve the desired look and feel, and JDeveloper is well-suited to such development. In another use case, custom components may be required that allow for interaction between portal elements and data (for example, using ADF task flows or portlets with event handling). Many such use cases exist.

As a WebCenter Portal developer, you may be asked to create and configure:

- Custom portal extensions like task flows, data controls, and backing beans
- Portal infrastructure components like page templates and page styles
- Personalization components like custom data providers, function providers, and property set locators
- JSR 286 portlets (also called "Java portlets")
- WebCenter Portal Framework applications
- WebCenter Portlet Producer applications

Large-scale portal development projects, like intranets and extranets, require the effort of a multi-role team. The team may include user interface experts, application specialists, QA engineers, Java developers, and others who participate in the portal's overall development and maintenance. See also Section 3, "Working Productively in Teams."

2 Setting Up Your Development Environment

This chapter provides guidance and tips to help you get started using JDeveloper for WebCenter Portal development activities.

This chapter includes the following topics:

- Section 2.1, "Introduction"
- Section 2.2, "General Setup Tasks"
- Section 2.3, "Setup Tasks Specific to WebCenter Portal Framework Applications"
- Section 2.4, "Setup Tasks Specific to WebCenter Portlet Producer Applications"
- Section 2.5, "Setting Up JDeveloper for Personalization"

2.1 Introduction

This chapter distinguishes between tasks that are general and tasks that are application-specific. General tasks apply no matter what kind of application you are developing. For instance, installing JDeveloper and the WebCenter Portal Extension are general setup tasks. Other tasks described in this chapter apply only if you are developing specific kinds of applications, like WebCenter Portal Server Extension or WebCenter Portal Framework applications.

2.2 General Setup Tasks

This section describes setup tasks that do not depend on what kind of application you are developing.

- Section 2.2.1, "Installing Oracle JDeveloper"
- Section 2.2.2, "Installing the WebCenter Portal Extension for JDeveloper"
- Section 2.2.3, "Setting the User Home Directory Environment Variable"
- Section 2.2.4, "Managing the Integrated WebLogic Server"
- Section 2.2.5, "Configuring WebCenter Back-End Services"
- Section 2.2.6, "Creating Application Resource Connections"
- Section 2.2.7, "Preparing for Team Development and Source Control"

2.2.1 Installing Oracle JDeveloper

Oracle JDeveloper provides an integrated development environment (IDE) for developing portals and custom portal components. For information on obtaining and installing Oracle JDeveloper, see the Oracle JDeveloper page on OTN at:

```
http://www.oracle.com/technetwork/developer-tools/jdev/overview/index.html
```

Once JDeveloper is installed, Oracle recommends that you increase the maximum PermGen size as follows:

1. Open the following file in a text editor:

   ```
   JDEV_HOME/jdev/bin/jdev.conf
   ```

   where *JDEV_HOME* is the location where JDeveloper is installed on your machine.

2. Set `AddVMOption -XX:MaxPermSize=512`.
3. Restart JDeveloper.

2.2.2 Installing the WebCenter Portal Extension for JDeveloper

The WebCenter Portal extension is an add-in that provides JDeveloper with the complete set of WebCenter Portal capabilities and features. To install the WebCenter Portal extension:

1. Start Oracle JDeveloper.
2. If the Select Default Roles dialog displays, select **Default Role** to enable all technologies, and click **OK**.
3. If a dialog opens asking if you want to migrate settings from an earlier version, click **No**.
4. From the **Help** menu, select **Check for Updates**.
5. Click **Next** in the Welcome page of the Check for Updates wizard.

   > **Note:** If you are behind a firewall, you may need to configure a proxy server to access the extensions. From the Updates wizard, a dialog will appear in which you can enter your HTTP Proxy Server settings. Click the **Help** button in any dialog for more information. For detailed information, see the "Proxy Settings and JDeveloper" topic in the Oracle JDeveloper online help.

6. On the Source page, select **Search Update Centers**.
7. Check **Oracle Fusion Middleware Products** and **Official Oracle Extensions and Updates** and click **Next**.
8. From the generated list, search for the **WebCenter Framework and Services Design Time** extension, select it, and then click **Finish**.
9. When prompted, restart JDeveloper.

For more information on obtaining and installing WebCenter Portal, see the Oracle WebCenter Portal page on OTN at:

http://www.oracle.com/technetwork/middleware/webcenter/portal/overview/index.html

See also the *Installation Guide for Oracle WebCenter Portal*.

2.2.3 Setting the User Home Directory Environment Variable

Oracle strongly recommends that you set an environment variable for the user home directory that is referenced by JDeveloper. By setting this variable, you can avoid receiving long pathname errors that are known to occur in some circumstances.

For detailed instructions on setting this variable on Windows, Linux, UNIX, and Mac OS X operating systems, see the "Setting the User Home Directory" section in the *Installation Guide for Oracle JDeveloper*.

2.2.4 Managing the Integrated WebLogic Server

This section discusses the Integrated WebLogic Server used by JDeveloper.

- Section 2.2.4.1, "What Is the Integrated WebLogic Server?"
- Section 2.2.4.2, "Starting and Stopping Integrated WebLogic Server"
- Section 2.2.4.3, "Configuring the JVM for the Integrated WebLogic Server"
- Section 2.2.4.4, "The WebCenter Preconfigured Server Readme File"

2.2.4.1 What Is the Integrated WebLogic Server?

The Integrated WebLogic Server is a runtime service that references an instance of Oracle WebLogic Server and is bundled with JDeveloper. The Integrated WebLogic Server allows developers to run, test, and debug WebCenter Portal Framework applications from within JDeveloper.

2.2.4.2 Starting and Stopping Integrated WebLogic Server

For detailed information managing the Integrated WebLogic Server, see the topic "Deploying to Integrated WebLogic Server" in the JDeveloper Online Help. Other options, such as running in debug mode and logging into the WebLogic Server Administration Console are also covered in that section.

2.2.4.3 Configuring the JVM for the Integrated WebLogic Server

Although it is not required, you have the option of changing the default Java Virtual Machine (JVM) settings the Integrated WLS in the `setDomainEnv.sh`. This file is located in JDEV_SYSTEM_DIRECTORY/DefaultDomain/bin.

The default memory values are:

```
-Xmx512m -XX:PermSize=128m -XX:MaxPermSize=512m
```

When creating or referring to the `JDEV_SYSTEM_DIRECTORY`, keep in mind that, on a Windows platform, a WebCenter domain name cannot contain spaces, and the domain cannot be created in a folder that has a space in its path. Also, pages in Portal Framework application are not rendered if there is a space in the path to the system directory in Oracle JDeveloper. Therefore, ensure that `DOMAIN_HOME` and `JDEV_SYSTEM_DIRECTORY` paths do not contain spaces.

2.2.4.4 The WebCenter Preconfigured Server Readme File

The WebCenter Preconfigured Server Read Me file contains valuable information about how to use Integrated WLS. In addition, the file contains links to preconfigured portlet producer test pages.

> **Note:** The links to the preconfigured portlet producers only work if the portlet producers are deployed to the server. The portlet producers are not deployed by default. You must deploy them before the links will resolve. For information on deploying the preconfigured producers, see Section 2.4.1.1, "Deploying the Preconfigured Portlet Producers."

You can access the Preconfigured Server Read Me file by selecting **WebCenter Portal Preconfigured Server Readme** from the Oracle JDeveloper Help menu.

2.2.5 Configuring WebCenter Back-End Services

To use certain Oracle WebCenter Portal components, you must install schemas into a supported database. This section discusses the schema installation for Oracle, SQL Server, and DB2 databases.

For information on which databases that WebCenter supports, see the document "Oracle Fusion Middleware Supported System Configurations" on OTN.

Table 2–1 lists the schemas that are used with WebCenter Portal and the methods by which you can install them. The Repository Creation Utility (RCU) is the recommended approach for all the schemas. However, for WebCenter Portal schema, you have the option of installing with a SQL script, as explained below.

Table 2–1 Database Schema Summary

Schema	Description	Installation Method
WebCenter	To use Tag, Links, Lists, Polls, and People Connections, you must have WebCenter Portal's schema installed in your database.	▪ RCU (preferred) ▪ SQL script (On Oracle databases only. See below for details.)
Portlets	For storing customizations in portlet producers.	RCU only
Activities	For Activity Graph and Analytics products.	RCU only
Discussions/WebCenter Portal Discussions Crawler	Used as the back end for discussions and announcements.	RCU only

2.2.5.1 Installing Schemas with RCU

Oracle recommends that you use RCU to install all WebCenter database schemas. For detailed information, see the "Creating Schemas" section in the *Repository Creation Utility User's Guide*.

2.2.5.2 Installing WebCenter Portal Schema with a SQL Script

To use Tag, Links, and People Connections, you must have the WebCenter Portal schema installed in your database.

To install the WebCenter Portal schema:

1. From the **Tools** menu, select **DataBase**, and then select **SQL Worksheet**.
2. In the Select Connection Dialog you can either select an existing connection or create a new connection. If you already have a database connection for an

administrator user to your database you can select that connection. If you don't have a connection then follow the next steps to create a new connection:

1. In the Select Connection dialog, click the plus icon to create a connection.
2. Use the Create Database Connection dialog to create a connection to the database where you will create the schema. This connection is not associated to the WebCenter Portal Framework Application.

Table 2–2 Create Database Connection Dialog Settings

Setting	Recommended Value
Create Connection In	IDE Connections
Connection Name	Use any name of your choice, for example: `my_connection`.
Connection Type	Oracle JDBC
Username	SYS
Password	Enter the SYS user password.
Role	SYSDBA
Driver	thin
Host Name	Enter the server name where the database is running. For example: `myserver.example.com`.
SID	Enter the database SID, for example: `mydbl01`.
JDBC Port	Enter the database port, for example: `1521`.

3. Click **Test Connection** to verify that the connection works.
4. Click **OK** to close the Create Database Connection dialog.

2.2.5.3 Installing WebCenter Portal Schema with a SQL Script

To use Tag, Links, and People Connections, you must have the WebCenter Portal schema installed in your database.

To install the WebCenter Portal schema:

1. From the **Tools** menu, select **DataBase**, and then select **SQL Worksheet**.
2. In the Select Connection dialog, click the pencil icon to edit the connection.

> **Note:** For information on creating database connections, see Section 2.2.6, "Creating Application Resource Connections."

3. Modify the connection to use an administrator username and password, such as `SYS` (using the `SYSDBA` role) then click **OK**.
4. Click **OK** to close the Select Connection dialog.
5. From the Tools menu, choose **SQL Worksheet**.
6. Enter the following SQL statement in the SQL Worksheet panel:

```
@@JDEV_HOME/jdeveloper/jdev/extensions/oracle.webcenter.install/sql/oracle/wc_
schema.sql
```

where `JDEV_HOME` is the location where JDeveloper is installed on your machine.

7. Click the **Execute Statemen**t icon, or press **F9**, to run the script.
8. At the prompt, enter `webcenter` as the name for the schema and a password for the schema, such as `welcome1`. The name of the schema *must* be `webcenter`.
9. If prompted for the Default Tablespace and Temporary Tablespaces, re-enter the default values `users` and `temp`, then accept them.

2.2.6 Creating Application Resource Connections

Connections allow applications to access external data and services. For example, if you wish to use the Content Presenter task flow to display content from an Oracle WebCenter Content Server repository, you need to configure a connection to the repository. If you intend to consume portlets from a portlet producer, you need to configure the producer connection.

> **Tip:** A good practice is to create and test your connections once and check them into your source control system. Then, other developers on your team can check out the connections and use them. This technique also allows your team to keep in sync whenever a connection changes.

This section discusses connections and describes the different ways to access the wizards for creating new connections. See also Section 2.2.6.3, "Where Can I Learn More About Connections?."

2.2.6.1 Where Are Connections Located?

Depending on how you invoke a wizard to create a connection, connections are placed in one of the following locations:

- Under Application Resources in the Application Navigator

  Connections created here can be used in the current application only. This is the most common way to create a repository connection.

  For certain features, you can drag and drop a connection from Application Resources onto a page to create different types of task flow regions. To learn more, refer to the individual chapters on tools and services for WebCenter Portal. See

- Under IDE Connections in the Resource Palette

  Connections created here can be reused across applications. To use these connections in an application, you just have to drag and drop the connection from the Resource Palette onto the Connections node in that application.

2.2.6.2 How Do I Access the Connection Wizards?

To access a connection wizard from the New Gallery:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **Connections**, select the type of connection you want to create, and click **OK**.

   Depending on your selection, the **Create <*Connection_Type*> Connection** dialog opens.
3. The **Create Connection in** option is set to **Application Resources** by default.

   You can select **IDE Connections** to create a connection in the Resource Palette.

To access a connection wizard from the Application Navigator:

1. Right-click the **Connections** node under Application Resources and select **New Connection**, then select the connection type from the context menu.
2. Depending on your selection, the **Create <*Connection_Type*> Connection** dialog or wizard opens.

   The **Create Connection in** option is set to **Application Resources** by default.

To access a connection wizard from the Resource Palette:

1. Click the **New** icon in the Resource Palette, select **New Connection**, then select the connection type from the context menu.
2. Depending on your selection, the **Create <*Connection_Type*> Connection** dialog or wizard opens.

   The **Create Connection in** option is set to **IDE Connections** by default.

2.2.6.3 Where Can I Learn More About Connections?

For information about creating and consuming connections, see:

- Chapter 25, "Configuring Content Repository Connections"
- Chapter 63, "Consuming Portlets"
- Part IV, "Integrating and Publishing Content"
- Chapter 7, "Deploying and Testing Your Portal Framework Application"

2.2.7 Preparing for Team Development and Source Control

It's important to consider the overall team development environment. To be useful, a team development environment must be configured to allow developers to share common resources, like databases, content repositories, and source code. A well-planned team environment allows you to quickly and consistently develop, build, and update your portals.

> **Tip:** Typically, one member of the development team creates a new portal application in JDeveloper and checks it in to the source control repository. A team member can create any required database or content repository connections and check those in as well.

For more detailed information on team development topics like source control and file sharing, see Chapter 3, "Working Productively in Teams."

2.3 Setup Tasks Specific to WebCenter Portal Framework Applications

This section describes tasks that you only need to perform if you are creating WebCenter Portal Framework application.

- Section 2.3.1, "Preparing for Iterative Development in a Portal Framework Application"
- Section 2.3.2, "Additional Configurations"

2.3.1 Preparing for Iterative Development in a Portal Framework Application

This section discusses the iterative development feature for WebCenter Portal Framework applications.

Enabling iterative development lets you make changes to your portal application while it is running on the Integrated WebLogic Server and immediately see the effect of those changes by refreshing the browser. For more information on iterative development, see Section 8.7, "Understanding Iterative Development."

> **Note:** The iterative development option disables many performance optimization features, which can cause your application to run more slowly.

- Section 2.3.1.1, "Enabling Iterative Development"
- Section 2.3.1.2, "Turning Off Iterative Development"

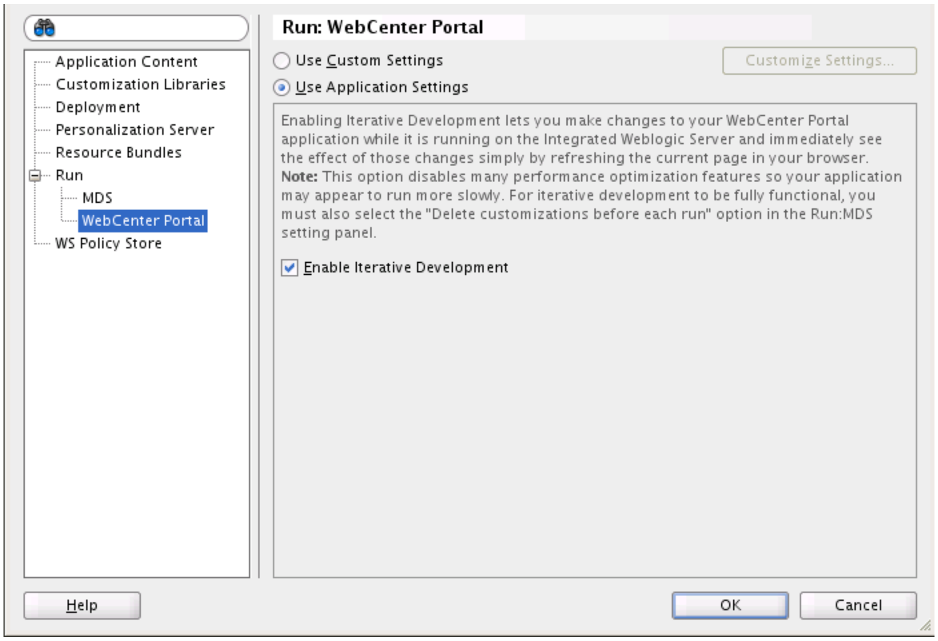
2.3.1.1 Enabling Iterative Development

This section explains how to enable iterative development, if it has been disabled. When you enable this feature, you are turning off all caching, which can cause your application to run more slowly.

> **Note:** The iterative development feature is enabled by default when you create a new Portal Framework application.

1. Select **Application Properties** from the Application menu.
2. Along the left side of the Application Properties dialog, expand the **Run** node.
3. Select **WebCenter Portal**.
4. Select **Enable Iterative Development**, as shown in Figure 2–1.

Figure 2–1 Enabling Iterative Development



Run: WebCenter Portal

○ Use Custom Settings

● Use Application Settings

Enabling Iterative Development lets you make changes to your WebCenter Portal application while it is running on the Integrated Weblogic Server and immediately see the effect of those changes simply by refreshing the current page in your browser. **Note:** This option disables many performance optimization features so your application may appear to run more slowly. For iterative development to be fully functional, you must also select the "Delete customizations before each run" option in the Run:MDS setting panel.

☑ Enable Iterative Development

5. Under the **Run** node in the left pane of the dialog, select **MDS**.

6. In the right pane, select **Delete customizations before each run**. Doing so clears the MDS of any runtime customizations every time the application is run.
7. Click **OK**.

2.3.1.2 Turning Off Iterative Development

This section explains how to turn off iterative development. Iterative development is enabled by default. It's a good practice to turn off iterative development for testing purposes before you deploy your application to a production server.

There are other several reasons why you might consider turning off iterative development, such as:

- Because turning on iterative development disables all caching, you might turn off this feature if you have a very large portal and the lack of caching is causing performance problems.
- When this feature is turned off, there is no difference between a portal instance that is running on the Integrated WebLogic Server and an instance that is deployed to a managed server.

To turn off iterative development:

1. Select **Application Properties** from the Application menu.
2. Along the left side of the Application Properties dialog, expand the **Run** node.
3. Select **WebCenter Portal**.
4. Unselect **Enable Iterative Development**.
5. Click **OK**.

2.3.2 Additional Configurations

Additional configurations that may be required for WebCenter Portal Framework applications are covered in Section 2.2.5, "Configuring WebCenter Back-End Services" and Section 2.2.6, "Creating Application Resource Connections."

2.4 Setup Tasks Specific to WebCenter Portlet Producer Applications

This section describes tasks that you only need to perform if you are creating WebCenter Portlet Producer application. For more information about WebCenter Portlet Producer applications, see Chapter 57, "Introduction to Portlets."

2.4.1 What You May Need to Know About Preconfigured Portlet Producers

WebCenter Portal provides a variety of ready-to-use portlets that you can add to your portal pages. This section provides a brief description of the preconfigured producers and the portlets they provide. It contains the following subsections:

- Section 2.4.1.1, "Deploying the Preconfigured Portlet Producers"
- Section 2.4.1.2, "Registering Deployed Portlet Producers"
- Section 2.4.1.3, "Accessing OmniPortlet and Web Clipping"
- Section 2.4.1.4, "The WSRP Sample Portlet Producers and Portlets"
- Section 2.4.1.5, "The PDK-Java Sample Portlet Producer and Portlets"

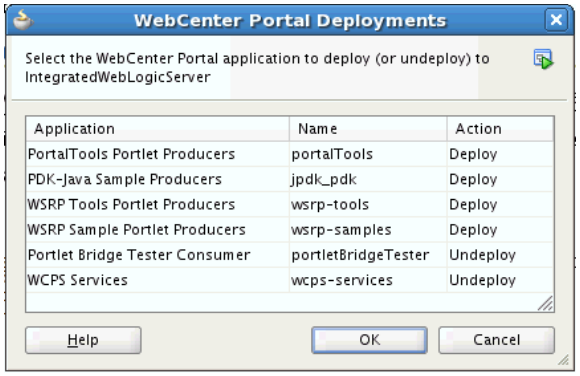
2.4.1.1 Deploying the Preconfigured Portlet Producers

The preconfigured portlet producers are not deployed by default – you must deploy them manually, as explained in this section.

> **Note:** These producer applications consume memory and require CPU time during deployment. This contributes to the WebLogic Server startup time and base memory footprint. For these reasons, it makes sense to only deploy the applications you need. For more information tuning the deployment of internal applications, see the "On-demand Deployment of Internal Applications" section in *Deploying Applications to Oracle WebLogic Server*.

1. If it is not running, start the Integrated WebLogic Server. The server must be running for this feature to be enabled.
2. From the Run menu, select **WebCenter Portal Deployments**.
3. In the WebCenter Portal Deployments dialog box, select the producer you wish to deploy and click **OK**. The dialog is shown in Figure 2–2. Each of the preconfigured producers is described in more detail in the following sections.

Figure 2–2 WebCenter Portal Deployments Dialog



Select the WebCenter Portal application to deploy (or undeploy) to IntegratedWebLogicServer

Application	Name	Action
PortalTools Portlet Producers	portalTools	Deploy
PDK-Java Sample Producers	jpdk_pdk	Deploy
WSRP Tools Portlet Producers	wsrp-tools	Deploy
WSRP Sample Portlet Producers	wsrp-samples	Deploy
Portlet Bridge Tester Consumer	portletBridgeTester	Undeploy
WCPS Services	wcps-services	Undeploy

2.4.1.2 Registering Deployed Portlet Producers

After a portlet producer is deployed, you can register it. Portlets from registered producers can then be selected from Oracle JDeveloper's Application Resources panel.

For information about registering portlet producers, see Chapter 63, "Consuming Portlets." For information about adding portlets to pages, see Section 63.5, "Adding Portlets to a Page."

2.4.1.3 Accessing OmniPortlet and Web Clipping

The Integrated WLS contains PortalTools, which provides access to the *design time at runtime* OmniPortlet and Web Clipping portlet. Design time at runtime means that users define portlet content after the portlet is placed on an application page and the page is run.

To access the OmniPortlet and Web Clipping portlet producers:

1. Start the Integrated WebLogic Server.
2. From the **Help** menu, select **WebCenter Preconfigured Server Readme**.

3. In the Readme file, go to the heading **Accessing the PortalTools Portlet Producers Test Pages**, and click the **PortalTools Welcome Page** link.

   This opens the PortalTools Welcome page.

   > **Note:** The Portal Tools Portlet Producers component must be deployed before the PortalTools Welcome page can be accessed through the WebCenter Preconfigured Server Readme page. For details, see Section 2.4.1.1, "Deploying the Preconfigured Portlet Producers."

4. On the PortalTools Welcome page, copy the URL of the Web Clipping Producer link, the OmniPortlet Producer link or the Sample Portlet Producer link, and use it as the producer URL in the Oracle PDK-Java Portlet Producer Registration Wizard.

   > **Note:** For information about registering a portlet producer, see Chapter 63, "Consuming Portlets."

Once you have registered a producer, its portlets become available on Oracle JDeveloper's Application Resources panel. In the Application Resources panel, under the Connections node, select a producer name to list its portlets, then drag a portlet onto a portal page. (For information about adding portlets to pages, see Section 63.5, "Adding Portlets to a Page.".)

The PortalTools Welcome page contains producer URLs for three producers:

- The **Web Clipping producer** provides the Web Clipping portlet, which is a browser-based declarative tool that enables dynamic reuse of content from another web source. When the source changes, the content in the Web Clipping portlet also changes. With the Web Clipping portlet, you use a web browser to navigate to the web page that contains the desired content. Using Web Clipping Studio, which is accessed through the portlet, drill down through a visual rendering of the target page to choose the desired content. For detailed information about the Web Clipping portlet, see Chapter 65, "Creating Content-Based Portlets with Web Clipping."

  > **Note:** Instead of using the Web Clipping portlet , consider using a clipper pagelet using Oracle WebCenter Portal's Pagelet Producer. For more information, see the "Managing the Pagelet Producer" chapter in the *Administering Oracle WebCenter Portal*.

- The **OmniPortlet producer** provides OmniPortlet, which is a declarative portlet-building tool that enables you to build portlets against a variety of data sources, including XML files, character-separated value files (for example, spreadsheets), web services, databases, and web page. OmniPortlet users can also choose a prebuilt layout for the data. Prebuilt layouts include tabular, news, bullet, form, chart, or HTML. For information about OmniPortlet, see Chapter 64, "Creating Portlets with OmniPortlet."

- The **Sample Portlet Producer** includes portlets built with OmniPortlet that are for demonstration purposes only. The portlet samples include a scrolling RSS portlet and a simple RSS portlet. Note that the sample producer is for demonstration and should not be used to create real-use portlet instances.

2.4.1.4 The WSRP Sample Portlet Producers and Portlets

The Integrated WLS includes sample WSRP portlet producers and portlets you can use with your application.

Note: You can find the source code for the sample portlets is in the following EAR file:

```
JDEV_
HOME/jdeveloper/webcenter/modules/oracle.portlet.server_
11.1.1/wsrp-samples.ear
```

where *JDEV_HOME* is the location where JDeveloper is installed on your machine.

To access WSRP sample portlet producers:

1. Start the Integrated WebLogic Server.
2. From the **Help** menu, select **WebCenter Portal Preconfigured Server Readme**.
3. In the Readme file, go to the heading **Accessing the WSRP Portlet Producers Test Pages**, and click the link for the **WSRP Tools Portlet Producers** or **Sample Portlet Producer**.

   Note: The portlet producers are not deployed by default. You must deploy a producer application before it can be accessed through the WebCenter Preconfigured Server Readme page. For details, see Section 2.4.1.1, "Deploying the Preconfigured Portlet Producers."

   Both links open different WSRP Producer Test Pages—one that has Parameter Form and Parameter Display portlets, the other for different WSRP producer versions of sample portlets.

4. Copy the Web Services Description Language (WSDL) URL for a WSRP producer—either WSRP v1 WSDL or WSRP v2 WSDL.

   Use the copied link as the producer URL in the WSRP Producer Registration Wizard.

   Note: For information about registering a portlet producer, see Chapter 63, "Consuming Portlets."

Depending on where the portlet producer connection was registered, its portlets appear either under Application Resources or in the Resource Palette. From here, you can drag and drop a variety of sample portlets onto your Portal Framework application pages.

2.4.1.5 The PDK-Java Sample Portlet Producer and Portlets

The Integrated WLS includes sample PDK-Java portlet producers and portlets you can use with your application. Use the PDK-Java sample portlets to familiarize yourself with the types of functionality that are available through PDK-Java portlets.

To access PDK-Java sample portlet producers:

1. Start the Integrated WebLogic Server.

2. From the **Help** menu, select **WebCenter Preconfigured Server Readme**.
3. In the Readme file, go to the heading **Accessing the PDK-Java Portlet Producers Test Pages**, and copy the link location for the **PDK-Java Sample Producer** or **PDK-Java Struts Sample Producer** link.

   Note: These producers must be deployed before they can be accessed through the WebCenter Preconfigured Server Readme page. For details, see Section 2.4.1.1, "Deploying the Preconfigured Portlet Producers."

   Use the copied link as the producer URL in the Oracle PDK-Java Portlet Producer Registration Wizard.

   Note: For information about registering a portlet producer, see Chapter 63, "Consuming Portlets.".

Depending on where the portlet producer connection was registered, its portlets appear either under Application Resources or in the Resource Palette. From here, you can drag and drop a variety of sample portlets onto your Portal Framework application pages.

2.4.1.6 The Portlet Bridge Tester Consumer

The tester is used to test portletized page or task flow in JDeveloper. The tester is deployed by default. For more information, see Section 58.4, "Testing a Portletized Page or Task Flow in JDeveloper."

2.4.1.7 WCPS Services

WebCenter Personalization Services is deployed by default, and is unrelated to portlet producers. For information about WebCenter Personalization, see Chapter 66, "Personalizing Oracle WebCenter Portal Applications."

2.5 Setting Up JDeveloper for Personalization

Personalization provides a dynamically derived user experience for your Portal Framework application. Personalization evaluates defined sources of input data, generates a decision based on that evaluation, and applies this information to a declaratively defined Personalization scenario. Personalization, for example, can return content or change application flow based on information about a user in a Human Resources database, targeting the application experience for that specific user. For more information, see Chapter 66, "Personalizing Oracle WebCenter Portal Applications."

Before you can develop and use personalization components you need to add certain components to your portal project. JDeveloper makes this process easy to do:

1. Be sure the WebCenter Portal Extension is installed into your JDeveloper environment. The WebCenter Portal Extension includes the required data integration component JAR files. See Section 2.2.2, "Installing the WebCenter Portal Extension for JDeveloper."
2. Create an application, such as a WebCenter Portal Framework application.

3. Add the WebCenter Personalization technology scope to your project. This technology scope adds the JDeveloper-specific tooling features, like the scenario editor, to the project.

    1. Right-click your project and select **Project Properties**.
    2. Select **Technology Scope** in the Project Properties dialog.
    3. Select **WebCenter Personalization** in the list of available scopes and move it to the Selected column.
    4. Click **OK**.

After you complete these steps, you are ready to develop and test personalization components in JDeveloper. For more information, see Chapter 66, "Personalizing Oracle WebCenter Portal Applications."

3 Working Productively in Teams

This chapter contains information for a team development environment, where developers are sharing files in Oracle JDeveloper. It includes information about source (or version) control systems, namely Subversion.

This chapter includes the following topics:

3.1 Using Source Control for WebCenter Portal Development

You can use source control in WebCenter Portal similar to the way you would use source control in any other development environment.

JDeveloper includes Subversion for source control. Oracle also provides free extensions to other source support systems, such as Concurrent Versions System (CVS), Dimensions, and ClearCase. You can install these extensions directly from inside JDeveloper through the **Help - Check for Updates** menu option, which is the recommended way to install extensions. If you cannot connect to the internet from your JDeveloper instance, then download the extension from Oracle Technology Network (OTN) at `http://www.oracle.com/technetwork/index.html`. Point the **Check for Updates** wizard to the local file you download.

> **Note:** You may need to configure a proxy server to access the extensions. For details, see the "Proxy Settings and JDeveloper" topic in the Oracle JDeveloper online help.

For more complete and extensive information about setting up and using SubVersion and other source control systems with JDeveloper, see the "Developing in Teams" topic in the Oracle JDeveloper online help.

3.2 Using Oracle Team Productivity Center

Oracle Team Productivity Center is an Application Lifecycle Management tool that enables software development teams to collaborate and work productively when developing portals using JDeveloper. This also is a free extension to JDeveloper.

Oracle Team Productivity Center integrates task, bug, and defect repositories, such as JIRA, Bugzilla, and its own built-in task repository into the IDE. It provides a chat interface inside JDeveloper and other team working benefits, such as recording details of files checked into the source control system against tasks and developer productivity aids, such as saving the context of your IDE.

For more information, or to download Oracle Team Productivity Center, go to Oracle Technology Network (OTN) at `http://www.oracle.com/technetwork/index.html`.

3.3 Deciding Which Files to Check in to Source Control

An important aspect of working with any source control system is understanding which files to check in and which actions might affect those files. In general, as you your team members begin creating new projects, you will see which files are created, and then can determine what you wish to check into source control. It's difficult to summarize all the possible interactions with files you may encounter; however, this section offers a few general tips.

Table 3–1 lists a few of the components with which developers typically interact, and provides links to more information about those components and their related files.

Table 3–1 Commonly Encountered Components

Component	For More Information...
Pages	For information about page metadata files, see the "Introduction to the ADF Metadata Files" section in the *Fusion Developer's Guide for Oracle Application Development Framework*.
Portlets	For information about portlet and producer metadata files, see Appendix A, "WebCenter Portal Files." See also, Section 59, " Building Standards-Based Java Portlets Using JSR 286."
Task Flows	For detailed information about ADF task flows, see the "Getting Started with ADF Task Flows" section in *Fusion Developer's Guide for Oracle Application Development Framework*.
Data Controls	See the *Fusion Developer's Guide for Oracle Application Development Framework* for detailed information about data controls.

For information on other features and related files you may wish to review when planning your source control strategy, see Appendix A, "WebCenter Portal Files." The appendix lists and describes Portal Framework files, system files, JDeveloper files, and others.

3.4 Implementing Common Requirements One Time

It is good practice for the project administrator to implement any common developer requirements one time and then check in that version for all to use. By planning ahead and having the administrator take care of these common requirements up front, you can reduce redundancy and error.

For example, suppose two developers must add OmniPortlet on different pages of a portal. If the project administrator has registered the OmniPortlet producer, then it is available for both of them to use. If not, then each developer likely registers the OmniPortlet producer separately, leading to unnecessary duplication and confusion.

Another example: suppose many developers need content from the same content repository. One person should set up and check in the needed connection first. Other developers then can simply reuse the same data control.

3.5 Portlet Producer Considerations

When working in a team environment, bear in mind the following considerations pertaining to portlet producers:

- Section 3.5.1, "Portlet Producer Connections"
- Section 3.5.2, "Combining Portlets from Different Portlet Producers"

3.5.1 Portlet Producer Connections

When building an EAR file for your project, connections are loaded for the entire portal rather than individual projects. For example, suppose you have a portal with two projects: P1 and P2. P1 has 100 registered producers and P2 has no producers. When you build an EAR file for either project, all 100 of P1's producer connections are loaded into `connections.xml`. Note, though, that you can also edit `connections.xml` manually.

When you run the predeployment tool to create a targeted EAR file, all of the connections in `connections.xml` must be accessible. Hence, in our example, the generation of a targeted EAR file for either project would fail if any of the 100 portlet producer connections for P1 are unavailable for some reason. Given this behavior, you must carefully consider how you plan to subdivide your overall development effort into portals and projects.

3.5.2 Combining Portlets from Different Portlet Producers

In some cases, you might have multiple developers building portlets and ultimately you want those portlets to be combined under a single portlet producer. The developers must be conscious of some potential issues.

- Portlet names and JSP paths could clash. Portlet developers should use prearranged class package names and JSP paths to avoid naming clashes when portlets are combined within one portlet producer in one portal.
- When you create a JPS portlet in the Portlet wizard, the directory for the portlet modes defaults to `portlet`*`n`*`\html\`*`mode_name`*, where *`n`* is a number that increments for each portlet you create. To avoid directory and file name clashes, portlet developers should change the directory name on the Content Type and Portlet Modes page of the Portlet wizard. Select the portlet mode and then change the directory name in the corresponding field to something unique.
- When you combine portlets into one portlet producer, you must manually merge the portlet descriptor files, avoiding identifier clashes as you do so as follows:
  - JPS portlet identifiers in the `portlet.xml` and `oracle-portlet.xml` files are generated automatically starting from `portlet1`. When you manually merge multiple portlet descriptor files into one, you must change any portlet identifiers that clash with one another.
  - Similarly, the PDK-Java portlet identifiers in `provider.xml` are automatically generated starting from `1`. When you manually merge multiple `provider.xml` files, you must change any portlet identifiers that clash with one another.

- You must manually merge any web descriptor (`web.xml`) changes; for example, security role information.
- For PDK-Java portlets, you also might need to manually merge `.properties` files.
- When using many different portlets, parts of files might not be checked in properly because they are overwritten by someone else or because JDeveloper does not pick up the changed files correctly. For example, you might deploy a portal with many types of portlets and see the following error in two of the three OmniPortlets:

  ```
  mdsId
  oracle/adf/portlet/OmniPortlet_1172537210873/ap/Portlet100_0b4156e9_0111_1000_
  8001_82235f273a39.pxml not found

  mdsId
  oracle/adf/portlet/OmniPortlet_1172537210873/ap/Portlet100_250498fc_0111_1000_
  8002_a9fe7286a54e.pxml not found
  ```

  If you receive error messages like these, then ensure that all `*.pxml` files from the development environment are copied over to the deployed environment.
- Your portlet customizations might not appear in your deployed environment. Make sure that the content of the `oracle\adf\portlet\<`*`portletInstanceName`*`>.pxml` file is correct and that it refers to the proper *`*.pxml`* files.

4

Preparing Your Application for WebCenter Portal Tools and Services

This chapter describes how to prepare your application to consume tools and services in Oracle WebCenter Portal.

This chapter includes the following topics:

- Section 4.1, "Understanding WebCenter Portal Tools and Services"
- Section 4.2, "Preparing Your Framework Application for Tools and Services"
- Section 4.3, "Customizing How Services Render Resources"
- Section 4.4, "Configuring General Settings"

4.1 Understanding WebCenter Portal Tools and Services

Oracle WebCenter Portal tools and services enrich portals and Web sites with social computing services, personal productivity services, online awareness and communications, content integration, and Web analytics.

This section summarizes the key technologies. This can help you determine which tools and services to implement and the best way to customize your user interface.

> **Note:** WebCenter Portal tools and services expose their functionality through task flows that you can add to the pages of your application. If these task flows do not quite meet your requirements, you can customize them to change their look and feel or functionality. For example, you can add text, change labels, remove regions or components, or show additional attributes. For more information, see Chapter 23, "Customizing WebCenter Portal Tools and Services Task Flows."

This section includes the following subsections:

- Section 4.1.1, "Understanding WebCenter Portal Horizontal Tools and Services"
- Section 4.1.2, "Understanding WebCenter Portal APIs"
- Section 4.1.3, "Using WebCenter Portal Data Controls"

4.1.1 Understanding WebCenter Portal Horizontal Tools and Services

Some tools and services in WebCenter Portal are considered *horizontal* in that they interact with other tools and services across an application.

Table 4–1 lists integration points in WebCenter Portal.

Table 4–1 Integration Points in WebCenter Portal

WebCenter Portal Tool or Service	RSS	Search	Tags	Links	Comments and Likes	Activity Stream	Activity Graph	Notifications	Analytics
Activity Graph						X	n/a		X
Announcements	X	X		X		X		X	
Blogs		X	X	X	X	X	X	X	X
Discussions	X	X	X	X	X (replies on topics)	X	X (replies)	X	
Documents, including wikis		X	X	X	X	X	X	X	X
Events		X partial		X		X		X	
Instant Messaging and Presence (IMP)								X	
Lists	X	X	X	X		X		X	
Mail								X	
Notes		X		X					
People Connections		X partial	X partial		X (Activity Stream, Message Board)	X (Message Board, Profiles, Feedback	X (Message Board)	X	X
Polls									
Recent Activities	X								
Search		n/a	X			X partial			X
Tags		X	n/a			X			

Note: Search (listed in the table) uses WebCenter Portal search adapters to search each available component. However, large-scale implementations should be configured to use Oracle SES search for best performance. Oracle SES searches applications for the following resources:

- Documents, including wikis and blogs
- Announcements and discussions

For more information, see Chapter 45, "Integrating Search."

4.1.2 Understanding WebCenter Portal APIs

This section describes the APIs available for WebCenter Portal tools and services.

Note the following considerations when multiple customization options are available:

- Use REST APIs to build a custom client for accessing WebCenter Portal; for example, an iPhone application that interacts with WebCenter Portal.

- REST APIs may provide the fastest and easiest way to customize the user interface and develop custom components. Consider using data controls or native APIs to build a custom user interface for accessing WebCenter Portal.
- Use data controls or native APIs to build a custom portal or composite Framework application.
- Use data controls or native APIs if you are proficient with Java, JDeveloper, and ADF. To use other languages, especially JavaScript, use REST APIs.

Table 4–2 lists tools and services with available APIs.

Table 4–2 Supported Technologies for Tools and Services

WebCenter Portal Tool or Service	Data Controls	Java APIs	REST APIs	Back End APIs
Activity Graph	Section 46.3.1, "Using the Recommendation Data Control"	*Java API Reference for Oracle WebCenter Portal*	Section 46.3.2, "Using the Activity Graph REST APIs"	
Analytics	Section 47.3.1, "Using SQL Data Controls"	*Java API Reference for Oracle WebCenter Portal*		
Announcements				Web Services with Oracle WebCenter Portal's Discussions Server (requires configuration, because WebCenter Portal is set up with custom authentication) See the Jive Forums documentation on the Oracle Fusion Middleware documentation library (in the WebCenter Portal product area)

See Also: *Java API Reference for Oracle WebCenter Portal* for more information about Expression Language APIs

4.1.3 Using WebCenter Portal Data Controls

Several tools and services provide data controls for building a customized user interface with a Framework application or task flow. Deploying this task flow into an ADF library allows for a portable consumption of the task flow; for example, you could add it to a resource catalog for a page template in a portal in a WebCenter Portal application.

You do not need to integrate a tool or service before you can use its data control to edit the user interface. An application is configured for the respective tool or service when one of its data controls or task flows is used.

Note: Oracle ADF architecture provides data controls for the user interface to understand the structure of your data. Metadata describes data collections, properties, methods, and types. When you drag and drop attributes, collections, and methods onto a page, JDeveloper automatically creates the bindings from the page to the associated tools and services.

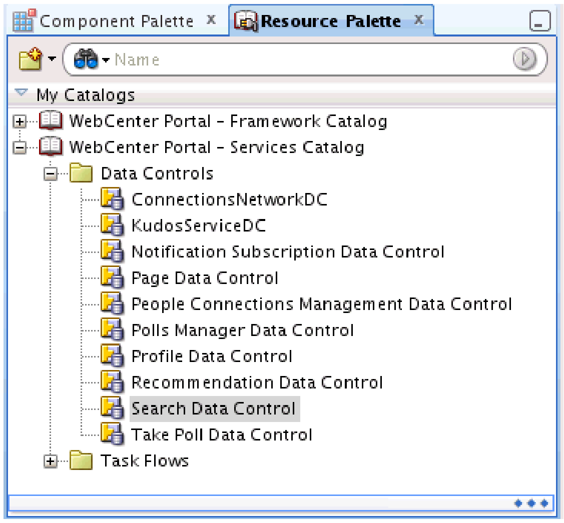
See *Fusion Developer's Guide for Oracle Application Development Framework* for detailed information about data controls.

Note: For ADF Web service data controls, connection details are not propagated from stage to production. For the data control to work, you must import the connections at the target instance.

To use a built-in data control:

1. In JDeveloper, create a WebCenter Portal Framework application with any connections required.
2. In the Resource Palette, expand My Catalogs, WebCenter Portal - Services Catalog, and Data Controls.
3. Right-click the data control and choose **Add to Project**.

Figure 4–1 Data Controls in the Resource Palette



Component Palette ×
Resource Palette ×
Name
My Catalogs
WebCenter Portal - Framework Catalog
WebCenter Portal - Services Catalog
Data Controls
ConnectionsNetworkDC
KudosServiceDC
Notification Subscription Data Control
Page Data Control
People Connections Management Data Control
Polls Manager Data Control
Profile Data Control
Recommendation Data Control
Search Data Control
Take Poll Data Control
Task Flows

4. Drag and drop methods and properties from the data control to an ADF JSF page.

> **Note:** There are two other ways to add data controls to your application:
>
> - From the Resource Palette, choose IDE connections, and navigate to the data control. Right-click the data control, and select **Add to Project**.
> - From Project Properties, choose Libraries and Classpath, and click the **Add Library** button. With this approach, you must know the JDeveloper library that contains the data control you want.

4.2 Preparing Your Framework Application for Tools and Services

This section describes the steps you must take to prepare your application to use WebCenter Portal tools and services. It includes the following subsections:

- Section 4.2.1, "How to Prepare Your Application to Consume Tools and Services"
- Section 4.2.2, "Setting Up a Database Connection"
- Section 4.2.3, "Setting Up an External Application Connection"

4.2.1 How to Prepare Your Application to Consume Tools and Services

You can configure any application to include a tool or service. When you create an application in JDeveloper, you can choose to base the application on a template. Although not a requirement, WebCenter Portal's Framework application template makes all the appropriate connection wizards and tag libraries readily visible and available in the New Gallery and Component palette. When you consume a task flow or component, the necessary libraries are automatically added to the project.

Depending upon the tool or service you plan to consume, your application must meet certain prerequisites. For example, if the tool must know the identity of users, then your application must provide some level of security with user authentication.

This section includes the following subsections:

- Section 4.2.1.1, "Implementing Security for Tools and Services"

- Section 4.2.1.2, "Setting Up SSL-Protected Connections"

4.2.1.1 Implementing Security for Tools and Services

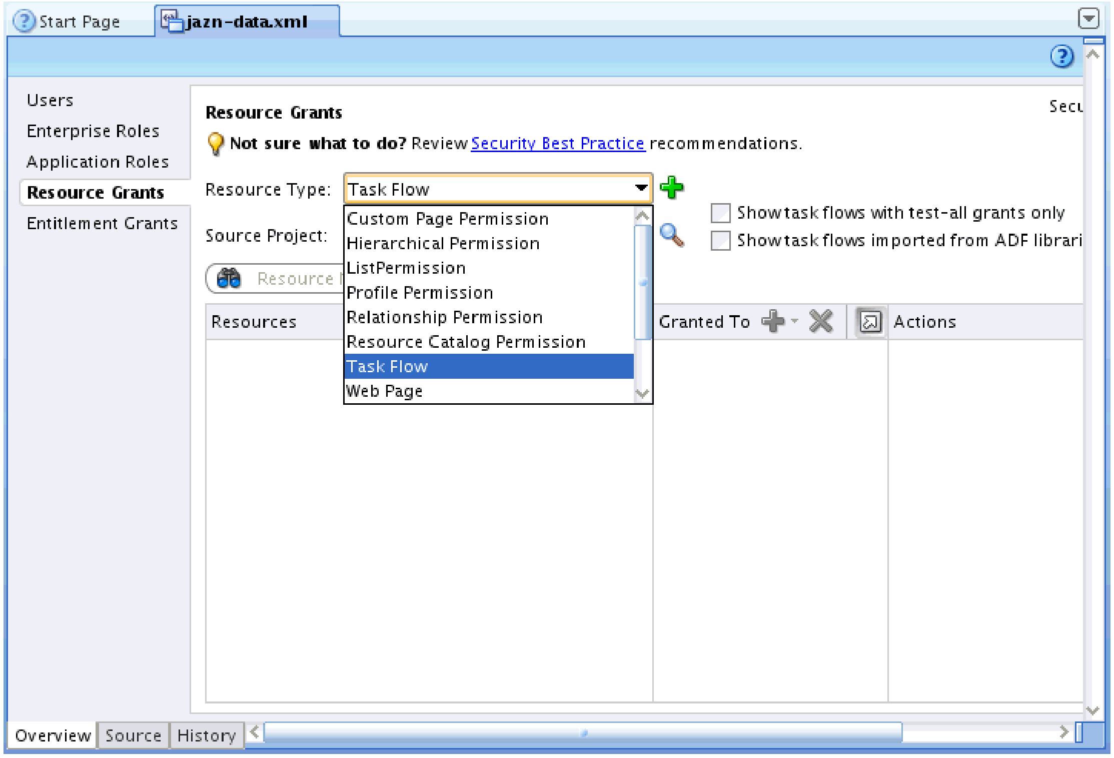
Some tools must know the identity of the user (for example, search needs the user's identity for saving searches). For these tools and services, you must at least configure your application to authenticate users such that they have distinct identities for the purposes of user customization and preferences.

ADF security is configured by default if you created your application using WebCenter Portal's Framework application template.

> **See Also:**
>
> - Section 74.3, "Configuring ADF Security" for details on how to implement a basic security solution for your Framework application
> - Chapter 74, "Securing Your WebCenter Portal Framework Application" for details on how to implement a complete security solution for your Framework application

After you configure ADF security for your application, you can open the `jazn-data.xml` file and modify your sample user's privileges for each task flow. To open the ADF Security Policies Editor, locate the file in the Application Resources panel and double-click its name, or select Application - Secure - Resource Grants (Figure 4–2). The Resource Type drop down controls the set of grants that are shown in the table. You can show only the grants for a particular permission type by selecting it from the list.

Figure 4–2 ADF Security Policies in the jazn-data.xml File



Resource Grants

Not sure what to do? Review Security Best Practice recommendations.

Resource Type: Task Flow

□ Show task flows with test-all grants only

□ Show task flows imported from ADF librari

4.2.1.2 Setting Up SSL-Protected Connections

If you are setting up a back-end connection in JDeveloper, and the connection is being made to an SSL-protected endpoint (with a valid certificate from a trusted certificate authority) then you need prepare your environment accordingly.

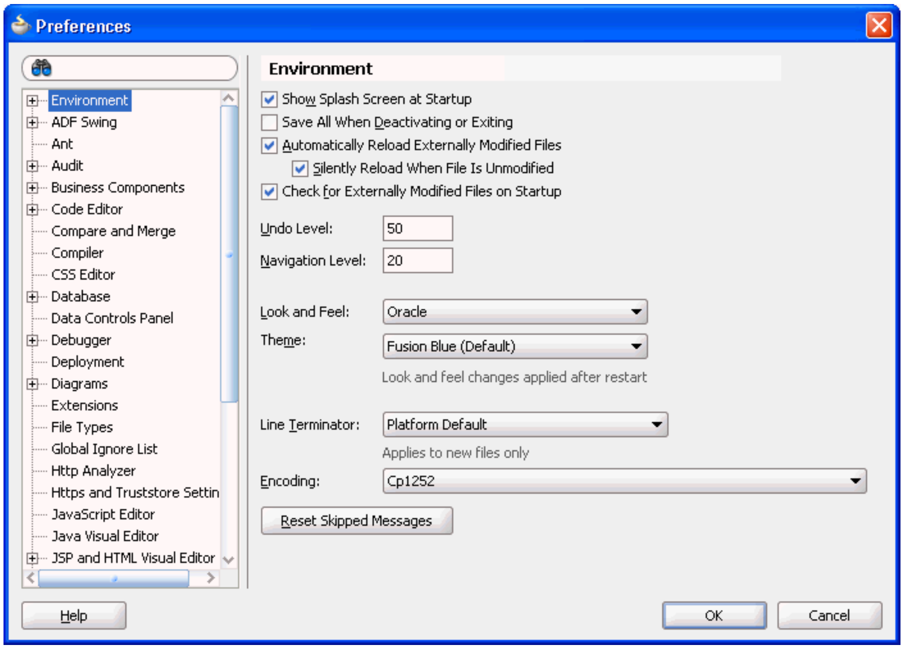
> **Note:** This Preferences setting change is required only for connections made using Integrated WLS as the default server. If you are deploying to a Managed Server, this settings change is not required.

To set preferences for SSL-protected connections:

1. From the JDeveloper tool bar, select **Tools > Preferences**.

   The Preferences dialog displays (Figure 4–3).

Figure 4–3 Preferences Dialog



Environment

☑ Show Splash Screen at Startup
☐ Save All When Deactivating or Exiting
☑ Automatically Reload Externally Modified Files
☑ Silently Reload When File Is Unmodified
☑ Check for Externally Modified Files on Startup

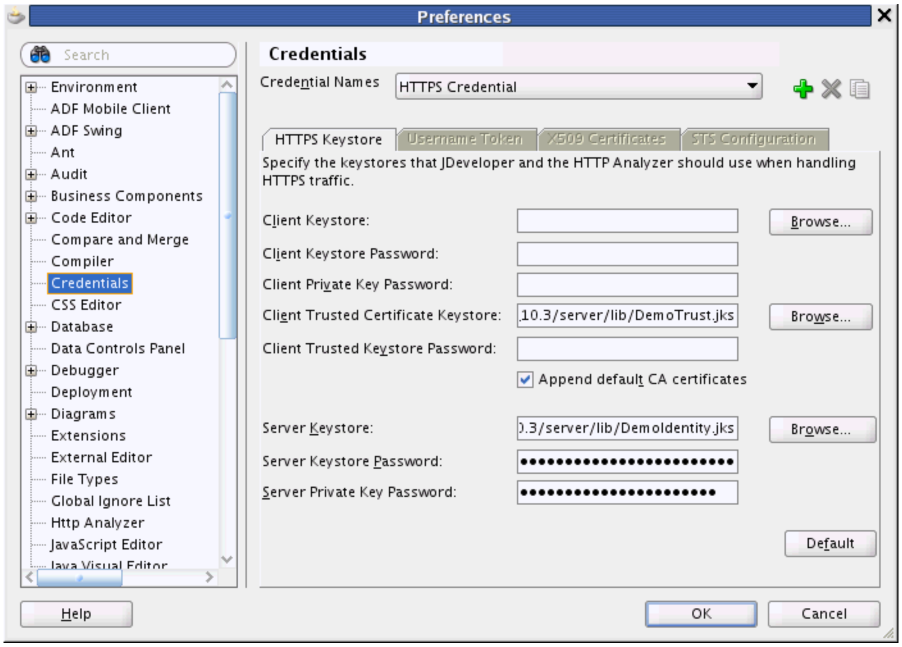
Undo Level: 50
Navigation Level: 20

Look and Feel: Oracle
Theme: Fusion Blue (Default)
Look and feel changes applied after restart

Line Terminator: Platform Default
Applies to new files only
Encoding: Cp1252

2. On the Preferences dialog, click **Credentials** (Figure 4–4).

Figure 4–4 Credentials Pane



Credential Names: HTTPS Credential

Specify the keystores that JDeveloper and the HTTP Analyzer should use when handling HTTPS traffic.

Client Keystore:

Client Keystore Password:

Client Private Key Password:

Client Trusted Certificate Keystore: 10.3/server/lib/DemoTrust.jks

Client Trusted Keystore Password:

☑ Append default CA certificates

Server Keystore:).3/server/lib/DemoIdentity.jks

Server Keystore Password: ••••••••••••••••••••••••

Server Private Key Password: ••••••••••••••••••••••

3. Change the value of **Client Trusted Certificate Keystore** to:

   <*JAVA_HOME*>/jre/lib/security/cacerts

   where <*JAVA_HOME*> is the location of the Java home directory.

4. Click **OK**.

4.2.2 Setting Up a Database Connection

Many tools and services require a connection to a database schema where relevant information is stored. For example, with links, relationship mapping information, such as what object is linked to what other object, is stored in the database.

Table 4–3 lists the tools and services that require a database connection.

Table 4–3 Associated Data Source

Tool or Service	Database Schema
Activity Graph	ACTIVITIES schema
Activity Stream	WEBCENTER schema
Analytics	ACTIVITIES schema
Blogs	WEBCENTER schema
Comments	WEBCENTER schema
Documents (including wikis and blogs) that want to include Comments and Activity Stream	WEBCENTER schema
Links	WEBCENTER schema
Lists	WEBCENTER schema

Table 4–3 (Cont.) Associated Data Source

Tool or Service	Database Schema
Oracle Portal Adapter	PORTAL schema (name of the Oracle Portal schema) For more information, see the section "Setting Up the Environment to Use the Federated Portal Adapter" in the *Administrator's Guide for Oracle Portal*.
People Connections	WEBCENTER schema
Polls	WEBCENTER schema
Tags	WEBCENTER schema
Announcements	DISCUSSIONS schema
Discussions	DISCUSSIONS schema

See Also:

- Section 2.2.5, "Configuring WebCenter Back-End Services" for information about installing the schemas
- The "Deploying the Application to a WebLogic Managed Server" section in *Administering Oracle WebCenter Portal* for data source considerations when deploying your application to a production environment

To create the database connection:

1. In the Application Navigator, expand the **Application Resources** panel.
2. Right-click **Connections**, then click **Database.**
3. Enter the following information for your database connection:
   - **Connection Name**: `webcenter/CustomPortal` or `activities/CustomPortal`

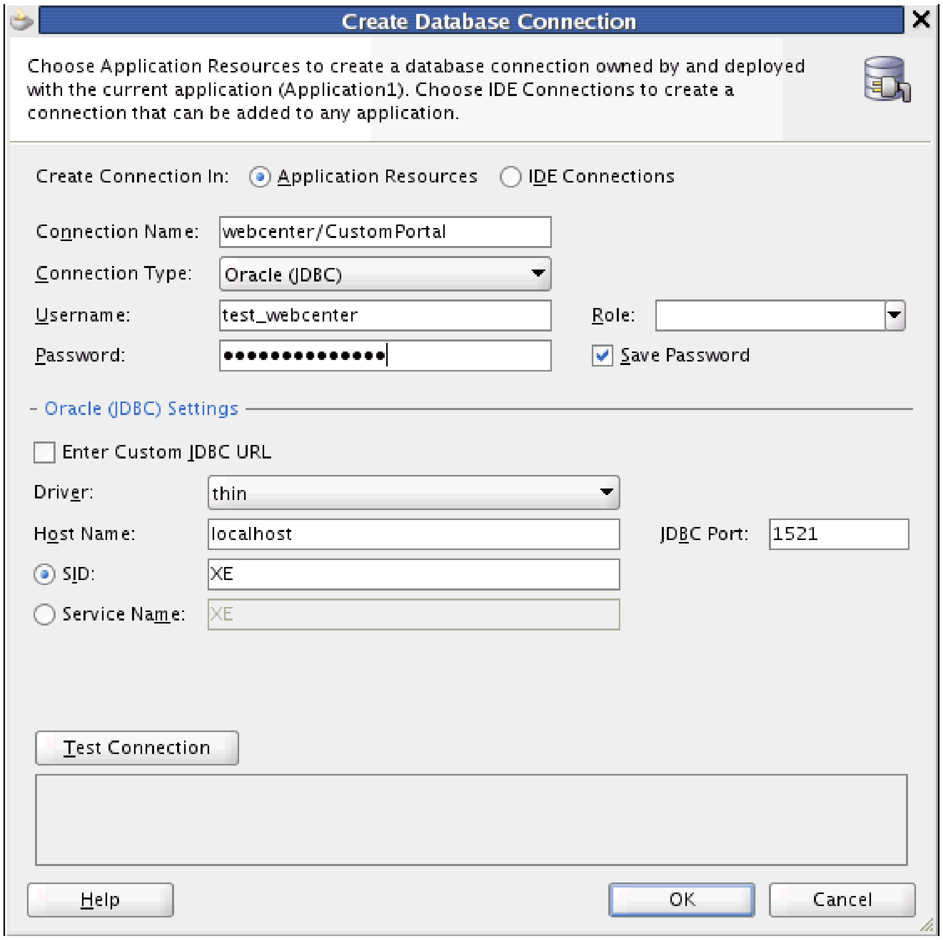
     Note: Oracle recommends that you use these names for ease of deployment to a Framework managed server.

     - If your application contains task flows that use the WebCenter Portal schema, then name the database connection `webcenter/CustomPortal`.
     - If the application contains task flows that use the Activities schema, then name the database connection `activities/CustomPortal`.

   - **Connection Type**: `Oracle (JDBC)`
   - **Username:** `username`
   - **Password**: `password`
   - **Host**: *host where you install the WebCenter Portal schema*; for example, `localhost`
   - **JDBC Port:** *port*; for example, `1521`
   - **SID**: *system identifier for the database with the same JDBC*; for example, `ORCL`

> **Note:** If the **Save Password** checkbox is not selected, then when deploying from JDeveloper to a managed server or the Integrated WebLogic Server, you must manually create the data source after deployment.
>
> For detailed information on how to create a JDBC data source for Oracle WebLogic Server, see the *Fusion Developer's Guide for Oracle Application Development Framework*.

Figure 4–5 Database Connection



Create Database Connection

Choose Application Resources to create a database connection owned by and deployed with the current application (Application1). Choose IDE Connections to create a connection that can be added to any application.

Create Connection In: ● Application Resources ○ IDE Connections

Connection Name: webcenter/CustomPortal

Connection Type: Oracle (JDBC)

Username: test_webcenter

Role:

Password: ••••••••••••••

☑ Save Password

Oracle (JDBC) Settings

□ Enter Custom JDBC URL

Driver: thin

Host Name: localhost

JDBC Port: 1521

● SID: XE

○ Service Name: XE

4. Click **OK**.

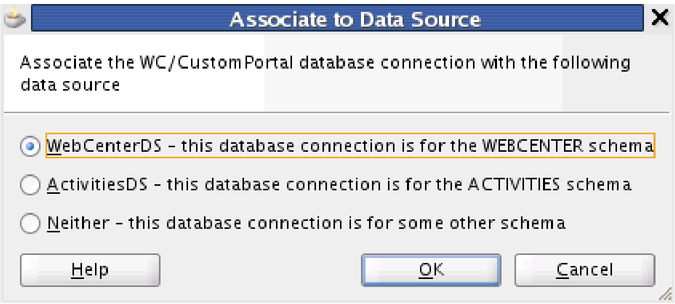
5. In the Associate to Data Source dialog, select the appropriate schema.

   - If you named the connection `webcenter/CustomPortal`, then select to associate this connection to the WebCenter Portal schema.

   - If you named the connection `activities/CustomPortal`, then select to associate this connection to the Activities schema.

   Click **OK** (Figure 4–6).

Figure 4–6 Associating to Data Source from the Connection Wizard



Associate to Data Source

Associate the WC/CustomPortal database connection with the following data source

● WebCenterDS - this database connection is for the WEBCENTER schema

○ ActivitiesDS - this database connection is for the ACTIVITIES schema

○ Neither - this database connection is for some other schema

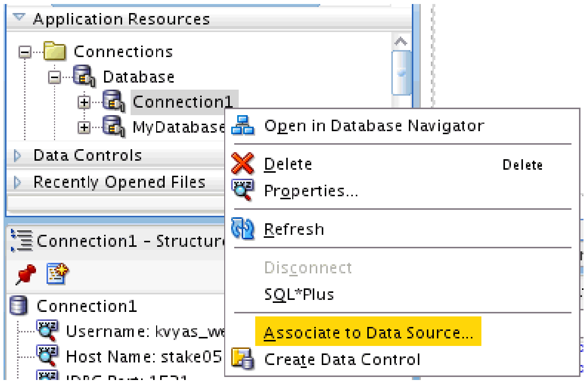
The data source association applies separately to each project in the workspace. If there is more than one WebCenter Portal project in the workspace, then the dialog displays a dropdown list allowing the user to choose which project to configure.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control.
>
> See the guide *Administering Oracle WebCenter Portal* for more information.

4.2.2.1 Associating Existing Database Connections

For existing database connections, you can associate data sources by right-clicking the connection and selecting **Associate to Data Source** (Figure 4–7).

Figure 4–7 Associating to Data Source for Existing Connections



4.2.3 Setting Up an External Application Connection

When a tool or service interacts with an application that handles its own authentication, you can associate that application with an external application definition to allow for credential provisioning.

The following tools and services permit the use of an external application to connect with it and define authentication for it:

- Documents
- Events

- Instant Messaging and Presence
- Mail
- RSS Viewer (when using a secured RSS feed)

> **See Also:**
>
> - Chapter 28, "Integrating Documents," Chapter 34, "Integrating Instant Messaging and Presence," Chapter 35, "Integrating Mail," and Chapter 52, "Integrating RSS" for more information about setting up an external application
> - Section 74.13, "Working with External Applications" for more information about external applications in general

4.3 Customizing How Services Render Resources

Many services used with WebCenter Portal provide access to resources. For example, search results can include links to documents, tags, activities, and other types of resources. This section explains how to specify the way such resources are rendered in the portal.

- Section 4.3.1, "Overview of Resource Rendering Options"
- Section 4.3.2, "Rendering Resources in the Same Browser Window"
- Section 4.3.3, "Rendering Resources in an ADF Inline Popup"
- Section 4.3.4, "Rendering Resources in a New Browser Window"
- Section 4.3.5, "Setting Rendering Behavior with the resourceActionBehavior Tag"
- Section 4.3.6, "Updating adf-config.xml in Deployed Framework Applications"

4.3.1 Overview of Resource Rendering Options

Figure 4–8 shows sample results for a search. There are numerous clickable elements in the results, including links to user profiles, documents, tags, blogs, and wiki pages.

Figure 4–8 Sample Search Results

For Portal Framework applications, most services render their resources directly in the browser window.

The possible resource rendering behaviors available within WebCenter Portal are:

- **Full-screen rendering in the same browser window.** This option is the default for most services. The resource is opened in a viewer task flow by navigating from the browser to the resource using the same browser window. See Section 4.3.2, "Rendering Resources in the Same Browser Window."
- **ADF inline popup.** This option opens the resource in an inline popup (a dialog-like window that pops up and is contained within the current browser window.) See Section 4.3.3, "Rendering Resources in an ADF Inline Popup."
- **New browser window.** This option renders the resource in a new browser window. See Section 4.3.4, "Rendering Resources in a New Browser Window."

4.3.2 Rendering Resources in the Same Browser Window

By default, most resources are rendered full-screen in the same browser window.

> **Note:** In some special cases, resources are intentionally rendered by default in an inline popup dialog, as explained in Section 4.3.5, "Setting Rendering Behavior with the resourceActionBehavior Tag."

To explicitly set the default rendering to the browser window, you can do the following:

1. In the Application Navigator, open the **Application Resources** list.
2. Open the Descriptors folder and then open the **ADF META-INF** folder.
3. Open the `adf-config.xml` file in the editor and add a `<resource-handler>` element, as shown in Example 4–1. In this example, the DefaultResourceActionHandler (the default class to which rendering is delegated) specifies the desired behavior. If you were to remove the `<resource-handler>` element from `adf-config.xml` entirely, the behavior would be exactly the same. The behavior specified in Example 4–1 applies to all services.

Example 4–1 Specifying In-Browser Rendering

```
<wpsC:adf-service-config
xmlns="http://xmlns.oracle.com/webcenter/framework/service">
   <resource-handler
       class="oracle.webcenter.framework.resource.view.DefaultResourceActionHandler"/>
</wpsC:adf-service-config>
```

4.3.3 Rendering Resources in an ADF Inline Popup

To change the default rendering from the browser window to an ADF inline popup dialog, do the following:

1. In the Application Navigator, open the **Application Resources** list.
2. Open the Descriptors folder and then open the **ADF META-INF** folder.
3. Open the `adf-config.xml` file in the editor and add a `<resource-handler>` element, as shown in Example 4–2. In this example, the

DefaultResourceActionHandler (the default class to which rendering is delegated) is overridden by the `display-as-popup=true` attribute.

Example 4–2 Specifying ADF Inline Popup for Rendering

```
<wpsC:adf-service-config
xmlns="http://xmlns.oracle.com/webcenter/framework/service">
   <resource-handler
       class="oracle.webcenter.framework.resource.view.DefaultResourceActionHandler"
       display-as-popup="true" />
</wpsC:adf-service-config>
```

If the user clicks the **Maximize** button in an inline popup, then the currently specified default handler is invoked. For DefaultResourceActionHandler, the resource appears full-screen in the browser. If PopUpResourceActionHandler is specified in `adf-config.xml`, then it displays in a new browser window. See also Section 4.3.4, "Rendering Resources in a New Browser Window."

4.3.4 Rendering Resources in a New Browser Window

To change the default rendering from within the browser window to a new browser window, do the following:

1. In the Application Navigator, open the **Application Resources** list.
2. Open the Descriptors folder and then open the **ADF META-INF** folder.
3. Open the `adf-config.xml` file in the editor and add the `<resource-handler>` element, as shown in Example 4–3. In this case, rendering is delegated to the PopUpResourceActionHandler class.

Example 4–3 Specifying a Separate Browser for Rendering

```
<adf-service-config
xmlns="http://xmlns.oracle.com/webcenter/framework/service">
    <resource-handler
class="oracle.webcenter.framework.resource.view.PopUpResourceActionHandler" />
</adf-service-config>
```

4.3.5 Setting Rendering Behavior with the resourceActionBehavior Tag

Rendering behavior that is set in `adf-config.xml` can be overridden on the resource link itself using the `resourceActionBehavior` tag and setting the `useResourcePopup` attribute to values of `always`, `never` or `appDefined`.

WebCenter Portal uses this technique for targeted cases where a full navigation does not make sense. For example, search results may include the resource's author. When you click this user name link, you see the popup summary profile of the author without navigating away from the search result.

If `useResourcePopup` is not set, or if it is set to `appDefined` on the resource link, then the `display-as-popup` attribute in `adf-config.xml` is honored.

> **Note:** In cases where WebCenter Portal services override the `<resource-handler>` by design, the `useResourcePopup` tag is set to `always` in their `resourceActionBehavior` tags. You can change this by customizing the task flow itself.

4.3.6 Updating adf-config.xml in Deployed Framework Applications

In deployed applications, the `<resource-handler>` settings in `adf-config.xml` can be added and updated using WLST commands. For command syntax and examples, see the sections, "setWebCenterServiceFrameworkConfig" and "getWebCenterServiceFrameworkConfig" in *WebLogic Scripting Tool Command Reference*.

4.4 Configuring General Settings

Optionally, you can enable users to set the time zone, the date and time format, the language (locale), and the accessibility mode for the tools and services you add to your application. You can provide these capabilities through WebCenter Portal General Settings. This contains values that you can access either directly from the JSF page(s) in your Framework application or indirectly through an API. General Settings covers the following areas:

- **Time Zone:** By default, displays the time defined by the server running the application. This is based on `java.util.Timezone`; for example, `GMT+0800`. It also supports the format `Region/Country`; for example, `Europe/Amsterdam`.
- **Date/Time:** By default, configured to the style `java.text.DateFormat.SHORT`. This is based on `java.text.DateFormat`; for example, `java.text.DateFormat.MEDIUM`. Supported values are `SHORT`, `MEDIUM`, `LONG` and `FULL`.
- **Language:** By default, defined by the locale of the user's browser. This is based on `java.util.Locale`; for example, `fr-CA`.
- **Accessibility Settings:** A value to use with the `accessibility-mode` setting in the `trinidad-config.xml` file. Valid values are `default`, `inaccessible`, or `screenReader`.
- **Application Skin:** A value to use with the `skin-family` setting in the `trinidad-config.xml` file. This is based on the Trinidad `skin-family` attribute. Valid values are defined by skins included with the application.

To use this directly from your application, use Expression Language in your JSF pages to access the `generalSettings` managed bean. The style is based on the `java.util.Timezone`, and the pattern is based on `java.text.SimpleDateFormat`.

When you add `generalSettings` as the value attribute of an ADF component, for example `af:activeOutputText`, you can open the Expression Builder, then navigate to **JSF Managed Beans > generalSettings** to view the preference values for the bean.

General Settings supports both pattern-based and style-based formats. If a pattern is not specified, then the style is used. By default, the patterns are not specified or null.

Figure 4–9 shows the Insert EL Expression dialog with General Settings.

Figure 4–9 Expression Builder for the generalSettings JSF Managed Bean

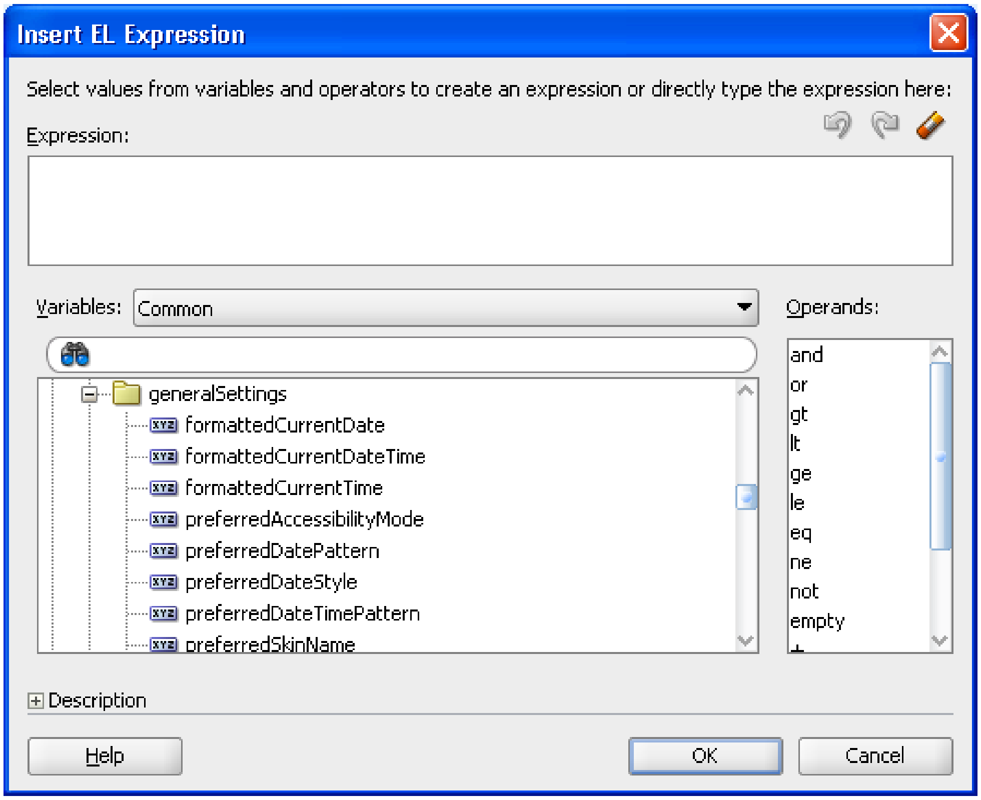

Table 4–4 describes the preference values for General Settings.

Table 4–4 General Settings Managed Bean Preference Values and Descriptions

General Settings Preference Value	Description
`formattedCurrentDate`	Displays the current date in the user's selected locale.
`formattedCurrentDateTime`	Displays the current date and time in the user's selected locale.
`formattedCurrentTime`	Displays the current time in the user's selected locale.
`preferredAccessibilityMode`	Preferred accessibility mode (`default`, `inaccessible`, or `screenReader`) for use in the `accessibility-mode` setting in `trinidad-config.xml`.
`preferredDateStyle`	Java date style to be used in `dateStyle` attributes when displaying dates and times.
`preferredTimeStyle`	Java time style to be used in `timeStyle` attributes when displaying dates and times.
`preferredDatePattern`	Java date pattern to be used when displaying dates, and not times.The pattern must be a valid `java.text.SimpleDateFormat` pattern; for example: `dd-MMM-yyyy`. This takes precedence over `preferredDateStyle`.
`preferredTimePattern`	Java time pattern to be used when displaying times, and not dates. This takes precedence over `preferredTimeStyle`.
`preferredDateTimePattern`	Java date/time pattern to be used when displaying dates and times. This takes precedence over `preferredDateStyle` and `preferredTimeStyle`.
`userTimeZone`	Java time zone to be used in `timeZone` attributes when displaying dates and times.
`preferredSkinName`	Preferred skin name to use with the `skin-family` setting in `trinidad-config.xml`.

For example, to display the current date and time in the user's selected locale, time zone, and format, add the following to your page:

Example 4–4 Code for Displaying Current Date and Time in User's Locale

```
<af:outputText value="#{generalSettings.formattedCurrentDateTime}"/>
```

Or, to display a specific date and time:

Example 4–5 Code for Displaying Specified Date and Time

```
<af:outputText value="#{row.dateTimeValue}">
    <af:convertDateTime type="both"
                        dateStyle="#{generalSettings.preferredDateStyle}"
                        timeStyle="#{generalSettings.preferredTimeStyle}"
                        timeZone="#{generalSettings.userTimeZone}"
                        locale="#{facesContext.externalContext.requestLocale}" />
                        pattern="#{generalSettings.preferredDateTimePattern}"
    </af:outputText>>
```

To take advantage of the preferred accessibility mode, you must add an EL (Expression Language) expression to the application's `trinidad-config.xml` file to set the accessibility mode; for example:

Example 4–6 Setting the Accessibility Mode in trinidad-config.xml

```
<accessibility-mode>#{generalSettings.preferredAccessibilityMode}</accessibility-m
ode>
```

4.4.1 Building a Preferences User Interface

You can build a user interface using the General Settings API to enable users to either accept the default settings or apply their desired settings. The API contains the same preference values described in Table 4–4.

Any tool or service in WebCenter Portal that displays a date and time uses the settings configured in General Settings. For information on using the General Settings API to build a preferences user interface, see the Javadoc for `oracle.webcenter.generalsettings`. Specifically, the `oracle.webcenter.generalsettings.model` package contains APIs to get and set preference values for each of the settings. Use these APIs to build a custom user interface to allow users to view and set their preferred values.

> **See Also:** *Java API Reference for Oracle WebCenter Portal*

4.4.2 Using General Settings to Specify the User's Locale

By default, ADF obtains the user's locale from the user's browser settings. You can change this behavior to have the user's preferred locale be set in the application using a Preferences UI.

To make the behavior change, include `oracle.webcenter.generalsettings.model.filter.GeneralSettingsLocaleFilter` as a servlet filter in `web.xml` and `adfBindings`. This servlet filter sets the default locale (ADF Locale) from the General Settings locale preference instead of from the user's browser.

Add the General Setting locale filter to `web.xml` with the following rules:

Define the filter. For example:

```
      <filter>
         <description>
            WebCenter General Settings locale setting.
         </description>
         <filter-name>
            generalSettingsLocaleFilter
         </filter-name>
         <filter-class>

oracle.webcenter.generalsettings.model.filter.GeneralSettingsLocaleFilter
         </filter-class>
      </filter>
```

Add the filter after the `adfBindings` filter with the same servlet-name. For example:

```
      <filter-mapping>
         <filter-name>
            generalSettingsLocaleFilter
         </filter-name>
         <servlet-name>Faces Servlet</servlet-name>
      </filter-mapping>
```

If this filter *is not* set, then the locale is sourced first from the client browser locale setting, and then from the ADF locale setting.

If this filter *is* set, then the locale is sourced from the General Settings. If the General Settings locale preference does not exist, then it reverts to the non-filter default behavior.

Part II

Building WebCenter Portal Framework Applications

This part contains the following chapters:

5

Understanding WebCenter Portal Framework Applications

This chapter introduces the architecture, components, and features of a WebCenter Portal Framework application.

> **Note:** Oracle recommends creating new portals using Portal Builder, rather than Portal Framework. While custom Portal Framework applications may provide a greater degree of flexibility when developing your portal solution, such flexibility typically forfeits product supportability and the ability to upgrade to new WebCenter Portal releases. Using Portal Builder avoids these constraints without sacrificing complexity or scalability. Building portals using Portal Builder is covered in *Building Portals with Oracle WebCenter Portal*.

This chapter includes the following topics:

- Section 5.1, "What Is a WebCenter Portal Framework Application?"
- Section 5.2, "Creating a WebCenter Portal Framework Application"
- Section 5.3, "Exploring the Features of a WebCenter Portal Framework Application"
- Section 5.4, "How are WebCenter Portal Framework Application Files Organized?"
- Section 5.5, "What Is the Portal Life Cycle?"
- Section 5.6, "Developing Your Portal's Look and Feel"
- Section 5.7, "Changing Default Portal Preferences"
- Section 5.8, "Using Iterative and Round-Trip Development Techniques"
- Section 5.9, "Running and Testing a Portal"
- Section 5.10, "WebCenter Portal Framework Applications at Runtime"
- Section 5.11, "Changing the Default Home Page and Login/Logout Target Pages"
- Section 5.12, "Customizing Session Timeouts"
- Section 5.13, "Basic Portal Development Tasks"

5.1 What Is a WebCenter Portal Framework Application?

A WebCenter Portal Framework application is a standard ADF web application that includes portal features, like navigation, pages, page templates, content, and more. This chapter discusses these features in detail.

5.2 Creating a WebCenter Portal Framework Application

> **Note:** Oracle recommends creating new portals using Portal Builder, rather than Portal Framework. While custom Portal Framework applications may provide a greater degree of flexibility when developing your portal solution, such flexibility typically forfeits product supportability and the ability to upgrade to new WebCenter Portal releases. Using Portal Builder avoids these constraints without sacrificing complexity or scalability. Building portals using Portal Builder is covered in *Building Portals with Oracle WebCenter Portal*.

JDeveloper makes it easy to create a new WebCenter Portal Framework application. A wizard guides you through the details and creates a workspace with the required project structures and files. You develop, deploy, and test your portal from within this workspace.

The basic steps for creating a framework application and the resulting project structures are described in Chapter 6, "Creating WebCenter Portal Framework Applications."

5.3 Exploring the Features of a WebCenter Portal Framework Application

Oracle WebCenter Portal Framework adds a number of portal-specific features to an ADF web application. These features are included by default when you create a new application using the WebCenter Portal Framework Application template.

This section discusses some of the main portal features you'll need to know about.

- Section 5.3.1, "Summary of Features"
- Section 5.3.2, "Understanding Pages, Page Templates, and the Portal Page Hierarchy"
- Section 5.3.3, "Securing WebCenter Portal Framework Pages"
- Section 5.3.4, "Understanding the Navigation Model and the Navigation Registry"
- Section 5.3.5, "Understanding Resource Catalogs and the Catalog Registry"
- Section 5.4.4, "Showing Hidden Files in the Application Navigator"

5.3.1 Summary of Features

The basic features provided in a Portal Framework application include:

- **Page hierarchies** – A page hierarchy organizes pages into a tree structure, with a parent-child relationship between pages. This hierarchical structure allows the convenient propagation or inheritance of security settings from pages to sub pages. See Section 5.3.2, "Understanding Pages, Page Templates, and the Portal Page Hierarchy."

- **Navigation models** – A navigation model provides the back-end data to the navigation user interface that is displayed in the portal. Navigation models are highly flexible, with a wide set of APIs that control navigation to pages, task flows, external sites, portlets, and specific content items. See Section 5.3.4, "Understanding the Navigation Model and the Navigation Registry."
- **Navigation Registries** – A navigation *registry* defines the set of elements that a user can add to a navigation at runtime using the Resource Manager. For information on the Resource Manager, see the "Managing Assets for a Portal Framework Application" section in the *Administering Oracle WebCenter Portal*. See also Chapter 10, "Developing a Navigation Model."
- **Delegated administration** – Delegated administration provides a mechanism for securing portal resources based on user roles. For example, you can allow users in one role (managers, for instance) to access all portal features, but deny certain features to users in another role (employees, for instance). Page hierarchies are the primary container for delegated administration. In both the JDeveloper and browser-based environments, you apply delegated administration to a page hierarchy, and the specific security assignments are automatically propagated down through the hierarchy through pages and sub pages. See Chapter 74, "Securing Your WebCenter Portal Framework Application."
- **Customization** – Users can customize their own portal pages by, for example, adding or removing portlets, changing skins, or rearranging the portal layout. See Section 15, "Creating Pages and Adding Resources."
- **Page templates** – Page templates allow you to define entire page layouts and apply them to pages to create a consistent layout across the portal. For more information, see Section 5.6, "Developing Your Portal's Look and Feel." See also the "Using Page Templates" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.
- **Catalogs and the Catalog Registry** – Catalogs are arbitrary collections of task flows, portlets, content items, and other elements that can be added to an application at runtime. See Chapter 14, "Developing Resource Catalogs."
- **Catalog Registries** – A catalog *registry* defines the set of items that are available for inclusion in your resource catalog. See Chapter 14, "Developing Resource Catalogs."
- **Skins** – Skins define the colors, fonts, images, and some dimensional details like heights and widths, of your application components to present a consistent look and feel across the portal. See Chapter 13, "Developing Skins."
- **Portal Preferences** – You can change default preferences for a portal, including default navigation model, page template, and other components. See Section 5.7, "Changing Default Portal Preferences."

JDeveloper tooling includes editors for creating and modifying page hierarchies, navigation models, catalogs and the catalog registry, page templates, page styles, skins, and delegated administration. In addition, browser-based tools are provided to allow end users and administrators to perform some of these functions. See also Section 5.10.2, "Browser-Based WebCenter Portal Administration Console."

5.3.2 Understanding Pages, Page Templates, and the Portal Page Hierarchy

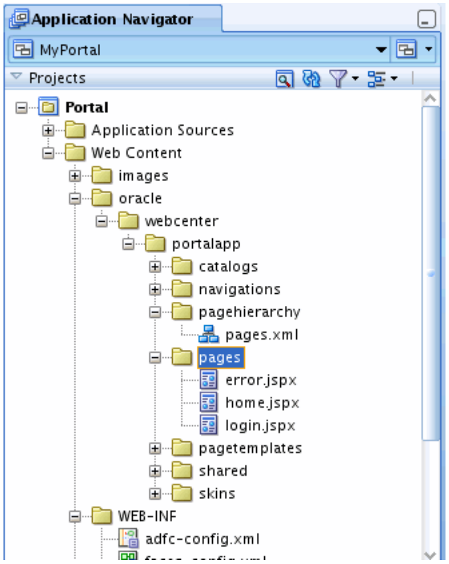
This section introduces three related pieces of an Oracle WebCenter Portal Framework application: pages, page templates, and page hierarchies.

A portal consists of one or more *pages*, and pages play a crucial role in a portal's structure and organization. Generally, a page is a container for one or more entities like task flows, portlets, and content. Pages also typically include a navigation interface, like a navigation tree, tabs, or bread crumbs. In a Portal Framework application, you can find a set of default pages in the Portal project under the folder `oracle/webcenter/portalapp/pages`, as shown in Figure 5–1.

> **Note:** For important information on the organization of files in Portal Framework applications, see Section 5.4, "How are WebCenter Portal Framework Application Files Organized?"

> **Note:** For pages to be used in the page hierarchy, they must be located under `oracle/webcenter/portalapp`.

Figure 5–1 Contents of the pages Folder

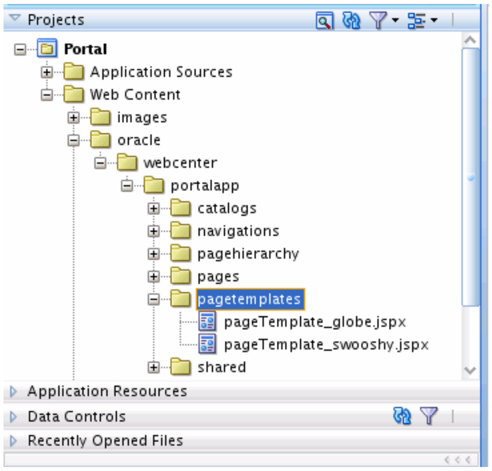


A *page template* lets you specify view elements that you wish to be common to all of your pages. A page template is a JSPX file that includes ADF layout components and other elements. Typically, page templates define a page layout, with headers, footers, and content areas. In addition, the page template usually specifies the positioning and style of the navigation UI for your pages. For example, if you want all of your pages to include the same set of tabs, or if you want each page to have a tree navigation panel and bread crumbs, you can add these components to the template.

> **Tip:** Page templates are referenced by the pages that use them. If you change the underlying page template, all the pages that reference the template automatically inherit the change.

You can find the page template folder in `oracle/webcenter/portalapp/pagetemplates`, as shown in Figure 5–2. Notice that the folder contains two default page templates that are included out of the box.

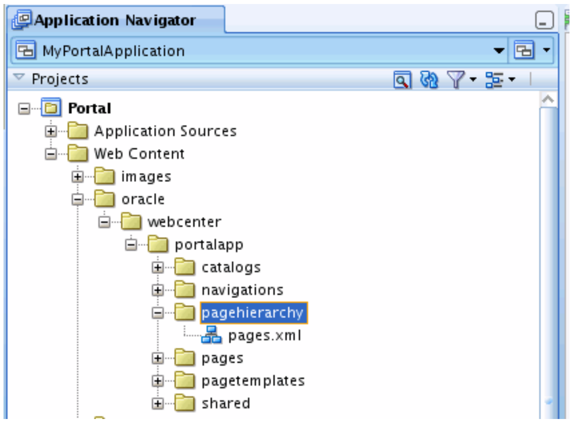
Figure 5–2 Contents of the pagetemplates Folder



A *page hierarchy* is a logical structure that arranges pages through a set of parent-child relationships, where any page can have one or more sub pages. This hierarchical model not only helps define the overall structure of the portal, but also allows child pages to inherit the security policies specified by their parent. The ability for pages to propagate security policies down the hierarchy is particularly convenient for very large portals with dozens or even hundreds of pages: you don't have to set security for every page. Note that when you create a new page, its security policy is automatically set based on where it resides in the page hierarchy.

You can find the page hierarchy files in the `oracle/webcenter/portalapp/pagehierarchy` folder, as shown in Figure 5–3.

Figure 5–3 Contents of the pagehierarchy Folder



Note: The page hierarchy files are XML files that contain the metadata that define the page hierarchy structure. It is not recommended that you attempt to edit these files directly; rather, use the Page Hierarchy editor to create and work with page hierarchies, as explained below.

A basic page hierarchy model is included with applications created from the WebCenter Portal Framework Application template. You can modify the page hierarchy with the Page Hierarchy editor in JDeveloper. To access this editor:

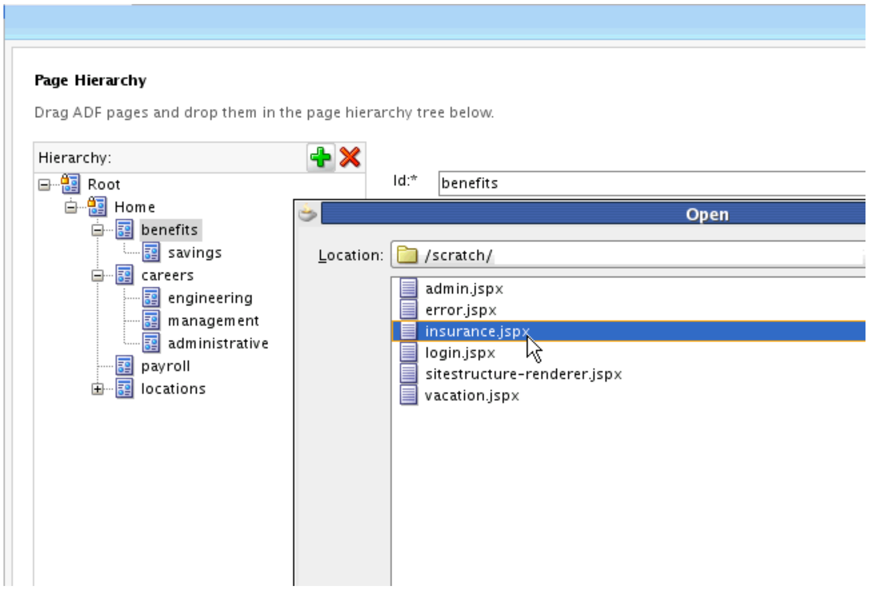
1. Open the portal project in the Application Navigator, as shown in Figure 5–3.
2. Right-click the `pagehierarchy` folder.
3. Select **Edit Page Hierarchy** from the menu.

> **Tip:** You can also bring up the Page Hierarchy editor by right-clicking a portal page file (JSPX file) and selecting **Edit Page Hierarchy** from the menu or by opening a page hierarchy file directly.

After you have created pages for your portal, use the editor to build up the site structure. You can drag and drop pages (one or several at a time) from anywhere in the `oracle/webcenter/portalapp` folder in the Application Navigator directly into the Page Hierarchy editor and position them in the hierarchy as you wish.

Alternatively, you can use the **Add** button located above the hierarchy pane. Clicking this button pops up a dialog that allows you to choose a page from within your project. This page is added as a child of the page that is currently selected in the editor, as shown in Figure 5–4.

Figure 5–4 Adding a Page to the Page Hierarchy



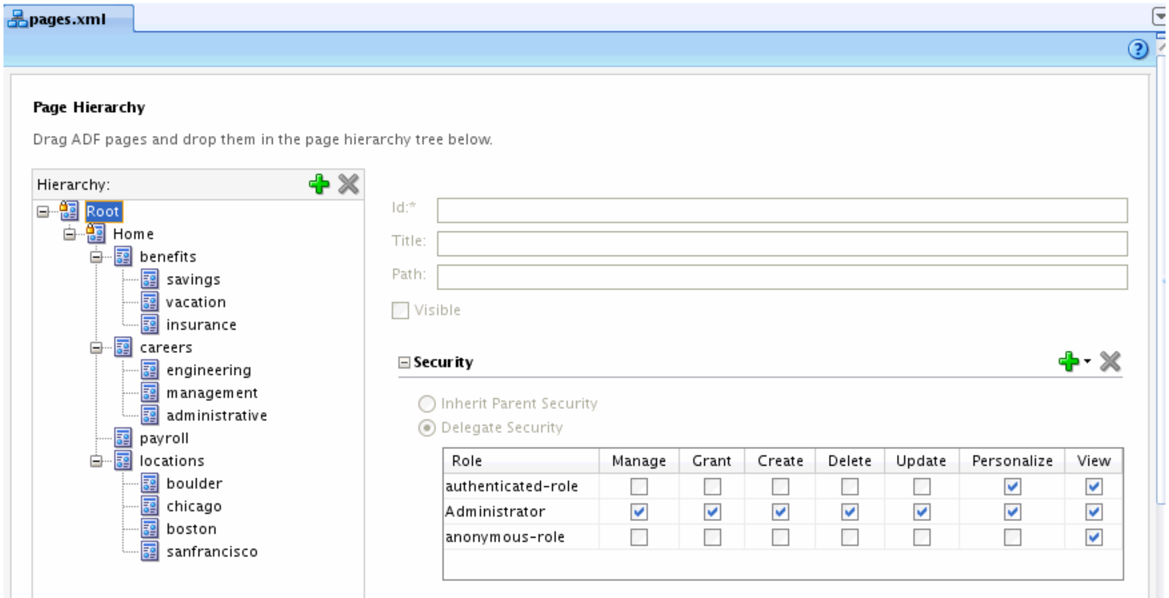
In the editor, you can rearrange page nodes within the tree display simply by dragging and dropping them. For large hierarchies, you may also find it useful to use the Change Parent dialog by right-clicking a page in the hierarchy and choosing **Change Parent Page**. This dialog allows you to choose a new parent for the selected page from a separate window, instead of having to scroll through a hierarchy that may be too large to view all at once.

> **Tip:** Right-click a node in the Page Hierarchy editor and select **Go to Page** to open the associated JSPX (portal page) file.

> **Note:** For each new level you create in the page hierarchy, a `pagehierarchy/pages/*Pages.xml` file is created. These files contain a reference to the pages in that level. For more information, see Section 74.6.2, "Building a Page Hierarchy."

Figure 5–5 shows the structure of a simple human resources site that includes top level pages Benefits, Careers, Payroll, and Location. The Benefits, Careers, and Location pages each have multiple child pages.

Figure 5–5 Page Hierarchy Editor



Page Hierarchy

Drag ADF pages and drop them in the page hierarchy tree below.

- Root
  - Home
    - benefits
      - savings

anonymous-role	☐	☐	☐	☐	☐	☐	☑

Notice how this hierarchy is realized when you run the portal, shown in Figure 5–6. In this example, the pages use the default page template, which includes a navigation bar. The bar is rendered as tab-like links across the page. Because this navigation UI was added to the page template, it will appear consistently on all pages that use the template. In addition to the default navigation component, you could add a navigation tree, bread crumbs, or other styles of navigation UI to the page template. In many cases, the template will include two or more navigation components.

For more information on page templates, see Section 5.6, "Developing Your Portal's Look and Feel." For more information on the default navigation model and on creating navigation models and user interfaces, see Section 10, "Developing a Navigation Model."

For more information on page hierarchies, see Section 74.6.2, "Building a Page Hierarchy."

5.3.3 Securing WebCenter Portal Framework Pages

Note: See also Section 6.5, "How Is Framework Application Security Configured by Default?"

At design time, you can set up security for your portal's pages in the Page Hierarchy editor. As mentioned previously, the page hierarchy defines the structural relationships between pages (parent-child) and it allows for child pages to inherit the security policies of their parents.

Note: You can secure pages either through the ADF page security model or through the hierarchical WebCenter Portal page security model. When a page is added to the page hierarchy, it implies that it's secured through the hierarchical security model. See also Section 74.6, "Using the Page Hierarchy Security Editor."

As shown in Figure 5–7, the Page Hierarchy editor includes a Security section that lets you specify role-based security policies for pages. The security interface lets you decide whether you want the policies to be inherited or delegated. If you specify inheritance, then the security policies for that page will be inherited from its parent page. If you delegate security, then that policy will override the parent's security and the policy will be propagated to all child pages that are inheriting security.

Tip: A small padlock icon appears next to pages for which the inherited security settings are overwritten. In other words, you'll see this icon to indicate pages that have delegated security set on them.

For example, in Figure 5–7, the Payroll page is configured so that Administrators have full access to the page, while authenticated users can only view and personalize the page. Anonymous users cannot access the page at all. Later, in Section 5.3.4, "Understanding the Navigation Model and the Navigation Registry," we'll discuss how the security policy set for a page also affects the appearance of the navigation UI. In this example, because the Payroll page is only available to Administrators and authenticated users, the navigation UI will only show the Payroll page link to authenticated users and Administrators. For all other users, the Payroll link will not show up at all.

5.3.4 Understanding the Navigation Model and the Navigation Registry

It's important to distinguish the navigation model from the page hierarchy. First, the page hierarchy specifies a parent-child relationship between pages. As discussed previously, pages can have one or more child pages. Secondly, the page hierarchy allows for security policies to be inherited from parent pages to child pages, or sub pages, down through the hierarchy. Note that page hierarchy only specifies a relationship between pages; other resources, like task flows, portlets, and external links cannot be included in a page hierarchy.

The page hierarchy provides a security inheritance model that allows administrators to easily control security on portals that have a very large number of pages. For example, if your portal has 100 pages, you can specify security policies on the root of the page hierarchy, and all 100 pages will inherit those policies. Then, if you wish to modify the settings on any page below the root, you can do that, and those settings will propagate to any of that page's sub-pages. You can also override the inherited settings and apply security settings to individual pages anywhere in the hierarchy.

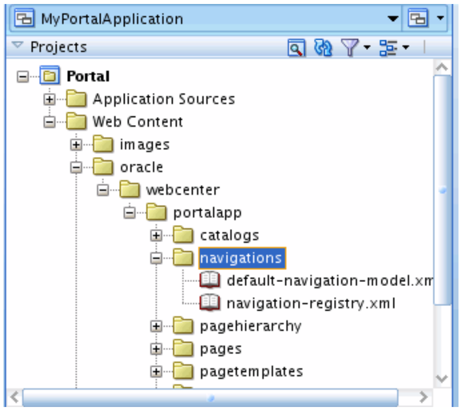
The navigation model, by contrast, defines a navigational structure, keeps track of navigational data, and provides that data to the view layer of the application. While a page hierarchy only consists of pages, a navigation model can consist of a variety of resources, like task flows, pages, external links, and others.

It's important to note that the navigation model is aware of the security policies that have been applied to the elements (pages, links, task flows, and so on) that the navigation model controls. If the authenticated user is not authorized to see a particular page, the navigation model, by default, hides any navigational links to that page. For any resources that do not have security defined in the portal, like external links, the developer has to control visibility manually. One way to do this is to add an EL expression to the page or page template to control visibility (show/hide) of the resource. For more information, see Chapter 10, "Developing a Navigation Model."

For example, if your portal pages include a tree navigation UI, that UI asks the navigation model questions like: what pages or other elements can the user navigate to and what is the current navigational state of the portal. The first question informs which links the UI can display. The second informs the UI how to display those links. If the navigation view is a tree, the model tells the UI, for example, which page is currently selected. This allows the tree UI to display the node representing that page correctly, as an open folder for example, or as a selected page.

In JDeveloper, use the Navigation Editor to modify the navigation model. To open the editor, double-click the file `default-navigation-model.xml` in the `navigations` folder, shown in Figure 5–8.

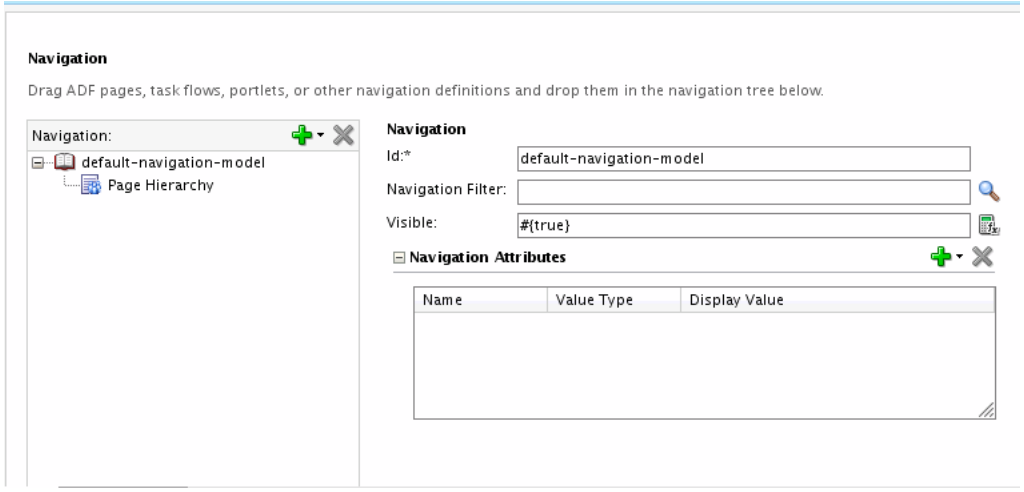
Figure 5–8   Contents of the navigations Folder



The `navigation-registry.xml` file is used by the Resource Manager when a user creates or edits a navigation model. The registry defines the superset of all items that are available to be included in a model that you create or edit. You can create multiple navigation models for an application, but an application can only have one navigation registry file. For more information on the navigation model, the Navigation Editor, and the registry, see Chapter 10, "Developing a Navigation Model."

The default navigation model, shown in Figure 5–9, includes one node called Page Hierarchy. By default, this node points to the default page hierarchy file, `pages.xml`, in the pagehierarchy folder. This node tells the navigation model to refer to the page hierarchy's structure and communicate that structure to the navigation UI so that it can be rendered. As seen previously in Figure 5–6, the default UI displays the page hierarchy as tab-like links. The information provided by the model allows each link to display its sub-page links in a drop-down menu whenever the mouse pointer hovers over it.

Figure 5–9   The Default Navigation Model



Drag ADF pages, task flows, portlets, or other navigation definitions and drop them in the navigation tree below.

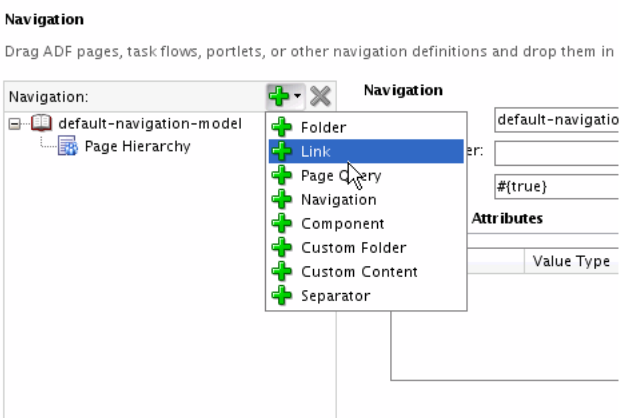
Id:* default-navigation-model

Navigation Filter:

Visible: #{true}

The navigation model can include several kinds of navigation elements. As we've seen, the model can include both page hierarchies and single pages. But you can also create navigation to other elements, like links to external web pages or specific content.

Figure 5–10 Adding a Link to the Navigation Model



For more information, see Chapter 10, "Developing a Navigation Model."

5.3.5 Understanding Resource Catalogs and the Catalog Registry

A catalog specifies a collection of an otherwise unrelated group of elements, like layout components, task flows, portlets, documents, and others, that an authorized user can add to a portal at runtime. Oracle WebCenter Portal's Composer uses catalogs at runtime to determine which elements an authorized user can add to a portal page.

The Portal Framework application template includes a default resource catalog (`default-catalog.xml`) and a catalog registry file (`catalog-registry.xml`). These files are located in `oracle/webcenter/portalapp/catalogs`.

When a user edits pages at runtime using Composer, the default catalog file specifies all of the items that are available to be added to a page. The catalog registry file is used by the Resource Manager when a user creates or edits a resource catalog. The registry defines the superset of all items that are available to be included in a catalog that you create or edit.

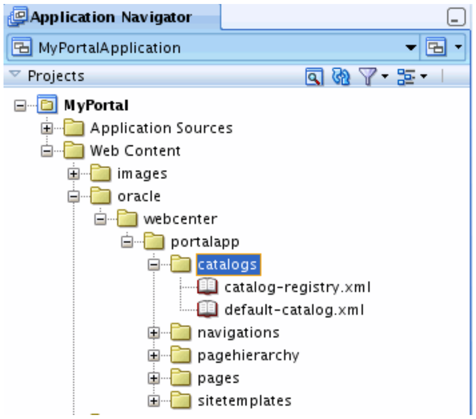
You can create multiple catalogs for an application, but an application can only have one catalog registry file. For more information, see Chapter 14, "Developing Resource Catalogs."

At development time, you can edit existing catalogs using the Resource Catalog editor. To open the editor, open the catalog file (for example, `default-catalog.xml`) in the `catalogs` folder in Application Navigator, as shown in Figure 5–11.

To create a new catalog, select **New** from the File menu. In the New Gallery dialog, select the **All Technologies** tab, then select **Portal Framework** under the Web Tier node. Then, select **Resource Catalog** and click **OK**. Use the Create Application Resource Catalog dialog to create the new catalog.

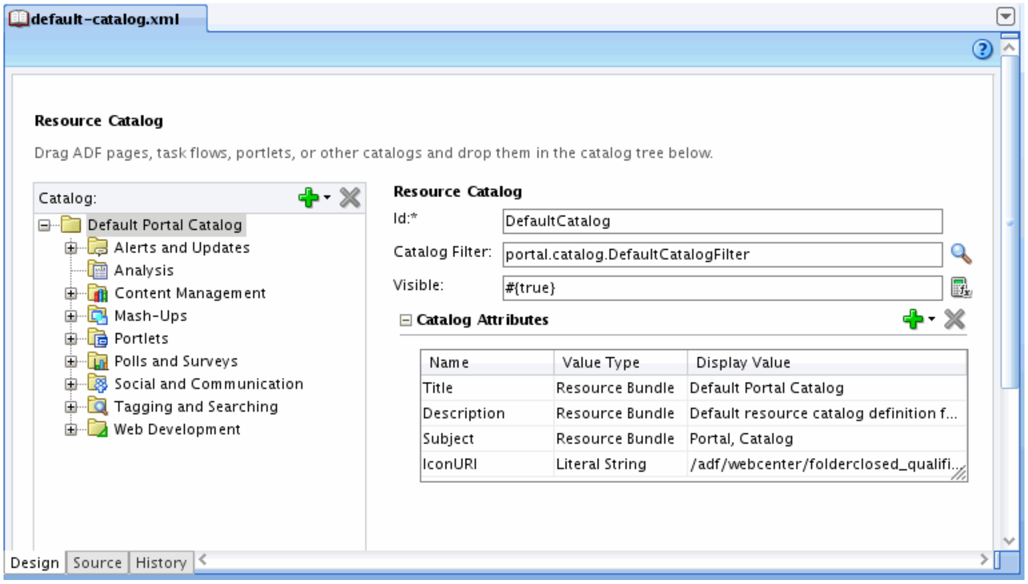
> **Tip:** You can also edit navigation registries using the Resource Catalog editor.

Figure 5–11 Contents of the catalogs Folder



The Resource Catalog editor is shown in Figure 5–12.

Figure 5–12 Resource Catalog Editor in JDeveloper



Resource Catalog

For example you can create separate catalogs for each of several departments.

Tip: Individual catalog entries can be shown or hidden based on user roles.

5.4 How are WebCenter Portal Framework Application Files Organized?

When you run through the Portal Framework application wizard, a large number of project artifacts are configured and installed in the project directory. JDeveloper presents a streamlined view of your project in the Application Navigator. You can also view your portal project directly on your filesystem.

- Section 5.4.1, "Understanding the Organization of a WebCenter Portal Framework Application"
- Section 5.4.2, "Viewing Your Portal Project on the Filesystem"
- Section 5.4.3, "Viewing Your Portal Project in JDeveloper"
- Section 5.4.4, "Showing Hidden Files in the Application Navigator"

5.4.1 Understanding the Organization of a WebCenter Portal Framework Application

This section explains how a Portal Framework application is organized, and why it is organized the way it is.

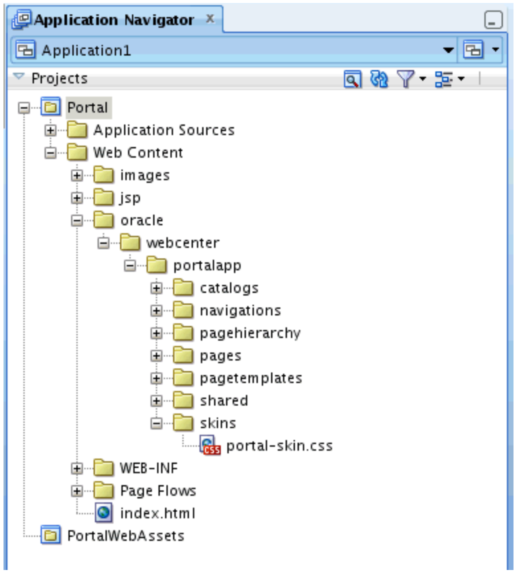
5.4.1.1 How Is a WebCenter Portal Framework Application Organized?

When you create a new Portal Framework application in JDeveloper, a large number of files are automatically placed in the project. You can see these files organized in the Application Navigator view in JDeveloper.

Looking at the Application Navigator, the first thing you will notice is that a Framework application consists of two projects. The first is called (by default) **Portal**, as shown in Figure 5–14. You can change this name when you create the application or anytime afterwards. Most of the files in a project are placed in the `<application_root>/<project_root>/public_html/oracle/webcenter/portalapp` directory.

The second project is called **PortalWebAssets**. The PortalWebAssets project includes static application resources like HTML and image files. By separating the static resources into a separate project, it is possible to deploy those resources to a dedicated server. For more information, see Section 6.4, "Understanding the PortalWebAssets Project."

Figure 5–14 WebCenter Portal Framework Application in the Application Navigator



5.4.1.2 Why Is a WebCenter Portal Framework Application Organized the Way It Is?

It is important to understand the following distinctions between files that are stored in your application:

> **Note:** It is important to understand these distinctions because some files, like XML files, you might not expect to find under `public_html`. (Because in a standard Web application, most files under this directory are directly URL accessible from a browser once the application is deployed.) Developers must keep in mind that portal files require this particular structure; you must not attempt to create portal artifacts in other locations.

- Files located in the `<application_root>/<project_root>/public_html/oracle/webcenter/portalapp` directory:
  - are deployed to the Metadata Services (MDS) repository.
  - can be registered as portal resources and managed at runtime with the Resource Manager.
  - are generally secured using WebCenter Permissions (if they are portal resources).
- Files located elsewhere under `<application_root>/<project_root>/public_html`:
  - are deployed to the application WAR file.
  - cannot be registered as portal resources and therefore cannot be managed with the Resource Manager.
  - are secured using the native permission class of the artifact.

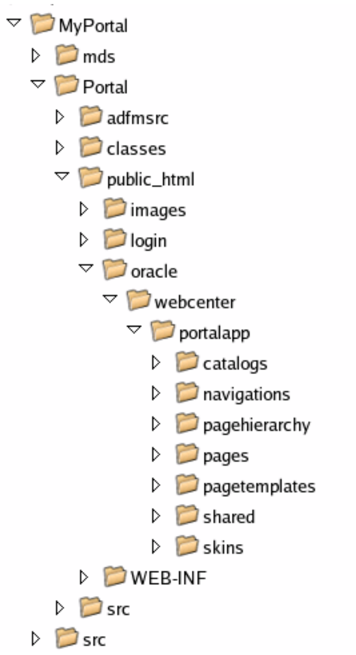
It is important to understand that a Portal Framework application is structured this way so that you can make informed decisions when you create your own pages. In some cases, specifically with JSPX pages, you might not want to create a page under `oracle/webcenter/portalapp`. It depends on the intended use of the page in your application.

5.4.2 Viewing Your Portal Project on the Filesystem

The simplest way to locate your project files on the file system is to select a file or folder in the Application Navigator and then select **Copy Path** from the Edit menu. This function places the path to the file or folder on the clipboard, which you can then paste into a command shell or file browser.

Figure 5–15 shows the filesystem organization of a sample Portal Framework application. Many of the project's files are organized under the `public_html` folder.

Figure 5–15 Sample WebCenter Portal Framework Application on the Filesystem



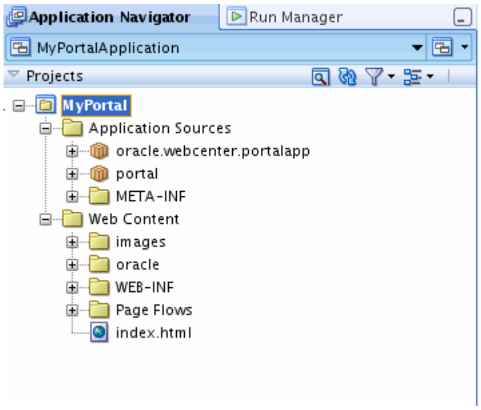
As you will see, JDeveloper presents a somewhat different, more streamlined view of your project, as discussed in the next section, Section 5.4.3, "Viewing Your Portal Project in JDeveloper."

5.4.3 Viewing Your Portal Project in JDeveloper

The intent of the project view in JDeveloper is to present the project files that a developer is likely to work with. These files include pages, page hierarchies, navigation models, page templates, catalogs, XML configuration files, Java source files, images, and so on.

In JDeveloper, portal projects are organized into two folders: Application Sources and Web Content, as shown in Figure 5–16.

Figure 5–16 Organization of a Portal Project in JDeveloper



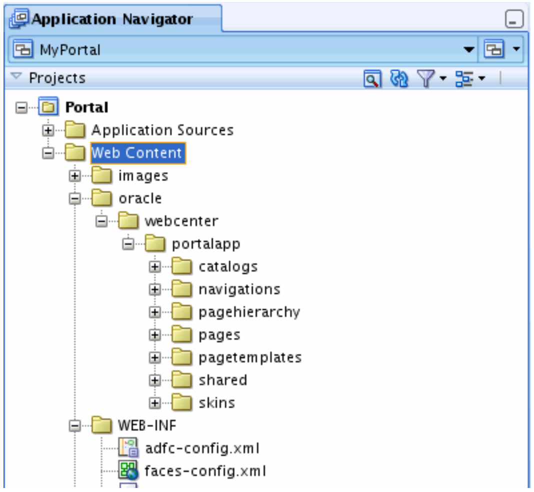
The **Application Sources** folder is primarily a repository for source code and page definition files. In addition to any Java classes you write for your application, Application Sources includes:

- **oracle.webcenter.portalapp** – Includes XML definition files for pages, page templates, page catalogs, navigations. A page definition file specifies ADF bindings, page parameters, and permission settings. For example, the page definition file specifies the page's parent and child pages, if any. The file also specifies security policy information, like the operations that are permitted on the page. Default page definition files are created automatically when you add a portal page to a page hierarchy.
- **portal** – Includes resource bundles, source code, and other Java artifacts.
- **META-INF** – Includes files for specifying data bindings and page template metadata.

The **Web Content** folder contains all of the files that make up your web project, like pages, page hierarchies, navigation models, and so on. These are the files that you will actively create and modify as you develop your Portal Framework application.

Figure 5–17 shows the basic structure of the Web Content folder. Note that many of the files you will create and modify are located in the `oracle/webcenter/portalapp` sub folder. This folder's contents – catalogs, navigations, page hierarchy, pages, skins, and pagetemplates – make up the basic components of a portal. For detailed information on these portal components, see Section 5.4.1, "Understanding the Organization of a WebCenter Portal Framework Application."

Figure 5–17 The Web Content Folder



> **Tip:** If you prefer to view the local file system hierarchy in the Application Navigator, click the **Navigator Display Options** icon in the Projects panel and select **Group by Directory**.

The **PortalWebAssets** project includes static application resources like HTML and image files. By separating the static resources into a separate project, it is possible to deploy those resources to a dedicated server. For more information, see Section 6.4, "Understanding the PortalWebAssets Project."

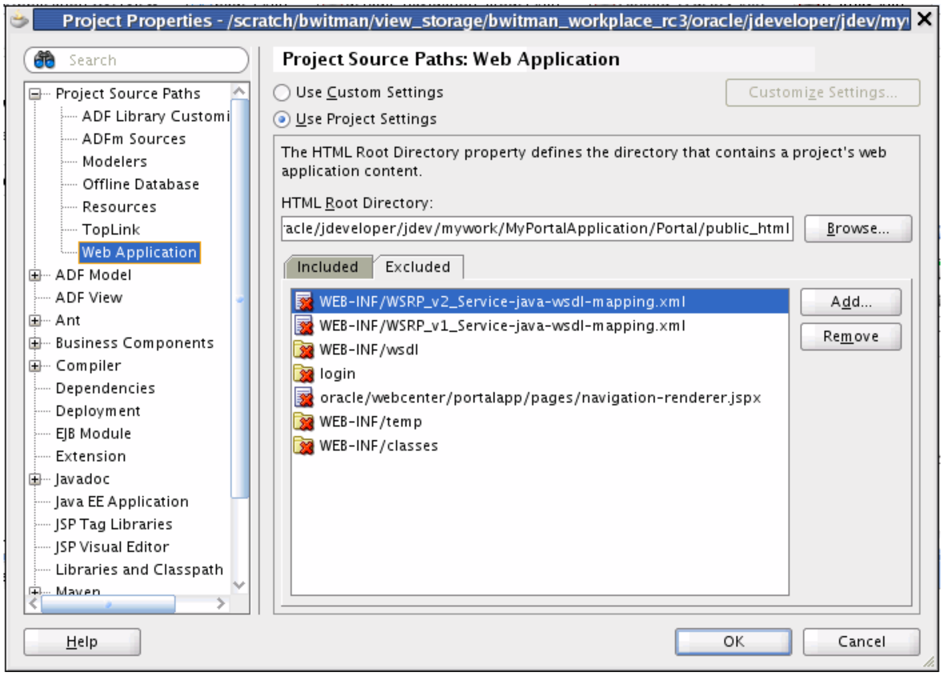
5.4.4 Showing Hidden Files in the Application Navigator

By default, a few files are excluded from view in the Application Navigator. These files are excluded because it is unlikely you'll ever need to edit them. However, because there are some use cases where you might want to edit them, you need to be able to add them back to the JDeveloper UI.

To locate the excluded files:

1. Right-click the project folder and select **Project Properties** from the menu.
2. In the Project Properties dialog, select **Web Application** under the Project Source Paths node.
3. Select the Excluded tab, as shown in Figure 5–18.

Figure 5–18 The Exclude Tab



Project Source Paths: Web Application

○ Use Custom Settings

● Use Project Settings

The HTML Root Directory property defines the directory that contains a project's web application content.

HTML Root Directory: acle/jdeveloper/jdev/mywork/MyPortalApplication/Portal/public_html

WEB-INF/WSRP_v2_Service-java-wsdl-mapping.xml
WEB-INF/WSRP_v1_Service-java-wsdl-mapping.xml
WEB-INF/wsdl
login
oracle/webcenter/portalapp/pages/navigation-renderer.jspx
WEB-INF/temp
WEB-INF/classes

4. Select an element from the excluded list and click **Remove** to remove it from the excluded list. As a result, the element is automatically included in the appropriate folder in the Application Navigator.

As an example, the `navigation-renderer.jspx` file is used to render resources in the context of a page template. If you wanted to change the way an external URL is displayed within a page, you would first remove the `navigation-renderer.jspx` file from the excluded list in order for it to appear under the `pages` folder in the Application Navigator. Then, you could open the page and edit it as desired.

5.5 What Is the Portal Life Cycle?

The portal life cycle describes the creation process of a portal from development through staging and testing to a production server. Many actors participate in the life cycle including software developers, content modelers, content contributors, IT administrators, portal site administrators. For detailed information on managing all the stages of the portal life cycle, see Chapter 8, "Understanding the WebCenter Portal Framework Application Life Cycle."

5.6 Developing Your Portal's Look and Feel

You can design the look and feel by adding certain presentation elements, such as banners, navigations, and footers, around the content area. Once you settle on a look and feel that is suitable for your portal structure, you can save these settings as a page template, which can be used to create a portal. In addition, you may want use the same settings across pages in your portal. With the use of page templates and page styles, you can achieve some consistency across pages in your portal. See Chapter 5.6, "Developing Your Portal's Look and Feel."

You can also develop custom skins for your portal. A skin is a style sheet based on the CSS 3.0 syntax specified in one place for an entire application. Instead of providing a style sheet for each component in your application or inserting a style sheet on each page, you can create one skin for the entire application. Every component automatically uses the styles as described by the skin. When you use a skin, you do not have to make design-time changes to portal pages to change their appearance. See Chapter 13, "Developing Skins."

Although the basic look and feel design can be created in JDeveloper at design time, the Resource Manager enables administrators and users with the appropriate privileges to continue developing the portal's look and feel after the application has been deployed. For example, the Resource Manager lets you add and remove pages, add navigation user interfaces, and change the page templates, skins, and page styles. For more information about these and other Resource Manager features, see Chapter 15, "Creating Pages and Adding Resources."

5.7 Changing Default Portal Preferences

A Portal Framework application includes a set of preferences that specify certain default portal components. This section describes these preferences and explains how to change their default values.

5.7.1 What Are the Default Portal Preferences?

Table 5–1 lists the portal preferences and their default configuration files.

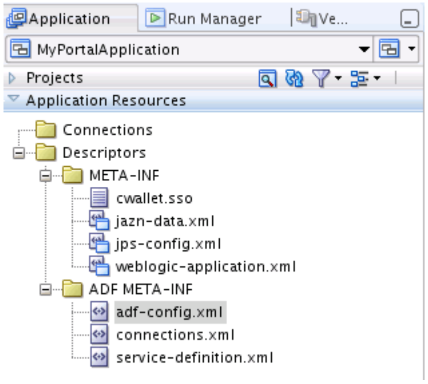
Table 5–1 Default Preferences

Preference	Default Setting
Navigation Model	`/oracle/webcenter/portalapp/navigations/default-navigation-model.xml`
Resource Catalog	`/oracle/webcenter/portalapp/catalogs/default-catalog.xml`
Page Template	`/oracle/webcenter/portalapp/pagetemplates/pageTemplate_globe.jspx`
Navigation Renderer	`/oracle/webcenter/portalapp/pages/navigation-renderer.jspx`
Skin	`portal`

5.7.2 How to Change the Default Preferences in JDeveloper

To change the default preferences in JDeveloper, directly edit the `adf-config.xml` file. To locate this file in JDeveloper, open the **Application Resources** part of the Application Navigator. Then, open the **Descriptors** folder and the **ADF META-INF** folder, as shown in Figure 5–19.

Figure 5–19 Location of the adf-config.xml File in JDeveloper



For example, to change the default navigation model file, edit the value of this preference:

```
<portal:preference id="oracle.webcenter.portalapp.navigation.model"
   desc="Default Navigation Model"
   value="/oracle/webcenter/portalapp/navigations/default-navigation-model.xml"
   resourceType="navigation" display="true"
/>
```

Preferences can also be changed at runtime under the **Configurations** tab of the Administration page. From this page, you can configure the default page template, skin, resource catalog, and navigation component in a runtime application. For details, see the "Configuring Defaults for Portal Framework Applications" section in the *Administering Oracle WebCenter Portal*.

5.8 Using Iterative and Round-Trip Development Techniques

Iterative development is a productivity feature that helps speed up the development process. Iterative development lets you make and save changes to your Portal Framework application in JDeveloper while the app is running on the Integrated WebLogic Server and immediately see the effect of those changes simply by refreshing the current page in your browser. The iterative development feature is enabled by default in a Framework application. For information on enabling the iterative development feature in Portal Framework applications, see Section 2.3.1, "Preparing for Iterative Development in a Portal Framework Application." See also Section 8.7, "Understanding Iterative Development."

Round-trip development refers to features and techniques that allow you to retrieve resources from a deployed, runtime portal back to JDeveloper for maintenance or enhancement. After modifying a resource in JDeveloper, you can use the Resource Manager to upload the resource back to the deployed portal. WebCenter Portal's round-trip development features provide a simple, convenient way to modify portal resources without redeploying the entire application.

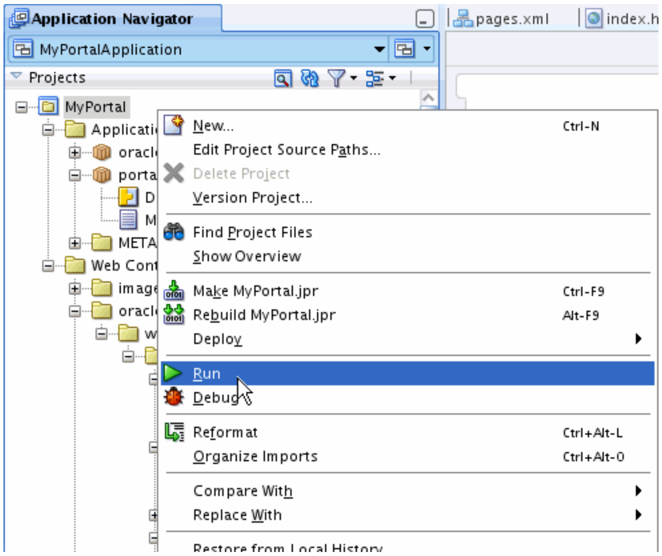
5.9 Running and Testing a Portal

JDeveloper provides several ways to run a Portal Framework application for testing purposes in the Integrated WebLogic Server in JDeveloper:

- Right-click the portal project name in the Application Manager and select **Run**, as shown in Figure 5–20. If the server is not running, this action starts the server and (re)deploys the application.

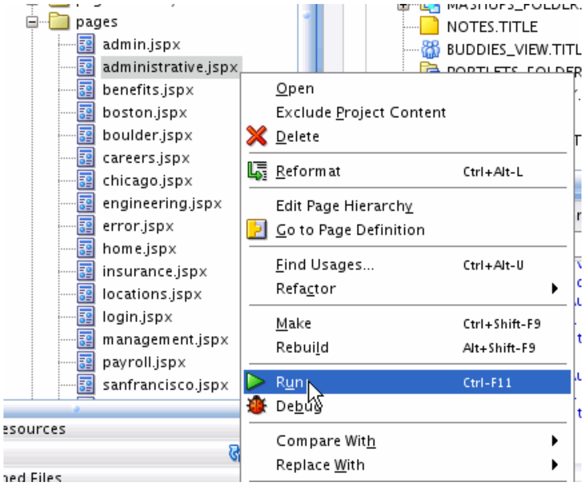
  > **Tip:** You can change the default portal home page. For details, see Section 5.11, "Changing the Default Home Page and Login/Logout Target Pages."

Figure 5–20 Running the Portal



- Right-click a page in the pages folder in the Application Manager and select **Run**, as shown in Figure 5–21. If the server is not running, this action starts the server, (re)deploys the application, and displays the selected page.

Figure 5–21 Running a Page



- You can also run a portal by selecting **Run *portal name*** from the **Run** menu.

5.10 WebCenter Portal Framework Applications at Runtime

Oracle WebCenter Portal Framework provides a number of interesting runtime features. Runtime features refer to features that are accessible from a browser.

- Section 5.10.1, "Preserving Runtime Customizations on the Integrated WebLogic Server"
- Section 5.10.2, "Browser-Based WebCenter Portal Administration Console"
- Section 5.10.3, "How Security Settings Affect the Runtime Portal"
- Section 5.10.4, "Editing of Portal Resources Using Browser-Based Tools"

5.10.1 Preserving Runtime Customizations on the Integrated WebLogic Server

If you are using the Integrated WebLogic Server in a development environment (running the portal through JDeveloper) any changes you make to the portal at runtime (using the Resource Manager) are discarded upon redeployment by default. For example, if you use the Resource Manager to make changes like adding entitlements to a page, changing the layout, or modifying the navigation model, these changes will not be preserved the next time you redeploy the application. For more information on the Resource Manager, see Chapter 15, "Creating Pages and Adding Resources."

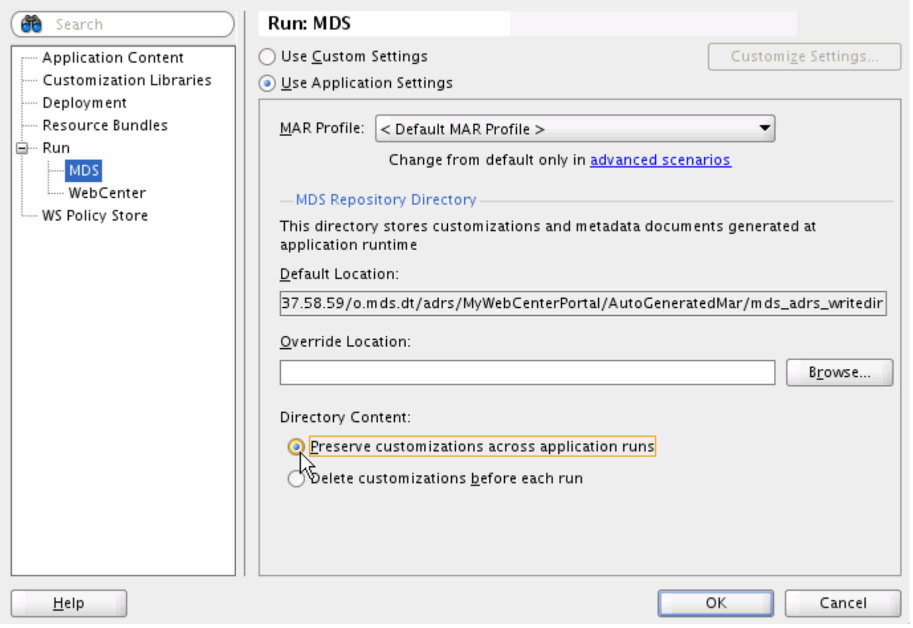
Note: The information in this section only applies to a portal that is running with the Integrated WebLogic Server in a development environment. When you deploy the portal to a production environment, runtime changes are never discarded.

Note: Customizations are not preserved by default as a convenience for developers working in the JDeveloper environment. When you modify a file at runtime, a new version of the file is written to the MDS write directory. This new version then takes precedence over the version in JDeveloper. At that point, if you change a setting in JDeveloper and refresh your browser, the change will not show up. Therefore, while you're working in JDeveloper, it's much more convenient and natural not to preserve runtime customizations.

It is possible to change the default behavior, and preserve runtime customizations between runs. For example, you may wish to do this to enable certain testing scenarios. To allow customizations to be preserved between application deployments (runs):

1. Select **Application Properties** from the Application Menu.
2. In the Application Properties dialog, select **MDS** under the Run node.
3. Under Directory Content, select **Preserve customizations across application runs** to disable the default, which is to discard customizations before each run. See Figure 5–22.

Figure 5–22 Selecting Preserve Customizations Across Application Runs



Run: MDS

○ Use Custom Settings

● Use Application Settings

MAR Profile: < Default MAR Profile >

Change from default only in advanced scenarios

MDS Repository Directory

This directory stores customizations and metadata documents generated at application runtime

Override Location:

Directory Content:

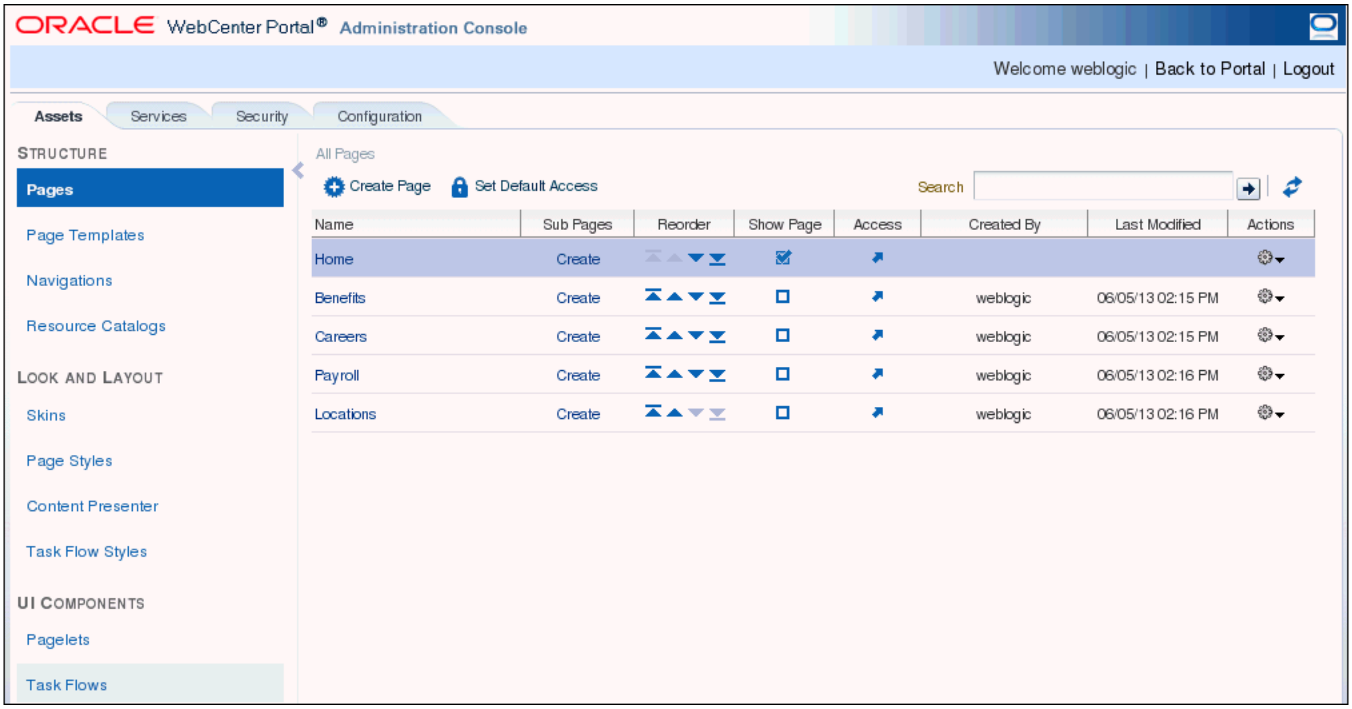
● Preserve customizations across application runs

○ Delete customizations before each run

5.10.2 Browser-Based WebCenter Portal Administration Console

WebCenter Portal Framework applications include a WebCenter Portal Administration Console that lets you work with resources, services, security, and portal configurations. The WebCenter Portal Administration Console is located at this URL: `http://`*`server`*`:`*`port`*`/`*`context_root`*`/admin`, and is shown in Figure 5–23.

Figure 5–23 The WebCenter Portal Administration Console



Name	Sub Pages	Reorder	Show Page	Access	Created By	Last Modified	Actions
Home	Create		☑				
Benefits	Create		□		weblogic	06/05/13 02:15 PM	
Careers	Create		□		weblogic	06/05/13 02:15 PM	
Payroll	Create		□		weblogic	06/05/13 02:16 PM	
Locations	Create		□		weblogic	06/05/13 02:16 PM	

> **Tip:** You can change the default URL for the WebCenter Portal Administration Console by editing the `<url-pattern>` attribute of the `<servlet-mapping>` element in the `web.xml` file. The default `<url-pattern>` is `admin`, but you can change it to something else if you want.

For more information on the Resource tab (the Resource Manager), see Section 5.10.4, "Editing of Portal Resources Using Browser-Based Tools" and Chapter 15, "Creating Pages and Adding Resources." Security topics are discussed in Chapter 74, "Securing Your WebCenter Portal Framework Application."

5.10.3 How Security Settings Affect the Runtime Portal

Role based security policies control which pages, resources, and navigational elements visitors can see and manipulate (create, delete, update, and so on). The design time (JDeveloper) page editor lets you set these policies on pages or hierarchies of pages, as discussed in Section 5.3.3, "Securing WebCenter Portal Framework Pages." Oracle WebCenter Portal Framework respects these security polices in the following ways:

- Pages (and certain other resources, like task flows) can only be viewed by users who are authorized to see them. The same principle holds for operations users can perform on pages, like Grant, Create, Delete, Update, and Personalize.
- Navigation to a resource (like a page or task flow) is hidden if that page is unavailable to the authenticated user. For example, if a user is not authorized to visit the **Payroll** page, the link to that page will not show up in any of the navigational user interfaces.
- Resources that are available within a Resource Catalog are adjusted based on security policies. If a user is not authorized to access a particular resource, such as a task flow, that resource will not appear in the Resource Catalog.

5.10.4 Editing of Portal Resources Using Browser-Based Tools

The WebCenter Portal Administration Console includes a Resources tab that lets you work with several portal-specific features at runtime:

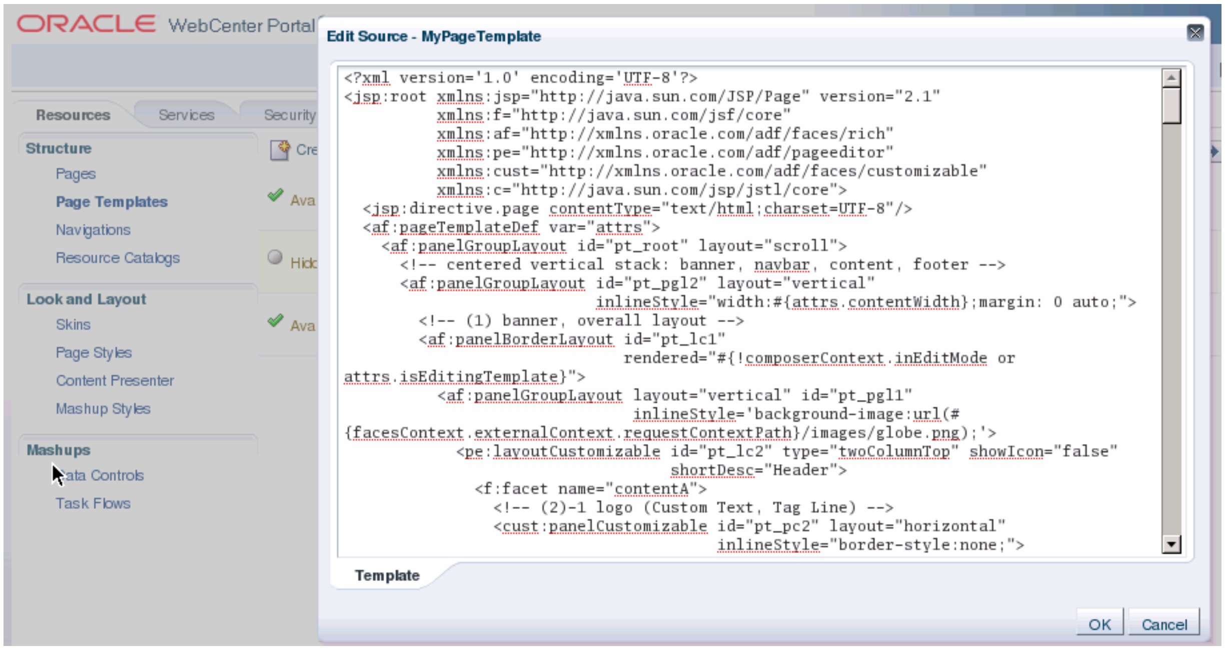
- Pages
- Page templates
- Navigation models
- Resource Catalogs
- Skins
- Page styles
- Content Presenter display templates
- Mashup styles
- Data controls
- Task flows

Using the Resource Manager, portal users can also download resources, or an entire application, from the runtime environment, edit them in JDeveloper, and then upload them back into the deployed application.

The Edit Source feature in the Resource Manager lets you edit the source code of resources in the runtime application. For example, if you upload a portal resource (like a page template), you can then edit it directly in the Resource Manager. Just select the resource, and choose Edit Source from the Edit menu. A source editing window appears, as shown in Figure 5–24.

> **Note:** Some resources, like the `default-navigation-model`, are not editable. If you want to edit these resources, make a copy first and edit the copy.

Figure 5–24 Editing a Page Template Source File at Runtime



```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"
          xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"
          xmlns:c="http://java.sun.com/jsp/jstl/core">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <af:pageTemplateDef var="attrs">
    <af:panelGroupLayout id="pt_root" layout="scroll">
      <!-- centered vertical stack: banner, navbar, content, footer -->
      <af:panelGroupLayout id="pt_pgl2" layout="vertical"
                           inlineStyle="width:#{attrs.contentWidth};margin: 0 auto;">
        <!-- (1) banner, overall layout -->
        <af:panelBorderLayout id="pt_lc1"
                              rendered="#{!composerContext.inEditMode or
attrs.isEditingTemplate}">
          <af:panelGroupLayout layout="vertical" id="pt_pgl1"
                               inlineStyle='background-image:url(#
{facesContext.externalContext.requestContextPath}/images/globe.png);'>
            <pe:layoutCustomizable id="pt_lc2" type="twoColumnTop" showIcon="false"
                                   shortDesc="Header">
              <f:facet name="contentA">
                <!-- (2)-1 logo (Custom Text, Tag Line) -->
                <cust:panelCustomizable id="pt_pc2" layout="horizontal"
                                        inlineStyle="border-style:none;">
```

5.11 Changing the Default Home Page and Login/Logout Target Pages

The file `oracle/portalapp/pages/home.jspx` is the default home page for a new Portal Framework application. This section explains how to change this default home page to another page or any navigable resource like a URL, portlet, or task flow.

- Section 5.11.1, "Understanding How the Home Page Is Specified"
- Section 5.11.2, "How to Change the Default Home Page"
- Section 5.11.3, "How Is the Default Index Page Specified?"
- Section 5.11.4, "Specifying the Target Page After a Login or Logout"

5.11.1 Understanding How the Home Page Is Specified

The default Portal Framework application includes an `index.html` file, which is located in the portal project directory. This index file contains the following redirect statement:

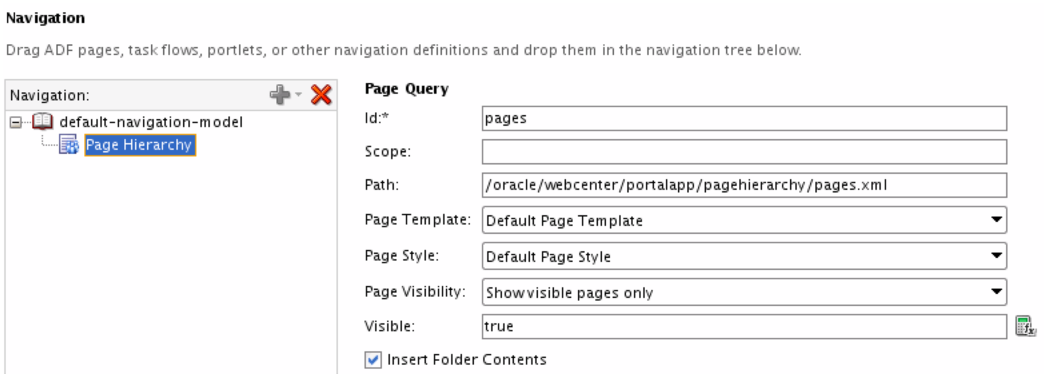
```
<meta http-equiv="refresh" content="0;url=./faces/wcnav_defaultSelection" />
```

Note: The redirect statement in `index.html` refers to the portal navigation model, not to a page as you might expect. Pointing the redirect to the navigation model allows the `currentSelection` attribute to be set properly, which allows the current selection to be highlighted in the user interface.

The URL element `pages_home` refers to the "home" page specified in the page hierarchy. (The prefix "`pages_`" is added to the folder name simply to ensure a unique ID.) As Figure 5–25 shows, the **Insert Folder Contents** checkbox is selected in the Navigation dialog. The **Insert Folder Contents** option replaces the specified folder ("`home`" in this case) with the *contents* of the folder. Therefore, in this example, the portal looks for a folder called "`home`" in the page hierarchy. Note too that Page Hierarchy is specified as an element in the navigation model.

To help you understand how the default portal home page is specified, note that in the navigation model a default node called `pages` is created by default. This node's navigation path points to the page hierarchy file, `pages.xml`, as shown in Figure 5–25.

Figure 5–25 The Default Navigation Model



Navigation

Drag ADF pages, task flows, portlets, or other navigation definitions and drop them in the navigation tree below.

Page Query

Id:* pages

Scope:

Path: /oracle/webcenter/portalapp/pagehierarchy/pages.xml

Page Template: Default Page Template

Page Style: Default Page Style

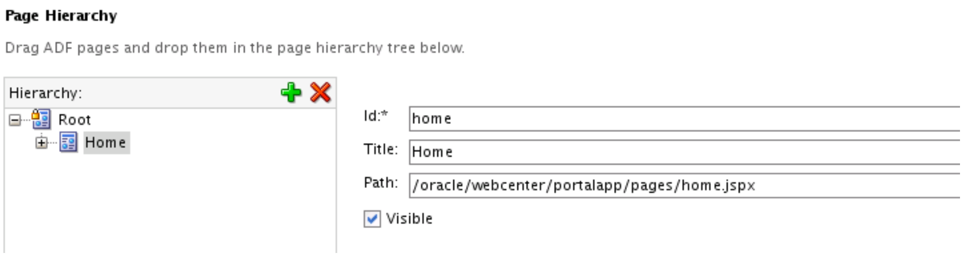
Page Visibility: Show visible pages only

Visible: true

☑ Insert Folder Contents

Upon navigating to `pages.xml`, the node called `home` is located, and that node's path is `/oracle/webcenter/portalapp/pages/home.jspx`, as shown in Figure 5–26.

Figure 5–26 The Default Page Hierarchy



Page Hierarchy

Drag ADF pages and drop them in the page hierarchy tree below.

Id:* home

Title: Home

Path: /oracle/webcenter/portalapp/pages/home.jspx

☑ Visible

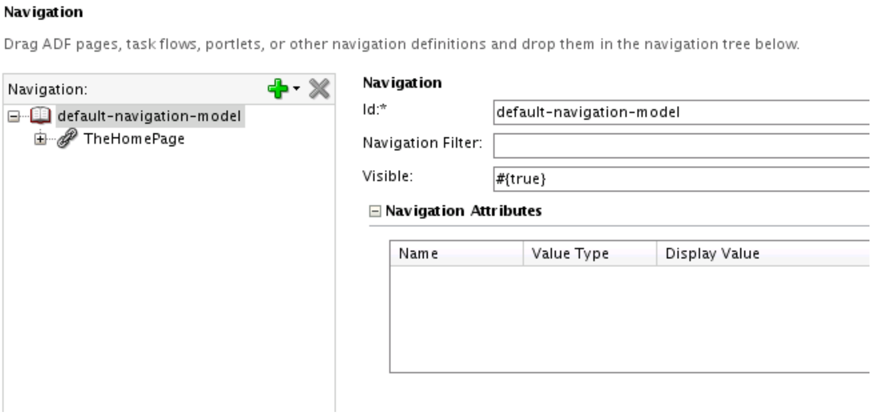
5.11.2 How to Change the Default Home Page

To change the default home page, simply change the redirect statement in `index.html` to the pretty URL of another resource that is referenced in the navigation model. For example, you might create a new home page and redirect to it – a common use case. Simply specify the new page to be your portal's home page by changing the redirect in `index.html` to the new page's pretty URL. (You can drag the new page in the navigation model to create a page link element.) For example, if the link ID in the navigation model is `TheHomePage`:

```
<meta http-equiv="refresh" content="0;url=./faces/wcnav_defaultSelection" />
```

where `.faces/wcnav_defaultSelection` is the pretty URL that points to the link element defined in the navigation model.

Figure 5–27 Navigation Model with New Home Page Element



Navigation

Drag ADF pages, task flows, portlets, or other navigation definitions and drop them in the navigation tree below.

Navigation:
- default-navigation-model
  - TheHomePage

Navigation

This is the Home Page

Copyright 2010 - Oracle and/or its affiliates. All rights reserved.

5.11.3 How Is the Default Index Page Specified?

The default index page for the Integrated Weblogic Server instance is `index.html`. A new portal project includes this file, by default, in the `Web Content` folder.

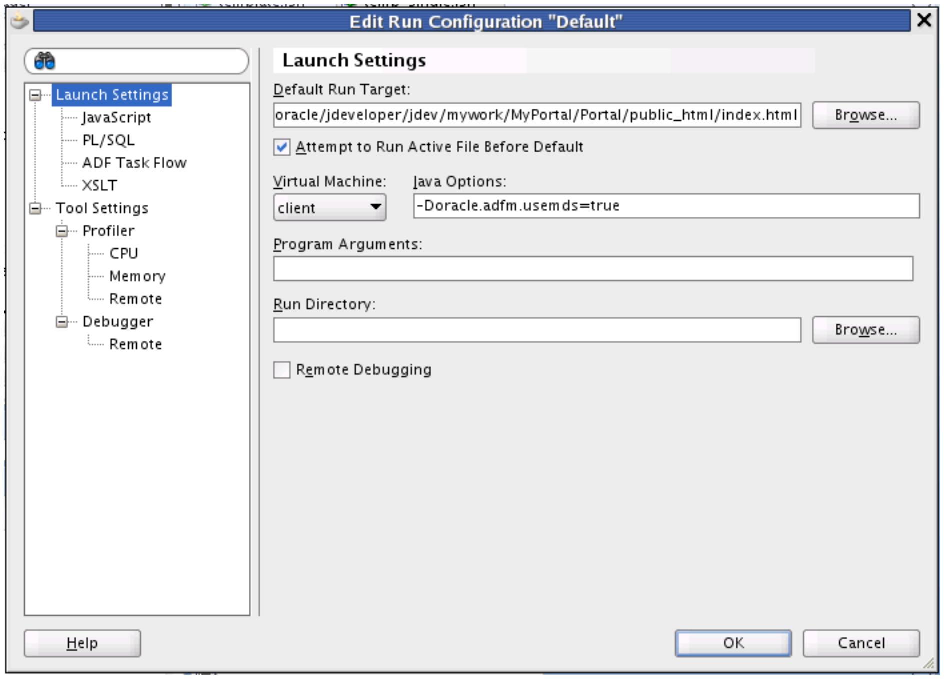
To change the default index file, `index.html`, to another file, you have two choices. One way to change this default index file is to edit the `<welcome-file-list>` element in the `web.xml` file:

```
<welcome-file-list>
    <welcome-file>/index.html</welcome-file>
</welcome-file-list>
```

Another way to change the default index page is to use the Edit Run Configuration "Default" dialog box. To access this dialog, open the project properties dialog, then, select the **Run/Debug/Profile** option. Click **Edit** to bring up the Edit Run

Configuration "Default" dialog where you can change the default index page, as shown in Figure 5–29.

Figure 5–29 Edit Run Configuration "Default" Dialog



Launch Settings

Default Run Target: oracle/jdeveloper/jdev/mywork/MyPortal/Portal/public_html/index.html

☑ Attempt to Run Active File Before Default

Virtual Machine: client

Java Options: -Doracle.adfm.usemds=true

Program Arguments:

Run Directory:

□ Remote Debugging

5.11.4 Specifying the Target Page After a Login or Logout

To specify the target page after a login or logout, edit the `<navigation-rule>` element in the `WebContent/WEB-INF/faces-config.xml` configuration file in your portal project, as shown in Example 5–1. You can change the target pages to any other navigation resource's pretty URL or Faces page.

Example 5–1 Specifying the Target Page for Login and Logout

```
<navigation-rule>
    <from-view-id>*</from-view-id>
    <navigation-case>
      <from-outcome>login_success</from-outcome>
      <to-view-id>/pages_home</to-view-id>
      <redirect/>
    </navigation-case>
    <navigation-case>
      <from-outcome>logout_success</from-outcome>
      <to-view-id>/pages_home</to-view-id>
      <redirect/>
    </navigation-case>
</navigation-rule>
```

For example, to redirect the user to a post-logout page follow these steps:

1. Create the post-logout page and add content to it. For example:

   ```
   /oracle/webcenter/portalapp/pages/postlogout.jspx
   ```

2. Modify the navigation rule in `faces-config.xml`. For example:

```
<navigation-case>
  <from-outcome>logout_success</from-outcome>
  <to-view-id>/oracle/webcenter/portalapp/pages/postlogout.jspx</to-view-id>
  <redirect/>
</navigation-case>
```

After a successful logout, the user is redirected to the specified page.

5.12 Customizing Session Timeouts

You can customize session timeout popups in a Portal Framework application by configuring the default timeout value. You can also customize the text that appears in the popup by modifying the resource strings.

This section contains the following topics:

- Section 5.12.1, "Customizing the Session Timeout Default Value"
- Section 5.12.2, "Customizing the Session Timeout Default Message"

5.12.1 Customizing the Session Timeout Default Value

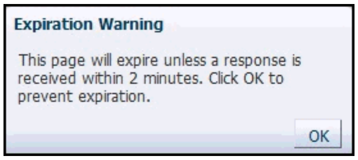
For better performance, Oracle recommends that the HTTP session timeout value for Portal Framework applications be set to a lower value (for example, 10 minutes) than the out-of-the-box value of 45 minutes. The lower number helps the server's performance, particularly during significant load. The longer the session time, the longer the server will have to hold memory until the inactive sessions expire.

Configuring the session timeout value to a lower number, for example, 10 minutes, can be done through the `web.xml` file:

```
<session-config>
  <session-timeout>10</session-timeout>
</session-config>
```

After this value is set, a warning popup appears, with a default value of two minutes, before the session is set to expire (Figure 5–30).

Figure 5–30 Timeout Warning Popup

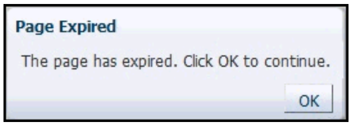


Expiration Warning

This page will expire unless a response is received within 2 minutes. Click OK to prevent expiration.

After the warning has expired, the message that the page has expired appears (Figure 5–31).

Figure 5–31 Page Expired Popup



Page Expired

The page has expired. Click OK to continue.

Although these messages are usually valid in many Portal Framework deployments, in the majority of Portal Framework applications, a session is equivalent to being logged in. For example, in the instance of a public user, the appearance of these messages may not be expected behavior. However, you can easily configure to disable these messages and keep them from appearing.

When a request is sent to the server, a session timeout value is written to the page and the session timeout warning interval is defined by the context parameter `oracle.adf.view.rich.sessionHandling.WARNING_BEFORE_TIMEOUT`.

Use the `oracle.adf.view.rich.sessionHandling.WARNING_BEFORE_TIMEOUT` context parameter to set the number of seconds prior to the session time out when a warning message is displayed. If the value of `WARNING_BEFORE_TIMEOUT` is less than 120 seconds, if client state saving is used for the page, or if the session has been invalidated, the feature is disabled. The session time-out value is taken directly from the session.

In Example 5–2, the `STATE_SAVING_METHOD` value is set to `client`, and the value correlates to the value needed for a page's `af:document` tag. This tag, has the `stateSaving` property set to default, which means it gets the value from the `init-context-param`. Notice that the `WARNING_BEFORE_TIMEOUT` value has been set to `0`. Out-of-the-box, the default value is 120 seconds.

Example 5–2 Session Timeout Warning Configuration

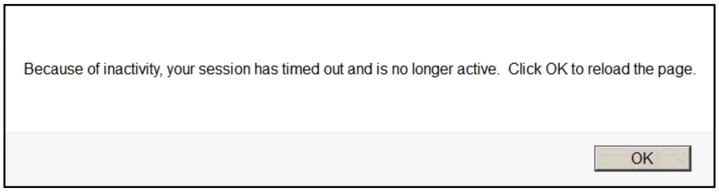
```
<context-param>
  <param-name>javax.faces.STATE_SAVING_METHOD</param-name>
  <param-value>client</param-value>
</context-param>

<context-param>
  <param-name>
     oracle.adf.view.rich.sessionHandling.WARNING_BEFORE_TIMEOUT
  </param-name>
    <param-value>0</param-value>
</context-param>
```

WARNING: Any value less than the default value of 120 seconds will disable the popup.

This configuration only prevents the warning message from appearing. Any subsequent page action, partial-page event, or navigation through an `af:commandLink` will produce the un-handled, `ViewExpiredException` (`ADF_FACES-60098`) in the `Faces, RESTORE_VIEW`, lifecycle (Figure 5–32):

Figure 5–32 Inactivity Timeout Message



Because of inactivity, your session has timed out and is no longer active. Click OK to reload the page.

The following log shows the details of this issue:

```
javax.faces.application.ViewExpiredException: viewId:/programs - ADF_
FACES-30108:The view state of the page has expired because of inactivity. Reload
the page.

at weblogic.servlet.internal.TailFilter.doFilter(TailFilter.java:26)
```

Note: For a Portal Framework application, the use of goLinks that use the pretty URL navigation model as the destination is preferred. goLinks will not have this particular issue, since the framework will handle creating a new state.

A way of handling this issue is to extend the Portal Framework application to support a custom exception handler. However, an alternative approach is discussed.

The solution is to use a servlet filter to handle the exception and then enable the application to control the recovery destination. For example, one scenario is to be able to either return to the page that the user was previously on, or navigate to the page that the user chooses through one of the (navigation model) page links. The following code supports this scenario:

```
import javax.servlet.Filter;
import javax.servlet.FilterChain;
import javax.servlet.FilterConfig;
import javax.servlet.ServletException;
import javax.servlet.ServletRequest;
import javax.servlet.ServletResponse;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

public class SessionExpiryFilter implements Filter {
    private FilterConfig _filterConfig = null;

    public SessionExpiryFilter() {
        super();
    }

    public void init(FilterConfig filterConfig) throws ServletException {
        _filterConfig = filterConfig;
    }

    public void doFilter(ServletRequest servletRequest,
                         ServletResponse servletResponse,
                         FilterChain filterChain) throws IOException,
                                                         ServletException {
        String requestedSession =
            ((HttpServletRequest)servletRequest).getRequestedSessionId();
        String currentWebSession =
            ((HttpServletRequest)servletRequest).getSession().getId();
        String requestURI =
            ((HttpServletRequest)servletRequest).getRequestURI();
        boolean sessionOk =
            currentWebSession.equalsIgnoreCase(requestedSession);
        System.out.println("currentWebSession == requestedSession? : " +
sessionOk);
        if (!sessionOk && requestedSession != null) {
            ((HttpServletResponse)servletResponse).sendRedirect(requestURI);
            System.out.println("redirecting to : " + requestURI);
        } else {
            filterChain.doFilter(servletRequest, servletResponse);
            System.out.println("session is OK");
        }
    }

    public void destroy() {
        _filterConfig = null;
    }
}
```

The code essentially compares the value of the session IDs. If the IDs do not match, then a redirect executes to the page that is determined by the `getRequestURI()`. Otherwise, the request is handled normally.

The following is how the servlet filter is registered with the application through the `web.xml` file:

```
<filter>
 <filter-name>AppSessionExpiryFilter</filter-name>
   <filter-class>ateam.sample.SessionExpiryFilter</filter-class>
 </filter>
<filter-mapping>
  <filter-name>AppSessionExpiryFilter</filter-name>
   <servlet-name>Faces Servlet</servlet-name>
</filter-mapping>
```

Note: Both the popup and inactive session error messages can be easily managed. However, since WebCenter ADF is an application framework, once the session has been timed out (invalidated), the state of the application is lost as well. This means any managed beans, ADF bindings, and so on, is reset to the initial state. In addition, any information that was being persisted in a managed bean is also lost.

5.12.2 Customizing the Session Timeout Default Message

To customize the session timeout default messages, you need to customize the default strings provided in the out-of-the-box session timeout popups. The steps to create custom resource strings, which will override the default values, are detailed in this section.

The default session timeout messages are shown in Figure 5–30 and Figure 5–31.

All the text-based resource strings (for example, Expiration Warning, and so on) are customizable. These resource strings are contained in a bundle (`RichBundle.java`), which is declared in the skin (`CSS`). In order to override the defaults, a custom resource bundle must be created and then declared in a custom skin.

Note: The custom skin declaration in the `trindad-skins.xml` should also declare to extend the default skin, so the other default resource strings can be picked up.

Example 5–3 is an example of the `trinidad-skins.xml`, which declares the custom resource bundle:

Example 5–3 Custom Resource Bundle in trinidad-skins.xml

```
<?xml version="1.0" encoding="windows-1252" ?>
<skins xmlns="http://myfaces.apache.org/trinidad/skin">
  <skin>
    <id>myskin.custom.desktop</id>
    <family>myskindemo</family>
    <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
    <style-sheet-name>css/myskindemo.css</style-sheet-name>
    <extends>fusionFx-v1.desktop</extends>
    <bundle-name>com.ateam.view.MyBundleOverride</bundle-name>
  </skin>
</skins>
```

After the skin is declared and selected in the `trinidad-skins.xml`, the last step is to create the resource bundle file that will hold the custom strings.

For this example, a java-based version for declaring the strings in the resource bundle is created. There are also other ways to declare the strings (for example, `.properties` and `.xliff`).

After the configuration to override the default bundle is done, the next step is to declare the strings themselves.

The five default resource strings used are as follows:

```
af_document.PRE_SESSION_TIMEOUT_CONFIRM_TITLE = Expiration Warning

af_document.PRE_SESSION_TIMEOUT_MSG = This page will expire unless a
response is received within {0} minutes. Click OK to prevent expiration.

af_document.PRE_SESSION_TIMEOUT_MSG_SECOND = This page will expire unless
a response is received within {0} seconds. Click OK to prevent expiration.

af_document.POST_SESSION_TIMEOUT_MSG = The page has expired af_
document.POST_SESSION_TIMEOUT_MSG_CONTINUE = Click OK to continue.

af_document.POST_SESSION_TIMEOUT_ALERT_TITLE = Page Expired
```

Example 5–4 shows an example of `MyBundleOverride.java`, which contains the custom resource strings.

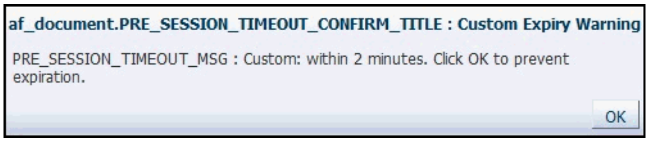
Example 5–4 Example of Custom Resource Strings

```
public class MyBundleOverride extends ListResourceBundle {
    @Override
    public Object[][] getContents() {
        return _CONTENTS;
    }

    static private final Object[][] _CONTENTS =
    {
      { "af_document.PRE_SESSION_TIMEOUT_CONFIRM_TITLE",
        "af_document.PRE_SESSION_TIMEOUT_CONFIRM_TITLE : Custom Expiry Warning" },
      { "af_document.PRE_SESSION_TIMEOUT_MSG",
        "PRE_SESSION_TIMEOUT_MSG : Custom: within {0} minutes. Click OK to prevent
expiration." },
      { "af_document.PRE_SESSION_TIMEOUT_MSG_SECOND",
        "PRE_SESSION_TIMEOUT_MSG_SECOND : Custom: This page will expire unless a
response is received within {0} seconds. Click OK to prevent expiration." },
      { "af_document.POST_SESSION_TIMEOUT_MSG",
        "POST_SESSION_TIMEOUT_MSG : This is a custom message from MyOverride
Bundle" },
      { "af_document.POST_SESSION_TIMEOUT_MSG_CONTINUE",
        "POST_SESSION_TIMEOUT_MSG_CONTINUE : Custom continue Message" },
      { "af_document.POST_SESSION_TIMEOUT_ALERT_TITLE",
        "POST_SESSION_TIMEOUT_ALERT_TITLE : Custom Page Expired Title" }
      };
}
```

Based on the examples provided in this section, the customized messages before and after a session timeout appear, as shown in Figure 5–33 and Figure 5–34:

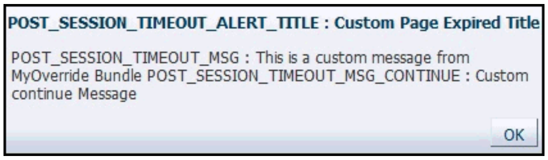
Figure 5–33   Custom Warning Message Before Timeout



af_document.PRE_SESSION_TIMEOUT_CONFIRM_TITLE : Custom Expiry Warning

PRE_SESSION_TIMEOUT_MSG : Custom: within 2 minutes. Click OK to prevent expiration.

Figure 5–34   Custom Message After Timeout



POST_SESSION_TIMEOUT_ALERT_TITLE : Custom Page Expired Title

POST_SESSION_TIMEOUT_MSG : This is a custom message from MyOverride Bundle POST_SESSION_TIMEOUT_MSG_CONTINUE : Custom continue Message

Tip: Clear the browser cache if you cannot view the updated strings.

5.13 Basic Portal Development Tasks

This section lists some of the basic tasks involved with developing Portal Framework applications.

- Set up an integrated team development environment with source control, a common database, and common content repository.
- Create a Portal Framework application using the WebCenter Portal Framework Application template.
- Design the overall structure of your portal, sketching out the top level pages and sub pages that will comprise your portal.
- Consider security for your portal. Decide which pages users will be allowed to visit. Create appropriate roles to accommodate these decisions.
- Begin thinking about your portal's overall look and feel, and begin working on a page template.
- Consider which WebCenter Portal features you want to include in your portal. For example, do you want to add a wiki or a blog or an activity stream? See Section 4.1, "Understanding WebCenter Portal Tools and Services."
- Create pages based on your overall portal structure. The pages can be blank at this point, but creating them now allows you to begin assembling the page hierarchy.

- Create a page hierarchy using the Page Hierarchy editor.
- Create a navigation model. Think about the kinds of resources you want users to be able to navigate to. Examples include pages, external URLs, task flows, and content folders.
- Add navigation UI to the page template. Oracle WebCenter Portal Framework provides several options for navigation UI. The most commonly used option is to use EL directly in the page template. WebCenter also provides navigation task flows and a Java API for navigation.
- Begin applying security policies to the page hierarchy. Start by applying policies to the root node of the hierarchy. Those policies will be inherited by all other pages in the hierarchy. Then, fine-tune the security settings on individual pages or on sub-branches of the overall hierarchy.
- Work on the pages themselves, adding and configuring portlets, task flows, content, and other features.

6 Creating WebCenter Portal Framework Applications

This chapter explains how to create a new WebCenter Portal Framework application and discusses the organization and contents of a Portal Framework application workspace in JDeveloper.

This chapter includes the following topics:

- Section 6.1, "Creating a New WebCenter Portal Framework Application"
- Section 6.2, "Understanding the WebCenter Portal Framework Application Template"
- Section 6.3, "Building a Portal"
- Section 6.4, "Understanding the PortalWebAssets Project"
- Section 6.5, "How Is Framework Application Security Configured by Default?"
- Section 6.6, "What Configuration Files Should I Know About?"
- Section 6.7, "Adding Excluded Files to the Application Navigator"
- Section 6.8, "Developing Framework Portal Applications for High Availability"
- Section 6.9, "Securing the Portal"

6.1 Creating a New WebCenter Portal Framework Application

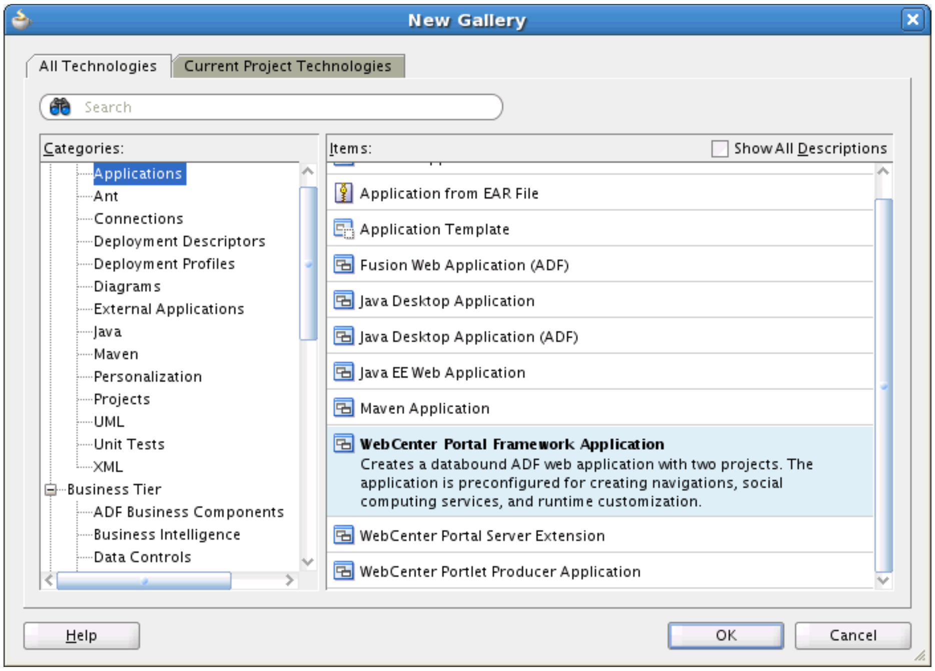
This section explains how to use the Create WebCenter Portal Framework Application wizard to create a new portal.

1. Access the application creation wizard. JDeveloper provides several ways for you to access this wizard. For example:

    - From the **File** menu, choose **New**. In the New Gallery dialog, expand **Applications**, select **WebCenter Portal Framework Application**, and click **OK**. For example, see Figure 6–1.

    > **Note:** When you select **WebCenter Portal Framework Application**, you are selecting an application *template* that populates the application with a pre-defined set of projects and files. For more information about this template, see Section 6.2, "Understanding the WebCenter Portal Framework Application Template."

Figure 6–1 New Gallery Dialog



Creates a databound ADF web application with two projects. The application is preconfigured for creating navigations, social computing services, and runtime customization.

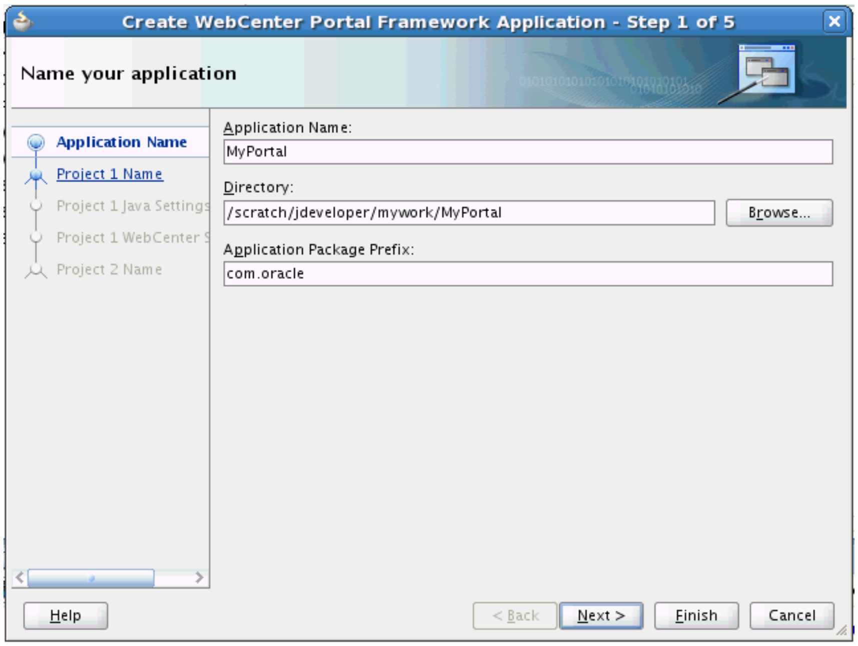
- From the Application menu, select **New**. In the dialog select **WebCenter Portal Framework Application**.
- If you have an existing application that is open, in the Application Navigator, right-click **<*Application-Name*>** and choose **New**. In the New Gallery dialog, expand **Applications**, select **WebCenter Portal Framework Application**, and click **OK**.
- If you have an existing application that is open, in the Application Navigator, from the **<*Application-Name*>** drop down menu, select **New Application**. In the New Gallery dialog, expand **Applications**, select **WebCenter Portal Framework Application**, and click **OK**.

Note: At this point, you are on the first page of the Create WebCenter Portal Framework Application wizard. The wizard includes five pages, which are explained in the following steps.

---

2. Enter a name for the application in the **Application Name** field, as shown in Figure 6–2.

Figure 6–2 Create WebCenter Portal Framework Application Wizard Step 1 of 5



Application Name: MyPortal

Directory: /scratch/jdeveloper/mywork/MyPortal

Application Package Prefix: com.oracle

3. In the **Directory** field, enter a path to the directory where you wish to store the application, or accept the default path.

   For example:

   ```
   C:\JDeveloper\mywork\Application1
   ```

   Optionally, click the **Browse** button to navigate to the desired directory.

4. If required, in the **Application Package Prefix** field, enter a prefix to use for packages created within this application.

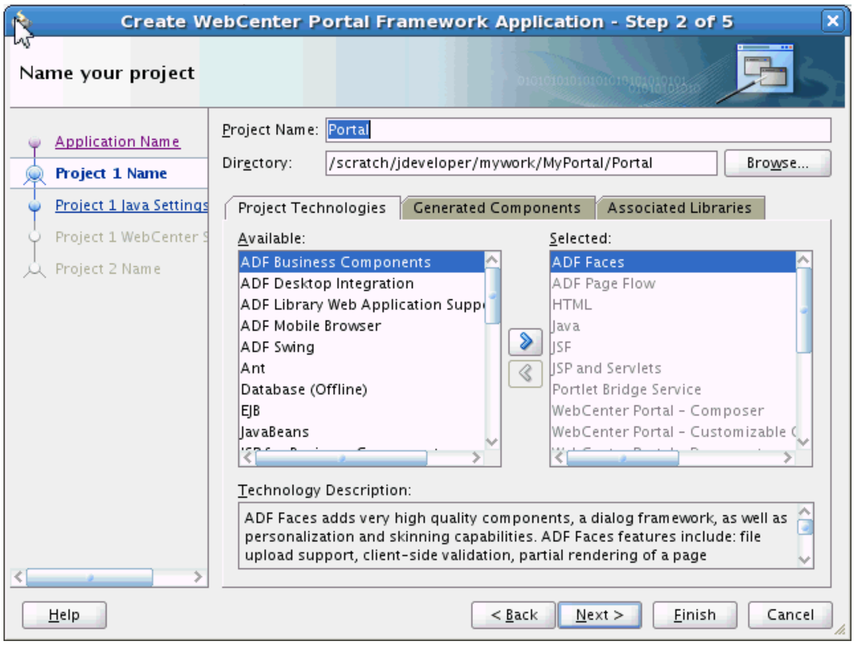
   Note: Depending on how you launched the wizard, you might see an Application Template list. If you do see this list, make sure **WebCenter Portal Framework Application** is selected.

   Tip: At this point, you could click **Finish** to create a project with default Framework features, including page hierarchies and navigations. We'll continue and review the rest of the wizard pages.

5. Click **Next**.

6. Enter a project name, as shown in Figure 6–3.

Figure 6–3 Create WebCenter Portal Framework Application Wizard Step 2 of 5



Create WebCenter Portal Framework Application - Step 2 of 5

Name your project

Project Name: Portal

Directory: /scratch/jdeveloper/mywork/MyPortal/Portal

Available:
- ADF Business Components
- ADF Desktop Integration
- ADF Library Web Application Supp
- ADF Mobile Browser
- ADF Swing
- Ant
- Database (Offline)
- EJB
- JavaBeans

Selected:
- ADF Faces
- ADF Page Flow
- HTML
- Java
- JSF
- JSP and Servlets
- Portlet Bridge Service
- WebCenter Portal - Composer
- WebCenter Portal - Customizable C

Technology Description:

ADF Faces adds very high quality components, a dialog framework, as well as personalization and skinning capabilities. ADF Faces features include: file upload support, client-side validation, partial rendering of a page

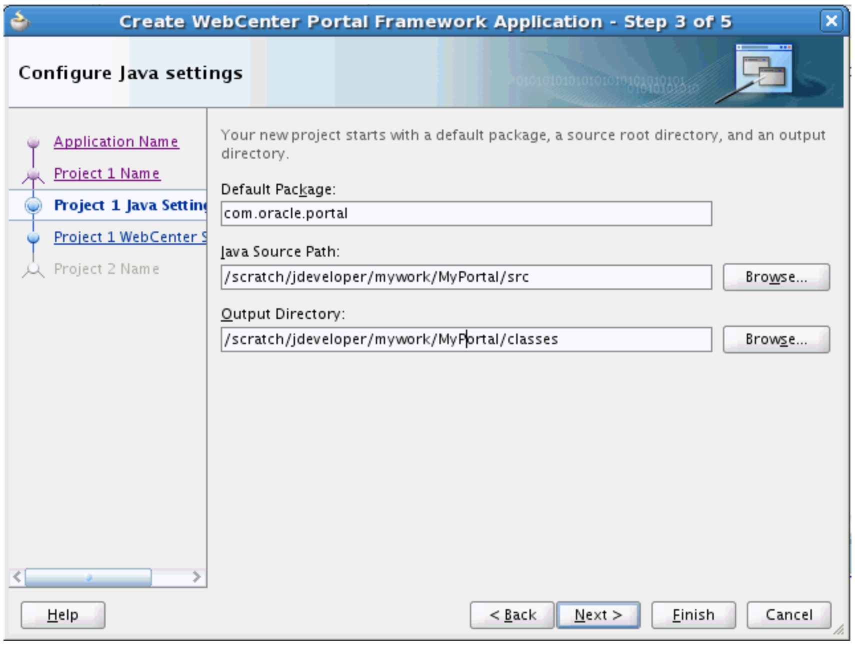
7. Enter a directory in which to place the project, or use the **Browse** button to select a directory.

8. If you wish, select the **Generated Components** and **Associated Libraries** tabs to view additional configuration files and libraries that will be added to the project. For more information, see Section 6.6, "What Configuration Files Should I Know About?"

9. Click **Next**.

10. If you wish, enter a Default Package name and directories for the default Java source files and output class files, as shown in Figure 6–4.

Figure 6–4 Create WebCenter Portal Framework Application Wizard Step 3 of 5



Create WebCenter Portal Framework Application - Step 3 of 5

Configure Java settings

Your new project starts with a default package, a source root directory, and an output directory.

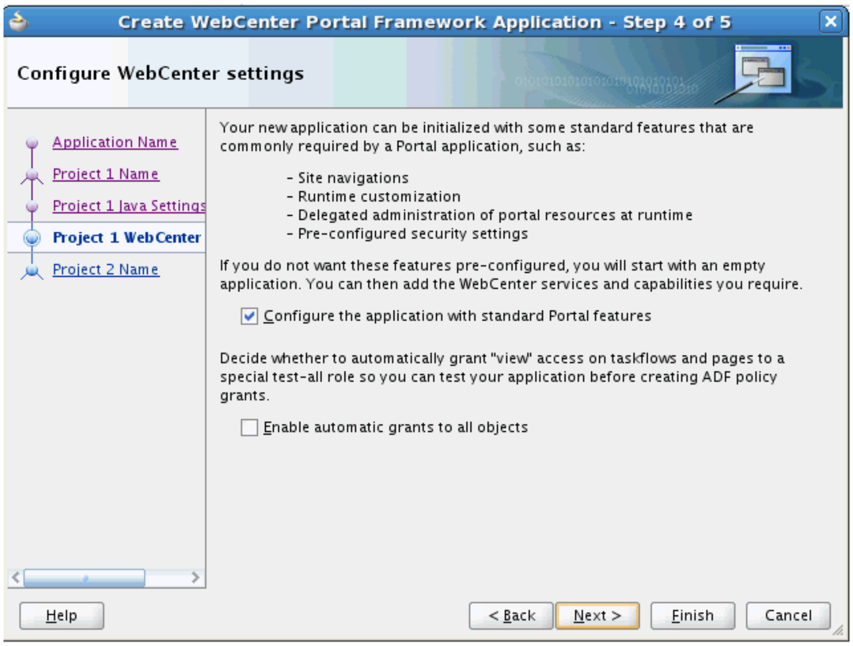
Default Package: com.oracle.portal

Java Source Path: /scratch/jdeveloper/mywork/MyPortal/src

Output Directory: /scratch/jdeveloper/mywork/MyPortal/classes

11. In the next wizard page, two check boxes appear, as shown in Figure 6–5. Generally, the default settings are recommended; however, see the following note for more information on this wizard page.

Figure 6–5 Create WebCenter Portal Framework Wizard Step 4 of 5



Create WebCenter Portal Framework Application - Step 4 of 5

Configure WebCenter settings

Your new application can be initialized with some standard features that are commonly required by a Portal application, such as:

- Site navigations
- Runtime customization
- Delegated administration of portal resources at runtime
- Pre-configured security settings

If you do not want these features pre-configured, you will start with an empty application. You can then add the WebCenter services and capabilities you require.

☑ Configure the application with standard Portal features

Decide whether to automatically grant "view" access on taskflows and pages to a special test-all role so you can test your application before creating ADF policy grants.

☐ Enable automatic grants to all objects

Note: If you want your application to include the features of Oracle WebCenter Portal Framework, like page hierarchies and navigations, leave the first box checked (**Configure the application with standard Portal features**). If you uncheck this box, the result is that you will create a traditional Oracle Fusion Web Application that does not contain Framework features.

Oracle recommends that you leave the first checkbox selected, unless you know for sure that you do not want to use the Oracle WebCenter Portal Framework features.

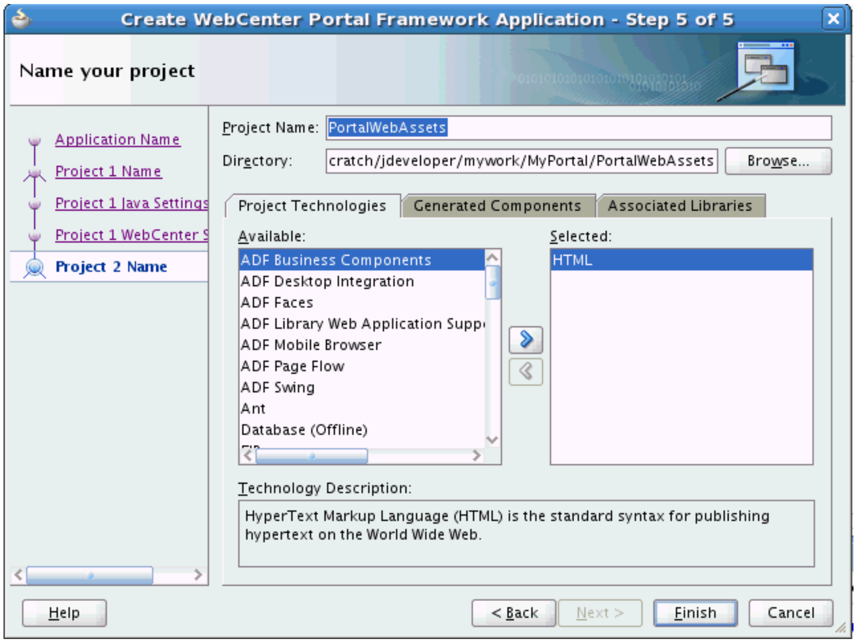
The second checkbox, **Enable automatic grants to all objects**, allows you to create a special role called test-all with View access on all taskflows and pages. This option is primarily added to make testing the application easier. It is unchecked by default.

---

12. Click **Next**.

13. In the final wizard page you are given a chance to configure the static application resources project. By default, this project is called PortalWebAssets. The project includes static application resources like HTML and image files. By separating the static resources into a separate project, it is possible to deploy those resources to a dedicated server. See For more information, see Section 6.4, "Understanding the PortalWebAssets Project."

Figure 6–6 Create WebCenter Portal Framework Application Wizard Step 5 of 5



Create WebCenter Portal Framework Application - Step 5 of 5

Name your project

Project Name: PortalWebAssets

Directory: cratch/jdeveloper/mywork/MyPortal/PortalWebAssets

Selected: HTML

Technology Description:

HyperText Markup Language (HTML) is the standard syntax for publishing hypertext on the World Wide Web.

14. Click **Finish** to create the WebCenter Portal Framework application.

6.2 Understanding the WebCenter Portal Framework Application Template

To readily find and use the appropriate components in your WebCenter Portal Framework application, you must ensure that the right technology scopes are set, tag libraries added, and required Java classes are added to the class path. Once you do this, relevant components are included in the Component Palette and relevant context menus become available in JDeveloper.

Fortunately, Oracle provides an out-of-the-box application template to ensure that scopes are set properly and the right tag and Java libraries are added to create WebCenter Portal Framework applications.

The **WebCenter Portal Framework Application** template populates the application with a *portal project* and a *static application resources* project. The portal project includes features like site navigation, page hierarchies, delegated administration, security, page templates, and runtime customization. A Framework application can consume portlets, incorporate content management services, and include WebCenter social computing services. The static application resources project includes static application resources like HTML and image files. By default, this project is called PortalWebAssets. By separating the static resources into a separate project, it is possible to deploy those resources to a dedicated server. See Section 6.1, "Creating a New WebCenter Portal Framework Application" and Section 6.4, "Understanding the PortalWebAssets Project."

> **Note:** In addition to populating the application with default files and folders, the template populates the Resource Palette with the **WebCenter Portal – Framework Catalog** and the **WebCenter Portal – Services Catalog**. The Services Catalog contains data controls and task flows that you can use to integrate WebCenter Portal tools and services in your application. The Framework Catalog contains a collection of components that are most commonly used for building portals. For more information see Chapter 14, "Developing Resource Catalogs."

6.3 Building a Portal

After you have created a new Portal Framework workspace, you can begin setting up navigation, adding pages, developing the look and feel, adding content, and working with other features or "assets." For a general overview of portal features, see Chapter 5, "Understanding WebCenter Portal Framework Applications." For more information on adding features to a portal, see Chapter 9, "Introduction to Portal Resource Management."

6.4 Understanding the PortalWebAssets Project

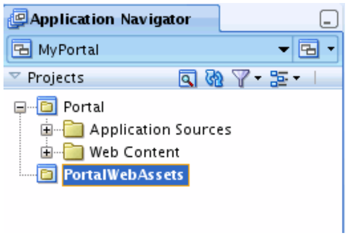
This section discusses the PortalWebAssets project. If you wish, you can place static resources like HTML files and images in this project. The PortalWebAssets project is created, by default, in new Portal Framework applications.

- Section 6.4.1, "Introduction"
- Section 6.4.2, "Decoupling the Static Application Resources Project"
- Section 6.4.3, "Deployment Options"
- Section 6.4.4, "Using EL to Manage Static Resources"

6.4.1 Introduction

Static resources for a web application, like HTML and image files, are typically bundled and deployed with the application. Requests for both dynamic and static resources are generally handled by the host application server. One way to optimize server performance is to separate the static resources from the application and deploy them on a different (possibly less expensive and more scalable) server. Portal Framework applications support this scenario with a static application resources project, which can include static resources like HTML and images. By default, this project is called PortalWebAssets, but you can rename the project if you wish. See Figure 6–7.

Figure 6–7 The PortalWebAssets Folder



To use the static resources project, simply add content (like HTML or image files) to the project. You can do this directly from the file system, by adding files under the `../PortalWebAssets/public_html` directory, or by adding in JDeveloper. For instance, to add an HTML file, select **New** from the File menu, and use the New Gallery wizard to create the resource.

> **Note:** CSS files used for skins must remain in the Portal Framework application project. Do not attempt to place skin CSS files in the static application resources project.

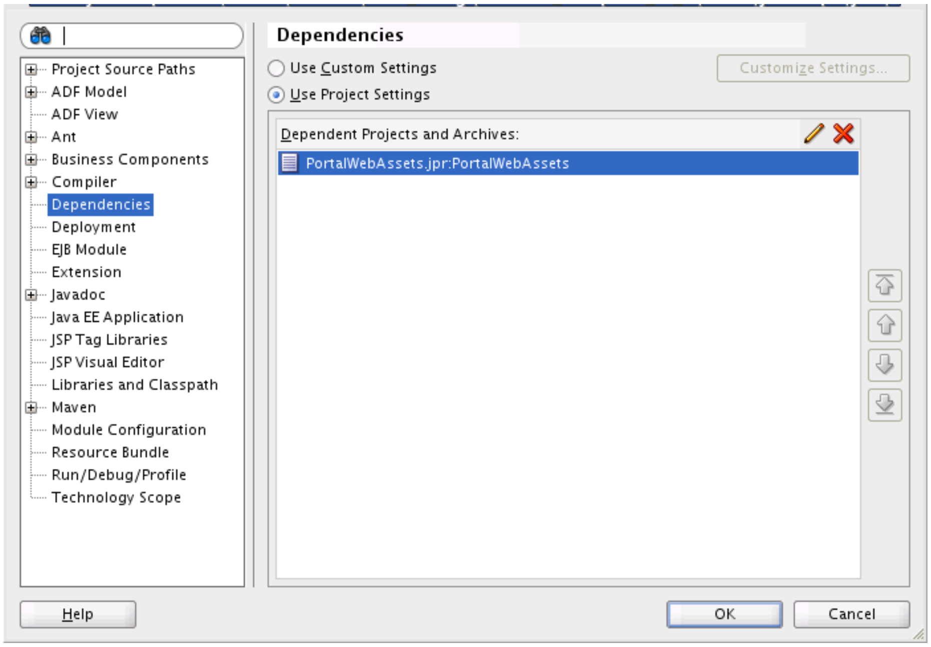
6.4.2 Decoupling the Static Application Resources Project

By default, a portal project includes the static application resources project (PortalWebAssets) as a dependency. This means they are built together and deployed to the same server. If you do not wish to deploy static resources to another server, then you do not need to take any action with respect to the static resources project.

If you wish to decouple the PortalWebAssets project from the Portal project, do the following:

1. Right-click the Portal project and select **Project Properties**.
2. In the Project Properties dialog, select the **Dependencies** node, as shown in Figure 6–8.

Figure 6–8 Project Dependencies Dialog



Dependencies

○ Use Custom Settings

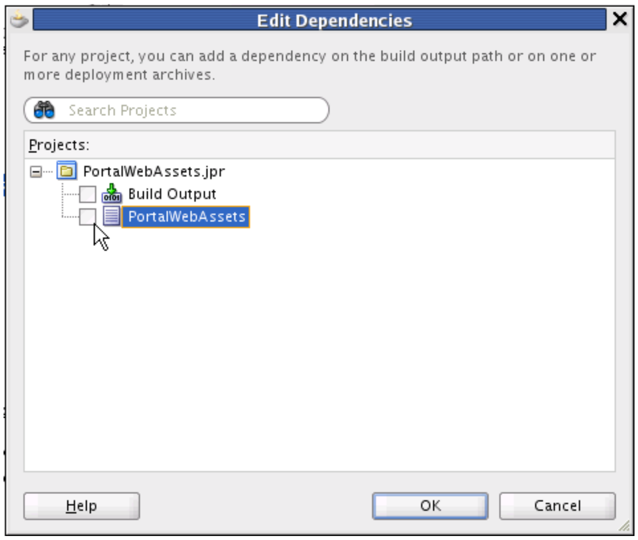
● Use Project Settings

Dependent Projects and Archives:

PortalWebAssets.jpr:PortalWebAssets

3. To remove the dependency, click the **Delete** button, or select the **Edit** button and deselect the project in the Edit Dependencies dialog, as shown in Figure 6–9.

Figure 6–9 The Edit Dependencies Dialog



Edit Dependencies

For any project, you can add a dependency on the build output path or on one or more deployment archives.

Projects:

PortalWebAssets.jpr

□ Build Output

□ PortalWebAssets

4. Generate two distinct archives (`Portal.ear` and `PortalWebAssets.jar`), and deploy them to separate servers. See Section 6.4.3, "Deployment Options."

6.4.3 Deployment Options

The `Portal.ear` file is typically deployed to the application's managed server. The `PortalWebAssets.jar` file can be deployed to any J2EE compliant server container, usually by creating a WAR deployment profile in the PortalWebAssets project and including it in an EAR deployment profile. Another, simpler, option is to unzip the JAR file into an Apache web server. See also Chapter 7, "Deploying and Testing Your

Portal Framework Application."

6.4.4 Using EL to Manage Static Resources

Developers can use EL expressions to dynamically generate the target URL for static resources. You have two options for using EL. With the first option, you need to define a base URL preference. The second allows you to map URLs dynamically.

6.4.4.1 Defining a Base URL Preference

This solution provides a single preference that uses a "base" URL to redirect resources to a desired server. With this option, EL expressions take a format that is illustrated by the following sample:

```
<af:image source="#{preferenceBean.baseResourceURL}/images/globe.png"/>
```

To configure this option, add a preference to the `adf-config.xml` file as follows:

```
<portal:preferences>
...
    <portal:preference id="oracle.webcenter.portalapp.baseresourceurl"
        desc="Default Base Resource URL EL"
        value=
       "#{request.scheme}://#{request.serverName}:#{request.serverPort}#{request.contextPath}"
       resourceType="BaseResourceURL" display="true"
    />
...
</portal:preferences>
```

The only limitation of this technique is that you can only map values to one server. There is only one preference value that can be returned. If you want to dynamically configure URLs, choose the technique described in the next section, Section 6.4.4.2, "Mapping URLs Dynamically."

6.4.4.2 Mapping URLs Dynamically

This solution lets you construct URLs dynamically through the ability to specify multiple namespaces. With this option, resources become a parameter to the preference, allowing the resources to be mapped to the correct namespace.

This solution supports two ADF component categories:

The first category includes static resources referenced by ADF Faces components. This type of call is illustrated by the following sample:

```
<af:image
source="#{preferenceBean.staticResourceURL['/oracle/webcenter/portalapp/static/ima
ges/globe.png']}"/>
```

The second category includes static resources referenced through the `inlineStyle` of ADF Faces components. This type of call is illustrated by the following sample:

```
<af:panelBorderLayout id="pt_pgl1"
inlineStyle='background-image:url(#{preferenceBean.staticResourceURL["/oracle/webc
enter/portalapp/static/images/globe.png"]});'>
```

The EL expression:

```
#{preferenceBean.staticResourceURL['<resource path>']}
```

performs a resource namespace lookup to derive the resource URL prefix. The input to the lookup is the path of the resource (for example:

/oracle/webcenter/portalapp/static/images/globe.png). To establish the mappings between resource namespaces and URLs, edit the <portal:resource-mappings> section of the adf-config.xml file.

To configure this option, add a preference to the adf-config.xml file as follows:

```
<portal:adf-portal-config>
    <portal:preferences>
    ...
    </portal:preferences>
    <portal:resource-mappings>
        <portal:resource-mapping path="/"
 url-prefix="#{request.scheme}://#{request.serverName}:#{request.serverPort}#{request.contextPath}"
       />
    </portal:resource-mappings>
</portal:adf-portal-config>
```

The lookup yields the prefix of the resource URL. The final value of the resource URL is derived by concatenating the URL prefix with the path to the resource. For example,

```
/oracle/webcenter/portalapp/static/images/globe.png
```

yields:

```
http://myserver/static_resources/oracle/webcenter/portalapp/static/images/globe.png
```

At development time, the url-prefix lookup always resolves to the application's context URL, for example: http://<server>:<port>/<context root>.

Example 6–1 shows a sample mapping configuration in adf-config.xml:

Example 6–1 Sample Namespace Lookup Mapping

```
<portal:adf-portal-config>
    <portal:preferences>
    ...
    </portal:preferences>
    <portal:resource-mappings>
        <portal:resource-mapping path="/oracle/webcenter/portalapp/static"
            url-prefix="http://myserver/static_resources"/>
        <portal:resource-mapping path="/mycompany/static/images"
            url-prefix="http://myserver/static_resources"/>
        <portal:resource-mapping path="/mycompany/myapp/static/images"
            url-prefix="http://myserver/static_resources/myapp2"/>
    </portal:resource-mappings>
</portal:adf-portal-config>
```

6.5 How Is Framework Application Security Configured by Default?

By default, a WebCenter Portal Framework application is configured with ADF security.

Default login and logout pages are also provided with the WebCenter Portal Framework Application template.

For more information on ADF security, see Chapter 74, "Securing Your WebCenter Portal Framework Application." See also the *Enabling ADF Security in a Fusion Web Application* section in the *Fusion Developer's Guide for Oracle Application Development Framework*.

6.6 What Configuration Files Should I Know About?

A number of automatically generated configuration files are placed under the WEB-INF and Page Flows folders of a portal project when you create a Portal Framework application.

This section briefly describes these file:

- Section 6.6.1, "The Framework Application Template Default web.xml File"
- Section 6.6.2, "The Framework Application Template Default faces-config.xml File"
- Section 6.6.3, "The Framework Application Template Default trinidad-config.xml File"
- Section 6.6.4, "The Framework Application Template Default adfc-config.xml File"

6.6.1 The Framework Application Template Default web.xml File

Part of Portal Framework application configuration is determined by the content of its Java EE application deployment descriptor file: web.xml. The web.xml file defines many application settings that are required by the application server.

> **Note:** Rather than being specified in web.xml, the context root path is assigned when the application is deployed.

Typical runtime settings include initialization parameters, custom tag library location, and security settings. Depending on the technology you use, other settings may be added to web.xml as appropriate.

> **Note:** For standard Java EE files like web.xml, there is usually a counterpart Oracle-specific file with additional Oracle-specific options, for example, weblogic.xml.

The web.xml file is located in the /public_html/WEB-INF directory relative to the project in your Portal Framework application.

When you first create your Portal Framework application, configuration settings for JSF servlet and mapping and for resource servlet and mapping are automatically added to the starter web.xml file.

The Faces Servlet entry inside <servlet></servlet> tags provides information about the JSF servlet, javax.faces.webapp.FacesServlet. This servlet manages the request processing life cycle for web applications that use JSF to construct the user interface. The configuration setting maps the JSF servlet to a symbolic name, *Faces Servlet*.

The resources entry inside <servlet></servlet> tags provides information about the ADF resource servlet used to serve up web application resources (images, style sheets, JavaScript libraries) by delegating to a ResourceLoader.

The <servlet-mapping></servlet-mapping> tags map the URL pattern to a servlet's symbolic name. You can use either a path prefix or an extension suffix pattern.

By default, JDeveloper uses the path prefix /faces/*. That is, when a URL, for example, http://localhost:8080/SRDemo/faces/index.jsp, is issued, the URL activates the JSF servlet, which strips off the faces prefix and loads the file /SRDemo/index.jsp.

Note: If you prefer to use the extension `jsf` for web pages instead of `jsp` or `jspx`, then you must set the `javax.faces.DEFAULT_SUFFIX` context parameter to `jsf`, for example:

```
<context-param>
   <param-name>javax.faces.DEFAULT_SUFFIX</param-name>
   <param-value>.jsf</param-value>
</context-param>
```

Then add a servlet mapping in `web.xml` that invokes the JSP servlet for files with the extension `jsf`.

To edit `web.xml` in Oracle JDeveloper, right-click `web.xml` in the Application Navigator and choose **Open** from the context menu. This opens `web.xml` in the Web Application Deployment Descriptor editor, in Overview mode. If you are familiar with configuration element names, then you can also use the XML editor to modify `web.xml`.

For information about the configuration elements you can use in the `web.xml` file, see the "Oracle ADF XML Files" section in the *Fusion Developer's Guide for Oracle Application Development Framework.*

6.6.2 The Framework Application Template Default faces-config.xml File

Use the `faces-config.xml` file to register a Portal Framework application's resources, such as custom validators and managed beans, and to define all page-to-page navigation rules. The default name of this file is `faces-config.xml`.

Depending on how resources are packaged, an application can have one or multiple `faces-config.xml` files. For example, you can create individual JSF configuration files for:

- Different areas of your application
- Each library containing custom components or renderers

For more information about creating multiple `faces-config.xml` files, see *Fusion Developer's Guide for Oracle Application Development Framework.*

Example 6–2 illustrates the default `faces-config.xml` file provided through the WebCenter Portal Framework Application template. This file is located in the `/public_html/WEB-INF` directory relative to the project in your Framework application.

Example 6–2 Default faces-config.xml File Provided Through the Framework Application Template

```
<?xml version="1.0" encoding="US-ASCII"?>
<faces-config version="1.2" xmlns="http://java.sun.com/xml/ns/javaee">
  <application>
    <default-render-kit-id>oracle.adf.rich</default-render-kit-id>

<view-handler>oracle.webcenter.portalframework.sitestructure.handler.CustomViewHandler</view-handle
r>
  </application>
  <lifecycle>
    <phase-listener>oracle.webcenter.skin.view.SkinPhaseListener</phase-listener>
  </lifecycle>
  <managed-bean>
    <managed-bean-name>preferenceBean</managed-bean-name>
```

```
<managed-bean-class>oracle.webcenter.portalframework.sitestructure.preference.PortalPreferences</ma
naged-bean-class>
    <managed-bean-scope>application</managed-bean-scope>
  </managed-bean>
  <navigation-rule>
    <from-view-id>*</from-view-id>
    <navigation-case>
      <from-outcome>login_success</from-outcome>
      <to-view-id>/pages_home</to-view-id>
      <redirect/>
    </navigation-case>
    <navigation-case>
      <from-outcome>logout_success</from-outcome>
      <to-view-id>/pages_home</to-view-id>
      <redirect/>
    </navigation-case>
  </navigation-rule>
</faces-config>
```

To edit the `faces-config.xml` file, double-click it in the Application Navigator. By default, the file is opened in the Editor window in *Diagram* mode, as indicated by the active **Diagram** tab at the bottom of the Editor window. When creating or modifying JSF navigation rules, Diagram mode enables you to visually create and manage page flows. For more information, see *Fusion Developer's Guide for Oracle Application Development Framework.*

To create or modify configuration elements other than navigation rules, use the Editor's Overview mode. Enter this mode by clicking the **Overview** tab at the bottom of the Editor window.

JSF allows multiple `<application>` elements in a single `faces-config.xml` file. When you use the JSF Configuration Editor, you can edit only the first instance. For any other `<application>` elements, you must edit the file directly using the XML editor. To use the XML editor, open the `faces-config.xml` file and go to the **Source** tab in the Editor window.

For reference information about the configuration elements you can use in the `faces-config.xml` file, see the "ADF Faces Configuration" section in the *Fusion Developer's Guide for Oracle Application Development Framework.*

6.6.3 The Framework Application Template Default trinidad-config.xml File

The default `trinidad-config.xml` file, available when you create a Portal Framework application, contains information about the application skin family. Additionally, it can contain information about the level of page accessibility support, page animation, time zone, enhanced debugging output, and the URL for Oracle Help for the Web (OHW). Like `faces-config.xml`, the `trinidad-config.xml` file has a simple XML structure that enables you to define element properties using JSF Expression Language (EL) or static values.

Example 6–3 illustrates the default `trinidad-config.xml` file provided through the WebCenter Portal Framework Application template. This file is located in the `/public_html/WEB-INF` directory relative to the project in your Framework application.

Example 6–3 Default trinidad-config.xml File Provided Through the Framework Application Template

```
<?xml version="1.0" encoding="US-ASCII"?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">

  <skin-family>#{preferenceBean.defaultTrinidadSkin}</skin-family>
  <skin-version>v1</skin-version>
</trinidad-config>
```

In addition to the skin family, you can define the following application values in the `trinidad-config.xml` file:

- Page animation
- Level of page accessibility support
- Time zone
- Enhanced debugging output
- Oracle Help for the Web (OHW) URL

For reference information about the `trinidad-config.xml` file, see the "ADF Faces Configuration" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

6.6.4 The Framework Application Template Default adfc-config.xml File

The `adfc-config.xml` file is the configuration file for an ADF unbounded task flow. This file contains metadata about the activities and control flows contained in the unbounded task flow. The default name for this file is `adfc-config.xml`.

If **ADF Page Flow** is specified as a Selected Technology on the Technology Scope page of the Project Properties dialog, a new `adfc-config.xml` source file is automatically created within the project. The `adfc-config.xml` file is the main source file for an unbounded task flow.

The `adfc-config.xml` file is located in the `/public_html/WEB-INF` directory relative to the project in your Portal Framework application.

> **Note:** If you do not plan to use task flows in your Framework application, you can delete the `adfc-config.xml` file.

For more information about task flows and the `adfc-config.xml` file, see the "Oracle ADF XML Files" section in the *Fusion Developer's Guide for Oracle Application Development Framework.*

6.7 Adding Excluded Files to the Application Navigator

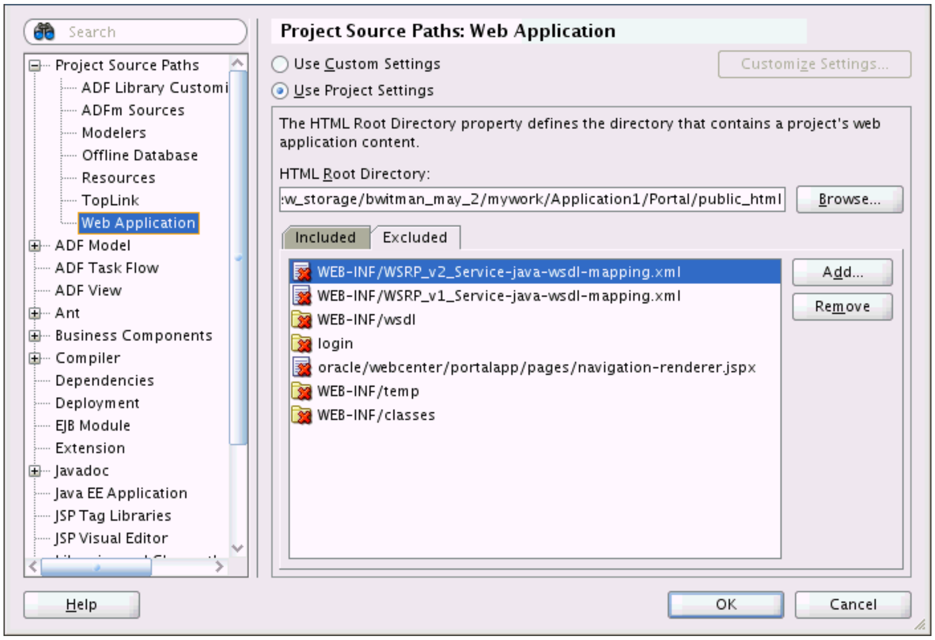
By default, a few files are excluded from view in the Application Navigator. These files are excluded because it is unlikely you'll ever need to edit them. However, because there are potentially some advanced use cases where you might want to edit them, you need to be able to add them back to the JDeveloper UI.

To locate the excluded files:

1. Right-click the project folder and select **Project Properties** from the menu.
2. In the Project Properties dialog, select **Web Application** under the Project Source Paths node.

3. Select the Excluded tab, as shown in Figure 6–10.

Figure 6–10 The Exclude Tab



Project Source Paths: Web Application

○ Use Custom Settings

● Use Project Settings

The HTML Root Directory property defines the directory that contains a project's web application content.

HTML Root Directory: :w_storage/bwitman_may_2/mywork/Application1/Portal/public_html

WEB-INF/WSRP_v2_Service-java-wsdl-mapping.xml
WEB-INF/WSRP_v1_Service-java-wsdl-mapping.xml
WEB-INF/wsdl
login
oracle/webcenter/portalapp/pages/navigation-renderer.jspx
WEB-INF/temp
WEB-INF/classes

4. Select an element from the excluded list and click **Remove** to remove it from the excluded list. As a result, the element is automatically included in the appropriate folder in the Application Navigator.

As an example, the `navigation-renderer.jspx` file is used to render resources in the context of a page template. If you wanted to change the way an external URL is displayed within a page, you would first remove the `navigation-renderer.jspx` file from the excluded list in order for it to appear under the `pages` folder in the Application Navigator. Then, you could open the page and edit it as desired.

6.8 Developing Framework Portal Applications for High Availability

High availability is very important in large WebCenter installations. It allows users to gracefully switch from one node to another node in the cluster. This allows user to keep their session in case a node goes down.

This section explains some guidelines to keep in mind to fully support an HA environment when implementing Framework Portal applications. Even if you are not implementing with HA in mind, these guidelines may help make your application perform better and with more stability.

The following subsections provide guidelines for implementing for a High Available environment:

- Section 6.8.1, "Introduction to High Availability for WebCenter Portal and JDeveloper"
- Section 6.8.2, "Serializing Managed Beans"
- Section 6.8.3, "Minimizing the Session Footprint"
- Section 6.8.4, "Application Configuration"
- Section 6.8.5, "Mutating Managed Beans"

- Section 6.8.6, "Replication Groups"

6.8.1 Introduction to High Availability for WebCenter Portal and JDeveloper

In order to know how we can implement a solution that supports High Availability (HA) we first need to understand how HA works and how WebLogic handles a fail-over.

Whenever you have configured a cluster of managed server for your application, WebLogic will replicate the HTTP session to a secondary machine. When the primary machine where the session is running on fails, WebLogic will point the user to the secondary machine and the user will be able to continue the work without losing hit data.

WebLogic duplicates those sessions by serializing the objects in the session and than transfers it to the secondary machine. Only the object that are stored in the session will be replicated. From an ADF perspective this means that managed bean with `pageFlowScope` and above will be replicated.

In order for this to work all object in the session need to be serializable. If not, the session cannot completely be replicated which means the user will lose data upon fail-over. WebLogic also need to be notified when the state of an object changes so it can propagate these changes to the secondary machine.

6.8.2 Serializing Managed Beans

One of the key items for a successful HA environment is that all object in the session are serializable. If objects cannot be serializable than WebLogic will not be able to replicate those object to the fail-over server.

ADF UI components are not serializable by design. This means that there are bindings in managed bean with PageFlowScope or SessionScope, the replication will fail.

If there is a need for referencing those UI components in managed bean than we recommend following the ComponentReference pattern which is described in following post: http://www.ateam-oracle.com/rules-and-best-practices-for-jsf-component-binding-in-adf/

In addition to this, if custom objects are referenced in the managed bean, you always have to make sure those objects implement the Serializable interface. If not, replication will fail and the user will lose data upon fail-over.

6.8.3 Minimizing the Session Footprint

The session footprint is an important factor when replicating the session. The bigger the session object is, the more traffic the replication will require to propagate the session to the secondary server.

Therefore it is important to keep track of your session footprint. The session footprint can be tracked with tools like JRockit Mission Control (for JRockit JVM) or VisualVM (for Hotspot JVM).

A session footprint of 3MB is considered very high in an ADF application. The reasons for a large footprint can be any of the following:

- Referencing UI components in a managed bean using `pageFlowScope` or above
- Referencing large data sets (View Objects) in managed beans using `pageFlowScope` or above

In order to minimize the footprint some design considerations can take place. When putting large objects in managed beans you always need to ask yourself the following question: Does the object really need to be stored in the `pageFlowScope`? Is `ViewScope` or `RequestScope` not enough? In a lot of the cases `ViewScope` will be sufficient.

Even if you need to pass on information from one view to another you still can use techniques like contextual events or passing parameters instead of storing an entire object in the session.

Lowering the session footprint will not only help in an HA environment. It will also help to optimize the heap size of the JVM. This will allow more users on the node than when a non-optimized implementation is used.

6.8.4 Application Configuration

In order for the application to work in a fail-over environment, we need to tell the application that it needs to behave like an HA application.

This need to be done in two files: `weblogic.xml` and `adf-config.xml`:

weblogic.xml

In order to enable support for session replication you need to tell WebLogic to replicate the persistent store in a clustered environment. This can be done with following code:

```
<weblogic-web-app>
    <session-descriptor>
    <persistent-store-type>
    replicated_if_clustered
    </persistent-store-type>
    </session-descriptor>
</weblogic-web-app>
```

adf-config.xml

In order for HA to work in an ADF environment we need to tell the controller to replicate the beans in `pageFlowScope` and `ViewScope`. This can be done by setting `adf-scope-ha-support` to `true`:

```
<adf-controller-config xmlns="http://xmlns.oracle.com/adf/controller/config">
 <adf-scope-ha-support>true</adf-scope-ha-support>
</adf-controller-config>
```

Business components

Business components also need some additional configurations in order to support HA:

```
jbo.dofailover='true'
jbo.ampooling='true'
```

6.8.5 Mutating Managed Beans

Managed beans with a scope higher than RequestScope (`ViewScope`, `pageFlowScope`) need to be propagated on the secondary node. The controller won't know automatically when those managed beans are changed.

Whenever you make changes in a managed bean and those changes need to be replicated, you need to notify the controller so it can make sure the updated value of the bean will be passed on the secondary node.

This can be done using the following code:

```
Map<String, Object> viewScope =
    AdfFacesContext.getCurrentInstance().getViewScope();
controllerContext ctx = ControllerContext.getInstance();
ctx.markScopeDirty(viewScope);
```

6.8.6 Replication Groups

Within an HA environment, each session will be replicated to a second node. Not all nodes in the cluster will have all of the session. This is to save network overhead and performance.

In order to have the best possible outcome, WebLogic will automatically replicate the session to a different machine than the current node. This is safe because if the machine fails, the session is available on a different machine.

If you have a big cluster with many machines it is possible that those machines are set up in different data centers. Therefore, WebLogic allows you to configure replication groups. Those are configured in order to tell WebLogic which secondary machine to use for each machine.

In order to configure the replication group you need to configure the cluster settings in the WebLogic console as shown in Figure 6–11:

6.9 Securing the Portal

You can define security for an entire portal, a collection of pages and sub-pages, or a single page. You can define security for individual custom components and actions provided by customizable components. In addition, for Oracle WebCenter Portal tools and services that connect to back-end servers using web services, you can provide secure identity propagation with WS-Security.

Because Oracle WebCenter Portal security is based on the JAAS and J2EE standards, enterprise roles defined in the existing identity management store can be leveraged directly when securing a Portal Framework application. You need not synchronize roles within the portal being built. It just references and uses the defined users and roles directly. Note also that you can use file-based security for the development phase of the portal and then easily switch over to enterprise identity management at deployment time.

Oracle WebCenter Portal also provides application roles that you can use to represent the policy of a portal. By associating permissions with an application role defined within the policy store, you can keep them self contained within the portal. On deployment, you can then associate users and enterprise roles with the application roles to grant those permissions to end users.

In some cases, it is desirable to leverage existing portals that have their own authentication mechanism, such as email. The email system is often on a different authentication system (with different user names and passwords) than the portal. The portal must map the email user to the portal user such that end users do not have to enter their user names and passwords each time they need information. Oracle WebCenter Portal Framework provides the means to securely manage these user names and passwords with the External Application functionality.

For more information about options for securing your Portal Framework application, see Chapter 74, "Securing Your WebCenter Portal Framework Application."

7 Deploying and Testing Your Portal Framework Application

This chapter describes how to run, deploy, and test Portal Framework applications using the Integrated WebLogic Server (IntegratedWebLogicServer), and how to deploy your applications from JDeveloper to a WebLogic Managed Server.

This chapter includes the following topics:

- Section 7.1, "Introduction to Oracle WebLogic Servers"
- Section 7.2, "Deploying a Portal Framework Application to the Integrated WebLogic Server"
- Section 7.3, "Deploying a Portal Framework Application to a WebLogic Managed Server"
- Section 7.4, "Transporting Customizations Between Environments"

Note: For information about deploying Oracle WebCenter Portal Personalization files, see Section 66.3, "Deploying Personalization Files." For information about deploying Portal Framework applications through other mechanisms, such as Oracle Enterprise Manager Fusion Middleware Control, Oracle WebLogic Administration Console, and WebLogic Scripting Tool (WLST) commands, see the "Deploying Portal Framework Applications" chapter in *Administering Oracle WebCenter Portal*.

7.1 Introduction to Oracle WebLogic Servers

This section provides an overview of the Integrated WebLogic Server and Oracle WebLogic Managed Servers. Using Oracle JDeveloper, you can test and deploy your applications on the Integrated WebLogic Server, and deploy applications to an Oracle WebLogic Managed Server that resides outside Oracle JDeveloper for staging and further testing or, if you have the required permissions, to an actual production environment.

Integrated WebLogic Server

The Integrated WebLogic Server comes packaged with Oracle JDeveloper. The Integrated WebLogic Server connection appears as IntegratedWebLogicServer in the Resource Palette under **IDE Connections > Application Server**. With the Integrated WebLogic Server, you can quickly and easily test your application at design time without needing to package the application and create and configure a WebLogic Managed Server.

When you run an application, an Integrated WebLogic Server instance for that application automatically starts. You can also start the instance manually by choosing the **Run > Start Server Instance (IntegratedWebLogicServer)** menu option in JDeveloper. Doing so creates a single server instance for all applications; any applications you run will then use this server instance.

Testing Portal Framework applications on the Integrated WebLogic Server helps to improve design-time tasks by:

- Optimizing deployment: the requirement to archive and copy files to a separate server for design time testing is eliminated.
- Instantly refreshing changes to the application: you can directly run most files from project directories, which enables you to make selected changes and refresh these changes while the application is running. For example, you can modify a task flow on a JSPX page, then refresh the page in the browser to view your changes without redeploying the application.
- Removing the requirement to undeploy applications after testing and debugging. If you stop the Integrated WebLogic Server, however, applications running on it are automatically undeployed.

To learn more about testing a Portal Framework application on the Integrated WebLogic Server, refer to Section 7.2, "Deploying a Portal Framework Application to the Integrated WebLogic Server."

WebLogic Managed Server

An Oracle WebLogic Managed Server resides outside of Oracle JDeveloper as part of a domain, and is managed by an Administration server within that domain. A WebLogic Managed Server hosts applications, along with the libraries and other resources needed by those applications. A domain, which is a logically related group of Oracle WebLogic Server resources, can have any number of Managed Servers. Managed Servers can be configured to run applications in a test environment, a production environment, or both.

To learn more about deploying a Portal Framework application to an Oracle WebLogic Managed Server, see Section 7.3, "Deploying a Portal Framework Application to a WebLogic Managed Server."

7.2 Deploying a Portal Framework Application to the Integrated WebLogic Server

The Integrated WebLogic Server is preconfigured so that you can run applications within Oracle JDeveloper without needing to create deployment profiles. However, when the Integrated WebLogic Server instance stops, the application is undeployed and therefore becomes unavailable. For a more persistent testing scenario, you can also deploy your application to the Integrated WebLogic Server. These two options are described in the following subsections:

- Section 7.2.1, "Running a Portal Framework Application in the Integrated WebLogic Server"
- Section 7.2.2, "Deploying a Portal Framework Application to the Integrated WebLogic Server"

7.2.1 Running a Portal Framework Application in the Integrated WebLogic Server

To run a Portal Framework application, you can right-click the Portal project in the Projects section in the Application Navigator and choose **Run**, or select **Run** from the Run menu or click the **Run** icon from the toolbar to run the current project.

When you run an application in JDeveloper, a server instance named after the application is automatically created. While the application is running, you can switch back and forth between JDeveloper and your browser to make changes at design time in your application, save the changes and then refresh your JSPX page in your browser to view those changes. While in JDeveloper, you can also watch the progress of your applications, as well as stop the server instance (and thus stop the application).

When you run the application page or project, it triggers the packaging and deployment of your Portal Framework application on an Integrated WebLogic Server instance named after the application. You can stop instances of the Integrated WebLogic Server by using the Run Manager panel (shown in Figure 7–1). You can access the Run Manager panel by selecting **Run Manager** from the View menu. To stop the Integrated WebLogic Server instance, just select **IntegratedWebLogicServer** and click the red Terminate icon on the Run Manager tab. You can also stop the instance using the red Terminate icon on the toolbar or the one in the Log window, or by selecting the **Terminate** option from the Run menu.

```

> **Note:** Secure attributes and credentials are migrated by default when running a Portal Framework application on the Integrated WebLogic Server.

7.2.2 Deploying a Portal Framework Application to the Integrated WebLogic Server

When you run your Portal Framework application as described in Section 7.2.1, "Running a Portal Framework Application in the Integrated WebLogic Server", the application is undeployed and becomes unavailable if the Integrated WebLogic Server instance stops. Even if you start IntegratedWebLogicServer again, the application remains unavailable. For a more persistent testing scenario, you can deploy your application to the Integrated WebLogic Server by using the **Deploy** option. This deployed application will always be available while the Integrated WebLogic Server is running.

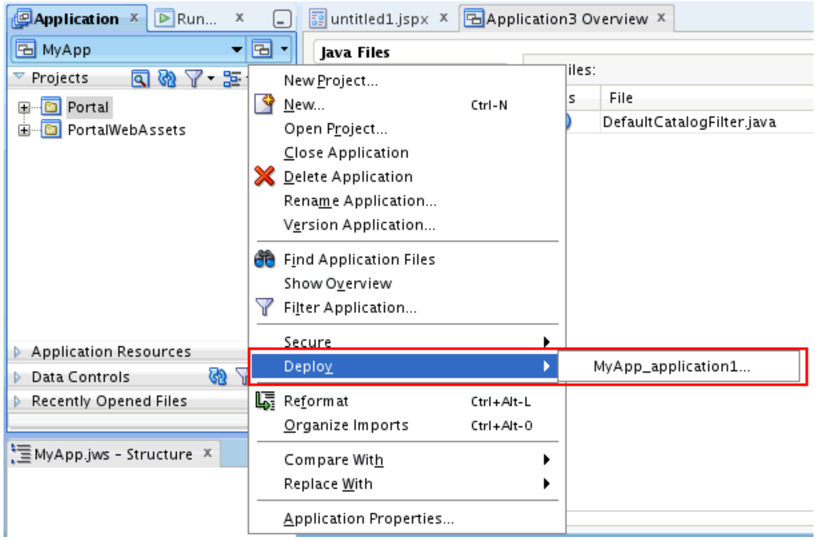
For more information about deploying applications, see the "Deploying Fusion Web Applications" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*.

> **Note:** Before deploying your Portal Framework application if you need to create local data sources for Oracle WebCenter Portal and for Activities used by the Analytics task flow, see Section 4.2.2, "Setting Up a Database Connection."

To deploy your application to the Integrated WebLogic Server:

1. Open your application in JDeveloper.
2. From the **Run** menu, select **Start Server Instance (IntegratedWebLogicServer)** to start the server instance.
3. From the **Application** menu, select **Deploy**, then select the default deployment profile, which is displayed in the format `application name_application1` (Figure 7–3)

Figure 7–3 Deploy Option on the Application Menu

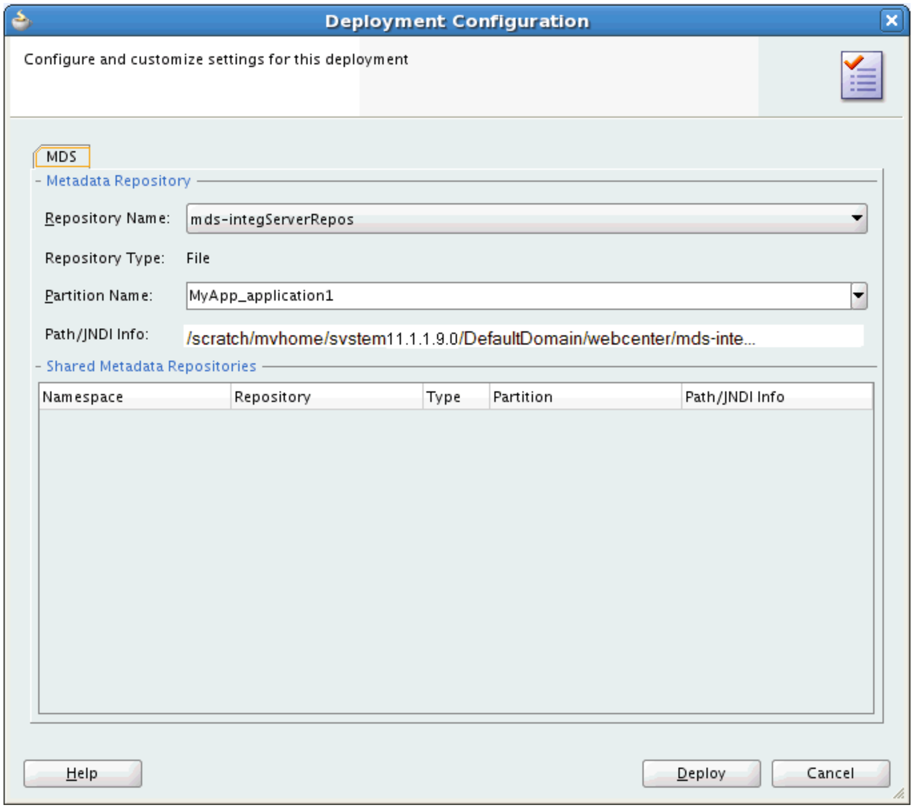


4. In the Deploy dialog, ensure **Deploy to Application Server** is selected, then click **Next**.
5. Select **IntegratedWebLogicServer**, and click **Next**.
6. On the Weblogic Options screen, to accept default selections click **Next**.

7. On the Summary screen, verify the deployment details, and click **Finish**.
8. In the Deployment Configuration dialog, click **Deploy**.

   The Deployment Configuration dialog enables you to choose the target metadata repository or shared metadata repositories. The file system MDS repository, pre-created by JDeveloper, displays in the Repository Name field (Figure 7–4).

Figure 7–4 Deployment Configuration Dialog



Deployment Configuration

Configure and customize settings for this deployment

Repository Name: mds-integServerRepos

Repository Type: File

Partition Name: MyApp_application1

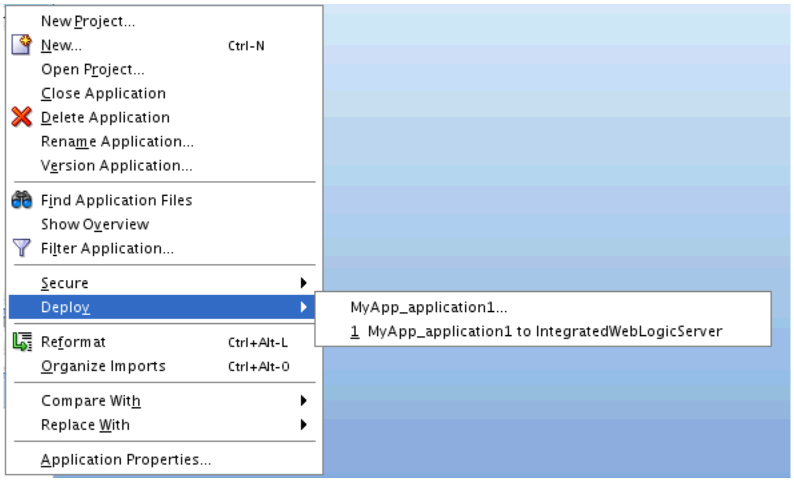
Path/JNDI Info: /scratch/mvhome/svstem11.1.1.9.0/DefaultDomain/webcenter/mds-inte...

Shared Metadata Repositories

Namespace	Repository	Type	Partition	Path/JNDI Info

Note that when you try to redeploy this application, the **Application > Deploy** menu provides the option to select the previous deployment target for your application, as shown in Figure 7–5. This is useful to skip the Deploy dialog screens and directly go to the Deployment Configuration dialog for redeploying to the previous target.

Figure 7–5 Application Menu Showing Deploy Options



7.3 Deploying a Portal Framework Application to a WebLogic Managed Server

When you are ready to test your Portal Framework application using an external test or staging site, you can deploy your applications directly from JDeveloper to an Oracle WebLogic Managed Server.

For information about deploying Portal Framework applications using Fusion Middleware Control, Oracle WebLogic Administration Console, and WLST commands, see the "Deploying Portal Framework Applications" chapter in *Administering Oracle WebCenter Portal*.

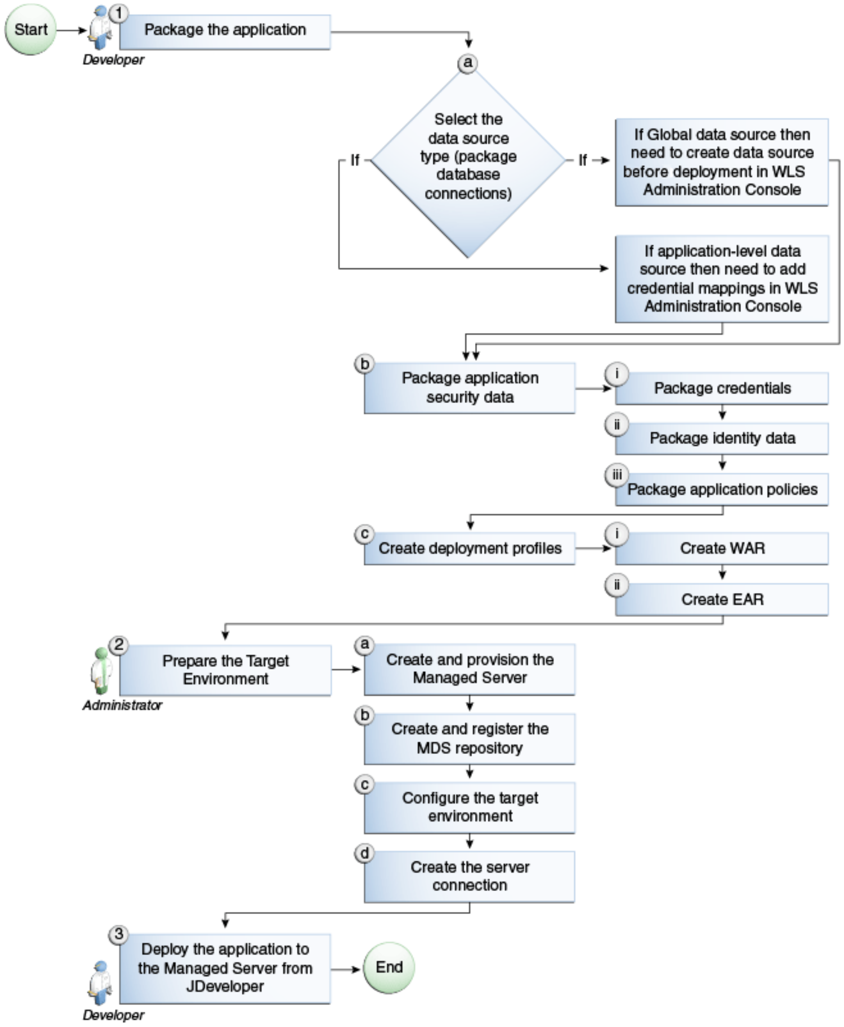
This section includes the following subsections:

- Section 7.3.1, "Deployment Roadmap"
- Section 7.3.2, "Packaging a Framework Application"
- Section 7.3.3, "Preparing the Target Environment for Deployment"
- Section 7.3.4, "Deploying a Portal Framework Application to a Managed Server"

7.3.1 Deployment Roadmap

The flowchart and table in this section provide an overview of the prerequisites and tasks required to deploy a Portal Framework application to an Oracle WebLogic Managed Server. Figure 7–6 shows the steps to deploy a Portal Framework application, and the roles that will carry them out.

Figure 7–6 Deploying a Framework Application to a Managed Server



Start
1
Developer
Package the application
a
Select the data source type (package database connections)
If
If
If Global data source then need to create data source before deployment in WLS Administration Console
If application-level data source then need to add credential mappings in WLS Administration Console
b
Package application security data
i
Package credentials
ii
Package identity data
iii
Package application policies
c
Create deployment profiles
i
Create WAR
ii
Create EAR
2
Administrator
Prepare the Target Environment
a
Create and provision the Managed Server
b
Create and register the MDS repository
c
Configure the target environment
d
Create the server connection
3
Developer
Deploy the application to the Managed Server from JDeveloper
End

Table 7–1 shows the tasks, sub-tasks and who will need to carry them out to deploy a Portal Framework application from JDeveloper.

Table 7–1 Deploying a Framework Application to a Managed Server

Actor	Task	Sub-task	Notes
Developer	**1.** Package the Application	**1.a** Select the data source type (package database connections)	You can use either a global data source or an application-level data source. If using a global data source, then you need to create the data source in the WLS Administration Console before deploying. If using an application-level data source, then you may need to add credential mappings using the WLS Administration Console after deploying (see the note below). **Note:** There are two options for deploying from JDeveloper. You can deploy directly to the Managed Server, or you can deploy to an EAR file and then deploy the EAR file using either Fusion Middleware Control, WLST or the WLS Admin Console. If you deploy directly from JDeveloper, the credential mapping step is not required as JDeveloper automatically handles the credential mapping. However, if you deploy the EAR file outside of JDeveloper, then this step is required.
		1.b Package application security data	This sub-task consists of packaging the credentials, identity data, and application policies.
		1.c Create deployment profiles	This sub-task consists of creating the WAR and EAR files. Out-of-the-box, there are default deployment profiles available. However, you may want to create your own deployment profile to specify the context root and application name as per your requirements.
Administrator	**2.** Prepare the Target Environment	**2.a** Create and provision the Managed Server	
		2.b Create and register the MDS repository	
		2.c Configure the target environment	
		2.d Create the server connection	
Developer	**3.** Deploy the Application to a Managed Server from JDeveloper		The final step is to deploy the application to the Managed Server from JDeveloper.

7.3.2 Packaging a Framework Application

When you deploy Portal Framework applications, you may also need to migrate your database connections and the related security for connecting to the databases. You will also need to create a set of project-level and application-level deployment profiles that indicate how a Portal Framework application and its associated files should be packaged so that the application can be deployed to an Oracle WebLogic Managed Server.

This section includes the following:

- Section 7.3.2.1, "Packaging Database Connections and Application Security"
- Section 7.3.2.2, "Creating Deployment Profiles"

7.3.2.1 Packaging Database Connections and Application Security

When you deploy Portal Framework applications, you'll also need to package your database connections and the related security for connecting to the databases. This section describes how to package a Portal Framework application that uses one of the two database connection types: JDBC data source and JDBC URL. This section also describes security migration for applications that use database connections that specify passwords, or external applications that specify shared or public credentials.

Based on the policy defined by your administrator (if, for example, your administrator does not allow any application-level data sources), you may need to migrate the database connections and respective credentials to the target server. The packaging options described below allow you to choose how the database connections should be treated.

This section includes the following sub-sections:

- Section 7.3.2.1.1, "Packaging the Database Connections"
- Section 7.3.2.1.2, "Packaging Application Security Data"

7.3.2.1.1 Packaging the Database Connections

If your Portal Framework application contains JDBC database connections, you'll need to choose how JDeveloper will migrate those database connections to the Oracle WebLogic Managed Server. You can choose from:

- *Global data source*:

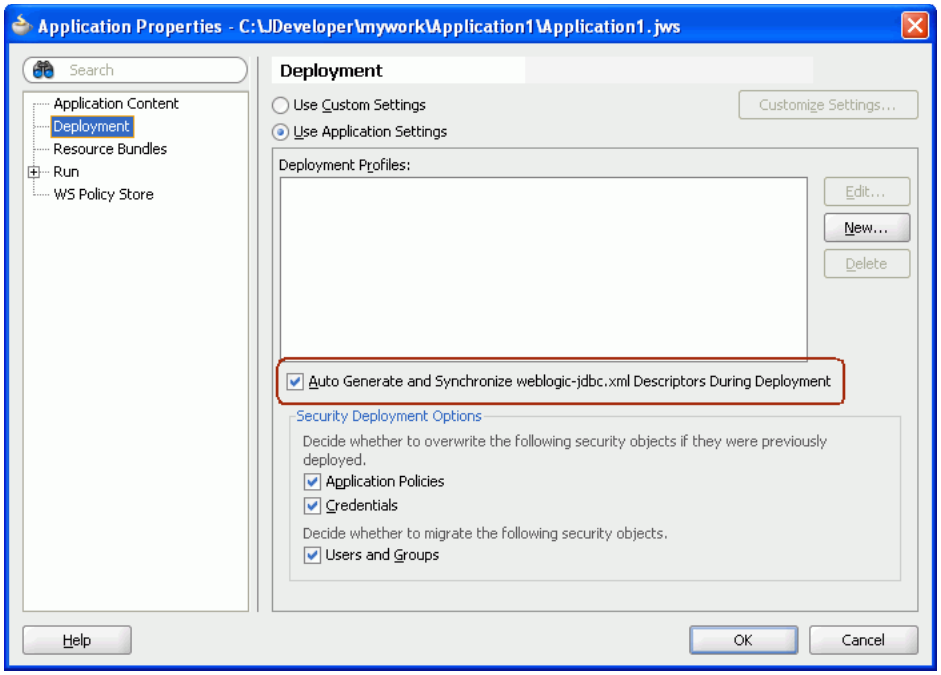
  Oracle recommends that you choose this type of data source if you plan to deploy an application EAR file to a Managed Server running in production mode using Fusion Middleware Control, the Oracle WebLogic Administration Console, or using a WLST (`wldeployer`) command.

  To choose a global data source, deselect the **Auto Generate and Synchronize weblogic-jdbc.xml Descriptors During Deployment** check box when you create the EAR file so that JDeveloper does not create an application-level data source with password indirection. Instead, create the global data source using Oracle WebLogic Administration Console prior to or after deploying the application to a Managed Server in production mode using the default WebCenter Portal and Activities schemas. For more information about creating global data sources, see the "Creating a JDBC Data Source" section in *Configuring and Managing JDBC Data Sources for Oracle WebLogic Server*.

- *Application-level data source with password indirection*:

  JDeveloper generates an application-level data source with password indirection by default when you run an application on the Integrated WebLogic Server. That is, when the **Auto Generate and Synchronize weblogic-jdbc.xml Descriptors During Deployment** check box is selected in the Application Properties dialog, as shown in Figure 7–7.

Figure 7–7 Auto Generate and Synchronize weblogic-jdbc.xml Descriptors During Deployment Checkbox



Application Properties - C:\JDeveloper\mywork\Application1\Application1.jws

Deployment

○ Use Custom Settings

● Use Application Settings

Deployment Profiles:

☑ Auto Generate and Synchronize weblogic-jdbc.xml Descriptors During Deployment

Security Deployment Options

Decide whether to overwrite the following security objects if they were previously deployed.

☑ Application Policies

☑ Credentials

Decide whether to migrate the following security objects.

☑ Users and Groups

To generate an application-level indirection data source, JDeveloper does the following:

- Generates a `<connection>-jdbc.xml` file (such as `WC-jdbc.xml`) for each connection in the Application Resource.
- Sets the indirect password attribute in the `<connection>-jdbc.xml` file:

```
<jdbc-driver-params>
<use-password-indirection>true</use-password-indirection>
</jdbc-driver-params>
```

- Updates `weblogic-application.xml` to add each `<connection>-jdbc.xml` file as a module. For example:

```
<module>
<name>WC</name>
<type>JDBC</type>
<path>META-INF/WC-jdbc.xml</path>
</module>
```

- Adds a resource reference to each JDBC JNDI name in the `web.xml` file, if this file exists. For example:

```
<resource-ref>
<description>WC-Connection</description>
<res-ref-name>jdbc/WCDS</res-ref-name>
<res-type>javax.sql.DataSource</res-type>
<res-auth>Container</res-auth>
</resource-ref>
```

If you choose to generate an application data source with password indirection, then you must add credential mappings using the Oracle WebLogic Administration Console to be able to activate the application. For more information on adding credential mappings, see the "Creating a JDBC Data Source" section in *Configuring and Managing JDBC Data Sources for Oracle WebLogic Server*.

> **Note:** Do not use WLST commands to deploy applications that use application-level data sources with password indirection, as WLST cannot set password indirection credential mappings on the server.

7.3.2.1.2 Packaging Application Security Data

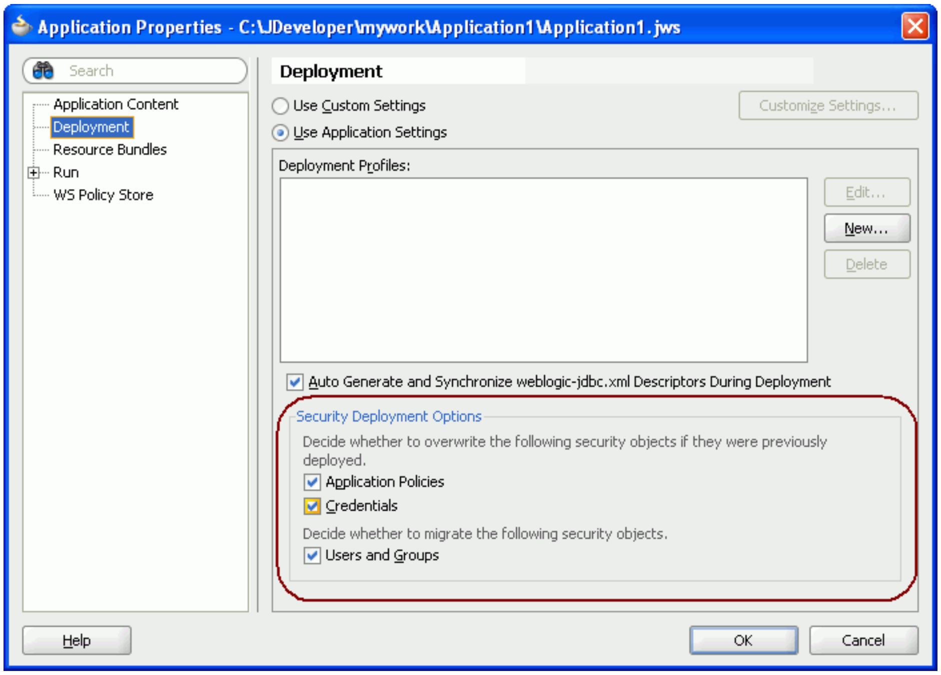
The following is applicable only if you have configured security in your application using the Configure ADF Security wizard, or the application contains connections with secure attributes such as a database connection password or external applications with shared or public credentials:

- Packaging Credentials
- Packaging Identity Data
- Packaging Application Policies

Packaging Credentials

If you do not intend to migrate credentials, then deselect the **Credentials** check box in the **Security Deployment Options** section in the Application Properties dialog (see Figure 7–8).

Figure 7–8 Security Deployment Options



Application Properties - C:\JDeveloper\mywork\Application1\Application1.jws

Deployment

○ Use Custom Settings

● Use Application Settings

Deployment Profiles:

☑ Auto Generate and Synchronize weblogic-jdbc.xml Descriptors During Deployment

Security Deployment Options

Decide whether to overwrite the following security objects if they were previously deployed.

☑ Application Policies

☑ Credentials

Decide whether to migrate the following security objects.

☑ Users and Groups

If you retain the default selection in the Security Deployment Options section, then the credential migration will behave as follows, depending on whether the WebLogic domain is in development or production mode:

- When you deploy a Portal Framework application to a Managed Server running in production mode, secure attributes of the connections packaged within your application and any shared or public credentials specified for external applications are not migrated to the domain-level credential store. This is because secure properties are likely to be different between development and production environments. Therefore, you must reconfigure secure attributes of connections and shared or public credentials for external applications using WLST commands or Fusion Middleware Control, as described in the security-related sections in *Administering Oracle WebCenter Portal*.

  For more information about credential migration behavior, see the "Managing the Credential Store" section in *Securing Applications with Oracle Platform Security Services*.

- When you deploy a Portal Framework application in development mode, you must first enable credential migration. To enable credential migration for an application to be deployed in development mode, start the Managed Server with `-Djps.app.credential.overwrite.allowed=true`, by adding the following option to the `setDomainEnv.cmd` or `setDomainEnv.sh` file located in *`domain`*`\bin`:

  ```
  set EXTRA_JAVA_PROPERTIES=-Djps.app.credential.overwrite.allowed=true %EXTRA_
  JAVA_PROPERTIES%
  ```

Packaging Identity Data

In Figure 7–8, in the Security Deployment Options section, the Users and Groups check box is selected by default. This indicates that the users and groups defined in the application's `jazn-data.xml` file will be migrated to the identity store configured for the WebLogic Managed Server, if the authenticator configured in the domain allows creation of users and groups. When migrating the identity store, you should deselect this option as users and groups defined in the identity store configured for the Managed Server should be used to access the application.

Packaging Application Policies

When the **Application Policies** check box is selected, then the `jps.policystore.migration` parameter in the `weblogic-application.xml` file is set to `OVERWRITE`. This means that during application deployment and redeployment, the application policies packaged with the application will be overwritten on the domain-level policy store for the domain to which the application is being deployed.

If the **Application Policies** check box is not selected, then the `jps.policystore.migration` parameter is set to `MERGE`. This means that the application policies will be migrated during application deployment but not during redeployment, and the existing application policies will not be overwritten.

7.3.2.2 Creating Deployment Profiles

Deploying your application to a Managed Server that resides outside JDeveloper using Fusion Middleware Control or the WLS Administration Console can only be done using a deployment profile, or Enterprise Archive (EAR) file. The EAR file packages (or archives) a Portal Framework application and its associated files so that the application can be deployed to an Oracle WebLogic Managed Server (this is typically done by a system administrator when the target is a production server).

Note: You can deploy Oracle ADF applications, such as Portal Framework applications, only as EAR files.

The EAR file contains application artifacts such as, `adf-config.xml`, `connections.xml`, `weblogic-application.xml`, `jazn-data.xml`, metadata archive (MAR) files, and all project-related WAR files. For Portal Framework applications containing MDS metadata or portlets, a metadata archive file (with the extension `.MAR`) is automatically generated and included in the EAR file. This file contains all MDS metadata and portlet customization data.

For Portal Framework applications, both the WAR (project-level) and EAR-level deployment profiles are created for you as you build your application. These are named:

```
<application name>_webapp1
<application name>_application1
```

respectively, where *`<application name>`* is the name given to the application at creation time.

If your application, however, was not created using the WebCenter Portal Framework Application template, then you may need to create a deployment profile file for your application. You may also want to create your own EAR file if you want to give it a specific name or change what's included in the EAR file through the Application Assembly section. For information about creating an EAR deployment profile for an application, see the "Deploying Fusion Web Applications" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*.

To create an EAR file:

1. Open your application in JDeveloper.

2. From the Application menu, choose **Deploy**, then select the name of the deployment profile. An EAR-level deployment profile is available out of the box, named *application name*_application1.

3. In the Deploy dialog, on the Deployment Action screen, select **Deploy to EAR**, then click **Next**.

4. On the Summary screen, verify the deployment details, and click **Finish**.

   This creates the EAR file in the **deploy** folder located in *`JDEV_HOME`*`\mywork\`*`application_name`*`\deploy\`, as shown in Figure 7–9.

```

7.3.3 Preparing the Target Environment for Deployment

This section describes how to create and provision a WebLogic Managed Server instance prior to deploying your Portal Framework application.

This section includes the following sub-sections:

- Section 7.3.3.1, "Creating and Provisioning an Oracle WebLogic Managed Server Instance"
- Section 7.3.3.2, "Creating and Registering the Metadata Service Repository"
- Section 7.3.3.3, "Configuring the Target Environment"
- Section 7.3.3.4, "Creating a WebLogic Managed Server Connection"

7.3.3.1 Creating and Provisioning an Oracle WebLogic Managed Server Instance

Before deploying a Portal Framework application, you must create a WebLogic Managed Server based on the "Oracle WebCenter Custom Portal" template that contains all the required shared libraries and an MDS Repository. For instructions on how to create a new managed server, see the "Extending an Existing Domain" section in *Installation Guide for Oracle WebCenter Portal*.

> **Note:** Oracle does not recommend deploying Portal Framework applications to any of the preconfigured Managed Servers created during Oracle WebCenter Portal installation, or to a domain Administration Server.

7.3.3.2 Creating and Registering the Metadata Service Repository

After creating and provisioning the WebLogic Managed Server instance, you must create and register a Metadata Service Repository (MDS) schema for the application on the WebLogic Domain's Administration Server instance, as described in the "Creating and Registering the Metadata Service Repository" section in *Administering Oracle WebCenter Portal.*

7.3.3.3 Configuring the Target Environment

After creating the Managed Server and creating and registering the MDS repository, continue by configuring the data sources, and the connections to the Identity Store, and the Policy and Credential Store. For information on configuring data sources, see the "Creating a JDBC Data Source" section in *Configuring and Managing JDBC Data Sources for Oracle WebLogic Server*. Note that when setting up the data source, you must provide a password or the connection may not be created when the application is deployed.

7.3.3.4 Creating a WebLogic Managed Server Connection

Before you can deploy your applications using JDeveloper to an Oracle WebLogic Managed Server instance that resides outside JDeveloper, you must create a connection to the Managed Server instance where you will deploy the application. Before you create a connection to an Oracle WebLogic Managed Server instance, ensure that the target Managed Server instance is up and running, and has the required libraries.

To create a connection to an Oracle WebLogic Managed Server:

1. In JDeveloper, from the File menu, select **New**.

2. In the New Gallery, expand General, select **Connections**, and then **Application Server Connection**.
3. Click **OK**.
4. In the Create Application Server Connection wizard, for Step 1, enter a name for the new connection (for example, `WC_CustomPortal`), and then click **Next**.
5. At Step 2, specify the user name and password for authentication, and then click **Next**.
6. At Step 3, enter the host name of the WebLogic Managed Server (for example, `webcenter.myserver.example.com`) and the port number (for example, 7888).
7. In the Weblogic Domain field, specify the name of the domain in which the WebLogic Managed Server instance is created (for example, `wc_domain`), and then click **Next**.
8. At Step 4, click **Test Connection**.

   If the test is successful, you now have a connection to the target WebLogic Managed Server.
9. Click **Finish**.

7.3.4 Deploying a Portal Framework Application to a Managed Server

You can deploy a Portal Framework application to a Managed Server using either local application or global data sources. Local application data sources can only be accessed by the deployed application. However, it's an easy way to deploy in that it needs no other data source configuration in order to work if deployed directly from JDeveloper.

Global data sources benefit from being able to be shared by other applications on the server where database connection configuration updates can be more easily maintained and picked up by all users of the global data source. For more information about data sources, see the "Choosing the Data Source" section in *Administering Oracle WebCenter Portal*.

This section contains the following subsections:

- Section 7.3.4.1, "Deploying to a Managed Server Using Local Data Sources"
- Section 7.3.4.2, "Deploying to a Managed Server Using Global Data Sources"

7.3.4.1 Deploying to a Managed Server Using Local Data Sources

When you deploy to a Managed Server, the application EAR file is generated. The EAR file packages the metadata archive (MAR file), which includes the metadata content to be deployed to an MDS repository. Additionally, the `adf-config.xml` file is reconfigured with a modified `mds-config` for the target deployment environment. Application-wide features, security, caching, and change persistence remain unchanged. Properties for other Oracle components, if any, are also configured in this file. Similarly, JSF and JSTL shared libraries are added in the `weblogic.xml` file during packaging.

To deploy a Portal Framework application to a Managed Server using local data sources:

1. In JDeveloper, in the Application Navigator, open the application to be deployed.
2. Create a local data source if your application contains task flows that use the WebCenter schema. If your application uses Analytics task flows, create a separate

local data source for the Activities schema. For information, see Section 4.2.2, "Setting Up a Database Connection."

3. From the Application menu, select **Application Properties**.

   The Application Properties dialog displays (Figure 7–10).

Figure 7–10 Application Properties Dialog

Shared Metadata Repositories

Namespace	Repository	Type	Partition	Path/JNDI Info

12. Continue by doing any post-deployment security or data source connection configurations that may be required as described in the "Post-Deployment Configuration" section in *Administering Oracle WebCenter Portal*.

7.3.4.2 Deploying to a Managed Server Using Global Data Sources

Deploying to a Managed Server using global data sources is recommended when the application is not intended to run on a Managed Server created with the WebCenter Custom Portal template, or is intended to run against custom data sources not named `WebCenterDS` or `ActivitiesDS`.

Oracle recommends using the default data source names, but if you use nondefault pre-seeded data sources, then you must name your data sources accordingly and follow the pre- or post-deployment global data source creation steps to create data sources that map to the names you have chosen. For more information, see the "Choosing the Data Source" section in *Administering Oracle WebCenter Portal*.

To deploy to a Managed Server using global data sources:

1. Open the application to be deployed in JDeveloper.
2. Determine the JNDI names your application will be using for the data sources.

   The JNDI names will depend on whether you've created a database connection for your application in JDeveloper or are using the defaults. The following table shows the default JNDI names:

Data Source	JDeveloper JNDI Name	Default JNDI Name
WebCenterDS	jdbc/*WebCenterConnectionNameDS* (where *WebCenterConnectionName* is the name of the WebCenter schema database connection)	jdbc/webcenter/CustomPortalDS
ActivitiesDS	jdbc/*ActivitiesConnectionNameDS* (where *ActivitiesConnectionName* is the name of the Activities schema database connection)	jdbc/activities/CustomPortalDS

3. From the Application menu, select **Application Properties**.

4. Choose **Deployment** from the navigation panel to display the Deployment options.

5. Deselect the `Auto Generate and Synchronize weblogic-jdbc.xml Descriptors During Deployment` check box if selected and click **OK**.

6. From the Application menu, select **Deploy**, and then the application name.

7. Select **Deploy to Application Server** and click **Next** (Figure 7–15).

Figure 7–15 Choosing a Deployment Action

12. Continue by doing any post-deployment security or data source connection configurations that may be required as described in the "Post-Deployment Configuration" section in *Administering Oracle WebCenter Portal*.

7.4 Transporting Customizations Between Environments

When migrating a deployed application to a new environment, post-deployment customizations made to pages, WebCenter Portal tools and services, and portlets (PDK-Java and WSRP version 2 producers) must be migrated too. Export and import utilities are available to assist with this process. For more information, see the "Managing Export, Import, Backup, and Recovery for Portal Framework Applications" chapter in *Administering Oracle WebCenter Portal*.

8 Understanding the WebCenter Portal Framework Application Life Cycle

This chapter discusses tasks, tools, and techniques for managing a WebCenter Portal Framework application throughout its life cycle.

This chapter includes the following topics:

8.1 What Is the WebCenter Portal Framework Application Life Cycle?

The WebCenter Portal Framework application life cycle refers to the path a Framework Portal application takes from development through production. The phases of the life cycle typically include development, testing, staging, and production. Each phase requires certain tasks to be performed. Some tasks are performed only once, like setting up a content repository. Others are performed more frequently, like nightly builds. The phases of the portal life cycle are described in Table 8–1.

Table 8–1 WebCenter Portal Framework Application Life Cycle Phases

Life Cycle Phase	Primary Actors/Roles	Description
Development	■ Developers ■ Content Modelers ■ Content Contributors	The development portal is primarily source control and file-based. Developers work locally in JDeveloper and deploy to the Integrated WebLogic server. The development portal typically employs test data and content. Some of the features that are developed in this phase of the life cycle include: ■ portlets ■ task flows ■ shared libraries ■ skins ■ navigation models ■ page templates ■ display templates ■ content models ■ data transfer and interportlet communication ■ security The code from the development environment is built (usually nightly) and deployed to a clean, independent, targeted environment. WebCenter provides a build script that can be adapted for this purpose. See Section 8.8, "Configuring a Nightly Build Script."

Table 8–1 (Cont.) WebCenter Portal Framework Application Life Cycle Phases

Life Cycle Phase	Primary Actors/Roles	Description
Testing	■ Developers ■ QA Engineers ■ IT Administrators	The development portal is built (usually nightly) and deployed to an independent testing environment. The test environment typically includes a Metadata Service (MDS) and policy store that are database-based, and a dedicated Oracle WebCenter Content instance. The testing environment may contain test data and test content that will not become part of the production portal. Portlet producers may be shared between the test and development environments. However, if the usage load is high, Oracle recommends that separate instances be created.
Staging	■ Site Managers ■ IT Administrators ■ Content Contributors	The staging environment provides a stable environment where final configuration and testing takes place before the portal is moved to production. Content contributors add content and refine the portal structure. Typically, the staging environment includes a dedicated Oracle WebCenter Content server, as well as dedicated portlet producer server(s). The staging server is often maintained as a mirror of the production site.
Production	■ Site Managers ■ IT Administrators ■ Content Contributors	A production portal is live and available to end users. A portal in production can be modified with tools like the Resource Manager and Oracle WebCenter Portal's Composer. For instance, an administrator might add additional portlets to a portal or reconfigure the contents of a portal. Individual users with proper authorization can also customize their view. See *Administering Oracle WebCenter Portal*. WebCenter provides a propagation tool for migrating metadata to the production environment. See Section 8.13, "Using the Propagation Tool to Propagate From Staging to Production." Content is provisioned using Oracle WebCenter Content replication tools. See Section 8.14, "Propagating Content From Oracle WebCenter Content." WebCenter provides WLST commands for importing and exporting portlet preferences. For more information, see Section 8.16, "Migrating Portlet Preferences."

8.2 What Are the Major Life Cycle Tasks?

Each phase of the life cycle requires actors (developers, administrators, content contributors, and others) to perform certain tasks. This section provides an overview of the kinds of tasks that are performed during each phase of the portal life cycle.

- Section 8.2.1, "One-Time Setup Tasks"
- Section 8.2.2, "Development Environment Tasks"
- Section 8.2.3, "Nightly Build Environment Tasks"
- Section 8.2.4, "Testing Environment Tasks"
- Section 8.2.5, "Stage Environment Tasks"
- Section 8.2.6, "Production Environment Tasks"

8.2.1 One-Time Setup Tasks

You must perform certain preparatory steps to set up the development, build/test, stage, and production environments. Table 8–2 provides a general list of these preliminary setup tasks and the environments to which they apply. See also Section 8.8, "Configuring a Nightly Build Script" and Section 8.9, "Setting Up a Staging or Production Environment for the First Time."

Table 8–2 Typical One-Time Setup Tasks

Setup Task	Development	Build/Test	Stage	Production
Install JDeveloper	Yes	No	No	No
Install Oracle WebCenter Portal	Yes	Yes	Yes	Yes
Install Oracle WebLogic Server; create a domain and managed servers	No	Yes	Yes	Yes
Create required database schemas using RCU	No	Yes	Yes	Yes
Install and configure Oracle WebCenter Content	Yes	Yes	Yes	Yes
Install identity management components, such as Oracle Access Manager	No	Yes	Yes	Yes
Create the required Oracle Platform Security Services policies in the policy store	No	Yes	Yes	Yes
Create required user credentials in the credential store	No	Yes	Yes	Yes
Create connections to back end servers	Yes	Yes	Yes	Yes
Create build scripts	Yes	No	No	No
Create deploy and configure scripts	No	No	Yes	Yes
Integrate/configure Oracle WebCenter Portal Personalization *	Yes	Yes	Yes	Yes

* For more information on Oracle WebCenter Portal Personalization, see the chapter "Managing Personalization" in the *Administering Oracle WebCenter Portal* and Chapter 66, "Personalizing Oracle WebCenter Portal Applications."

Another technique for setting up an environment for the first time is to clone an existing instance. Typically, this strategy is used to clone a production instance from a stage instance. For detailed information on this "test to production" technique, see the section "Moving from a Test to a Production Environment" in the *Administrator's Guide*.

8.2.2 Development Environment Tasks

In a development environment, each developer has a local JDeveloper instance that is connected to a source control system and a shared Oracle WebCenter Content repository. Developers store metadata and code in source control. Portlets are deployed independently to a producer server and consumed by the portal.

In a development environment, developers typically build and run the application locally using the Integrated WebLogic Server. Both MDS and the Policy Store are file-based in the local development environment.

For more information, see Chapter 2, "Setting Up Your Development Environment" and Chapter 3, "Working Productively in Teams."

8.2.3 Nightly Build Environment Tasks

On a daily basis, developers work in JDeveloper and run code changes locally on the Integrated WebLogic Server, and code changes are checked into a source control system.

If you wish to set up a build environment that produces a clean environment that is built each night, there are certain tasks that must be performed with each build, including:

- Creating schema (typically with Oracle Repository Creation Utility – RCU)
- Creating and setting up the domain
- Creating and configuring managed servers
- Deploying the application

WebCenter provides sample build scripts that you can modify and use for your environment. See Section 8.8, "Configuring a Nightly Build Script." Nightly builds are usually made available to people within the organization, like QA engineers, technical writers, managers, and others. See also Section 8.4, "Understanding the Build and Test Environments."

For information on integrating Oracle WebCenter Portal Personalization into your development environment, see Section 66.2, "Integrating Personalization in Your Application."

8.2.4 Testing Environment Tasks

Usually, the testing environment is a mirror of the nightly build environment that is accessed by QA engineers. The tasks involved in providing a clean test environment are usually the same as creating a clean build environment. See also Section 8.4, "Understanding the Build and Test Environments."

8.2.5 Stage Environment Tasks

Runtime tools play a bigger role in the staging environment than in the development environment. Nonetheless, occasional updates from development will need to be deployed to the stage environment. To facilitate these more intermittent updates, WebCenter provides a set of deploy and configure scripts that you can copy and modify to suit your environment. The deploy and configure scripts isolate the information that is variable between environments, like the server names, ports, content management connections, and so on. For more information, see Section 8.5.1, "Provisioning the Staging Environment" and Section 8.12, "Deploying and Configuring the Application on Targeted Servers."

For information on integrating and configuring Oracle WebCenter Portal Personalization, see the section "Personalization Prerequisites and Limitations" in the *Administering Oracle WebCenter Portal*.

8.2.6 Production Environment Tasks

When changes are tested and approved in the stage environment, they need to be pushed to the production environment. WebCenter provides a Propagation tool in the WebCenter Portal Administration Console that moves all portal metadata from the staging to the production server. For more information, see Section 8.13, "Using the Propagation Tool to Propagate From Staging to Production."

WebCenter provides WLST commands for importing and exporting portlet preferences. For more information, see Section 8.16, "Migrating Portlet Preferences."

8.3 Who Participates in the Portal Life Cycle?

Many different people participate in the portal life cycle. In general, these people (the primary actors in Table 8–1) fall into one or more of these general roles:

- **Developer** – Uses JDeveloper and the build scripts described in Section 8.8, "Configuring a Nightly Build Script."
- **IT Administrator** – Uses the deploy and configuration scripts described in Section 8.12, "Deploying and Configuring the Application on Targeted Servers."
- **Site managers** – Have administrative privileges for the Portal Framework application. Site managers use the WebCenter Portal Administration Console to modify the layout, content, and security settings of the portal. See also *Administering Oracle WebCenter Portal* and Section 8.15, "Managing Security Through the Life Cycle."
- **Content modelers** – Uses Oracle WebCenter Content's Site Studio designer to model content. Refer to Site Studio and Oracle WebCenter Content documentation for more information.
- **Content contributors** – Develops whatever content appears in or is available from the portal, including images, document files, video and audio content, and so on.

8.4 Understanding the Build and Test Environments

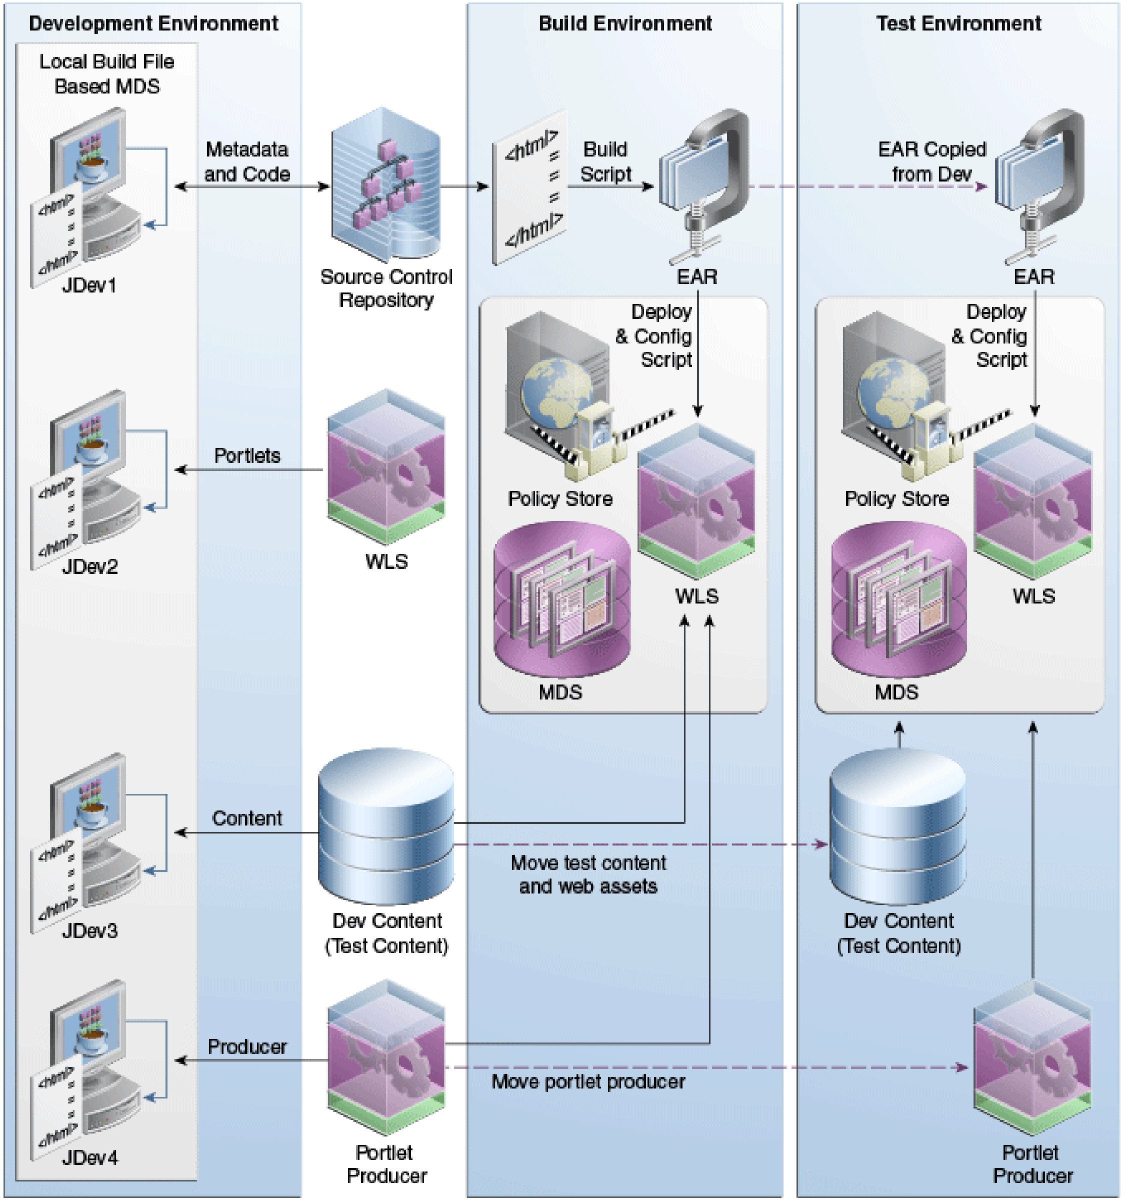
Although developers typically build and run locally, an automated nightly build environment is recommended. The build environment represents a clean deployment of the Portal Framework application.

To set up the build environment, back end servers and connections must be installed and created once. For example, the build environment requires WebLogic Server instance, and typically includes access to an installed Oracle WebCenter Content instance. In addition, the build environment includes a database-based MDS and policy store.

Figure 8–1 illustrates the general flow from development to build to test environments.

Note: Figure 8–1 does not depict all possible portal features. For example, Oracle WebCenter Portal Personalization is not depicted in the diagram. For more information, see Section 66.3, "Deploying Personalization Files."

Figure 8–1 Flow from Development to Build to Test Environments



A common practice is to use Ant-based build scripts to construct the EAR from source control and deploy it. The EAR includes metadata, code, and seeded policies. The build script also packages into the EAR metadata customizations made to portlets. See Section 8.8, "Configuring a Nightly Build Script." Some tasks performed by the build scripts include:

- creating schema (with RCU)
- setting up the managed server and domain
- building and deploying the EAR
- performing other setup tasks

The best practice is to use Oracle WebCenter Content archive tools to move Oracle WebCenter Content test content and web assets between the environments. See Section 8.14, "Propagating Content From Oracle WebCenter Content." For information on deploying portlets, see Chapter 61, "Deploying Portlet Producers."

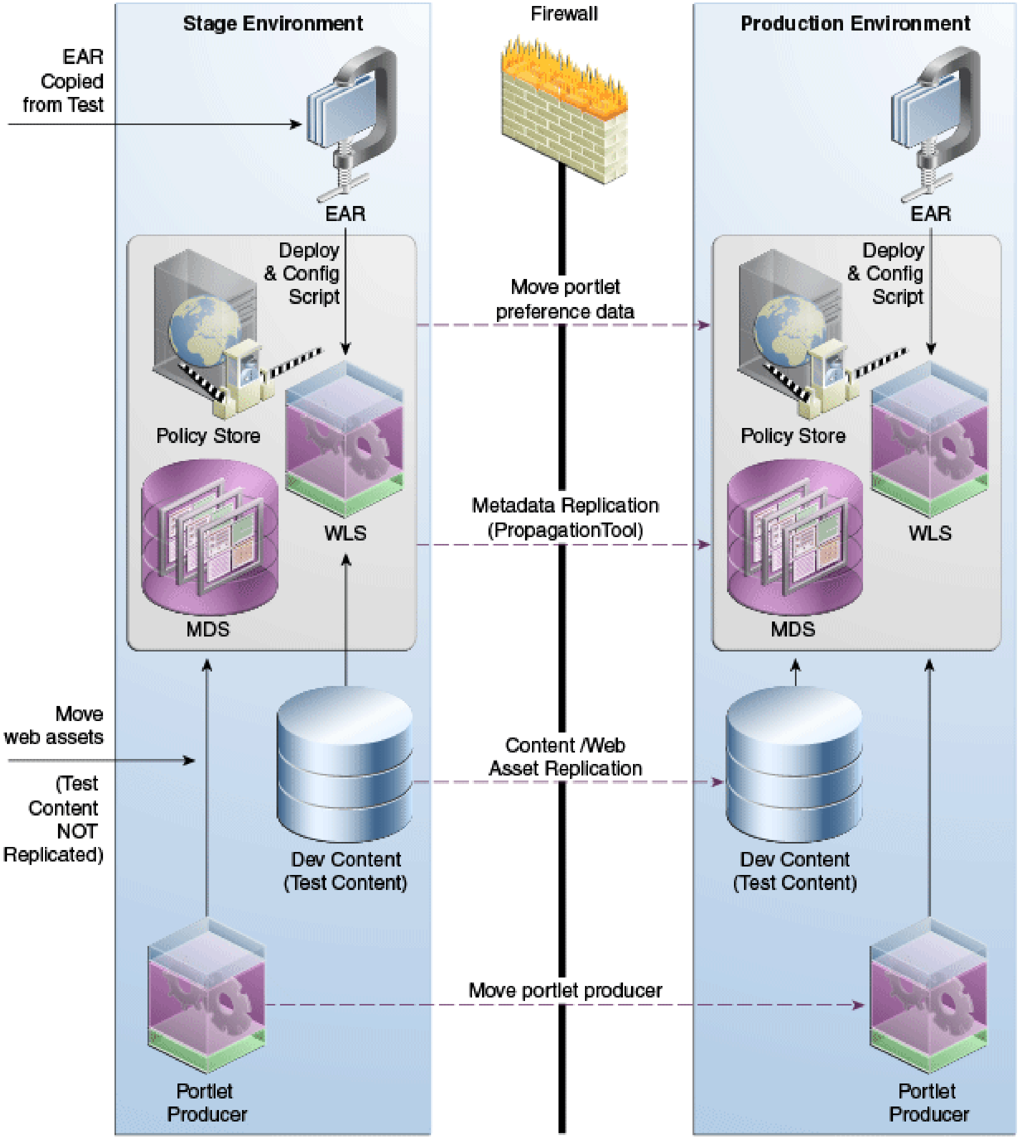
For information on integrating Oracle WebCenter Portal Personalization into your development environment, see Section 66.2, "Integrating Personalization in Your Application."

8.5 Understanding the Staging and Production Environments

This section discusses the staging and production phases of the portal life cycle. Figure 8–2 illustrates the general flow from staging to production environments.

Note: Figure 8–2 does not depict all possible portal features. For example, Oracle WebCenter Portal Personalization is not depicted in the diagram. For more information, see Section 66.3, "Deploying Personalization Files."

Figure 8–2 Flow from Staging to Production Environments



8.5.1 Provisioning the Staging Environment

The staging environment provides a stable environment where final configuration and testing takes place before the portal is moved to production. Typically, the staging environment includes a dedicated Oracle WebCenter Content server, as well as dedicated portlet producer server(s). For a list of typical setup tasks, see Table 8–2.

If you are setting up the staging environment for the first time, see Section 8.9, "Setting Up a Staging or Production Environment for the First Time." For information on making incremental changes to the staging environment, see Section 8.12, "Deploying and Configuring the Application on Targeted Servers."

If you wish, you can move Oracle WebCenter Content content and web assets between the testing and staging environment using Oracle WebCenter Content archive tools. See Section 8.14, "Propagating Content From Oracle WebCenter Content." For information on migrating portlets, see Section 8.16, "Migrating Portlet Preferences."

For a complete list of requirements, dependencies, and options for WebCenter Personalization, see the section "Personalization Prerequisites and Limitations" in the *Administering Oracle WebCenter Portal*.

8.5.2 Adding Content to the Staging Environment

Content developers can add content directly to the staging server using Oracle WebCenter Content content contribution tools. Content workflow features of Oracle WebCenter Content can be used to manage content approvals. WebCenter also provides browser-based tools for creating and editing content. For example, you can:

- Edit existing Oracle WebCenter Content region data files
- Create new Oracle WebCenter Content region data files
- Edit existing HTML content
- Upload new images

8.5.3 Moving the Portal from Staging to Production

Once the staging environment is fully provisioned and tested, it can be moved to the production environment and made accessible to users. In a live production environment, you can make incremental updates to metadata, content, and web assets using automated scripts and/or replication techniques.

Typically, these updates are performed by a site manager rather than by individual content contributors. For more information, see Section 8.13, "Using the Propagation Tool to Propagate From Staging to Production."

Any content model or region definition changes can be pushed to the production server by the site manager. Oracle WebCenter Content Replication can be used to replicate content between the stage and production server. See Section 8.14, "Propagating Content From Oracle WebCenter Content."

WebCenter provides WLST commands for importing and exporting portlet preferences. For more information, see Section 8.16, "Migrating Portlet Preferences."

8.6 Tools for Managing the Life Cycle

WebCenter Portal is built on top of JDeveloper and Oracle ADF, which provide several benefits in the life cycle management of your application:

- **Development framework** – JDeveloper and Oracle ADF provide the tools and framework you can use to build and update your application. Adding portlets, content, and customization capabilities to your Portal Framework application is simply a matter of dragging and dropping the appropriate objects in either a source or WYSIWYG environment.
- **Iterative Development** – WebCenter provides an iterative development feature that greatly increases team productivity. See Section 2.3.1, "Preparing for Iterative Development in a Portal Framework Application."
- **Round-Trip Development:** Round-trip development refers to features and techniques that allow you to retrieve resources from a deployed, runtime portal back to JDeveloper for maintenance or enhancement. For more information on round-trip development, see Section 9.6, "Working with Round-Trip Development."
- **Enterprise deployment:** When you are ready to deploy your application to a production environment, you can use the deployment scripts provided by WebCenter. For more information, see Section 8.12, "Deploying and Configuring the Application on Targeted Servers" and Section 8.13, "Using the Propagation Tool to Propagate From Staging to Production." For more information about deployment, see Chapter 7, "Deploying and Testing Your Portal Framework Application."

  > **Note:** Services for WebCenter Portal typically require some back end, such as Oracle WebCenter Portal's Discussions Server, to be available in the deployment environment.

- **Standards-based administration:** Browser-based tools enable administrators to deploy, configure, and manage Portal Framework applications and WebCenter Portal tools and services. In addition, tools built on industry standards-based JMX methods offer administrators granular control and monitoring mechanisms for health status, performance, and popularity. Tools for obtaining historical performance and status reporting over time (within a single Oracle Application Server context) are also provided. Portal Framework application metrics are delivered using the familiar Application Server Control monitoring and management interface. For more information, see *Administering Oracle WebCenter Portal*.

8.7 Understanding Iterative Development

- Section 8.7.1, "What Is Iterative Development?"
- Section 8.7.2, "How Does Iterative Development Work?"
- Section 8.7.3, "Enabling Iterative Development"

8.7.1 What Is Iterative Development?

Iterative development lets you make changes to your Portal Framework application while it is running on the Integrated WebLogic Server and immediately see the effect of those changes simply by refreshing the current page in your browser. The iterative development feature works by disabling certain optimization features. Iterative development allows developers to work more quickly and efficiently when building a portal.

For example, iterative development lets you see changes to these components almost instantly upon a browser refresh:

- page definitions
- navigation model
- page hierarchy
- existing JSPX files
- page templates
- resource catalog
- addition of task flows to pages
- addition of portlets to pages

The following kinds of operations are not supported by iterative development. These operations require you to re-run the application:

- Creating any *new* file explicitly (JSPX, page definition, and so on)
- Editing any configuration file, like `web.xml` or `adfc-config.xml`.
- Creating a new file implicitly. For instance, when you add a sub-page to a node in the page hierarchy, a new `*pages.xml` file is created.

8.7.2 How Does Iterative Development Work?

Iterative development works by turning off certain MDS and runtime layer caches. Because these performance optimization features are disabled, you might notice some slower performance when running your application in a development environment.

> **Note:** When an application is deployed to the Integrated WebLogic Server, the `org.apache.myfaces.trinidad.CHECK_FILE_MODIFICATION` flag is automatically set to `true` in the `web.xml` file on the server. This setting causes the server to automatically check the modification time of your JSP and skinning CSS files, and discard saved state when they change. This configuration occurs whether or not the iterative development feature is enabled.

When iterative development is enabled, the following changes to application configuration occur:

- The MDS Cache size is set to `0`. This setting causes all metadata files to be re-loaded on each request.
- The Navigation Model cache is invalidated on each request.

For skin development, you can set the application to use uncompressed skins. This setting is not the default and should only be used in a development environment. You can update `web.xml` to enable this functionality with the following context parameter:

```
<context-param>
    <param-name>org.apache.myfaces.trinidad.DISABLE_CONTENT_COMPRESSION</param-name>
    <param-value>true</param-value>
</context-param>
```

Note: When consuming Oracle JSF Portlet Bridge Portlets in your portal, ADF attempts to share the skin between the consumer and producer. Therefore, if you are disabling compression on the consumer, you should also do that on the producer. Otherwise, the producer will not generate the correct code to match the uncompressed IDs generated by the consumer. See also Chapter 58, "Creating Portlets from JSF Applications Using the Oracle JSF Portlet Bridge."

Note that if you edit the base definition (source) of a resource at runtime while the portal is running in the Integrated WebLogic Server, iterative development will not work as expected: if you edit the resource file in JDeveloper and save, you will not see the change when the running page is refreshed. The reason is because when a resource is edited at runtime at the base document level in the Integrated WebLogic Server, a *copy* of the resource's base document is created in the MDS write directory. From that point forward, this copied version will be used, and the version of the base document in JDeveloper will be ignored. If you run into this issue and want to pick up changes made to the file in JDeveloper, you will need to re-run the application after taking the following steps:

1. In the Application Navigator, click the **Application Menu** icon next to your application's name and choose **Application Properties**.
2. In the Application Properties dialog, expand the **Run** node in the left pane, then select **MDS**.
3. In the right pane, select **Delete customizations before each run**. Doing so clears the MDS of any runtime customizations every time the application is run.
4. Click **OK**.

8.7.3 Enabling Iterative Development

For details, see Section 2.3.1.1, "Enabling Iterative Development."

8.8 Configuring a Nightly Build Script

When you create a Portal Framework application, an Ant build script and properties file are created automatically for you in the main application directory on the filesystem. These files are:

- `build.xml`– Includes a standard set of targets for cleaning, compiling, building, and deploying the application. You can check this file into source control so that it is available to the developers.
- `build.properties` – Specifies the location of the JDeveloper workspace file (`.jws` file) for your application and the output folder for the application WAR file. Note that the `build.xml` file includes the `build.properties` file, which enables `build.xml` to pick up these environment-specific variables. You can customize the properties file to match the setup and environment variables used in your build environment.

Before running the build script, be sure `JAVA_HOME` and `ANT_HOME` environment variables are set properly. For example:

```
JAVA_HOME = /path_to_your_java_installation/jdk
ANT_HOME = /path_to_your_ant_installation
```

To build and deploy your application, use the ant target `all`. For example:

```
ant all
```

If you are using Oracle WebCenter Portal Personalization to provide personalization features for your portal, you must perform a manual update to the `build.xml` file. For details, see Section 66.3, "Deploying Personalization Files."

8.9 Setting Up a Staging or Production Environment for the First Time

For detailed information on setting up and provisioning a staging or production environment for the first time, see the section "Moving Oracle WebCenter Portal to a New Target Environment," in the *Administrator's Guide*. See also Section 8.15, "Managing Security Through the Life Cycle" for information on moving security policies and credentials to an environment for the first time.

8.10 Moving a WebCenter Portal Framework Application to an Existing Environment

In this scenario, you have a working production environment with Oracle WebCenter Portal installed and configured and you want to test changes in your applications or configuration before rolling those changes into the production environment. For example, you have modified existing security policies or configurations.

Oracle recommends that you use the deploy and configure scripts to update existing environment. Sample scripts are provided with WebCenter, and you are free to modify them to suit your environment. For detailed information, see Section 8.12, "Deploying and Configuring the Application on Targeted Servers" and Section 66.3, "Deploying Personalization Files."

WebCenter provides a Propagation tool that is built in to the WebCenter Portal Administration Console. The Propagation tool is for moving your application from the staging environment to the production environment. See Section 8.13, "Using the Propagation Tool to Propagate From Staging to Production."

For information on moving Oracle WebCenter Content content, see Section 8.14, "Propagating Content From Oracle WebCenter Content."

For information on moving security policies and credentials, see Section 8.15, "Managing Security Through the Life Cycle."

For more information, see the section "Moving Oracle WebCenter Portal to an Existing Target Environment," in the *Administrator's Guide*.

8.11 Deploying to Managed Servers

Portal Framework application developers working in JDeveloper typically deploy their application locally to the Integrated WebLogic Server. For other phases of the life cycle – testing, staging, and production – deployment to a suitable managed server is recommended. Or, for portlet development, you need to deploy to the Services Producer Managed Server. For more information on deploying to managed servers, see Section 7.3, "Deploying a Portal Framework Application to a WebLogic Managed Server" and Section 66.3, "Deploying Personalization Files." See also the section "Creating a Managed Server" in *Administering Oracle WebCenter Portal*.

8.12 Deploying and Configuring the Application on Targeted Servers

During its life cycle, a typical portal is deployed to testing, staging, and production servers. This section describes a technique for deploying and configuring a Portal Framework application on a targeted server.

- Section 8.12.1, "Introduction"
- Section 8.12.2, "Using the Deploy and Configure Script"

8.12.1 Introduction

WebCenter provides a configurable script that allows you to easily deploy and configure your application to these server instances. The build and deploy script takes a simple properties file parameter that specifies the server and connection information for the targeted server. You only need to create this properties file one time for each targeted server. Then, you execute the deploy and configure script with the appropriate properties file as a parameter.

Oracle recommends that you use the scripts described in this section to deploy your application rather than using ojdeploy. The best practice is to use the Ant task provided by JDeveloper to build your application, and then to use the scripts described in this section to deploy and configure the application. The ojdeploy command-line utility allows you to deploy your application from JDeveloper without starting the JDeveloper IDE.

Note: The propagation tool, described in Section 8.13, "Using the Propagation Tool to Propagate From Staging to Production," is primarily used by site administrators to push approved site structure changes to production without incurring any downtime.

Tip: The build and deploy script isolates the information that is variable between environments, like the server names, ports, content management connections, database connections, and so on. Most aspects of the Portal Framework application do not need to change when you redeploy it to another server. For example, the name of the application doesn't change.

8.12.2 Using the Deploy and Configure Script

The deploy and configure script described in this section is primarily used when the production application is mostly read only and live. In this scenario, content contributors make active changes to the staged application and receive content approval before that content is moved to production. Oracle recommends that you use automatic content replication so that content is moved from stage to production after appropriate workflow approvals. See Section 8.14, "Propagating Content From Oracle WebCenter Content."

Security changes are not affected by the deploy and configure scripts. To push site structure changes to production, administrators can use the propagation tool, as described in Section 8.13, "Using the Propagation Tool to Propagate From Staging to Production." See also Section 8.15, "Managing Security Through the Life Cycle."

To deploy and configure your application to a target environment:

1. In a terminal window, go to the directory that contains the deploy and configure scripts. These scripts are called: `create_profile.csh` and `deploy_and_`

config.csh. These files reside in WEBCENTER_HOME/webcenter/scripts/stage2prod, where WEBCENTER_HOME is the directory where WebCenter is installed.

> **Note:** The deploy and configure scripts in stage2prod are samples only. You are free to develop your scripts in a different location (after copying the sample and making changes to it for your deployed environment).

2. First, you need to provide some target environment-specific information in the setup.properties file, like the target server URL, user name, and password. The setup.properties file is located in WEBCENTER_HOME/webcenter/scripts/stage2prod/setup. Simply open the file setup.properties and add the appropriate values for the target environment. A sample file is shown in Example 8–1.

> **Note:** For WebLogic Sever deployments, you can ignore properties listed under WebSphere Server properties. See also the section "Using the Deploy and Configure Script for Applications Deployed on WebSphere" in the *Third-Party Application Server Guide*.

Example 8–1 Sample setup.properties File

```
# Adminserver
admin.jmx.url=t3\://hostname\:7001
admin.user=weblogic
admin.password=welcome1

# Application
webcenter.app.name=webapp
webcenter.app.server=WC_CustomPortal
webcenter.app.version=V2.0
```

3. Update the create_profile.csh and deploy_and_config.csh to reflect the deployed environment.

   ```
   setenv WC_HOME <webcenter_home>
   setenv SCRIPTS_DIR <scripts_home>
   ```

   WC_HOME is the WebCenter Home and SCRIPTS_DIR is where the scripts are located. By default, the scripts are here: $WC_HOME/webcenter/scripts/stage2prod. If you copied the scripts to another location, then set SCRIPTS_DIR to that location.

4. Run the create_profile script. The input to this script is the setup.properites file. For example, in a Linux environment, enter:

   ```
   ./create_profile.csh
   ```

   This script examines your application environment and produces an output properties file called wcconfig.properties in WEBCENTER_HOME/webcenter/scripts/stage2prod/setup.

5. If you wish, rename the output file, wcconfig.properties, to a name that reflects the target environment. For example, if the target environment is your stage environment, you might call the file output file wstage.properties.

The wcconfig.properties file specifies all the configuration information needed to run the portal on the target environment. For example, it includes settings for content management repository, omni portlet, WSRP producers, Oracle WebCenter Portal Personalization and others. Example 8–2 shows a sample profile.properties file.

Example 8–2 Sample profile.properties File

```
webcenter.wcps.app.name=wcps-services
webcenter.wcps.app.server=WC_Utilities
admin.jmx.url=t3\://hostname\:7001
doclib.Content.cis.socket.host=hostname
app.mds.jndi=jdbc/mds/SpacesDS
webcenter.app.archive=/net/hostname/scratch/webapp.ear
doclib.Content.cis.socket.port=9444
webcenter.wcps.archive=/net/hostname/scratch/wcps.mar
webcenter.app.name=webapp
admin.user=weblogic
app.mds.repository=mds-SpacesDS
app.mds.partition=wcps-services
webcenter.app.version=V2.0
web.OmniPortlet.url=http\://hostname\:7101/portalTools/omniPortlet/providers/omniP
ortlet
app.restart=false
webcenter.app.server=WC_CustomPortal
```

Note: All properties in the profile.properties must have a value. If a property is not needed, delete it or comment it out rather than leave the value empty.

6. Run create_profile to create a properties file for each of your target environments. For example, you might create one each for your test, stage, and production environments.
7. Edit the deploy_and_config script to accept as input the wcconfig.properties file (or whatever you renamed it).
8. Run the deploy_and_confg script. The input to this script is the profile.properties file (or whatever you renamed the file). For example, in a Linux environment, might enter:

   ```
   ./deploy_and_config.csh
   ```

The deploy_and_config script takes one of two "modes" as input. These modes are deploy_config and p13n_metadata. For example:

```
./deploy_and_config.csh p13n_metadata
```

The deploy_config mode is the default mode if no input is passed to deploy_and_config.csh. The deploy_config mode does the deployment and configuration tasks. If you only need to update the personalization metadata, you can override the default behavior by passing in p13n_metadata as the input to the script.

This script deploys and configures the Portal Framework application to run on the target environment.

8.12.3 Managing Post-Deployment Changes

All WebCenter Portal configuration changes performed after the application is deployed are stored as customizations in MDS. For example, if your application had some connections defined in `connections.xml`, and you then deployed the application on another managed server, and performed configurations using Oracle Enterprise Manager Fusion Middleware Control Console or WLST, then these changes are stored in MDS as customizations. Subsequently, if you deploy a newer EAR file, the connection changes you performed earlier would still be in effect, and will override the connection definition within the EAR file. The configuration changes performed with the Fusion Middleware Control Console or WLST persist after a redeployment. See also the section "Oracle WebCenter Portal Administration Tools" in the *Administering Oracle WebCenter Portal*.

> **Note:** When you deploy a portlet producer, the customizations are uploaded to the currently configured producer connection. Oracle recommends that you use the deploy and configure scripts to manage the producer connections (rather than reconfiguring them after deployment and then redeploying the application). The deploy and configure scripts ensure that the producer customizations are redeployed correctly whenever the connection information changes.

8.13 Using the Propagation Tool to Propagate From Staging to Production

The WebCenter Portal Administration Console includes a propagation tool for moving portal metadata from a staging to a production server. Site administrators use this tool occasionally to push approved site structure changes to the production server without incurring any downtime.

> **Note:** The Propagation tool supports propagating portal metadata and Oracle WebCenter Portal Personalization files. For more information about propagating Personalization files, see Section 66.3.4, "Propagating Personalization Files."

> **Note:** WebCenter provides WLST commands for importing and exporting portlet preferences. Use these commands to replicate portlet preference data between the stage and production servers. For more information, see Section 8.16, "Migrating Portlet Preferences."

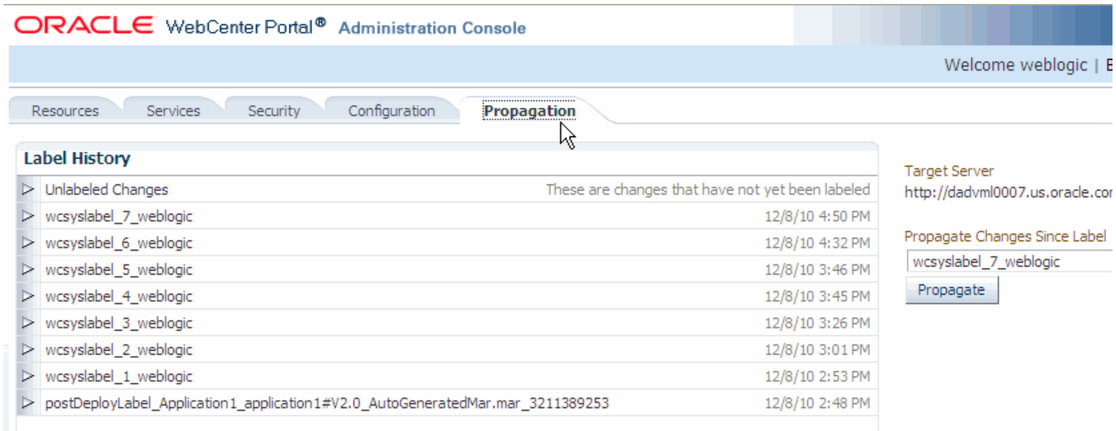
- Section 8.13.1, "Introduction to the Propagation Tool"
- Section 8.13.2, "Configuring the Propagation Tool"
- Section 8.13.3, "Propagating Portal Metadata"

8.13.1 Introduction to the Propagation Tool

WebCenter provides a propagation tool to move a portal metadata from staging to production. In practice, the staging environment and the production remain identical until changes are made to the staged portal. When the changes are tested and approved, an administrator uses the propagation tool to "push" the changes to the production server. This transfer does not require the production server to be restarted.

When properly configured, the Propagation tool shows up as a tab in the WebCenter Portal Administration Console, as shown in Figure 8–3.

Figure 8–3 The Propagation Tab



Label History

- ▷ Unlabeled Changes — These are changes that have not yet been labeled
- ▷ wcsyslabel_7_weblogic — 12/8/10 4:50 PM
- ▷ wcsyslabel_6_weblogic — 12/8/10 4:32 PM
- ▷ wcsyslabel_5_weblogic — 12/8/10 3:46 PM
- ▷ wcsyslabel_4_weblogic — 12/8/10 3:45 PM

Propagate Changes Since Label
wcsyslabel_7_weblogic

The Label History part of the Propagation tab lists the labels that were created for each propagation, labels created outside of the Propagation tab, such as labels created during deployment and labels created using WLST. Each label includes a list of files that change since the last propagation was performed. To view the contents of a label, click the arrow button to the left of the label name, as shown in Figure 8–4.

Figure 8–4 The Propagation Tab with Labels Opened

8.13.2 Configuring the Propagation Tool

> **Note:** If you are using the Propagation tool and if any of the MDS document file names contain multi-byte NLS characters, the stage machine should be configured for that NLS.

The Propagation tab only shows up in the WebCenter Portal Administration Console if the portal deployed to the staging server has a URL Connection configured. This URL connection must point to the production server and it must be named `ProductionURLConnection`.

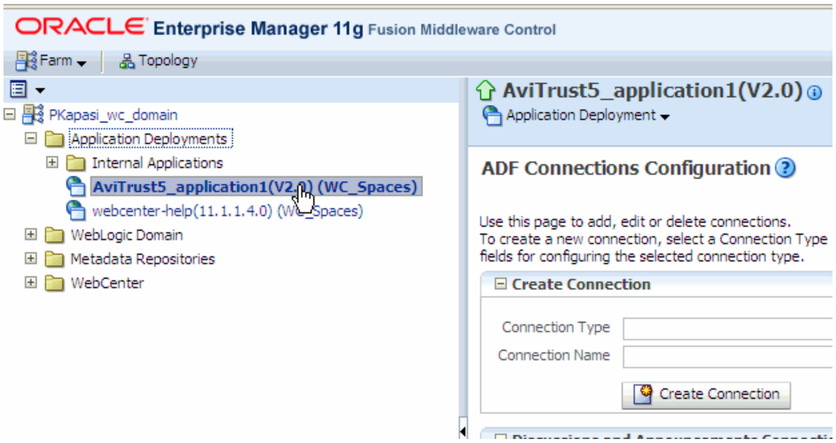
You have two choices for configuring the URL Connection: you can use the Fusion Middleware Control Console or Oracle WebLogic Scripting Tool (WLST). This section explains both techniques.

8.13.2.1 Configuring the URL Connection With Oracle Enterprise Manager Fusion Middleware Control Console

To configure the URL Connection with the Fusion Middleware Control Console:

1. In a browser, open the Fusion Middleware Control Console for your staging server domain. For details on starting the Fusion Middleware Control Console see *Oracle Enterprise Manager Administrator's Guide*.
2. In the navigation tree, open the Application Deployments folder and click on the application. See Figure 8–5.
3. In the application pane on the right, open the **Application Deployment** menu, then select **Configure ADF Connections** from the **ADF** submenu. The ADF Connections Configuration panel opens, as shown in Figure 8–5.

Figure 8–5 Selecting the Application in the Fusion Middleware Control Console

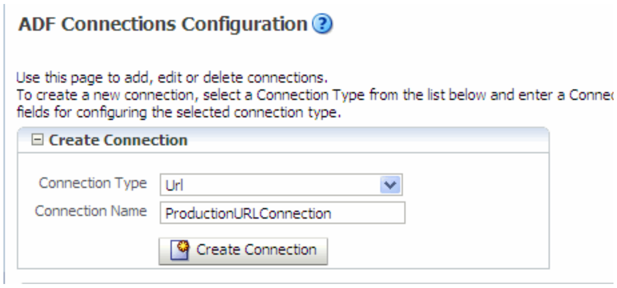


Use this page to add, edit or delete connections. To create a new connection, select a Connection Type fields for configuring the selected connection type.

4. In the Create Connection box, select the URL connection type and enter `ProductionURLConnection` as the Connection Name. See Figure 8–6.

> **Note:** You must name the connection `ProductionURLConnection`. The name is case sensitive.

Figure 8–6 Create Connection



ADF Connections Configuration

Use this page to add, edit or delete connections.
To create a new connection, select a Connection Type from the list below and enter a Connec
fields for configuring the selected connection type.

⊟ Create Connection

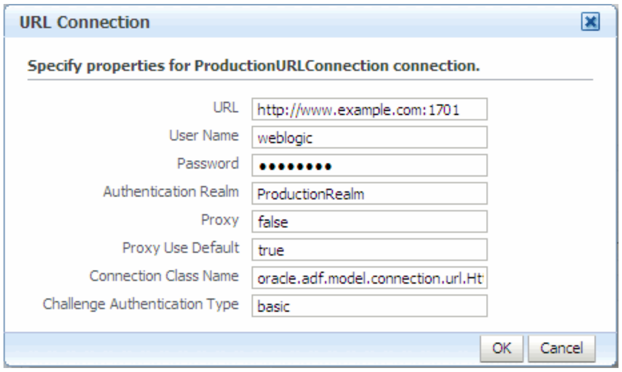
Connection Type: Url

Connection Name: ProductionURLConnection

5. In the URL Connections box, click **Edit**.
6. Complete the URL Connection dialog box as follows.
   - **URL** – Enter the URL (including hostname and port number) of the production server.
   - **Username** – Enter a username for the connection.
   - **Password** – Enter a password for the connection.
   - **Authentication Realm** – You must enter a value for the Authentication Realm. Do not leave this field blank. You can enter any arbitrary string, such as `ProductionRealm`.

     You can accept the default values for the remaining fields. See Figure 8–7.

Figure 8–7 URL Connection Dialog



URL Connection

Specify properties for ProductionURLConnection connection.

URL: http://www.example.com:1701

User Name: weblogic

Password: ••••••••

Authentication Realm: ProductionRealm

Proxy: false

Proxy Use Default: true

Connection Class Name: oracle.adf.model.connection.url.Ht

Challenge Authentication Type: basic

7. Click **OK** after you complete the URL Connection dialog.
8. Click **Apply** in the upper-right corner of the Fusion Middleware Control Console window.

8.13.2.2 Configuring the URL Connection with WLST

You can use a Oracle WebLogic Scripting Tool (WLST) command to create the URL Connection. Note that the parameters to the command are equivalent to the values entered in the URL Connection dialog in the Fusion Middleware Control Console, described in the previous section, Section 8.13.2.1, "Configuring the URL Connection With Oracle Enterprise Manager Fusion Middleware Control Console."

The following is an example of the WLST command with sample values specified for each parameter. Replace these values with values that pertain to your production server:

```
adf_createHttpURLConnection(appName='portalApp', name='ProductionURLConnection',
url='http://production_adminserver_host:7001', user='weblogic',
password='password_for_weblogic', realm='ProductionRealm'
```

For information on WLST, see the *WebLogic Scripting Tool Command Reference* on the Oracle Technology Network.

8.13.3 Propagating Portal Metadata

Use the propagation tool when you want to move changes made on the staging portal to the production portal.

1. Be sure the propagation tool is configured, as described in Section 8.13.2, "Configuring the Propagation Tool." To use the propagation tool, you must have Administrator's privileges.
2. Open the WebCenter Portal Administration Console. By default, the administration console is located at this URL:

   `http://<server>:<port>/<context_root>/admin`

For more information on using the WebCenter Portal Administration Console, see the section "Administering Portal Framework Applications Using the Administration Console" in the *Administering Oracle WebCenter Portal*.

3. Select the Propagation tab.

   > **Note:** If you don't see the Propagation tab it could be because you don't have administrator's privileges or the propagation tool was not configured properly as explained in Section 8.13.2, "Configuring the Propagation Tool."

4. Click **Propagate** to transfer the files to the production server.

8.14 Propagating Content From Oracle WebCenter Content

Oracle recommends that you use either manual or automated replication to move content from one environment to another. Another option is to manually propagate content; however, this option is only recommended if the source and target servers are unable to communicate with each other.

For detailed information on the tools and options for propagating Oracle WebCenter Content content, see the chapter "Understanding System Migration and Archiving" in the *Oracle WebCenter Content System Administrator's Guide for Content Server*. That chapter explains how to propagate Oracle WebCenter Content content by exporting and importing archive files. In addition, the chapter explains how to set up and use replication. Replication can automate the export, import, and transfer functions. For example, you can use replication to automatically export from one content server instance, transfer the archive to another computer, and import to another content server instance.

8.15 Managing Security Through the Life Cycle

This section discusses techniques for migrating security policies and credentials from one environment to another. Migration can be either automatic or manual. Automatic migration is typically used when the application is first deployed. Manual migration is used on redeployment.

8.15.1 Migrating Security Policies for First-Time Deployment

When jazn-data.xml with application policies is packaged in the EAR file, Oracle Platform Security Services (OPSS) performs policy migration based on the application configuration settings in weblogic-application.xml. Example 8–3 shows the recommended settings in weblogic-application.xml to achieve automatic policy migration for first-time deployment.

Example 8–3 Settings for Automatic Policy Migration (weblogic-application.xml)

```
<wls:application-param>
    <wls:param-name>jps.policystore.migration</wls:param-name>
    <wls:param-value>MERGE</wls:param-value>
</wls:application-param>

<wls:application-param>
    <wls:param-name>jps.policystore.removal</wls:param-name>
    <wls:param-value>OFF</wls:param-value>
</wls:application-param>

<wls:listener>

<wls:listener-class>oracle.security.jps.wls.listeners.JpsApplicationLifecycleListe
ner</wls:listener-class>
</wls:listener>
```

JpsApplicationLifecycleListener must be specified in weblogic-application.xml to enable policy and credential migration. Oracle recommends that jps.policystore.migration should be set to MERGE. With this configuration, polices packaged in jazn-data.xml will be always migrated during first time deployment. Oracle also recommends that jps.policystore.removal should be set to OFF so that application policies are not deleted from the policy store when the application is undeployed.

8.15.2 Migrating Security Policies On Redeployment

On redeployment, it is important to avoid overwriting policy changes made on the production system. When jps.policystore.migration parameter is set to MERGE, all new policies from the stage environment will be merged with production policies. With this setting, any changes made to existing policies, such as changing permissions for a role, deleting a role, or removing membership of a role, will not be migrated during redeployment, because such migration would cause a conflict.

If you want to overwrite the production policies with the staging environment security policies packaged in jazn-data.xml, use the migrateSecurityStore WLST command. See *Oracle Fusion Middleware Application Security Guide* for details on migrateSecurityStore command.

8.15.3 Migrating Credentials for First-Time Deployment

Application credential migration support is similar to application policy migration. JpsApplicationLifecycleListener supports credential migration in application deployment and redeployment with extra security enforcements.

With application credentials in cwallet.sso and packaged in an EAR file in the META-INF/ directory, OPSS will perform credential migration to system credential store based on the configuration settings in weblogic-application.xml.

Example 8–3 shows the recommended settings in weblogic-application.xml to achieve automatic credential migration for first-time deployment.

Example 8–4 Settings for Automatic Credential Migration (weblogic-application.xml)

```
<wls:application-param>
    <wls:param-name>jps.credstore.migration</wls:param-name>
    <wls:param-value> MERGE </wls:param-value>
</wls:application-param>
```

Oracle recommends that jps.credstore.migration should be set to MERGE so that at deployment and redeployment time all new credentials will be migrated. This setting will only migrate new credential key/value from cwallet.sso. Modification done to existing credential keys will not be migrated.

8.15.4 Migrating Credentials On Redeployment

If credentials are modified on stage and need to be moved to production, use the command migrateSecurityStore to migrate modified credentials. See *Oracle Fusion Middleware Application Security Guide* for details on migrateSecurityStore command.

8.16 Migrating Portlet Preferences

WebCenter provides WLST commands for importing and exporting portlet preferences. Exported preferences (customizations and personalizations) can be imported into a target application – for example, exported from the staging application and imported into the production application. For more information, see exportPortletClientMetadata and importPortletClientMetadata in "WebCenter Portal Custom WLST Commands" in the *WebLogic Scripting Tool Command Reference*. Also ensure that export and import are enabled. See Section 59.3.15, "How to Export and Import Portlet Producers at Design Time."

See also Section 61.5, "Deploying a Portlet Producer to a WebLogic Managed Server."

8.17 Rolling Back Production Site Changes

In rare instances, it might be necessary to roll back changes that are pushed to the production server from staging. The propagation model described in this chapter assumes that you are making a small number of changes to the staging instance and then pushing them to production using the propagation tool. If you ever need to roll back those changes, Oracle recommends that you manually undo the changes on the staging instance and push the modified staging instance back to production, after adequate validation and testing. By this process, you will have "rolled back" the original changes and the production system will be reverted to its original state.

9 Introduction to Portal Resource Management

This chapter describes the different portal resources available for you to use in your WebCenter Portal Framework applications, and some of the common operations you can perform on them. Portal resources include navigation models, page templates, page styles, resource catalogs, and so on.

This chapter includes the following topics:

- Section 9.1, "Introduction to Portal Resources"
- Section 9.2, "Creating Portal Resources"
- Section 9.3, "Editing Portal Resources"
- Section 9.4, "Deleting Portal Resources"
- Section 9.5, "Working with Portal Resources at Runtime"
- Section 9.6, "Working with Round-Trip Development"
- Section 9.7, "Working with WebCenter Portal Resources"

> **Tip:** Portal resources are also sometimes referred to as assets.

9.1 Introduction to Portal Resources

Portal Framework applications provide the following portal resources to help you define the structure, look and feel, and content of your portal:

- **Page Templates** define the interface that surrounds page content and help to apply a consistent look and feel across groups of pages. For more information, see Chapter 11, "Developing Page Templates."
- **Navigation Models** define how to link together information from multiple sources, such as pages, content repositories, and external web pages. For more information, see Chapter 10, "Developing a Navigation Model."
- **Resource Catalogs** define the components that users can add to their pages, page templates, and task flows. For more information, see Chapter 14, "Developing Resource Catalogs."
- **Skins** define the appearance and look and feel, including colors and fonts, of a specific portal or the entire application. For more information, see Chapter 13, "Developing Skins."
- **Page Styles** define the layout of a newly created page, and may also dictate the type of content the page supports. For more information, see Section 12.2, "Developing Page Styles."

- **Content Presenter Display Templates** define templates for displaying content. For more information, see Chapter 27, "Creating Content Presenter Display Templates."
- **Task Flow Styles** are used at runtime to define the layout of task flows created using Data Presenter to display data controls. For more information, see Section 12.3, "Developing Task Flow Styles."

9.2 Creating Portal Resources

The process for creating a portal resource depends on the type of portal resource.

Table 9–1 shows where to find further information about creating the different portal resources.

Table 9–1 Creating Portal Resources

Portal Resource	More Information
Page Template	Section 11.3, "Creating a Page Template"
Navigation Model	Section 10.2, "Creating a Navigation Model"
Resource Catalog	Section 14.2, "Creating a Resource Catalog"
Skin	Section 13.3, "Creating a Skin"
Page Style	Section 12.2.1, "How to Create a Page Style"
Content Presenter Display Template	Section 27.3, "Creating Content Presenter Display Templates"
Task Flow Style	Section 12.3.1, "How to Create a Task Flow Style"

9.3 Editing Portal Resources

The process for editing a portal resource depends on the type of portal resource.

Table 9–2 shows where to find further information about editing the different portal resources.

Table 9–2 Editing Portal Resources

Portal Resource	More Information
Page Template	Section 11.4, "Editing a Page Template"
Navigation Model	Section 10.3, "Editing a Navigation Model"
Resource Catalog	Section 14.3, "Editing a Resource Catalog"
Skin	Section 13.4, "Editing a Skin"
Page Style	Section 12.2.1, "How to Create a Page Style"
Content Presenter Display Template	Section 27.3, "Creating Content Presenter Display Templates"
Task Flow Style	Section 12.3.1, "How to Create a Task Flow Style"

9.4 Deleting Portal Resources

When a portal resource is no longer required, you may want to remove it.

Note: Before you delete a portal resource, you must ensure that the resource is not in use. If you mark a portal resource for deletion, it is deleted even if it is in use.

To delete a portal resource:

1. In the Application Navigator, right-click the portal resource that you want to delete and choose **Delete**.
2. The Confirm Delete dialog identifies if the portal resource is used within the application. Click **Show Usages** for more details.

   You can use this information to determine whether you really want to delete the portal resource.
3. Click **Yes** to continue and delete the navigation model. Click **No** to cancel the operation.

9.5 Working with Portal Resources at Runtime

Tip: At runtime, portal resources are referred to as assets.

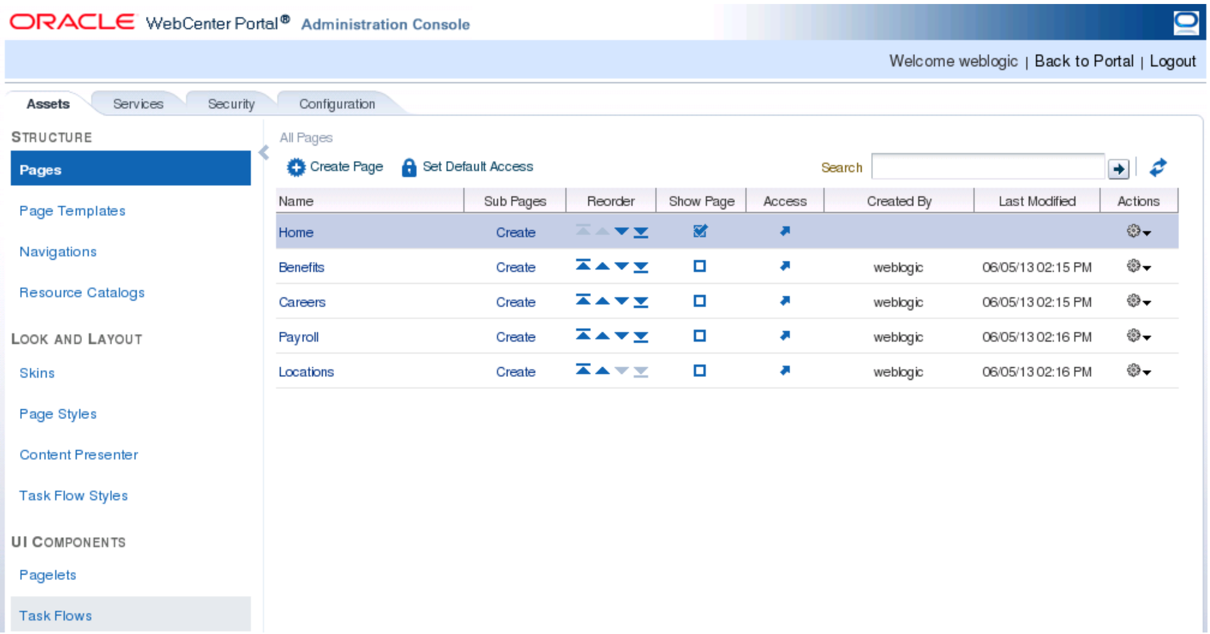
A portal is a constantly evolving application. While the initial framework for the portal is designed prior to deployment, this really acts as a starting point. The design of the portal is likely to be enhanced by the actual users of the portal.

This runtime resource management provides:

- **Runtime development**—Continue developing your portal after deployment by creating portal resources, such as pages, skins, and data controls at runtime. For more information, see Section 9.5.1.5, "How to Use the Assets Page at Runtime."
- **Round-trip development**—Pull portal resources from the deployed portal into JDeveloper for further development and then upload the enhanced resources back into the running application. For more information, see Section 9.6, "Working with Round-Trip Development."
- **Iterative development—**Supply a running portal with new or improved visualizations of metadata-only resources from JDeveloper without the need to redeploy or restart the application. For more information, see Section 2.3.1, "Preparing for Iterative Development in a Portal Framework Application."
- **Extension of WebCenter Portal**—Build and manage new WebCenter Portal resources in JDeveloper and package them on a periodic basis for distribution to the runtime portal. For more information, see Section 55.1, "Developing Assets for WebCenter Portal."

Portal Framework applications enable runtime portal resource management through the Assets page of the runtime administration console. Using the administration console, users with the appropriate privileges can continue developing the portal after the application has been deployed (Figure 9–1).

Figure 9–1 The Assets Page of the Runtime Administration Console



Name	Sub Pages	Reorder	Show Page	Access	Created By	Last Modified	Actions
Home	Create		☑				
Benefits	Create		□		weblogic	06/05/13 02:15 PM	
Careers	Create		□		weblogic	06/05/13 02:15 PM	
Payroll	Create		□		weblogic	06/05/13 02:16 PM	
Locations	Create		□		weblogic	06/05/13 02:16 PM	

At runtime, users with the appropriate privileges can create and manage the following resources:

- Pages
- Page templates
- Navigation models
- Resource catalogs
- Skins
- Page styles (can be created at runtime only by copying an existing page style)
- Content Presenter display templates (cannot be created at runtime)
- Task flow styles (can be created at runtime only by copying an existing task flow style)
- Task flows
- Data controls

Using the Assets page of the runtime administration console, users can also download portal resources, or an entire application, from the runtime environment, edit them in JDeveloper, and then upload them back into the deployed application.

Users can also create portal resources from scratch in JDeveloper, export them to an archive file, and then upload them into the deployed portal. This is a very useful way of creating more fully functional portal resources for use in WebCenter Portal.

This process is known as round-trip development. For more information, see Section 9.6, "Working with Round-Trip Development."

9.5.1 Enabling Runtime Administration of Portal Resources

You can enable portal administrators to manage portal resources at runtime by exposing them on the Assets page of your application.

If you use the WebCenter Portal Framework Application template to create your application, the Assets page is automatically provided as part of the runtime administration console.

If you prefer, you can add the Assets page to any other page in your application by adding the List of Resource Types task flow to that page.

For a portal resource to be exposed on the Assets page, and therefore available for runtime administration, it must be located under the `oracle/webcenter/portalapp` directory of the application project and explicitly identified as a portal resource.

This section includes the following topics:

- Section 9.5.1.1, "How to Add the Assets Page to a Page"
- Section 9.5.1.2, "How to Include a Portal Resource on the Assets Page"
- Section 9.5.1.3, "How to Update Portal Resource Properties"
- Section 9.5.1.4, "How to Remove a Portal Resource from the Assets Page"
- Section 9.5.1.5, "How to Use the Assets Page at Runtime"

9.5.1.1 How to Add the Assets Page to a Page

For applications created using the WebCenter Portal Framework Application template, the Assets page is available out of the box as part of the runtime administration console (Figure 9–1).

In addition, you can add the Assets page to any page in your application. This is especially useful if you do not want to use the WebCenter Portal Framework Application template, and the runtime administration console is therefore not part of your project.

When you add the Assets page to a page, anyone with view access to the page can view the Assets page and perform view related operations on portal resources, such as viewing resource properties, previewing resources, and so on. For users to be able to perform other operations on portal resources, such as creating new resources, editing resources, or deleting resources, they must have the appropriate permissions on the type of portal resource with which they want to work. These permissions can be provisioned using the Role Manager task flow. For more information, see Section 74.4, "Using the Role Manager Task Flow."

> **Tip:** By default, the `Administrator` role has manage access on all portal resource types available on the Assets page.

To add the Assets page:

1. Open the page to which you want to add the Assets page.
2. In the Resource Palette, expand the **WebCenter Portal - Services Catalog** and then **Task Flows**.
3. Select the **List of Asset Types** task flow and drag it to the desired location on the page.
4. From the menu that displays, select **Region**.

   You may be prompted to add the Assets page library to the project. Confirm by clicking **Add Library**.
5. The Assets page is added to the page.

6. To enable users to upload and download portal resources at runtime, the `usesUpload` property for the form that contains the Assets page task flow must be set to true:

```
<af:form id="f1" usesUpload="true">
```

9.5.1.2 How to Include a Portal Resource on the Assets Page

To include a portal resource on the Assets page, and therefore enable runtime administration of it, you must explicitly identify the resource as a portal resource.

For navigation models and resource catalogs, you have the option of identifying the resource as a portal resource when you first create it by selecting the **Create as Portal Resource** check box. For other resources, for example, page templates and skins, you must identify the resource as a portal resource after you create it.

To include a portal resource on the Assets page:

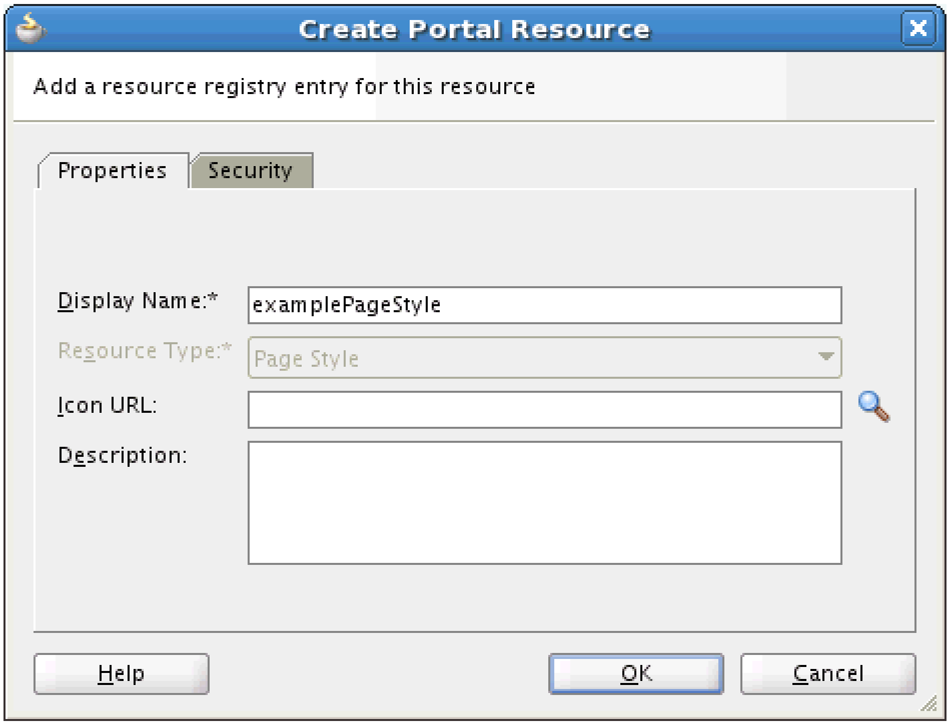
1. In the Application Navigator, right-click the portal resource that you want to include on the Assets page and choose **Create Portal Resource**.

> **Note:** If you do not see the **Create Portal Resource** option in the context menu, the resource is not under the `oracle/webcenter/portalapp` directory. To move the resource to the correct directory, right-click it, choose **Refactor**, and then **Move**.

2. In the Create Portal Resource dialog (Figure 9–2), in the **Display Name** field, edit the name if required.

   This is the name that is listed on the Assets page at runtime, so make sure that users are able to easily identify the resource from the display name.

Figure 9–2 The Create Portal Resource Dialog



Display Name:* examplePageStyle

Resource Type:* Page Style

Icon URL:

Description:

3. The **Resource Type** field identifies the kind of resource you are including on the Assets page. You cannot edit this field.

4. In the **Icon URL** field, enter the path and file name of an image to use as a graphical representation of the portal resource.

   This image is used for page styles only to specify the icon to display in the Create Page dialog.

5. In the **Description** field, enter a description for the portal resource. This description should help users determine if they want to use the resource in their application.

   The description is displayed below the portal resource's name on the Assets page.

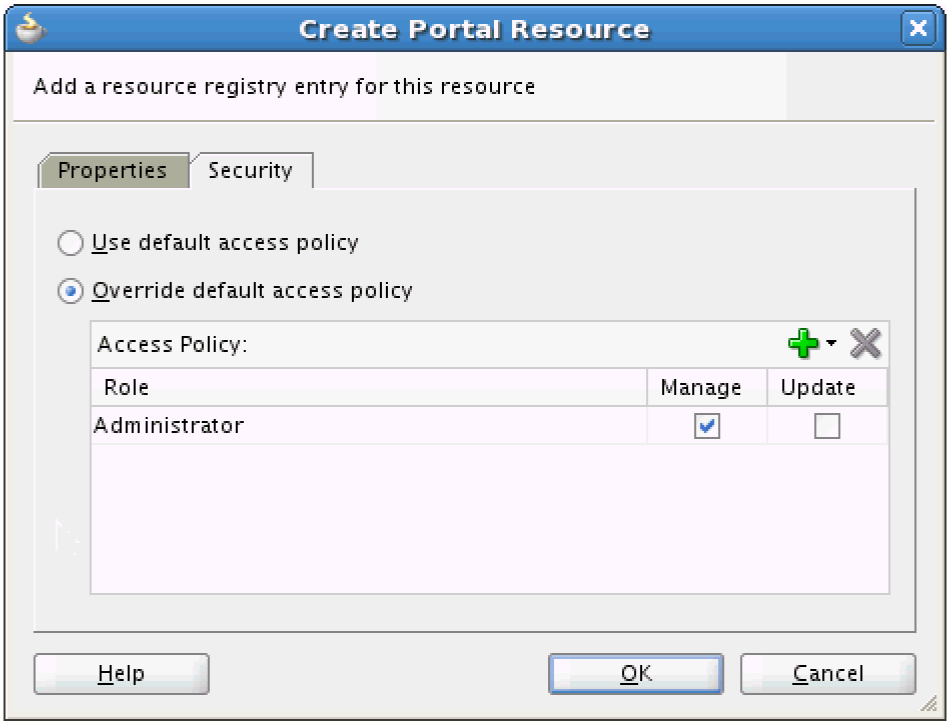
6. Provide values for any additional attributes supported by the portal resource.

7. If you want to specify resource-level security for the portal resource, click the **Security** tab. Otherwise, skip to step 11.

   Resource-level security enables you to override the application-level security for individual portal resources to specify who can edit and delete the resource at runtime.

8. Select **Override default access policy** (Figure 9–3).

Figure 9–3 Create Portal Resource - Security Tab



Add a resource registry entry for this resource

○ Use default access policy

● Override default access policy

Access Policy:

Role	Manage	Update
Administrator	☑	□

9. Click the **Add permissions to new role** icon (represented by a plus sign) and select the role for which you want to grant permissions.

10. Select the **Manage** check box to grant full access to the portal resource at runtime. Users with this role can edit and delete the portal resource.

    Select the **Update** check box to grant the permission to edit the portal resource at runtime. Users with this role can edit the portal resource, but they cannot delete it.

> **Note:** The user must also have the appropriate permissions to access the Assets page. For more information, see Section 9.5.1.1, "How to Add the Assets Page to a Page."

11. Click **OK**.

    The portal resource is exposed on the Assets page and users with the appropriate privileges can manage the resource at runtime.

9.5.1.3 How to Update Portal Resource Properties

You can update the details of portal resources that are exposed on the Assets page.

To update portal resource properties:

1. In the Application Navigator, right-click the portal resource that you want to edit and choose **Update Portal Resource**.
2. In the Update Portal Resource dialog, edit the fields as necessary.

   For information about the fields in this dialog, see Section 9.5.1.2, "How to Include a Portal Resource on the Assets Page."
3. When you are done, click **OK**.

9.5.1.4 How to Remove a Portal Resource from the Assets Page

If you no longer want users to be able to administer a particular portal resource at runtime, you can remove it from the Assets page.

To remove a portal resource from the Assets page:

1. In the Application Navigator, right-click the portal resource that you want to remove and choose **Remove Portal Resource**.
2. In the Remove Portal Resource dialog, click **Yes** to confirm that you want to remove the portal resource from the Assets page.

   The portal resource is removed from the Assets page and can no longer be managed at runtime. The portal resource itself is not deleted, so it is still available for use within the Portal Framework application.

9.5.1.5 How to Use the Assets Page at Runtime

At runtime, the Assets page provides access to administration tools for the resources available to the portal. For example, the administrator can create new portal resources (navigation models, page templates, skins, and so on), edit existing resources, upload resources exported from other applications, and so on.

For information about how to manage portal resources at runtime using the Assets page of the runtime administration console, see the "Managing Assets for a Portal Framework Application" section in *Administering Oracle WebCenter Portal*.

9.6 Working with Round-Trip Development

If you enable runtime administration of your portal resources, you may want to be able to pull those resources back into JDeveloper. For example, if a user adds a new navigation model to a portal at runtime, you may want to further refine it in JDeveloper. To do this, you must download the portal resource from the deployed application, using the Assets page. You can then import the portal resource into

JDeveloper, carry out your development work, export the resource, and finally upload it back into the deployed application. This is known as round-trip development.

You can do this with portal resources in any deployed Portal Framework application that includes the Assets page, including WebCenter Portal.

> **Note:** Oracle WebCenter Portal provides a JDeveloper project (`WebCenterSpacesResources`) to help you develop portal resources for WebCenter Portal. Section 55, "Developing Components for WebCenter Portal Using JDeveloper" explains how to use the `WebCenterSpacesResources` project to build resources for use in WebCenter Portal.

The process for round-trip development works as follows:

1. Build Portal Framework application in JDeveloper
2. Deploy application
3. Add or edit portal resources and add content to the application at runtime
4. Download portal resource to EAR file using the Assets page

   See Section 9.6.1, "How to Download a Portal Resource Using the Assets Page"
5. Import EAR file into JDeveloper

   See Section 9.6.2, "How to Import a Portal Resource into JDeveloper"
6. Edit portal resource in JDeveloper
7. Export portal resource to EAR file

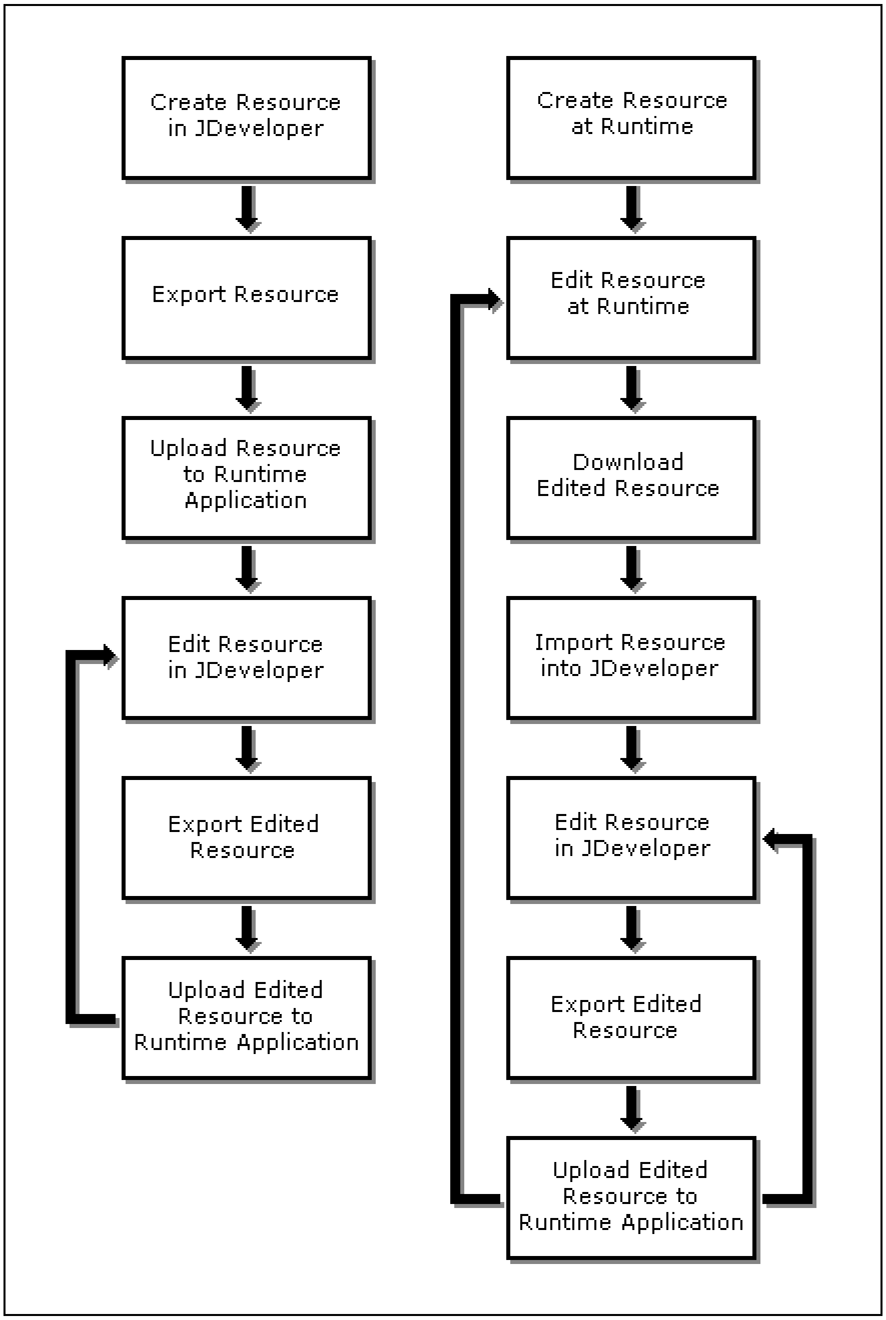
   See Section 9.6.3, "How to Export a Portal Resource from JDeveloper"
8. Upload portal resource to deployed application using the Assets page

   See Section 9.6.4, "How to Upload a Resource Using the Assets Page"
9. Repeat from step 3.

In addition, after the deployment of the application, developers can continue to create and edit portal resources in JDeveloper and upload those resources to the deployed application periodically.

Figure 9–4 illustrates the round-trip development process described above.

Figure 9–4 Round-Trip Development



Create Resource in JDeveloper
Export Resource
Upload Resource to Runtime Application
Edit Resource in JDeveloper
Export Edited Resource
Upload Edited Resource to Runtime Application
Create Resource at Runtime
Edit Resource at Runtime
Download Edited Resource
Import Resource into JDeveloper
Edit Resource in JDeveloper
Export Edited Resource
Upload Edited Resource to Runtime Application

This section includes the following topics:

- Section 9.6.1, "How to Download a Portal Resource Using the Assets Page"
- Section 9.6.2, "How to Import a Portal Resource into JDeveloper"
- Section 9.6.3, "How to Export a Portal Resource from JDeveloper"
- Section 9.6.4, "How to Upload a Resource Using the Assets Page"

Note: You cannot upload a task flow created in and exported from JDeveloper into a deployed application (or into WebCenter Portal), but you can import a task flow created at runtime into JDeveloper, modify it, and export it back to the runtime application. The steps to import, modify, and export task flows are the same as those for task flow styles. Therefore, the export, import, and edit tasks in this section are applicable for task flows and task flow styles.

For information about adding and exporting custom task flows, see Section 15.4, "Adding Custom Task Flows to a Page."

9.6.1 How to Download a Portal Resource Using the Assets Page

To edit a portal resource in JDeveloper, you first need to use the Assets page in the deployed application to download the portal resource to an EAR file that contains all the metadata for the resource.

For information about how to do this, see the "Downloading an Asset" section in *Administering Oracle WebCenter Portal*.

9.6.2 How to Import a Portal Resource into JDeveloper

When you have the EAR file, you can import it into JDeveloper, where you can then edit the portal resource.

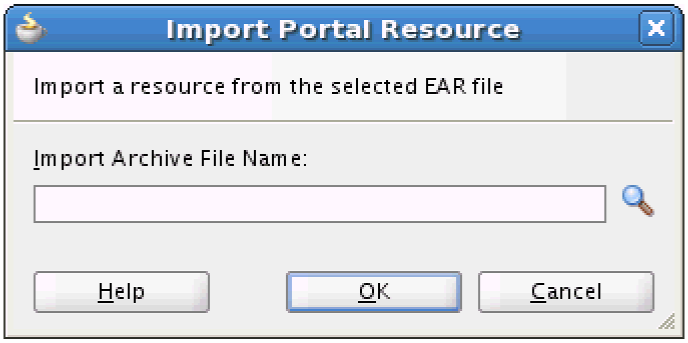
Note: You must import the portal resource into a Portal Framework application or an application that includes the appropriate technology scopes.

Note: When you import a portal resource into JDeveloper, if the resource already exists, the resource in JDeveloper is overwritten with the one from the archive. The original resource is saved to a temporary location, which is identified in the log.

To import a portal resource into JDeveloper:

1. In the Application Navigator, right-click the **Portal** project of the application into which you want to import the resource, and choose **Import Portal Resource**.
2. In the Import Portal Resource dialog (Figure 9–5), in the **Import Archive File Name** field, enter or browse for the archive file that contains the portal resource that you want to import.

Figure 9–5 The Import Portal Resource Dialog



Import Portal Resource

Import a resource from the selected EAR file

Import Archive File Name:

3. Click **OK**.

Note: Artifacts used or referenced by portal resources, such as icons and images, are not included in the archive when a portal resource is downloaded. When you import the portal resource, you must manage and move dependent artifacts manually. We recommend that you use a folder structure on your content server specifically for portal resource artifacts so that content is easy to identify and move, if required.

If you are managing legacy portal resources that store artifacts in MDS, we recommend that you relocate dependent artifacts to your content server. However, if you do need to move artifacts stored in MDS, you can use the MDS WLST commands `exportMetadata` and `importMetadata`.

9.6.3 How to Export a Portal Resource from JDeveloper

After editing the portal resource, you must export it to create an EAR file that can be uploaded to the deployed application.

To export a a portal resource from JDeveloper:

1. In the Application Navigator, right-click the resource that you want to export and choose **Export Portal Resource**.

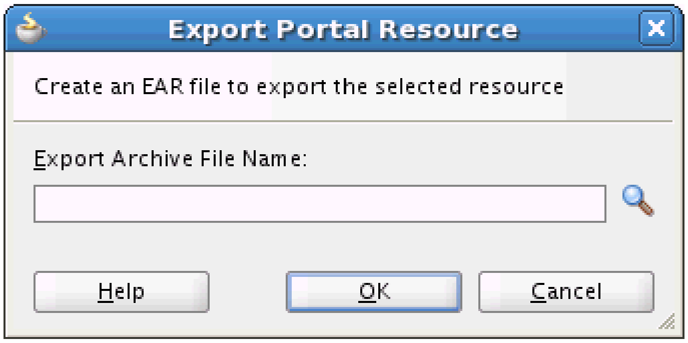
Note: If you do not see the **Export Portal Resource** option in the context menu, the resource is not a portal resource. For information about how to create the resource as a portal resource, see Section 9.5.1.2, "How to Include a Portal Resource on the Assets Page."

---

2. In the Export Portal Resource dialog (Figure 9–6), in the **Export Archive File Name** field, enter or browse for the path and file name for the export file.

   If you select an existing file, the contents of the file will be overwritten.

Figure 9–6 The Export Portal Resource Dialog



Export Portal Resource
Create an EAR file to export the selected resource
Export Archive File Name:
Help
OK
Cancel

3. Click **OK**.

   The export archive contains the files that make up the resource, for example, the JSPX file and the page definition. The archive also contains the `generic-site-resources.xml` file and the registry file with just the information about the exported resource.

> **Note:** Artifacts used or referenced by portal resources, such as icons and images, are not included in the archive. When you upload the portal resource, you must manage and move dependent artifacts manually. We recommend that you use a folder structure on your content server specifically for portal resource artifacts so that content is easy to identify and move, if required.
>
> If you are managing legacy portal resources that store artifacts in MDS, we recommend that you relocate dependent artifacts to your content server. However, if you do need to move artifacts stored in MDS, you can use the MDS WLST commands `exportMetadata` and `importMetadata`.

9.6.4 How to Upload a Resource Using the Assets Page

The final step is to take the EAR file of the updated resource and use the Assets page to upload the resource back into the deployed application.

For information about how to do this, see the "Uploading an Asset" section in *Administering Oracle WebCenter Portal*.

9.7 Working with WebCenter Portal Resources

WebCenter Portal is a web-based application that offers the very latest technology for building portals, social networking, communication, collaboration, and personal productivity. Out of the box, WebCenter Portal provides various built-in portal resources that users can leverage in their portals. If these built-in portal resources do not meet users' requirements, application administrators can build more within WebCenter Portal. For more information, see the "Creating Assets" section in *Building Portals with Oracle WebCenter Portal*.

> **Tip:** In WebCenter Portal, portal resources are referred to as assets.

In some cases, WebCenter Portal may not provide the necessary controls to create a portal resource that provides all the required functionality. In such cases, you can bring portal resources originally created in WebCenter Portal into JDeveloper for editing, and then upload them back into WebCenter Portal.

In addition, some portal resources used by WebCenter Portal, such as page styles and task flow styles, cannot be created in WebCenter Portal. Instead, these resources must be created in JDeveloper and then exported and uploaded to WebCenter Portal.

Oracle WebCenter Portal provides a special JDeveloper project (`WebCenterSpacesResources`) to help you develop portal resources for use in WebCenter Portal. For more information, see Section 55.1, "Developing Assets for WebCenter Portal."

When working with WebCenter Portal resources in JDeveloper, you should consider the following:

Navigation Models

- All the resources required for a WebCenter Portal navigation model exist within WebCenter Portal. Therefore, you should really only use JDeveloper to restructure WebCenter Portal navigation models and perform minor edits. First, you should create as much of the navigation model in WebCenter Portal as possible and add the required resources. You can then use JDeveloper to refine the order of the resources and set all required attributes and parameters.
- If you do want to use JDeveloper to add resources to a WebCenter Portal navigation model, you should obtain the path for the resource from WebCenter Portal by accessing the Show Properties dialog for the resource. For more information, see the "Viewing Information About an Asset" section in *Building Portals with Oracle WebCenter Portal*.
- When adding resources to a WebCenter Portal navigation model, you must manually enter the path to the resource. You cannot use the **Browse** icon. For example, to enter a link to a page, you must identify the ID of the page in WebCenter Portal and then enter that value manually as `page://`*`pathToXmlFile`*.

Page Templates

- The page template must include a facet definition called `content`.
- The page template must include at least one UI component with `class="WCPGTEMPLATE"`. The runtime editing of skins enables the targeting of the template background in a basic tab; it depends on this style being there.

10

Developing a Navigation Model

This chapter describes how to use Oracle JDeveloper to create and manage the navigation for your WebCenter Portal Framework applications.

This chapter includes the following topics:

10.1 Introduction to Navigation Models

Typically, a portal is made up of many pages that provide information from various different sources. Users need a way to easily move through all these pages to quickly access the specific information that they need. You provide this path through your portal's pages with your portal navigation.

You can also use your portal navigation to provide access to other resources, such as external pages, content repositories, portlets, and task flows.

A **navigation model** defines the content, structure, and metadata of the navigation. When you create the navigation model, you specify the items to include and the hierarchy of those items. Navigation models can include the following resources:

- Pages (individual pages and page hierarchies)
- External links

- Content (individual content items or the results of a content query)
- Other navigation models
- Portlets, task flows, and external applications

For more information, see Section 10.3, "Editing a Navigation Model."

You can also add resources that are dynamically generated:

- Custom Resources
- Components
- Custom Folders
- Custom Content

For more information, see Section 10.3.6, "How to Add Dynamically Generated Resources to a Navigation Model."

Seeded Navigation Model

When you create a new Portal Framework application, a navigation model is created for you (`default-navigation-model.xml`). You can build on this seeded navigation model or create your own. You might even want to create different navigation models for different user types.

> **Note:** If you create your own navigation model, rather than extend the seeded navigation model, we recommend that you set your navigation model as the default navigation model. For more information, see Section 10.4, "Selecting the Default Navigation Model."

After you have created your navigation model, you can expose it on any page or page template in your portal. For more information, see Section 10.11, "Visualizing Portal Navigation."

Runtime Management

Portal Framework applications support the runtime administration of navigation models to help users continue developing a portal even after it has been deployed. With runtime administration, authorized users can manage an application's navigation models, and create new ones, in a browser-based environment, with no requirement to install or understand JDeveloper. For more information, see Section 9.5, "Working with Portal Resources at Runtime."

Round-Trip Development

You can bring navigation models that have been created or modified at runtime back into JDeveloper to ensure that any changes are not lost if the portal is redeployed. You can also edit these navigation models to further enhance them if necessary, and upload them back into the deployed portal. For more information, see Section 9.6, "Working with Round-Trip Development."

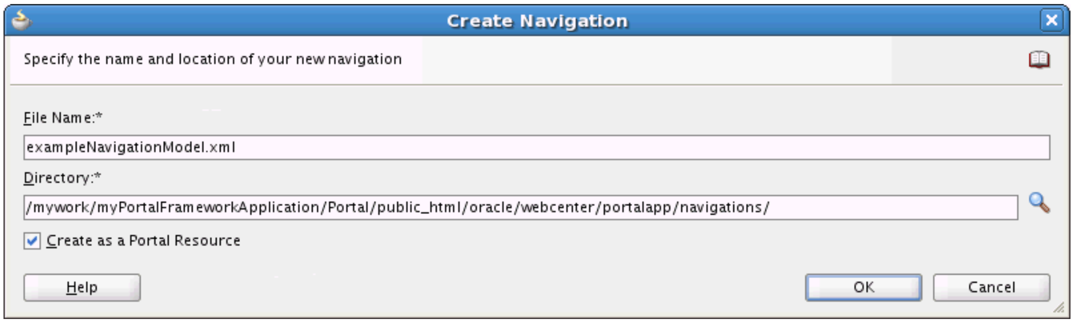
10.2 Creating a Navigation Model

If the seeded navigation model created for your application does not meet your requirements, you can create your own navigation model.

To create a navigation model:

1. In the Application Navigator, right-click the node where you want to create the navigation model (typically, `/oracle/webcenter/portalapp/navigations`) and choose **New**.
2. In the New Gallery, expand **Web Tier**, select **Portal Framework** and then **Navigation**, and click **OK**.
3. In the Create Navigation dialog (Figure 10–1), in the **File Name** field, enter a name for the XML file that represents the navigation model, for example `mainNavigation.xml`.

Figure 10–1 The Create Navigation Dialog



Create Navigation

Specify the name and location of your new navigation

File Name:*

exampleNavigationModel.xml

Directory:*

/mywork/myPortalFrameworkApplication/Portal/public_html/oracle/webcenter/portalapp/navigations/

☑ Create as a Portal Resource

4. In the **Directory** field, enter the full directory path of the location under which to create the navigation model definition XML file.

> **Note:** In a Portal Framework application, to expose the new navigation model in the Assets page of the runtime administration console, you must create the navigation model under the *`Application_Root`*`/Portal/public_html/oracle/webcenter/portalapp` directory. By default Portal Framework application includes a separate `navigations` directory.

5. Select **Create as a Portal Resource** to enable users with the appropriate permissions to manage the navigation model at runtime in the Assets page of the runtime administration console.

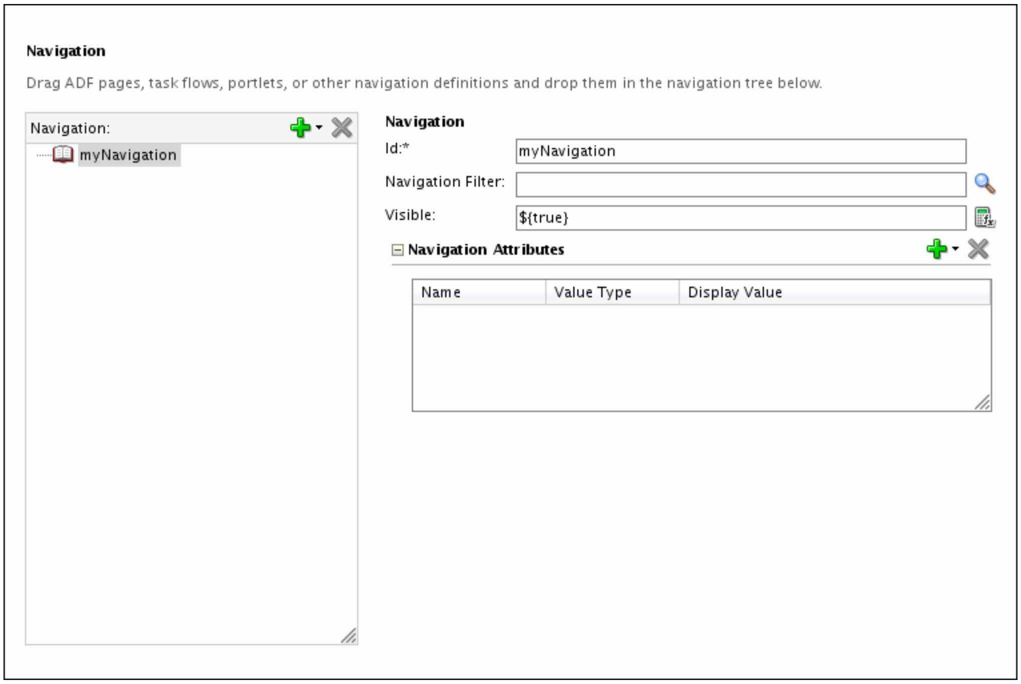
> **Note:** This option is available only if the directory you entered is the *`Application_Root`*`/Portal/public_html/oracle/webcenter/portalapp` directory or one of its subdirectories.

> **Tip:** If you do not select this option now, you can add the navigation model to the runtime administration console later by right clicking it and choosing **Create Portal Resource**.

6. Click **OK**.

   When you create a navigation model in a Portal Framework application, a navigation model definition file (an XML file) is created for the navigation model in the specified directory. The navigation model definition file opens in Design view (Figure 10–2).

Figure 10–2 A Navigation Model in Design View



Navigation

Drag ADF pages, task flows, portlets, or other navigation definitions and drop them in the navigation tree below.

Navigation: myNavigation

Navigation

Id:* myNavigation

Navigation Filter:

Visible: ${true}

Navigation Attributes

Name	Value Type	Display Value

The navigation model definition file is initially empty, so you must edit it to design the structure and content of your navigation model. For information, see Section 10.3, "Editing a Navigation Model."

> **Tip:** If you do not want to add resources from scratch, as a starting point, you could copy the source code of the `default-navigation-model.xml` file into the Source view of your new navigation model definition.

If you created the navigation model under the appropriate directory and selected the **Create as a Portal Resource** option, the navigation model is automatically available for runtime administration. For more information, see Section 9.5, "Working with Portal Resources at Runtime."

If you create your own navigation model in a Portal Framework application, rather than extend the seeded navigation model, it is recommended that you set your navigation model as the default navigation model for the application. This makes it much easier to consume the navigation model in your pages and page templates. For more information, see Section 10.4, "Selecting the Default Navigation Model."

10.3 Editing a Navigation Model

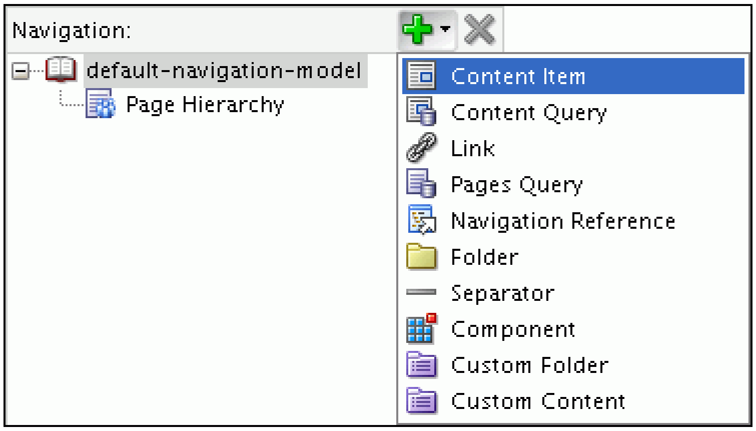
To define the content of your navigation model you can edit the seeded navigation model, `default-navigation-model.xml`, to add nodes for the resources that you want users to be able to access within your application. The seeded navigation model is created automatically when you create an application using the WebCenter Portal Framework Application template.

You can also create your own navigation model and edit that. For more information, see Section 10.2, "Creating a Navigation Model."

You can add nodes to a navigation model in two ways:

- Drag and drop resources from different areas in JDeveloper onto the navigation model in Design view.
- Use the options on the **Add new node** menu in the Design view for the navigation model (Figure 10–3).

Figure 10–3 The Navigation Model Add New Node Menu



In the Design view for the navigation model you can also modify and remove existing navigation model nodes.

This section includes the following topics:

- Section 10.3.1, "How to Drag and Drop a Resource onto a Navigation Model"
- Section 10.3.2, "How to Add a Page to a Navigation Model"
- Section 10.3.3, "How to Add a Folder to a Navigation Model"
- Section 10.3.4, "How to Add a Separator to a Navigation Model"
- Section 10.3.5, "How to Add Other Resources to a Navigation Model"
- Section 10.3.6, "How to Add Dynamically Generated Resources to a Navigation Model"
- Section 10.3.7, "How to Set Display Options for a Navigation Model or Navigation Model Node"
- Section 10.3.8, "How to Rearrange Nodes in a Navigation Model"
- Section 10.3.9, "How to Show or Hide a Navigation Model or Navigation Model Node"
- Section 10.3.10, "How to Edit a Navigation Model Node"
- Section 10.3.11, "How to Delete a Navigation Model Node"

10.3.1 How to Drag and Drop a Resource onto a Navigation Model

You can add the following resources to a navigation model by dragging and dropping them onto the desired location in the Design view of the navigation model definition file:

- **Pages**, from the Application Navigator. You are prompted to choose whether to add just the page itself or to add a page query that includes the page and its subpages.

- **URL connections,** from the Application Resources pane or Resource Palette.
- **Content items,** from a WebCenter Content connection in the Application Resources pane or Resource Palette.
- **Portlets,** from the Application Resources pane or Resource Palette.
- **Task flows,** from the Application Resources pane or Resource Palette.
- **External applications,** from the Application Resources pane or Resource Palette.
- **Navigation models,** from the Application Navigator. This embeds one navigation model inside another.

10.3.2 How to Add a Page to a Navigation Model

A navigation model is mostly made up of links to the various pages within the application. You can add links to any JSPX page in the application.

To add a page to a navigation model:

1. In the Application Navigator, right-click the navigation model to which you want to add the page, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the page.
3. Click the **Add new node** icon and choose **Link**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the navigation model.

   The ID is used to provide direct access to a node in the navigation model. For example, if you have a top level node with the ID `home`, and a child node below it with the ID `sales`, then the child node can be accessed using the following URL:

   ```
   http://host:port/application-context-root/servlet/home/sales
   ```

   Note: If the node is at the top level of the navigation model, the ID must not be one of the navigation URL reserved keywords. For more information, see Section 10.9, "Navigation URL Reserved Keywords."

   Tip: If the ID is not unique, or you enter any invalid characters, the border of the field becomes red.

5. From the **Type** drop-down list, select **Page**.
6. The **Factory Class** field is automatically populated with the appropriate value for pages and cannot be edited.
7. In the **URL** field, enter or browse for the URL to access the page. The URL should use the following format:

   ```
   page://pathToPage/pageName
   ```

   For example:

   ```
   page://oracle/webcenter/portalapp/pages/myPage.jspx
   ```

> **Tip:** If you are not sure of the path to the page, click **Browse Files** to locate the page in the application.

8. Select **Render URL in Page Template**, to render the page in the content area of the application using the specified page template.

   Select **Redirect to URL**, to cause the page to issue a client-side redirect to the defined URL.

9. In the **Visible** field, specify whether the page is listed in the navigation model when it is rendered at runtime. The default value is the EL expression `#{true}`, which means the page is listed for all users at all times. Enter `false` or `#{false}` to hide the page from all users at all times, or enter an EL expression to specify the conditions under which the page is listed. If the field is empty, the value defaults to `true`.

   > **Note:** Nodes in a navigation model are automatically filtered based on security. If a user does not have access to a page, it is not displayed in the rendered navigation model.

10. In the URL Attributes section, specify any desired display options for the page. For more information, see Section 10.3.7, "How to Set Display Options for a Navigation Model or Navigation Model Node."

11. In the URL Parameters section, enter values, as desired, for any parameters supported by the selected page.

    Click the **Add** icon to create a row in the Parameters table.

    For example, you can specify the size of the inline frame used to display the page by adding the `url_renderer_width` and `url_renderer_height` parameters and specifying a value in pixels.

12. Save the navigation model definition file.

10.3.3 How to Add a Folder to a Navigation Model

Navigation models can be organized hierarchically to create subsets of nodes in your navigation model or to group similar nodes together. This hierarchy can be collapsed at runtime to save space if you have a lot of nodes in your navigation model.

You can place a node under any other node in a navigation model to create this hierarchy. If you have a collection of nodes that do not have a node that can act as their parent, you can create a folder. A folder does not point to an underlying resource; it serves only to contain other navigation model nodes.

To add a folder to a navigation model:

1. In the Application Navigator, right-click the navigation model to which you want to add the folder, and choose **Open**.

2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the folder.

3. Click the **Add new node** icon and choose **Folder**.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the navigation model.

The ID is used to provide direct access to a node in the navigation model. For example, if you have a top level node with the ID `home`, and a child node below it with the ID `sales`, then the child node can be accessed using the following URL:

```
http://host:port/application-context-root/servlet/home/sales
```

Note: If the node is at the top level of the navigation model, the ID must not be one of the navigation URL reserved keywords. For more information, see Section 10.9, "Navigation URL Reserved Keywords."

Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

5. In the **Visible** field, specify whether the folder is displayed when the navigation model is rendered at runtime. The default value is the EL expression `#{true}`, which means the folder is displayed to all users at all times. Enter `false` or `#{false}` to hide the folder from all users at all times, or enter an EL expression to specify the conditions under which the folder is displayed. If the field is empty, the value defaults to `true`.
6. In the Folder Attributes section, specify any desired display options for the folder. For more information, see Section 10.3.7, "How to Set Display Options for a Navigation Model or Navigation Model Node."
7. In the Folder Parameters section, enter values, as desired, for any parameters supported by the folder.

   Click the **Add** icon to create a row in the Parameters table.
8. Save the navigation model definition file.

10.3.4 How to Add a Separator to a Navigation Model

Separators visually divide a navigation model into distinct groupings of nodes. Separators enable you to visually break up the nodes in the navigation model when it is rendered at runtime, making it easier to locate nodes.

To add a separator to a navigation model:

1. In the Application Navigator, right-click the navigation model to which you want to add the separator, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the separator.
3. Click the **Add new node** icon and choose **Separator**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the navigation model.

   The ID is used to provide direct access to a node in the navigation model. For example, if you have a top level node with the ID `home`, and a child node below it with the ID `sales`, then the child node can be accessed using the following URL:

   ```
   http://host:port/application-context-root/servlet/home/sales
   ```

> **Note:** If the node is at the top level of the navigation model, the ID must not be one of the navigation URL reserved keywords. For more information, see Section 10.9, "Navigation URL Reserved Keywords."

> **Tip:** If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

5. In the **Visible** field, specify whether the separator is displayed when the navigation model is rendered at runtime. The default value is the EL expression `#{true}`, which means the separator is displayed to all users at all times. Enter `false` or `#{false}` to hide the separator from all users at all times, or enter an EL expression to specify the conditions under which the separator is displayed. If the field is empty, the value defaults to `true`.
6. Save the navigation model definition file.

10.3.5 How to Add Other Resources to a Navigation Model

You can add other resources to your navigation model, including documents, external web pages, portlets, and task flows.

To add other resources to a navigation model:

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon, then choose the type of resource that you want to add:
   - **Content Item** to add a document
   - **Content Query** to add a collection of documents that meet specific query criteria
   - **Link** to add a portlet, task flow, external application, or web page
   - **Pages Query** to add a list of pages
   - **Navigation Reference** to embed another navigation model
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the navigation model.

   The ID is used to provide direct access to a node in the navigation model. For example, if you have a top level node with the ID `home`, and a child node below it with the ID `sales`, then the child node can be accessed using the following URL:

   ```
   http://host:port/application-context-root/servlet/home/sales
   ```

   > **Note:** If the node is at the top level of the navigation model, the ID must not be one of the navigation URL reserved keywords. For more information, see Section 10.9, "Navigation URL Reserved Keywords."

> **Tip:** If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

5. In the **Visible** field, specify whether the node is displayed when the navigation model is rendered at runtime. The default value is the EL expression `#{true}`, which means the node is displayed to all users at all times. Enter `false` or `#{false}` to hide the node from all users at all times, or enter an EL expression to specify the conditions under which the node is displayed. If the field is empty, the value defaults to `true`.
6. The remaining fields are specific to the resource type. See Table 10–1 for details.

Table 10–1 Fields for Navigation Model Resources

Field	Applies to	Description
Factory Class	Link Content Item	This field is automatically populated with the appropriate factory class for the resource type and cannot be edited.
Insert Folder Contents	Content Query Page Query	Select to display the results of the query directly in the rendered navigation model rather than displaying them under a folder.
Page Style	Page Query	Select the style of page to include in the navigation model.
Page Template	Page Query	Select the page template to use to display the resource when it is selected.
Page Visibility	Page Query	Select whether to include pages even if they have been flagged as hidden.

Path	Page Query
	Navigation Reference
		Enter the path and file name of the XML file that corresponds to the page that you want to use as the starting point of the page query. For example:
		`/oracle/webcenter/portalapp/pagehierarchy/pages/pages.xml`
		`/oracle/webcenter/portalapp/pagehierarchy/pages/productsPages.xml`

Query	Content Query	Enter the query criteria to identify the content to include in the navigation model, for example: `SELECT * FROM cmis:document WHERE cmis:name LIKE 'Foo%'` For more information about how to format the query and for more examples, see Chapter 31, "Content Management REST API."
Redirect to URL	Link Content Item	Select to issue a client-side redirect to the defined URL.
Render URL in Page Template	Link Content Item	Select to render the resource in the current page, using the specified page template.

Table 10–1 (Cont.) Fields for Navigation Model Resources

Field	Applies to	Description
Repository	Content Query	Enter or browse for the content repository whose content you want to search. **Note:** If you enter the repository name manually (that is, without using drag and drop or the Choose a Resource dialog), and if the connection for the repository is available only in the Resource Palette, then ensure that you first add the connection to the application (in the Application Resources pane).
Scope	Page Query	This field is not applicable to Portal Framework applications (the scope is always the current application).
Type	Link Content Item	Select the type of link that you want to add to the navigation model: **External Link**, **External Application**, **Page**, **Taskflow**, **Portlet**, **Content**.
URL	Link Content Item	Enter the location of the resource. If you do not know the location, click the **Browse Files** icon to browse for available resources. Table 10–2 provides the URL format to use for the different resource types. **Note:** If you enter the URL for a **Portlet**, **External Application**, or **Content** resource manually (that is, without using drag and drop or the Choose a Resource dialog), and if the connection for the resource is available only in the Resource Palette, then ensure that you first add the connection to the application (in the Application Resources pane.

Table 10–2 provides the URL format to use for the different resource types.

Table 10–2 Format for URL for Different Resource Types

Resource Type	Location in Application	URL Formats
External Link	None	Absolute or relative path to the web page to which you want to link. **Note:** If you use the **External Link** option to include a `mailto:` link in your navigation, your navigation UI must explicitly handle this type of link. For information, see Section 10.11, "Visualizing Portal Navigation."
External Application	External application connection in the Application Resources pane	`extapp://`*`externalApplicationId`*

Page	Application Navigator	`page://`*`pathToPage`*`/`*`pageName`*
		For example:
		`page://oracle/webcenter/portalapp/pages/myPage.jspx`

Table 10–2 (Cont.) Format for URL for Different Resource Types

Resource Type	Location in Application	URL Formats
Task Flow from an ADF Library	Resource Palette	`taskflow://`*pathToTaskFlow*`/`*taskFlowDefinitionFileName*`#`*taskFlowId* **Note:** Navigating directly to a task flow in this way enables you to set the parameters of the task flow. If you need additional control over the task flow, add it to a page and then add the page to the navigation model.
Task Flow Within the Application	Application Navigator	`taskflow://`*PathToTaskFlow*`/`*taskFlowDefinitionFileName*`#`*taskFlowId* **Note:** Navigating directly to a task flow in this way enables you to set the parameters of the task flow. If you need additional control over the task flow, add it to a page and then add the page to the navigation model.
Portlet	Portlet producer connection in the Application Resources pane or Resource Palette	`portlet://`*producerId*`/`*portletId* **Note:** If you provide navigation directly to a portlet in this way, then when users navigate to the portlet they will not be able to customize it. If you want users to be able to customize the portlet, then add it to a page to create a portlet instance, which can be customized, and then add that page to the navigation model.
Content	Content repository connection in the Application Resources pane or Resource Palette	`content://`*contentConnectionId*`/`*documentId*

7. In the resource's Attributes section, specify any desired display options for the resource. For more information, see Section 10.3.7, "How to Set Display Options for a Navigation Model or Navigation Model Node."

8. In the resource's Parameters section, enter values, as desired, for any parameters supported by the resource.

   Click the **Add** icon to create a row in the Parameters table.

   For links you can specify the size of the inline frame used to display the target of the link by adding the `url_renderer_width` and `url_renderer_height` parameters and specifying a value in pixels.

   If you want to use a Content Presenter display template to display a content item or the results of a content query, in the Parameters section, click the **Add icon**, and choose **templateView**.

   In the **Value** field for the **templateView** parameter, enter the display template view ID to use for rendering the content, for example:

   - For a single content item: `oracle.webcenter.content.templates.default.detail`
   - For a content query: `oracle.webcenter.content.templates.default.list.simple`

> **Note:** If you display a wiki page using a Content Presenter display template, by default any links within that wiki page are displayed in the Document Viewer. If you want to display wiki page links using Content Presenter, you must edit the `adf-config.xml` file. For more information, see Section 30.3.5, "Displaying Wiki Page Links Within Content Presenter."

10.3.6 How to Add Dynamically Generated Resources to a Navigation Model

As well as adding known resources to your navigation model, you can also add resources that are dynamically generated at runtime.

- **Custom resources** are links to third party resources.
- **Custom components** are resources, such as simple ADF Faces components, compound objects containing two or more components, or JSF Verbatim tags that let you add arbitrary HTML content inside them.
- **Custom folders** are configured to display their content dynamically at runtime. A custom folder is not added as a folder with resources; it contains only a reference to the factory class, which displays the resources dynamically.
- **Custom content providers** dynamically generate zero or more resources at runtime. They are very similar to custom folders, except that, when you add a custom folder, the folder is always displayed when the navigation model is rendered at runtime, even if it is empty. With custom content providers however, the folder is displayed at runtime only if it has content inside it.

To add dynamically generated resources to a navigation model:

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon, then choose the type of resource that you want to add:
   - **Link** to add a custom resource. You must also select **Other** from the **Type** drop-down list.
   - **Component** to add a custom component
   - **Custom Folder** to add a custom folder
   - **Custom Content** to add a custom content provider
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the navigation model.

   The ID is used to provide direct access to a node in the navigation model. For example, if you have a top level node with the ID `home`, and a child node below it with the ID `sales`, then the child node can be accessed using the following URL:

   ```
   http://host:port/application-context-root/servlet/home/sales
   ```

Note: If the node is at the top level of the navigation model, the ID must not be one of the navigation URL reserved keywords. For more information, see Section 10.9, "Navigation URL Reserved Keywords."

Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

5. In the **Visible** field, specify whether the node is displayed when the navigation model is rendered at runtime. The default value is the EL expression `#{true}`, which means the node is displayed to all users at all times. Enter `false` or `#{false}` to hide the node from all users at all times, or enter an EL expression to specify the conditions under which the node is displayed. If the field is empty, the value defaults to `true`.

6. The remaining fields are specific to the resource type. See Table 10–3 for details.

Table 10–3 Fields for Custom Navigation Model Resources

Field	Applies to	Description
Component Factory	Custom Component	Enter or browse for the Java class that implements the `oracle.adf.rc.component.ComponentFactory` interface and creates an instance of the component based on a set of parameters, for example, `oracle.adf.rc.component.XmlComponentFactory`. As you type the name, the field autocompletes with valid factory classes from the classpath. For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."
Content Provider	Custom Content	Enter or browse for the Java class that implements the `oracle.adf.rc.spi.plugin.catalog.CustomContentProviderV2 interface`. For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."
Factory Class	Custom Resource	Enter or browse for the `URLResourceFactory` implementation class that can resolve the URL for the custom resource.
Initial Context Factory	Custom Folder	Enter or browse for the Java class that implements the `javax.naming.spi.InitialContextFactory` interface and generates the folder based on a set of parameters. For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."
Insert Folder Contents	Custom Folder	Select to display the contents of the custom folder directly in the rendered navigation model rather than displaying them under the folder.
Path	Custom Folder	Enter the MDS path for the custom folder.

Table 10–3 (Cont.) Fields for Custom Navigation Model Resources

Field	Applies to	Description
Redirect to URL	Custom Resource	Select to cause the page to issue a client-side redirect to the defined URL.
Render URL in Page Template	Custom Resource	Select to render the resource in the current page, using the specified page template.
Type	Custom Resource	Select **Other**.
URL	Custom Resource	Enter the URL to access the resource.

7. In the resource's Attributes section, specify any desired display options for the resource. For more information, see Section 10.3.7, "How to Set Display Options for a Navigation Model or Navigation Model Node."

> **Note:** Typically for custom content providers, you will not need to specify any attributes, because the attributes for the resources generated by the content provider will be specified by the content provider.

8. In the resource's Parameters section:

   - For custom resources, enter values, as desired, for any parameters supported by the custom resource.
   - For custom folders, add the parameters that were defined while implementing the factory class. You can bind these parameters to other artifacts in the application.
   - For custom content providers, define the parameters on the custom content provider. The parameters you define here are passed to and interpreted by the `CustomContentProviderV2` implementation.

   Click the **Add** icon to create a row in the Parameters table.

9. Save the navigation model definition file.

10.3.7 How to Set Display Options for a Navigation Model or Navigation Model Node

You can specify various display options for a navigation model or any of its nodes to determine their appearance and behavior when the navigation model is rendered at runtime. The display options available depend on the type of the resource.

To set display options for a navigation model node:

1. In the Application Navigator, right-click the navigation model and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node for which you want to set display options.

   To set display options for the navigation model, select the root node.

3. In the resource's Attributes panel, click the **Add** icon and choose the attribute that you want to set. Table 10–4 lists the available attributes.

Table 10–4 Navigation Model Display Options

Attribute	Description
Title	The title displayed for the node when the navigation model is rendered at runtime.
AccessKey	A key mnemonic (single character) that users can enter to access the node without using the mouse.
Description	A description of the node.
IconURI	An icon to visually represent the node. This is displayed next to the Title when the navigation model is rendered at runtime.
Subject	Keywords to facilitate searching of the node.
Target	The location on the container page where the node is displayed when it is selected, either in the same browser window (`_self`), a new window (`_blank`), or a popup (`_popup`), or any other location supported by the navigation UI. **Note:** Popups are not supported for pages.
ToolTip	Text that displays to provide additional information about the node when users hover the mouse over the Title.
Modified	The date of the last modification of the node. This attribute is used for site map creation.
ChangeFrequency	How frequently the node is likely to change: `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`. This attribute is used for site map creation.
Significance	The priority of this node relative to other nodes in the navigation model, within the range `0.0` to `1.0`. This attribute is used for site map creation.
ExternalId	An ID to enable a direct reference to a node in the navigation model from a static link in the page. For more information, see Section 10.9, "Navigation URL Reserved Keywords."

4. From the **Value Type** drop-down list, choose:
   - **Literal String**—to specify a string as the value for the attribute.
   - **Resource Bundle**—to use a resource bundle to provide localized values for the attribute.
5. In the **Display Value** field, enter the value for the attribute. If you are using a resource bundle, click the **Browse** icon to select the resource bundle to search for the localized value.
6. Save the navigation model definition file.

10.3.8 How to Rearrange Nodes in a Navigation Model

You can move nodes around within a navigation model after you have added them. You can rearrange nodes in the following ways:

- Drag and drop a node from one location to another.

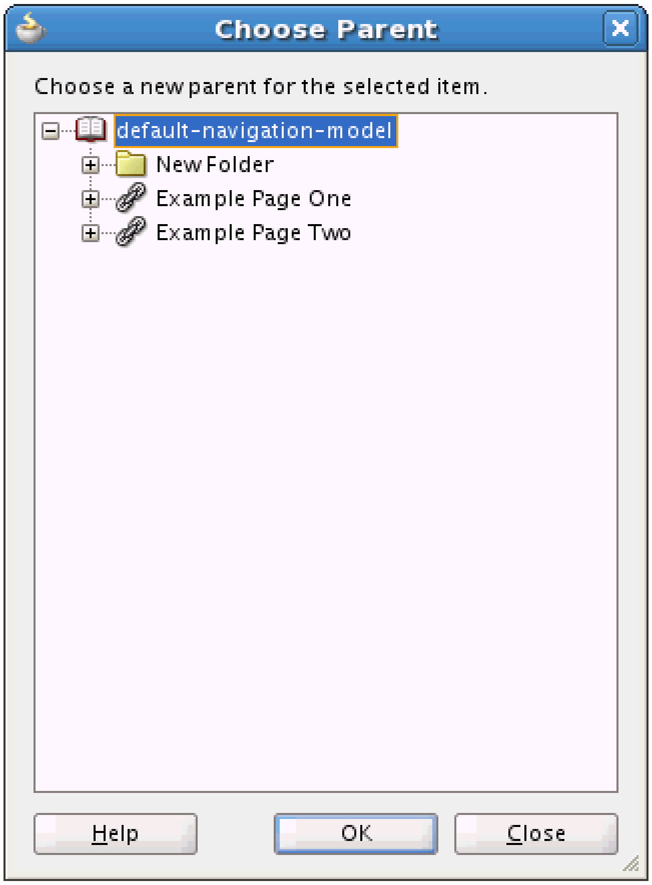
  To move a node within the navigation model, select the node and drag it to the desired position. To indent a node (child) under another (parent), select the child node and drag it over the top of the parent node.

- Use the **Change Parent** context menu option to move a node to a different location.

To rearrange a node using the Change Parent option:

1. In the Application Navigator, right-click the navigation model and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, right-click the node and choose **Change Parent** from the context menu.
3. In the Choose Parent dialog (Figure 10–4), select the parent node in which to include the node and click **OK**.

Figure 10–4 The Change Parent Dialog



Choose a new parent for the selected item.

- default-navigation-model
  - New Folder
  - Example Page One
  - Example Page Two

Note: Any node within a navigation model can be the parent of another node.

4. Save the navigation model definition file.

10.3.9 How to Show or Hide a Navigation Model or Navigation Model Node

You can specify whether or not a navigation model or one of its nodes is visible at runtime.

> **Tip:** As well as specifying an absolute true or false value, you can also dynamically determine whether or not the navigation model or node is available by using an EL expression to specify the conditions under which it is visible.

To show or hide a navigation model or navigation model node:

1. In the Application Navigator, right-click the navigation model and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node for which you want to set the visibility.

   To set the visibility of the navigation model, select the root node.
3. In the **Visible** field, specify whether the navigation model or node is available for use in the application. This field takes an EL value. The default is `#{true}`, which means the navigation model or node is visible. Enter `false` or `#{false}` to hide the navigation model or node, or enter an EL expression to specify the conditions under which the navigation model or node is available. If the field is empty, the value defaults to `true`.
4. Save the navigation model definition file.

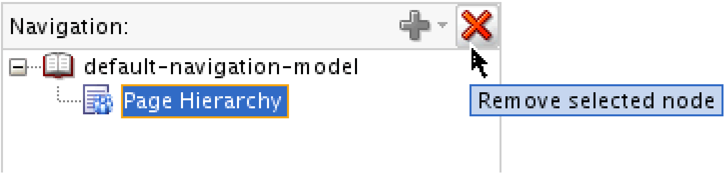
10.3.10 How to Edit a Navigation Model Node

To edit a navigation model node, select it in the Navigation section of the navigation model definition file. The resource's attributes and parameters are displayed in the right half of the page. You can edit values for these attributes and parameters and save the navigation model definition file. For details about a resource's attributes and parameters, see the appropriate section earlier in this chapter.

10.3.11 How to Delete a Navigation Model Node

To delete a resource, select it in the Navigation section of the navigation model definition file and click the **Remove selected node** icon (Figure 10–5).

Figure 10–5 Delete Option in the Navigation Model Design View



10.4 Selecting the Default Navigation Model

Every Portal Framework application defines a default navigation model that provides a convenient way to identify the navigation model that should be used by default by the application. You can then reference this default navigation model without having to specify its actual name. For example, in navigation EL expressions, the default navigation model is often referenced, such as in `#{navigationContext.defaultNavigationModel}`.

When you first create a Portal Framework application, the seeded navigation model, `default-navigation-model.xml`, is set as the application's default navigation model. If you subsequently create your own navigation model to use for the main navigation path through your application, rather than having to explicitly reference this navigation model whenever you want to use it, you can set it as the default. This greatly simplifies the process of using the navigation model in your application.

You can set the default navigation model for a Portal Framework application by editing the `oracle.webcenter.portalapp.navigation.model` preference in the `adf-config.xml` file.

To select the default navigation model:

1. In the Application Resources pane of the Application Navigator, right-click the **adf-config.xml** file, and choose **Open**.

   > **Tip:** To locate the `adf-config.xml` file, expand the **Descriptors** node, and then the **ADF META-INF** node.

2. Click the **Source** tab.
3. Locate the ADF preference with the following `id`:

   ```
   oracle.webcenter.portalapp.navigation.model
   ```

4. Set the `value` attribute to the path of the navigation model that you want to use as the default for the application, for example:

   ```
   value="/oracle/webcenter/portalapp/navigations/myNavigationModel.xml"
   ```

   Example 10–1 shows an example of the complete preference element.

Example 10–1 The Default Navigation Model ADF Preference

```
<preference id="oracle.webcenter.portalapp.navigation.model"
           desc="Default Navigation Model"
           value="/oracle/webcenter/portalapp/navigations/myNavigationModel.xml"
           resourceType="navigation" display="true"/>
```

5. Save the `adf-config.xml` file.

10.5 Filtering the Contents of a Navigation Model

You can use a filter to determine which nodes to include in the navigation model, based on specific criteria, when it is rendered at runtime.

> **Tip:** You can conditionally hide individual nodes in the navigation model by specifying an EL expression in the **Visible** field for the node. For more information, see Section 10.3.9, "How to Show or Hide a Navigation Model or Navigation Model Node."

To filter the contents of a navigation model:

1. In the Application Navigator, right-click the navigation model and choose **Open**.
2. In the Design view for the navigation model, in the **Navigation** panel on the left side, select the node that represents the navigation model (the root node).
3. In the **Navigation Filter** field, enter the name of a Java class to use to filter out selected nodes in the navigation model based on specific criteria.

   The Java class should implement the `oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter` interface.

Nodes are automatically filtered based on security. If a user does not have access to a particular resource, the node for that resource is not displayed when the navigation model is rendered at runtime.

4. Save your changes.

10.6 Deleting a Navigation Model

If a navigation model is no longer required within your application, you can delete it.

Note: If you delete an application's default navigation model, you must make sure to change the default navigation model to a valid navigation model. For more information, see Section 10.4, "Selecting the Default Navigation Model."

To delete a navigation model, right-click the navigation model in the Application Navigator and choose **Delete** from the context menu. For more information, see Section 9.4, "Deleting Portal Resources."

10.7 Editing the Navigation Registry File

The navigation registry is a resource catalog specifically for registering which resources users can add to navigation models at runtime. Each Portal Framework application contains one navigation registry file, `navigation-registry.xml`, which is created when you create the application. You can edit this file, for example, to remove the Navigation Reference resources so that users cannot embed other navigation models at runtime.

To edit the navigation registry:

1. In the Application Navigator, right-click the `navigation-registry.xml` file.

   Tip: You can find this file under *`Application_ Root`*`/oracle/webcenter/portalapp/navigations`.

2. Edit the file the same way as any other resource catalog. For more information, see Section 14.3, "Editing a Resource Catalog."

   You can add the following resources to the navigation registry:

   - Folder
   - Link
     - Task Flow
     - Portlet
     - Content
     - Other
   - Resource Catalog
   - Component
   - Custom Folder
   - Custom Content

You can also modify and remove existing resources in the navigation registry, and rearrange resources in the registry.

3. When you are finished, save the `navigation-registry.xml` file.

10.8 Editing the Navigation Renderer

The navigation renderer is a JSPX page that renders non-page resources when accessed through a navigation model, including:

- Portlets
- Content
- External links
- External applications
- Task flows

You can edit the navigation renderer page to change how these types of resources are rendered. For example, you may also want to add an image before or after the navigation renderer task flow or change from a flow to a stretch layout.

> **Note:** In the vast majority of cases, you should be able to edit the existing navigation renderer to meet your requirements. However, if required, you can create your own navigation renderer page. For example, the navigation renderer expects a `content` facet. If you want to use a different facet, you can create your own page and place the navigation renderer task flow in the appropriate location for your template.
>
> If you choose to create your own navigation renderer page, it must include a navigation renderer region that contains the navigation renderer task flow.
>
> To set your page as the navigation renderer for the application, edit the navigation renderer ADF preference (`oracle.webcenter.portalapp.navigation.renderer`) to point to the appropriate file. For detailed instructions for how to edit an ADF preference, see Section 10.4, "Selecting the Default Navigation Model."

The navigation renderer page is hidden by default, so you must first show it in your application before you can edit it.

To edit the navigation renderer:

1. In the Application Navigator, right-click the application project and choose **Project Properties**.
2. In the Project Properties dialog, expand the **Project Source Paths** node and select **Web Application**.
3. Select the **Excluded** tab.
4. Select the navigation renderer file (`navigation-renderer.jspx`) and click **Remove** to remove it from the list of excluded files.
5. Click **OK**.

   The navigation renderer JSPX file is now listed in the Application Navigator under the following node:

```
/oracle/webcenter/portalapp/pages/
```

6. In the Application Navigator, right-click **navigation-renderer.jspx** and choose **Open**.
7. Click the **Source** tab and edit the file as required.
8. When you are finished, save the `navigation-renderer.jspx` file.

10.9 Navigation URL Reserved Keywords

You can use specific reserved keywords to provide direct access to nodes within a navigation model. These reserved keywords are:

- `wcnav_defaultSelection`—Use to access the first navigable node of a navigation model
- `wcnav_currentSelection`—Use to access the currently selected node of a navigation model
- `wcnav_externalId`—Use to access the node within a navigation model with the specified external ID
- `wcnav_title`—Use to access the node within a navigation model with the specified title

You can use these keywords in an `af:goLink` component in a page or page template (Example 10–2) or in the URL of an External Link navigation item in a navigation model (Example 10–3).

Example 10–2 Providing Direct Access to a Navigation Model Node from a goLink Component

```
<af:goLink id="pt_glink1" text="Navigation Item"
           destination="/faces/wcnav_defaultSelection"/>
```

Example 10–3 Providing Direct Access to Navigation Model Node from an External Link Navigation Item

```
<url visible="#{true}"
     factoryClass="oracle.webcenter.portalframework.sitestructure.rc.UrlResourceFactory"
     id="externalLink"
     url="/faces/wcnav_externalId/myNavigationItem">
</url>
```

By default these URLs provide access to nodes within the default navigation model. To directly access a node in a non-default navigation model, you must specify the path of the navigation model by setting the `wcnav.modelPath` URL parameter, for example:

```
/faces/wcnav_externalId/myNavigationItem?wcnav
.modelPath=/oracle/webcenter/siteresources/scopedMD/
s7f446cab_f622_4b68_a83e_b7eaf28b52ec/navigation/gsr0271c712_721a_4565_9f0e_
755784a7093b/
myProjectNavigationModel
```

Depending on where you are using the link, you may need to encode the URL parameters, for example, if the external ID contains spaces or special characters you would specify the URL as `/faces/wcnav_externalId/my%2Fnav%2Fitem`.

10.10 Tips for Developing Navigation Models

When creating a navigation model for your Portal Framework application, consider the following:

- Try to use only one main navigation model. Using multiple navigation models limits the control of friendly URLs.
- Ensure that each section of your Portal Framework application has a friendly subroot name. For example, place all footer links under a Footer folder.
- Include all links that take users to another part of the Portal Framework application, including header and footer links, in the navigation model.
- Use external IDs to surface persistent links in the application so that external applications can reference them without breaking when navigation model nodes are moved.
- If a page defines parameters, you can set these parameters in the navigation model node to dynamically control how the page is rendered.
- Use page links as often as possible. For example, if you want to include a contact link, create a page to display the link and then include that page in the navigation model.
- Include all pages used within the portal as page links in the navigation model.

For more information, see the "Oracle WebCenter & ADF Architecture Team" blog.

10.11 Visualizing Portal Navigation

The **navigation visualization** determines how the navigation appears in the application. For example, navigation can be provided as a set of tabs along the top of each page, or perhaps as a tree structure along the side of the page. Another common navigation visualization is to provide a "master-detail" navigation, for example, tabs along the top of the page, with each tab having additional navigation provided as a tree structure along the side of the page.

Typically, you add navigation visualization to page templates, so that it can be defined in one place and propagated consistently across the whole portal. However, you can also add navigation visualization to individual pages.

Oracle WebCenter Portal provides several built-in navigation task flows in the **WebCenter Portal - Services Catalog** of the resource catalog that you can add to pages or page templates to visualize the navigation. These built-in navigation task flows provide a quick way to test your navigation model, but they provide a fairly simple navigation visualization. For more information about these built-in navigation task flows, see the "Adding Navigation to a Page Template" section in *Building Portals with Oracle WebCenter Portal*.

It is more likely that you will require a more advanced visualization. To do this, you must create your own navigation UI using ADF navigation components and the Oracle WebCenter Portal navigation APIs.

Note: If the navigation model referenced by the page or page template includes External Link navigation items that use `mailto:` links, you must explicitly handle these. The example below uses JSTL to inspect the navigation item's `externalURL` to see if it starts with the string `mailto:`. If it does, an ADF Faces `goLink` component is used to render the link.

```
<c:choose>
  <c:when test="${fn:startsWith(node.externalURL, 'mailto:')}">
    <af:goLink id="pt_gl_mail" text="#{node.title}"
               destination="#{node.externalURL}"/>
  </c:when>
  <c:otherwise>
    ...
  </c:otherwise>
</c:choose>
```

Oracle WebCenter Portal provides two sets of APIs for adding navigation to your portal:

- Expression Language (EL) APIs—Use EL expressions to obtain the navigation model and navigation nodes.
- REST APIs—Use standard HTTP methods to point to the navigation model and navigation nodes, returning a standard representation of any retrieved object. REST APIs can be used when using client-side programming languages, for example JavaScript + HTML, or environments, for example an iPhone.

Note: Any task flow that uses the navigation model to trigger navigation within an application must include a `parent-action` activity, named `wcnav_parentAction`, in the task flow definition that propagates the `wcnav_outcome` to the root level, as follows:

```
<parent-action id="wcnav_parentAction">
  <root-outcome>wcnav_outcome</root-outcome>
</parent-action>
```

This section includes the following topics:

- Section 10.11.1, "Using the Navigation Expression Language APIs"
- Section 10.11.2, "Using the Navigation REST APIs"
- Section 10.11.3, "Tips for Visualizing Portal Navigation"

10.11.1 Using the Navigation Expression Language APIs

Oracle WebCenter Portal provides a set of expression language (EL) APIs that you can use to obtain the navigation model and represent that navigation model as a runtime model. The runtime models can be bound directly to ADF Faces navigation components.

The available navigation EL expressions are listed in full in Section G.7, "ELs Related to Navigation."

This section includes the following topics:

- Section 10.11.1.1, "Introduction to the Navigation Context"

- Section 10.11.1.2, "Introduction to the Navigation Runtime Model"
- Section 10.11.1.3, "Introduction to the Navigation Resource"
- Section 10.11.1.4, "How to Render the Navigation Model as a List of Links"
- Section 10.11.1.5, "How to Render the Navigation Model as a Tree"
- Section 10.11.1.6, "How to Render the Navigation Model as a Three-Level Menu"
- Section 10.11.1.7, "How to Render the Navigation Model as Breadcrumbs"
- Section 10.11.1.8, "How to Render Master-Detail Navigation"

> **Note:** This section includes some examples of how to use the navigation EL APIs. For a full working example, see the default page templates (pageTemplate_globe.jspx and pageTemplate_swooshy.jspx) created when you create a Portal Framework application.

10.11.1.1 Introduction to the Navigation Context

The Navigation Context is the entry point to access all navigation elements within your system. Specifically, it enables you to access navigation models via preference, state, and direct reference, as well as providing the hooks to create custom UI to actually navigate to the nodes.

Navigation Model Access

- Default navigation model (preference)—This is the model specified by the ADF preference oracle.webcenter.portalapp.navigation.model in the adf-config.xml file. This enables you to define the general model to be used throughout your application and enables you to change the value in one place rather than having to go to each page and page template to set the value. The EL expression to retrieve the default navigation model is:

  ```
  #{navigationContext.defaultNavigationModel}
  ```

  > **Note:** For more information about how to set the oracle.webcenter.portalapp.navigation.model preference, see Section 10.4, "Selecting the Default Navigation Model."

- Current navigation model (state)—This model is the one used to navigate to the current view and, if it is not set, returns the default navigation model. Your application may contain multiple navigation models. The EL expression to retrieve the current navigation model is:

  ```
  #{navigationContext.currentNavigationModel}
  ```

  Using this expression enables you to have a single value within a page or page template (for example, for displaying breadcrumbs) and have it display the correct value without having to select a specific navigation model.

- Direct navigation model access (direct reference)—You can also select a specific navigation model by passing in the path to the XML definition of the model. The EL expression to retrieve a specific navigation model is:

  ```
  #{navigationContext.navigationModel['modelPath=path']}
  ```

where *path* is the path to the navigation model definition file, for example:

```
#{navigationContext.navigationModel['modelPath=/oracle/webcenter/portalapp/navi
gations/myNavigation']}
```

Note: You do not need to include the `.xml` file name extension.

Resource Navigation

Use these ELs for core bean operations for binding the navigation model to the UI component's `actionListener` attribute. For example:

```
#{navigationContext.processAction}
```

Examples

Example 10–4 creates a simple tree UI using the Navigation Context to access the current navigation model and render the tree using `<af:outputText/>`.

Example 10–4 Simple Tree Navigation UI

```
<af:tree var="node"
    value="#{navigationContext.currentNavigationModel.treeModel['startNode=/,
    includeStartNode=true,
    depth=1']}"
    id="t1">
  <f:facet name="nodeStamp">
    <af:outputText value="#{node.title}" id="ot1"/>
  </f:facet>
</af:tree>
```

Example 10–5 uses the Navigation Context's `processAction` listener to handle navigation for an ADF `commandImageLink` component, passing in the current node as the parameter called *node* as an attribute to the `actionListener`.

Example 10–5 Binding the Navigation Model to the UI Component

```
<af:tree var="node"
    value="#{navigationContext.currentNavigationModel.treeModel['startNode=/,
           includeStartNode=true,
           depth=1']}"
    id="t1">
  <f:facet name="nodeStamp">
    <af:commandImageLink text="#{node.title}"
        id="sm_c1b"
        actionListener="#{navigationContext.processAction}"
        inlineStyle="#{node.selected ? 'font-weight:bold;' : ''}">
      <f:attribute name="node" value="#{node}"/>
    </af:commandImageLink>
  </f:facet>
</af:tree>
```

10.11.1.2 Introduction to the Navigation Runtime Model

The Navigation Runtime Model exposes the underlying XML definition as runtime models, as well as providing direct access to individual nodes. The runtime models take into account such factors as security and visibility to produce a session-specific representation that can be bound to UI objects.

Note: Note the difference between the *navigation model* that you create to define the content, structure, and metadata of the navigation and the *navigation **runtime** model* that determines how the navigation model behaves at runtime.

You can access the whole model by using the default runtime model (`defaultTreeModel`, `defaultListModel`, `defaultMenuModel`, and `defaultSiteMap`), or access a specific sub-tree using the various parameters when creating the runtime model. For example:

```
#{navigationContext.defaultNavigationModel.menuModel['startNode=home,
    includeStartNode=false, depth=2']}
```

For more information about the underlying ADF Faces MenuModel, TreeModel, and ListModel, see the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

Model Access

You can create the following runtime models based on the underlying navigation model:

- UI Models
  - Tree model

    ```
    #{navigationContext.defaultNavigationModel.defaultTreeModel}
    #{navigationContext.defaultNavigationModel.treeModel['parameters']}
    ```

  - Menu model

    ```
    #{navigationContext.defaultNavigationModel.defaultMenuModel}
    #{navigationContext.defaultNavigationModel.menuModel['parameters']}
    ```

  - List model

    ```
    #{navigationContext.defaultNavigationModel.defaultListModel}
    #{navigationContext.defaultNavigationModel.listModel['parameters']}
    ```

- Search Engine Model
  - Sitemap

    ```
    #{navigationContext.defaultNavigationModel.defaultSiteMap}
    #{navigationContext.defaultNavigationModel.siteMap['parameters']}
    ```

Resource (or Node) Access

You can access specific nodes within the navigation model using the follow EL expressions:

- `#{navigationContext.defaultNavigationModel.currentSelection}`
- `#{navigationContext.defaultNavigationModel.rootNode}`
- `#{navigationContext.defaultNavigationModel.node['path']}`

Examples

Example 10–6 renders the current navigation model's menu model as a breadcrumb.

Example 10–6 Rendering the Navigation Model as a Menu Model

```
<af:breadCrumbs id="bc1"
    var="node"
    value="#{navigationContext.currentNavigationModel.defaultMenuModel}">
  <f:facet name="nodeStamp">
    <af:commandNavigationItem id="cni1"
        text="#{node.title}"
        actionListener="#{navigationContext.processAction}"
        partialSubmit="true">
      <f:attribute name="node" value="#{node}"/>
    </af:commandNavigationItem>
  </f:facet>
</af:breadCrumbs>
```

Example 10–7 produces a Sitemap for the application based on the default navigation model.

Example 10–7 Producing a Sitemap

```
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"  version="2.1"
    xmlns:f="http://java.sun.com/jsf/core">
  <jsp:directive.page contentType="text/xml;charset=UTF-8" />
  <f:view>
    ${navigationContext.defaultNavigationModel.defaultSiteMap}
  </f:view>
</jsp:root>
```

For more information about Sitemaps, see Section 10.13, "Using a Navigation Model to Create a Sitemap."

10.11.1.3 Introduction to the Navigation Resource

The Navigation Resource provides access to individual properties against each node within the navigation model. These fall into the following categories:

- **Attributes**—Common properties that the user can specify against any navigation element and are used for rendering the node on the page, including:
  - **Title**—The title displayed for the node when the navigation model is rendered at runtime.
  - **AccessKey**—A key mnemonic (single character) that users can enter to access the node without using the mouse.
  - **Description**—A description of the node.
  - **IconURI**—An icon to visually represent the node. This is displayed next to the Title when the navigation model is rendered at runtime.
  - **Subject**—Keywords to facilitate searching of the node.
  - **Target**—The location on the container page where the node is displayed when it is selected, either in the same browser window (`_self`), a new window (`_blank`), or a popup (`_popup`), or any other location supported by the navigation UI.
  - **ToolTip**—Text that displays to provide additional information about the node when users hover the mouse over the Title.
  - **Modified**—The date of the last modification of the node. This attribute is used for Sitemap creation.

  - **ChangeFrequency**—How frequently the node is likely to change: always, hourly, daily, weekly, monthly, yearly, never. This attribute is used for Sitemap creation.
  - **Significance**—The priority of this node relative to other nodes in the navigation model, within the range 0.0 to 1.0. This attribute is used for Sitemap creation.
  - **ExternalId**—An ID to enable a direct reference to any node in the navigation model from a static link in the page.

- **Parameters**—User-defined properties that are specific to each node. These are name/value pairs and can contain any value.
- **State**—Built-in properties that you can query and use to navigate to the node. For example:
  - Type of node, for example, folder or separator
  - Whether the node is navigable
  - The path to the node
  - Parent, child, or sibling node access
  - Whether the node is the currently selected node within the navigation model or on the selected node's path

  For a complete list, see Section G.7, "ELs Related to Navigation."

Examples

Example 10–8 renders an ADF `commandImageLink` component with various attributes.

Example 10–8 Rendering a commandImageLink with Attributes

```
<af:commandImageLink text="#{node.title}"
    id="cil1"
    actionListener="#{navigationContext.processAction}"
    shortDesc="#{node.attributes['ToolTip']}"
    accessKey="#{node.attributes['AccessKey']}"
    inlineStyle="#{node.selected ? 'font-weight:bold;' : ''}">
  <f:attribute name="node" value="#{node}"/>
</af:commandImageLink>
```

Example 10–9 accesses values passed from a node to the corresponding page through parameters.

Example 10–9 Passing Node Values to Page Parameters

`homePageDef.xml`

```
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel"
    version="11.1.1.55.96" id="homePageDef"
    Package="oracle.webcenter.portalapp.pages">
  <parameters>
    <parameter id="NavigationParameter"
        value="#{navigationContext.currentNavigationModel.currentSelection.parameters
            ['MyNavParam']}"/>
  </parameters>
```

Example 10–10 conditionally displays breadcrumb links based on whether you can navigate to the node. It also bases the UI component on the type of the node.

Example 10–10 Conditionally Displaying Navigation Nodes

```
<af:breadCrumbs id="bc1"
                var="node"
                value="#{navigationContext.currentNavigationModel.defaultMenuModel}">
  <f:facet name="nodeStamp">
    <af:switcher facetName="#{node.navigable}" id="swn1">
      <f:facet name="true">
        <af:commandNavigationItem id="cni1" text="#{node.title}"
                                  actionListener="#{navigationContext.processAction}"
                                  partialSubmit="true">
          <f:attribute name="node" value="#{node}"/>
        </af:commandNavigationItem>
      </f:facet>
      <f:facet name="false">
        <af:outputText value="#{node.title}" rendered="#{!node.separator}" id="ot3"/>
      </f:facet>
    </af:switcher>
  </f:facet>
</af:breadCrumbs>
```

10.11.1.4 How to Render the Navigation Model as a List of Links

One common way to visualize a portal's navigation is as a list of links. Clicking a link navigates to the resource associated with it.

Example 10–11 retrieves the list model for the current navigation model and renders it vertically on the page. The code iterates through the navigation model, binding each node in turn to an ADF `commandImageLink` component. If a node contains children, a second iterator renders those children on the page. If a node is not navigable, it is not rendered as a link. The currently selected node is displayed in bold.

Example 10–11 Navigation as a List of Links

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <af:iterator id="i1"
               value="#{navigationContext.currentNavigationModel.listModel['startNode=/,
                     includeStartNode=false']}"
               var="node">
    <af:panelGroupLayout layout="vertical">
      <af:commandImageLink id="cil2" text="#{node.title}"
                           actionListener="#{navigationContext.processAction}"
                           action="pprnav"
                           icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                           disabled="#{not node.navigable}"
                           inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandImageLink>
      <af:iterator id="i2" value="#{node.children}" var="node2">
        <af:panelList id="pl1">
          <af:commandImageLink id="cil3" text="#{node2.title}"
                               actionListener="#{navigationContext.processAction}"
                               action="pprnav"
                               icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                               disabled="#{not node2.navigable}"
                               inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
            <f:attribute name="node" value="#{node2}"/>
          </af:commandImageLink>
        </af:panelList>
      </af:iterator>
    </af:panelGroupLayout>
  </af:iterator>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

10.11.1.5 How to Render the Navigation Model as a Tree

Another common way to visualize portal navigation is as a tree structure. A navigation tree is typically listed down the side of the page, so it is a useful way of displaying the entire navigation hierarchy. Users can navigate immediately to any node in the navigation. The advantage of using a tree structure over a simple list of links, is that users can expand and collapse the different nodes of the navigation model.

To include a tree structure in your page or page template, you can bind the ADF Faces `tree` navigation component to your navigation model. Example 10–12 shows how to do this. In the example, the second level of the navigation hierarchy is collapsed by default, but an icon enables users to expand a node to show its children.

Example 10–12 Navigation as a Tree

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp2" height="20px"/>
  <af:tree id="tree1" var="node" initiallyExpanded="true"
          value="#{navigationContext.currentNavigationModel.treeModel['includeStartNode=false']}">
    <f:facet name="nodeStamp">
      <af:commandImageLink id="cil2" text="#{node.title}"
                           actionListener="#{navigationContext.processAction}"
                           action="pprnav"
                           icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                           disabled="#{not node.navigable}"
                           inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandImageLink>
    </f:facet>
  </af:tree>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

10.11.1.6 How to Render the Navigation Model as a Three-Level Menu

You can also render your navigation as a menu. In a menu, the top level of navigation is displayed. When the user hovers the mouse over a particular node, if that node has children, they are displayed as a popup menu.

Figure 10–13 retrieves the list model for the current navigation model and renders it vertically on the page. The code iterates through the navigation model. If a node contains children, then a second iterator iterates through those children. Nodes without children are rendered as menu items. In the second level of the navigation model, if any of the nodes have children, then a third iterator is executed. Again, nodes without children are rendered as menu items. At the third level of the navigation mode, nodes are rendered as menu items. Non-navigable nodes are not rendered as links. The currently selected node is displayed in bold.

Example 10–13 Navigation as a Menu

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <af:menuBar id="mb1">
```

```
    <af:iterator id="i1"
                 value="#{navigationContext.currentNavigationModel.listModel['startNode=/,
                       includeStartNode=false']}"
                 var="node">
      <af:switcher id="s1"
                   facetName="#{empty node.children ? 'leafNode' : 'parentNode'}">
        <f:facet name="parentNode">
          <af:menu id="m1" text="#{node.title}"
                   inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
            <af:iterator id="i2" value="#{node.children}"
                         var="node2">
              <af:switcher id="s2"
                           facetName="#{empty node2.children ? 'leafNode' : 'parentNode'}">
                <f:facet name="parentNode">
                  <af:menu id="m2" text="#{node2.title}"
                           inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
                    <af:iterator id="i3" value="#{node2.children}"
                                 var="node3">
                      <af:commandMenuItem id="cml3"
                                          text="#{node3.title}"
                                          actionListener="#{navigationContext.processAction}"
                                          action="pprnav"
                                          icon="#{node3.attributes[pageFlowScope.tnBean.iconKey]}"
                                          disabled="#{not node3.navigable}"
                                          inlineStyle="#{node3.onSelectedPath ?
                                                      'font-weight:bold;' : ''}">
                        <f:attribute name="node" value="#{node3}"/>
                      </af:commandMenuItem>
                    </af:iterator>
                  </af:menu>
                </f:facet>
                <f:facet name="leafNode">
                  <af:commandMenuItem id="cml1"
                                      text="#{node2.title}"
                                      actionListener="#{navigationContext.processAction}"
                                      action="pprnav"
                                      icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                                      disabled="#{not node2.navigable}"
                                      inlineStyle="#{node2.onSelectedPath ?
                                                  'font-weight:bold;' : ''}">
                    <f:attribute name="node" value="#{node2}"/>
                  </af:commandMenuItem>
                </f:facet>
              </af:switcher>
            </af:iterator>
          </af:menu>
        </f:facet>
        <f:facet name="leafNode">
          <af:commandMenuItem id="cml2" text="#{node.title}"
                              actionListener="#{navigationContext.processAction}"
                              action="pprnav"
                              icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                              disabled="#{not node.navigable}"
                              inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
            <f:attribute name="node" value="#{node}"/>
          </af:commandMenuItem>
        </f:facet>
      </af:switcher>
    </af:iterator>
  </af:menuBar>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

10.11.1.7 How to Render the Navigation Model as Breadcrumbs

To provide users with a quick way of orientating themselves within the portal navigation, you can provide a trail of breadcrumbs on the page. Breadcrumbs show the current location in the portal and the path taken through the navigation to get there. Users can then quickly return to any point along that path. Breadcrumbs are typically used on a page in addition to other forms of navigation.

To include breadcrumbs in your page or page template, you can bind the ADF Faces `breadCrumbs` navigation component to your navigation model. Example 10–14 shows how to do this.

Example 10–14 Navigation as Breadcrumbs

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <af:breadCrumbs id="bc1" var="node"
                  value="#{navigationContext.currentNavigationModel.menuModel[
                        'includeStartNode=false']}">
    <f:facet name="nodeStamp">
      <af:commandNavigationItem id="cil1" text="#{node.title}"
                                actionListener="#{navigationContext.processAction}"
                                action="pprnav"
                                icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                                disabled="#{not node.navigable}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandNavigationItem>
    </f:facet>
  </af:breadCrumbs>
  <af:spacer id="sp2" height="20px"/>
</af:panelGroupLayout>
```

10.11.1.8 How to Render Master-Detail Navigation

Often portals provide a "master-detail" navigation visualization, for example, as tabs along the top of the page, with each tab having additional navigation provided as a tree structure along the side of the page.

The master-detail navigation in Example 10–15 uses the same navigation model for the master and detail navigation. The master navigation renders the top level of the navigation model as a list of links along the top of the page. The detail navigation renders the children of the currently selected top level node as a tree.

> **Tip:** For the `c:set` tag to work correctly in the following examples, you must include the JSTL library by adding the following to the `jsp:root` tag:
>
> ```
> xmlns:c="http://java.sun.com/jsp/jstl/core"
> ```

Example 10–15 Master-Detail Navigation Using a Single Navigation Model

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <!-- Master -->
  <af:navigationPane id="np1" var="node" hint="bar" level="1"
                     value="#{navigationContext.navigationModel[
                           'modelPath=/oracle/webcenter/portalapp/navigations/master-detail']
                           .defaultMenuModel}">
```

```
    <f:facet name="nodeStamp">
      <af:commandNavigationItem id="cil1" text="#{node.title}"
                                actionListener="#{navigationContext.processAction}"
                                action="pprnav"
                                icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                                disabled="#{not node.navigable}"
                                inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">

        <f:attribute name="node" value="#{node}"/>
      </af:commandNavigationItem>
    </f:facet>
  </af:navigationPane>
  <af:spacer id="sp2" height="20px"/>
  <!-- Setup the parameters for detail query -->
  <c:set value="startNode=/${navigationContext.navigationModel[
             'modelPath=/oracle/webcenter/portalapp/navigations/master-detail']
             .currentSelection.prettyUrlPath[1]}, includeStartNode=false"
         var="currSel" scope="session"/>
  <!-- Detail -->
  <af:tree id="tree1" var="node2" initiallyExpanded="true"
           value="#{navigationContext.navigationModel[
                 'modelPath=/oracle/webcenter/portalapp/navigations/master-detail']
                 .treeModel[currSel]}">
    <f:facet name="nodeStamp">
      <af:commandImageLink id="cil2" text="#{node2.title}"
                           actionListener="#{navigationContext.processAction}"
                           action="pprnav"
                           icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                           disabled="#{not node2.navigable}"
                           inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node2}"/>
      </af:commandImageLink>
    </f:facet>
  </af:tree>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

The example above can also be written to use two different navigation models, one for the master navigation, and one for the detail navigation. Example 10–16 shows how.

Example 10–16 Master-Detail Navigation Using Multiple Navigation Models

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <!-- Master -->
  <af:navigationPane id="np1" var="node" hint="bar" level="1"
                     value="#{navigationContext.navigationModel[
                           'modelPath=/oracle/webcenter/portalapp/navigations/master']
                           .defaultMenuModel}">
    <f:facet name="nodeStamp">
      <af:commandNavigationItem id="cil1" text="#{node.title}"
                                actionListener="#{navigationContext.processAction}"
                                action="pprnav"
                                icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                                disabled="#{not node.navigable}"
                                inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandNavigationItem>
    </f:facet>
  </af:navigationPane>
  <af:spacer id="sp2" height="20px"/>
  <!-- Setup the parameters for detail query -->
  <c:set value="startNode=/${navigationContext.navigationModel[
              'modelPath=/oracle/webcenter/portalapp/navigations/master']
              .currentSelection.prettyUrlPath[1]}, includeStartNode=false"
        var="currSel" scope="session"/>
  <!-- Detail -->
  <af:tree id="tree1" var="node2" initiallyExpanded="true"
                     value="#{navigationContext.navigationModel[
                           'modelPath=/oracle/webcenter/portalapp/navigations/master']
                           .treeModel[currSel]}">
    <f:facet name="nodeStamp">
      <af:commandImageLink id="cil2" text="#{node2.title}"
                          actionListener="#{navigationContext.processAction}"
                          action="pprnav"
                          icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                          disabled="#{not node2.navigable}"
                          inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node2}"/>
      </af:commandImageLink>
    </f:facet>
  </af:tree>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

10.11.2 Using the Navigation REST APIs

Oracle WebCenter Portal provides REST APIs to access the navigation model of your application. Use the navigation REST APIs to access the interface used to visualize the navigation model. You would typically use REST when creating Rich Internet Applications that are client-side scripted and require the ability to interact with data from a server-side application. For example, the Oracle WebCenter Portal iPhone App uses REST APIs to interact with a Portal Framework application.

For an introduction to the REST APIs, see Chapter 53, "Using Oracle WebCenter Portal REST APIs."

To access the navigation REST APIs, construct a URL as follows:

```
http://host:port/<ApplicationContextRoot>/api/navigations/default-navigation-model
```

where host and *port* are the *hostname* and port number for the server where the portal is running, and *<ApplicationContextRoot>* is the context root for the portal application. For example:

```
http://localhost:7101/MyPortalApplication-Portal-context-root/api/navigations/defa
ult-navigation-model
```

The response to this request provides the entry point URI (`href`) for the navigation REST APIs, identified by the link element with the following `resourceType`:

```
urn:oracle:webcenter:navigations
```

Sending a `GET` request to this entry point URI returns a list of navigation models within the application, for example:

```
<sitestructure>
  ...
  <navigation-list>
    oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed/
    navigations/default-navigation
  </navigation-list>
  <navigation-list>
    oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed/
    navigations/admin-navigation
  </navigation-list>
  <navigation-list>
    oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed/
    navigations/myNavigation
  </navigation-list>
  ...
</sitestructure>
```

Using this information, you can start to retrieve information about specific navigation models and the nodes within them, using the URIs listed in Table 10–5. The URIs shown in Table 10–5 can be appended to the `http://host:port/<ApplicationContextRoot>` part of the URL to access the desired REST endpoint.

Table 10–5 REST URI Model for Navigation

REST URI	Returns
`.../api/navigations`	All navigation models in the application.
`.../api/navigations/default-navigation-model`	The properties of the default navigation model.
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*	The properties of the specified navigation model (*`modelId`*).
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources`	All root resources under the specified navigation model (*`modelId`*).
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources/`*`pathToResource`*`/`*`resourceId`*	The specified resource (*`resourceID`*) from the specified navigation model (*`modelId`*).
`...api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources/`*`pathToResource`*`/`*`resourceId`*`/children`	A navigation tree listing all the children of the specified resource (*`resourceId`*) from the specified navigation model (*`modelId`*).
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources/`*`pathToResource`*`/`*`resourceId`*`/children?depth=`*`dep`*	A navigation tree listing the children of the specified resource (*`resourceId`*) from the specified navigation model (*`modelId`*) up to a specified level (*`dep`*).

Each navigable node has a `prettyURL` element that you can use to drill down further in the navigation model hierarchy.

10.11.3 Tips for Visualizing Portal Navigation

When visualizing portal navigation model, consider the following:

- Use ADF Faces layout components to organize your page or page template, rather than HTML `div` and `span` tags. For more information, see the "Organizing Content on Web Pages" chapter in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.
- If your Portal Framework application is public facing, or you want to enable search engine optimization, add navigation visualization using the `af:goLink` component in conjunction with the `goLinkPrettyUrl` method. You can also use other variations, such as `goButton`, `goImageLink`, and `goMenuItem`.

  For example:

```
<af.goLink
  destination="#{navigationContext.defaultNavigationModel.node['pagePath']
              .goLinkPrettyUrl"}
  text="mylink" />
```

- Manage styling, decorative images, and geometry using skins.
- Select the page template using the default page template setting in `adf-config.xml` or using the **Render URL in Page Template** option for individual navigation links.
- If you use the `af:commandLink` component, or one of its variations such as `commandButton`; `commandMenuItem`; and so on, to visualize your portal navigation, you must use the following `web.xml` parameters to force the ADF framework to redirect instead of using PPR navigation:

  ```
  oracle.adf.view.rich.pprNavigation.OPTIONS
  oracle.webcenter.navigationframework.REDIRECT_OPTIONS
  ```

  For more information, see Section 10.12, "Setting Context Parameters."

For more information, see the "Oracle WebCenter & ADF Architecture Team" blog.

10.12 Setting Context Parameters

If you want to use the af.CommandLink component to visualize your portal navigation, you must set the `oracle.adf.view.rich.pprNavigation.OPTIONS` context parameter in the `web.xml` file to force the ADF framework to redirect instead of using partial page refresh (PPR).

If your application does not use PPR, the URL in the browser changes whenever a user navigates to a node in the navigation model. However, the URL shown by the browser does not reflect the current page; it shows the URL of the last page shown.

To enable the browser to display the URL of the current page, you can set the `oracle.webcenter.navigationframework.REDIRECT_OPTIONS` context parameter in the `web.xml` file.

> **Note:** Setting the `oracle.webcenter.navigationframework.REDIRECT_OPTIONS` context parameter affects performance by adding an extra request/response for every navigation.

To set context parameters:

1. In the Application Navigator, right-click the **web.xml** file and choose **Open**.
2. In the Overview Editor, expand the Context Initialization Parameters section.
3. Click the **Create Context Initialization Parameter** icon.
4. In the Name field, enter oracle.adf.view.rich.pprNavigation.OPTIONS.
5. In the Value field, enter off.

   This adds the following to the web.xml file:

   ```
   <context-param>
     <param-name>oracle.adf.view.rich.pprNavigation.OPTIONS</param-name>
     <param-value>off</param-value>
   </context-param>
   ```

6. In the **Name** field, enter `oracle.webcenter.navigationframework.REDIRECT_OPTIONS`.

7. In the **Value** field, enter `toPrettyURL`.

   This adds the following to the `web.xml` file:

   ```
   <context-param>
    <param-name>oracle.webcenter.navigationframework.REDIRECT_OPTIONS</param-name>
    <param-value>toPrettyURL</param-value>
   </context-param>
   ```

8. Save the `web.xml` file.

10.13 Using a Navigation Model to Create a Sitemap

When a search engine crawls a web site, it parses the HTML for standard links (for example, `<a href="url">text</a>`). However, ADF-based web sites generate links as JavaScript, which when executed in a browser, cause the page change or navigation. These JavaScript links cannot be interpreted by search engines.

Some popular search engines, such as Google and Bing, support Sitemaps. A Sitemap is an XML file that lists URLs for a site along with additional metadata about each URL (for example, when it was last updated, how often it usually changes, and how important it is relative to other URLs in the site), so that search engines can more intelligently crawl the site. By submitting a Sitemap to a search engine, or by referencing the Sitemap in your `robots.txt` file, you can feed a list of pages into the search engine for indexing.

For more information about Sitemaps, go to:

`http://sitemaps.org/`

Portal Framework applications can provide a Sitemap URL that you can register with search engines to get them to index your set of pages. If the user-agent of the search engine matches one supported by ADF, such as Google's googlebot or Microsoft's bingbot, the HTML is returned for the request instead of the JavaScript.

You can create a Sitemap for your application based on a navigation model, as shown in Example 10–17.

Example 10–17 Creating a Sitemap

```
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          Xmlns:f=http://java.sun.com/jsf/core">
  <jsp:directive.page contentType="text/xml;charset=UTF-8" />
  <f:view>
    ${navigationContext.defaultNavigationModel.defaultSiteMap}
  </f:view>
</jsp:root>
```

10.14 Switching the Locale Dynamically

The WebCenter Navigation Model supports localization of certain textual strings such as `Title`. The setting of the resource bundle based strings is configured through the Navigation Model editor. For more information see, Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource."

Once the strings have been defined and the application configured with the supporting Locales, you can view the changes when switching the browser language settings. This is easy to implement, however, if the requirement is to be able to dynamically switch the Locale through a user interaction such as a drop-down list, then you must create custom code to support this requirement. In this section, one possible solution for this requirement is presented. This section assumes that the `face-config.xml` file has already been modified to support the different Locales for the application. For more information see, Chapter 75, "Building Multilanguage Portals."

Example Solution

This example solution contains an ADF `af:selectOneChoice` (SOC) component, which will be responsible for enabling the user interaction for the dynamic switching of the Locale. The SOC will be wired to a managed bean that will serve two important functions: one function is to store the users Locale selection, and the other function is to provide the `valueChangeEvent` listener method to enable the setting of the new Locale. In this example, the new Locale is stored in a variable and accessed by the `valueChangeEvent`.

```
Locale preferredLocale

public void listChanged(ValueChangeEvent valueChangeEvent) {
   String locale = valueChangeEvent.getNewValue().toString();
   changeLocale(locale);
   setCurrentLocale(locale);
  setPreferredLocale(FacesContext.getCurrentInstance().getViewRoot().getLocale());
}
```

This method also calls the `changeLocale` method, which is responsible for updating the current view:

```
private void changeLocale(String lang) {
   Locale newLocale = new Locale(lang);
   FacesContext fctx = FacesContext.getCurrentInstance();
   fctx.getViewRoot().setLocale(newLocale);
   resetPage();
}
```

This method then finishes the Locale change by calling `resetPage()`:

```
public void resetPage() {
   FacesContext context = FacesContext.getCurrentInstance();
   UIViewRoot root = context.getViewRoot();
   _returnViewId = root.getViewId();
   if (_returnViewId == null)
      return;
   ExternalContext external = context.getExternalContext();
   Application application = context.getApplication();
   ViewHandler viewHandler = application.getViewHandler();
   String actionURL = viewHandler.getActionURL(context, _returnViewId);
   actionURL = external.encodeActionURL(actionURL);
   try {
      external.redirect(actionURL);
   } catch (IOException e) {
      String message = e.getMessage();
      // to do ...
   }
}
```

Now that the code is in place to handle the switching, the next step is to enable the dynamic switching. This behavior can be achieved by implementing a custom Phase

Listener to get the new Locale from the managed bean, then enable `UIViewRoot` to be set with this Locale. The code for handling this will be in the overridden `beforePhase()` method.

> **Note:** Example code has not been optimized and can contain performance contentions.

The code using `SiteStructureContext` is the focus in this example, and is necessary to ensure that the navigation model is updated. Otherwise, the model (Locale) can only be updated by the browser settings.

```
public void beforePhase(PagePhaseEvent pagePhaseEvent) {
   Integer phase = pagePhaseEvent.getPhaseId();
   if (phase.equals(ADFLifecycle.PREPARE_MODEL_ID)) {
   FacesContext fctx = FacesContext.getCurrentInstance();
   ChangeLocale changeLocale =
      ChangeLocale)fctx.getApplication().evaluateExpressionGet
      (fctx,"#{ChangeLocale}", Object.class);
   Locale preferredLocale = changeLocale.getPreferredLocale();
   UIViewRoot uiViewRoot = fctx.getCurrentInstance().getViewRoot();
   if (preferredLocale == null) {
       changeLocale.setPreferredLocale(uiViewRoot.getLocale());
   } else {
       uiViewRoot.setLocale(preferredLocale);
   }
   try {
      SiteStructureContext ctx = SiteStructureContext.getInstance();
      SiteStructure model = ctx.getDefaultSiteStructure();
      model.invalidateCache();
    } catch (ResourceNotFoundException rnfe) {
        rnfe.printStackTrace();
    }
 }
}
```

11 Developing Page Templates

This chapter describes how to use Oracle JDeveloper to design and develop page templates for portal pages displayed in WebCenter Portal Framework applications and portals built with WebCenter Portal (Portal Builder).

This chapter includes the following topics:

11.1 Introduction to Developing Page Templates

Page templates define how individual pages and groups of pages display on a user's screen, and help to ensure that the pages in a portal are consistent in structure and layout. If you change a page template, then all pages that reference that template automatically inherit the changes.

> **See Also:** For general information about page templates, see the "Using Page Templates" section in *Web User Interface Developer's Guide for Oracle Application Development Framework*.

Oracle recommends that you use JDeveloper to develop page templates for both Portal Framework applications and portals built with WebCenter Portal (Portal Builder). In JDeveloper, you can build fully functional page templates from scratch or you can refine and further develop existing page templates to suit your particular requirements. You can also develop page templates in Portal Builder, but the editing capabilities are limited.

When fully developed, you can upload page templates directly to WebCenter Portal (the portal server) for immediate use or for testing. Alternatively, you can export the page template to a file and upload the page template to WebCenter Portal later on through Portal Builder.

You can develop page templates in the following ways:

- Build page templates from scratch, as described in Section 11.3, "Creating a Page Template."
- Download out-of-the-box page templates provided with WebCenter Portal (Portal Builder), and modify them, as described in Section 11.4, "Editing a Page Template."
- Leverage the out-of-the-box page templates provided with JDeveloper, as described in Section 11.1.4, "Understanding the Built-In Page Templates in a WebCenter Portal Framework Application" and Section 11.4, "Editing a Page Template."

This section includes the following topics:

- Section 11.1.1, "Understanding Page Template Structure"
- Section 11.1.2, "Understanding Page Template Layout"
- Section 11.1.3, "Understanding Page Template Layout Components"
- Section 11.1.4, "Understanding the Built-In Page Templates in a WebCenter Portal Framework Application"

11.1.1 Understanding Page Template Structure

Typical elements of a page template include:

- Header, content area (different in each page), and footer. The header and footer commonly include brand-specific elements. For example, a header usually includes a logo and possibly a slogan, and a footer usually includes contact and copyright information.
- Navigation. A page template can expose the navigation for a portal in many ways. For example, on a mobile device, portal navigation may be shown as a popup or slide in/out. On a desktop browser, portal navigation is typically shown along the top of the page, or down the side of the page.
- Branding elements. For example, a page template my include a company logo, slogan, or copyright message.
- Links and actions. For example, a log in/log out link, drop-down menus, or global links (such as links to send a mail message to the web administrator or to display a privacy statement).
- Conditional elements. For example, some elements on the page might differ depending on whether the user is public or authenticated or depending on the user's role and privileges.

Figure 11–1 shows a sample application based on a page template that illustrates these elements.

11.1.2 Understanding Page Template Layout

One of the most important aspects of page template design is the layout of components, both elements of the template and page content. There are two basic strategies:

- A *flowing* layout is the most typical layout. Components are arranged side by side or one below the other, displayed using their natural size. When the content of the page extends beyond the size of the browser window, the browser displays scroll bars on the page.
- A *stretching* layout may be a suitable choice when your page content fills a large area, or you want the page content to grow and shrink depending on the size of the browser window. Components are stretched to occupy the available space on the page. For example, a stretching layout may be suitable when a page contains a table or graph that you want to fill up the whole content area, no matter what size it is. Another example is a page that contains an editing area, where you want the editor to be exactly as tall and wide as the space given to the content area. This layout has a region for the page content, and adds scroll bars to the region on the page when the content cannot be contained within the size of the browser window. In other words, individual components display scroll bars (which might mean that you have multiple scroll bars on one page).

  Stretching enables you to maximize the usage of the viewable area. You can use tabs, accordions, menus, and popups to expand your viewable area. When scroll bars are added to the page, the navigation area, page header, and page footer remain in view while the content area scrolls.

Because most web sites use a flowing layout, you will probably also want to use a flowing layout as it will likely feel more familiar to your users. However, stretching layouts are good for dashboards and applications that are rich in nature or when you want to mimic a desktop experience. You can also combine flowing and stretching layout on the same page.

Vertical Behavior

Depending on whether your layout is flowing or stretching, the vertical behavior of the page differs as follows:

- **Flowing layout:**
  - The header and/or footer might not always be visible
  - The height of the page is calculated based on the page contents
  - The content is never stretched vertically
  - The browser might display a scroll bar
- **Stretching layout:**
  - The header and footer are always visible
  - The height of the page is determined by the browser window
  - The content is stretched vertically
  - The content area might display a scroll bar

Horizontal Behavior

Depending on whether your layout is flowing or stretching, the horizontal behavior of the page differs as follows:

- **Flowing layout:**
  - If your page includes a side bar (for example, left-side navigation), the side bar might not always be visible
  - The width of the page is calculated based on the components
  - Some components might be stretched to fill up existing space
  - The browser might display a scroll bar
- **Stretching layout:**
  - If your page includes a side bar (for example, left-side navigation), the side bar is always visible
  - The width of the page is determined by the browser window
  - The content is stretched horizontally
  - The content might display a scroll bar

11.1.3 Understanding Page Template Layout Components

The underlying structure of a page template is provided by Oracle Application Development Framework (ADF) layout components. After you decide on the appropriate layout to use for your page template (see Section 11.1.2, "Understanding Page Template Layout"), you will use ADF layout components to create your page template. This is a complex task, and requires knowledge of the ADF components that will achieve the structure and layout you require, and best practices to employ (see Section 11.2, "Best Practices for Developing Page Templates").

See Also:

- For details on what different layout components look like, see the ADF Faces Rich Client demo online tool:

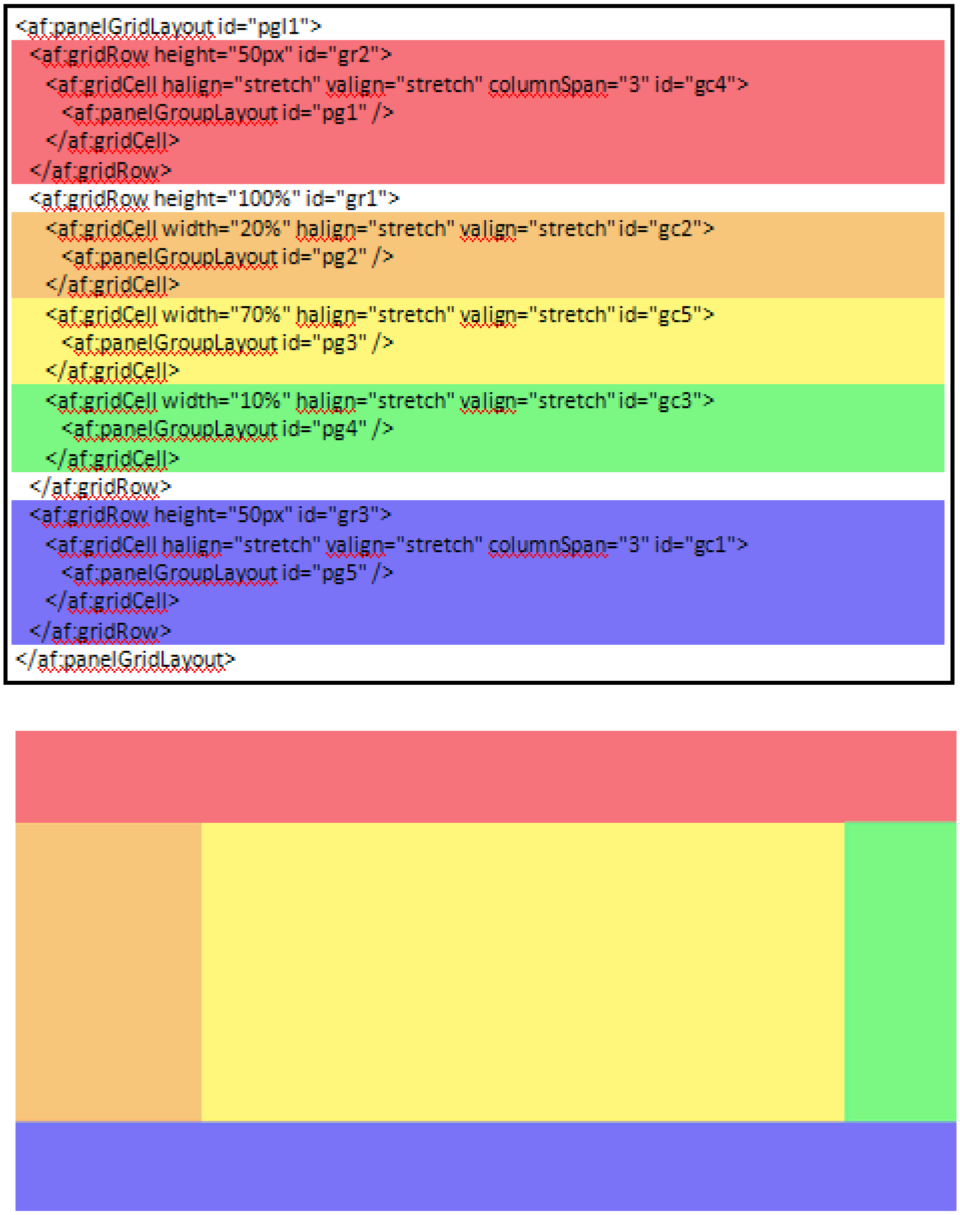
  `http://jdevadf.oracle.com/adf-richclient-demo/faces/visualDesigns/index.jspx`

  In the demo tool, you can select **Page** or **Page Template** from the **View Source** menu to see what layout components and attributes are used to achieve the page structure.
- Section 11.8, "Page Templates Tutorials and Examples"

Figure 11–2 and Figure 11–3 illustrate common ADF components used in a page template layout, showing the page template code followed by the generated layout:

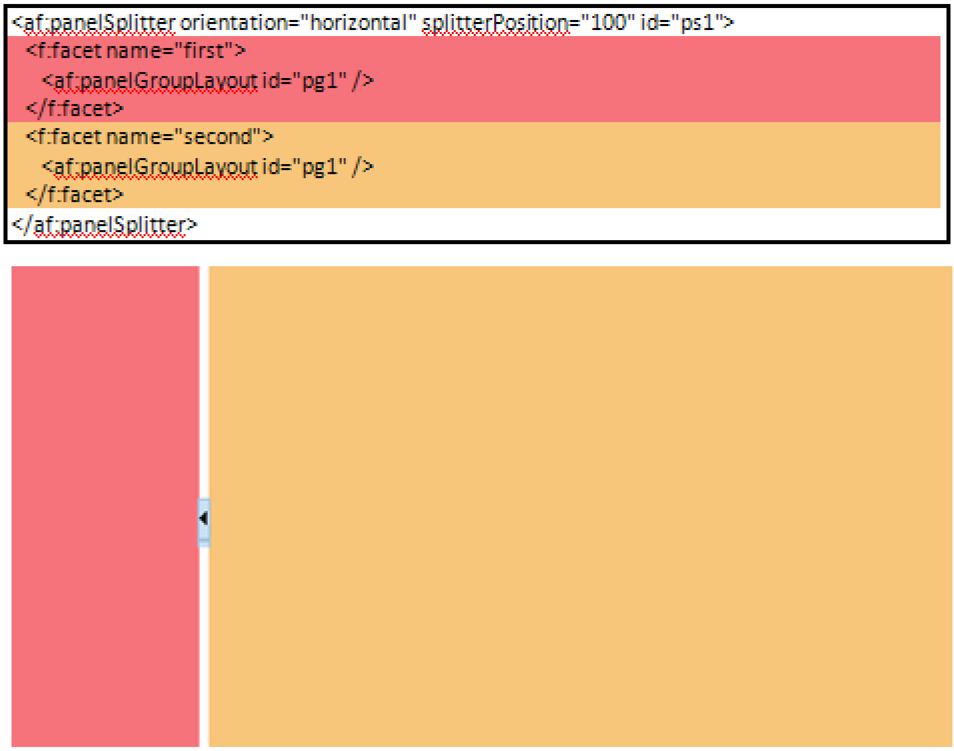
- `af:panelGridLayout`—a versatile layout component that uses rows (`gridRow`) and cells (`gridCell`) to define a structured layout. This component is the preferred general layout component as it offers a small client side footprint while being very flexible in layout capabilities. It allows you to more naturally define areas of the page to match your desired layout in the form of rows and columns. With `panelGridLayout`, you can easily specify fixed or variable column widths (% or pixels), which cannot be done as easily with other layout components. See Figure 11–2.
- `af:panelGroupLayout`—a flowing series of components arranged horizontally, vertically, or in scrollable structures. Typically, `panelGroupLayout` is used with flowing layouts, and with flowing content inside a stretching layout. It provides vertical and horizontal scroll bars if the content does not fit into the available space. See Figure 11–2 and Figure 11–3.
- `af:panelSplitter`—a stretched box divided into two user-modifiable sections. See Figure 11–3.

Figure 11–2 Page Template Code and Generated Stretching Layout: Example 1



```
<af:panelGridLayout id="pgl1">
  <af:gridRow height="50px" id="gr2">
    <af:gridCell halign="stretch" valign="stretch" columnSpan="3" id="gc4">
      <af:panelGroupLayout id="pg1" />
    </af:gridCell>
  </af:gridRow>
  <af:gridRow height="100%" id="gr1">
    <af:gridCell width="20%" halign="stretch" valign="stretch" id="gc2">
      <af:panelGroupLayout id="pg2" />
    </af:gridCell>
    <af:gridCell width="70%" halign="stretch" valign="stretch" id="gc5">
      <af:panelGroupLayout id="pg3" />
    </af:gridCell>
    <af:gridCell width="10%" halign="stretch" valign="stretch" id="gc3">
      <af:panelGroupLayout id="pg4" />
    </af:gridCell>
  </af:gridRow>
  <af:gridRow height="50px" id="gr3">
    <af:gridCell halign="stretch" valign="stretch" columnSpan="3" id="gc1">
      <af:panelGroupLayout id="pg5" />
    </af:gridCell>
  </af:gridRow>
</af:panelGridLayout>
```

Figure 11–3 Page Template Code and Generated Stretching Layout: Example 2



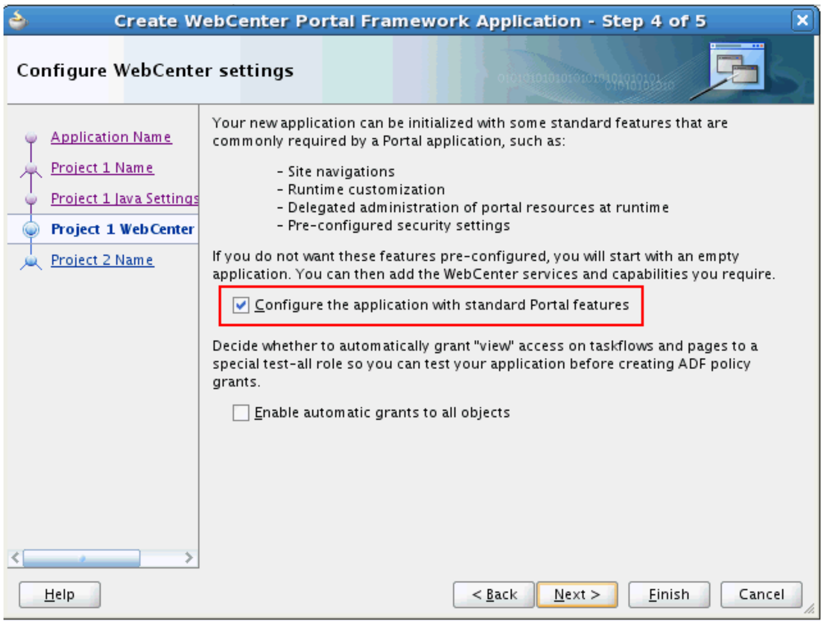
```
<af:panelSplitter orientation="horizontal" splitterPosition="100" id="ps1">
  <f:facet name="first">
    <af:panelGroupLayout id="pg1" />
  </f:facet>
  <f:facet name="second">
    <af:panelGroupLayout id="pg1" />
  </f:facet>
</af:panelSplitter>
```

11.1.4 Understanding the Built-In Page Templates in a WebCenter Portal Framework Application

Note: For information about the built-in page templates, see the "About Built-in Page Templates" section in *Building Portals with Oracle WebCenter Portal.* You can download these page templates and modify them in JDeveloper, as described in Section 11.4, "Editing a Page Template."

When you create a Portal Framework application, and select the **Configure the application with standard Portal features** check box (see Section 6.1, "Creating a New WebCenter Portal Framework Application"), as shown in Figure 11–4, two built-in templates are added to your application: `pageTemplate_globe.jspx` and `pageTemplate_swooshy.jspx`.

Figure 11–4 Create WebCenter Portal Framework Wizard Step 4 of 5



Create WebCenter Portal Framework Application - Step 4 of 5

Configure WebCenter settings

Your new application can be initialized with some standard features that are commonly required by a Portal application, such as:

- Site navigations
- Runtime customization
- Delegated administration of portal resources at runtime
- Pre-configured security settings

If you do not want these features pre-configured, you will start with an empty application. You can then add the WebCenter services and capabilities you require.

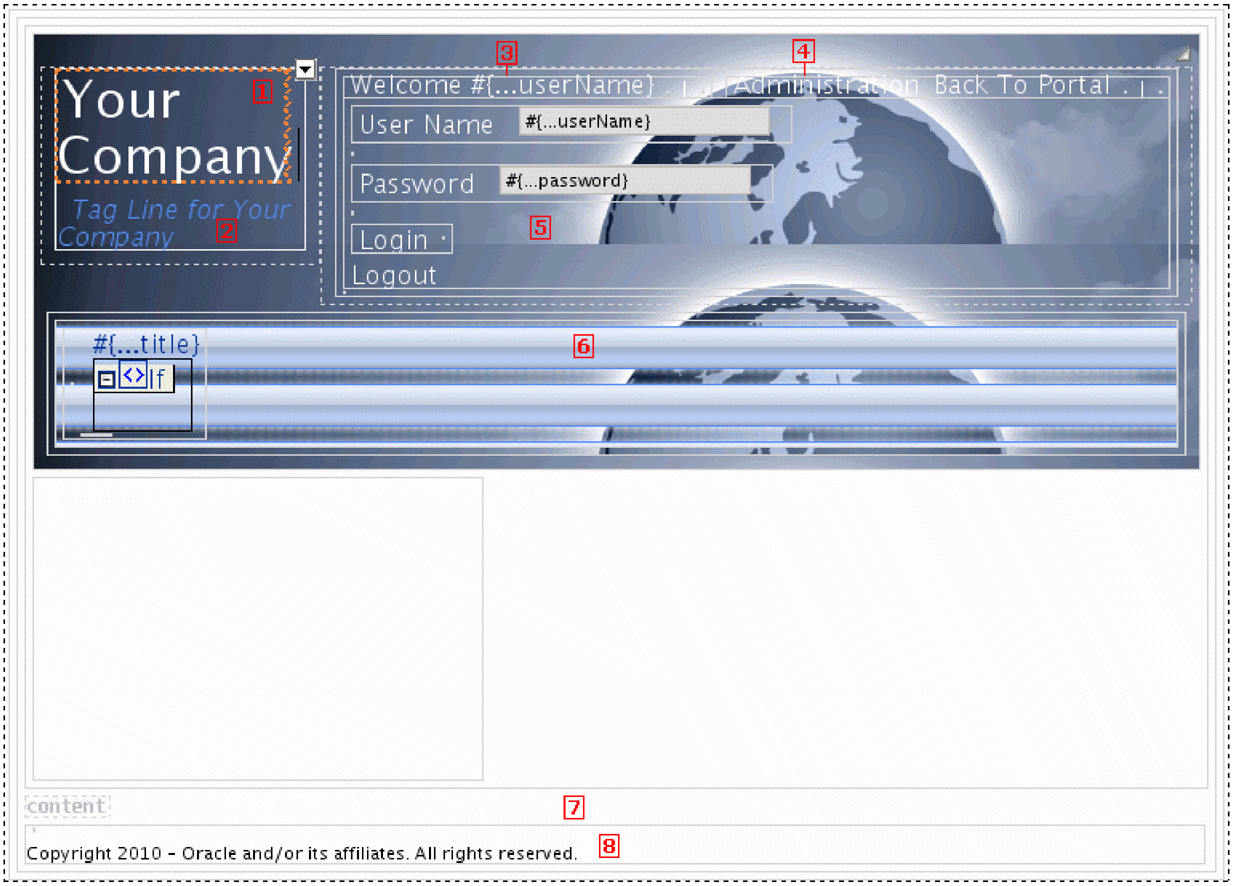
☑ Configure the application with standard Portal features

Decide whether to automatically grant "view" access on taskflows and pages to a special test-all role so you can test your application before creating ADF policy grants.

☐ Enable automatic grants to all objects

These built-in page templates both offer essentially the same functionality but with different graphics. Figure 11–5 shows the `pageTemplate_globe.jspx` page template.

Figure 11–5 Built-In Page Template - pageTemplate_globe.jspx



Copyright 2010 - Oracle and/or its affiliates. All rights reserved.

1. Link to the portal home page
2. Tag line
3. Welcome message
4. Link to the runtime administration console
5. Login area that converts to a logout link when users are logged in
6. Navigation bar
7. Area for adding content to pages based on the template
8. Copyright notice

These page templates use the following attributes:

Table 11–1 Built-In Page Template Attributes

Name	Type	Default Value
`contentWidth`	String	`960px`
`showNavigation`	Boolean	`true`
`showGreetings`	Boolean	`#{securityContext.authenticated}`
`showLogin`	Boolean	`true`
`showAdmin`	Boolean	`#{securityContext.authenticated}`
`isAdminPage`	Boolean	`false`
`isEditingTemplate`	Boolean	`false`

You can edit these built-in page templates to meet your particular requirements, or you can create your own from scratch. If you choose to create your own page templates, Oracle recommends that you refer to the latest built-in page templates, which provide examples of recommended layout components that include fewer task flows and faster performance. See the "About Built-in Page Templates" section in *Building Portals with Oracle WebCenter Portal.*

11.2 Best Practices for Developing Page Templates

Because page templates are present in every page of a portal, the design of your page templates should be carefully planned to optimize their performance and conform to best practices. This section provides tips for developing page templates for a portal.

Note about Page Templates in WebCenter Portal (Portal Builder):

The development of a page template is a complex task. Oracle recommends that you use JDeveloper to develop page templates for both Portal Framework applications and portals built with WebCenter Portal (Portal Builder). You can also develop page templates in Portal Builder, but the editing capabilities are limited.

When fully developed, you can upload page templates directly to WebCenter Portal (the portal server) for immediate use or for testing. Alternatively, you can export the page template to a file and upload the page template to WebCenter Portal later on through Portal Builder.

For more information, see Section 11.3, "Creating a Page Template," Section 11.4, "Editing a Page Template," and Section 55.1, "Developing Assets for WebCenter Portal."

Table 11–2 provides a quick reference summary of considerations and guidance for achieving the best results out of your page templates.

Table 11–2 Best Practices Summary for Page Templates

Considerations	Best Practices
Performance	While all of this section, "Best Practices for Developing Page Templates", is aimed at improving the performance of your page templates, there are a few general tips to keep in mind as overall best practices: ■ Minimize the use of embedded task flows. For examples, refer to the latest built-in page templates included with WebCenter Portal, described in the "About Built-in Page Templates" section in *Building Portals with Oracle WebCenter Portal.* ■ Minimize the use of ADF layout components, using `panelGridLayout` to implement your page template structure. The fewer ADF layout components, the easier it is to apply skins. ■ Avoid using images for decorative purposes (such as rounded corners). Consider using CSS instead of images. ■ Defer loading of ADF components, such as menus and dialogs, where possible. This can be controlled through ADF such as `contentDelivery`, `childCreation`, and so on. ■ Avoid elements that require extra time in rendering page templates and try to substitute for elements that require less processing time.

Table 11–2 (Cont.) Best Practices Summary for Page Templates

Considerations	Best Practices
Layout	One of the most important aspects of page template design is how to lay out components, both elements of the template and page content. Page templates can have a flowing layout or a stretching layout. For more details about these two strategies, see Section 11.1.2, "Understanding Page Template Layout." As a page template developer, you can control whether the content facet is in a stretching or flowing region of the page. Page content must be created taking the layout strategy into consideration. Once you decide on the best strategy for your page templates, see the following sections for tips on creating the layout you choose: ■ Section 11.2.1, "Best Practices for Creating Stretching Layouts" ■ Section 11.2.2, "Best Practices for Creating Flowing Layouts"
Navigation	A page template can expose the navigation for a portal in many ways. For example, in a desktop browser, portal navigation is typically shown along the top of the page, or down the side of the page: ■ A *top navigation* page template exposes the portal navigation in header area. Top navigation makes effective use of the horizontal space on the page, and is recommended when there are seven or fewer top level pages in the portal navigation. This page template design generally has a header, page and footer sections, and is an ideal starting point for sites that require a flowing layout. ■ A *side navigation* page template exposes the portal navigation in a sidebar on the left side of the page. The vertical nature of side navigation allows for a more lengthy list of navigation items, and is recommended when there are more than seven top level pages in the portal navigation. Choose a side navigation template for more complex navigation models. On different devices, other navigation models can be used. For example, in page templates optimized for mobile devices, navigation can be provided as either a popup or slide in/out. The navigation model provided out-of-the-box with WebCenter Portal (`Portal Default Navigation Model`) is a shared asset that can be embedded in a page template to provide ready-built navigation that can be customized and extended as desired. For more information, see the "Editing a Navigation Model" and "About Built-in Page Templates" sections in *Building Portals with Oracle WebCenter Portal*.
Skin	Each page template works together with a skin to determine the overall look and feel of the pages in your portal. While the page template controls the structure of components on the page, the skin controls the visual appearance of those components, such as the colors, fonts, and other aspects such as the position, height, and width of components on the page. Each page template can define a preferred skin to identify the skin that works best with that page template. When the page template is selected as the default page template for a portal or as the system default, the default skin automatically updates to the page template's preferred skin. For more information, see Chapter 13, "Developing Skins."

Table 11–2 (Cont.) Best Practices Summary for Page Templates

Considerations	Best Practices
Storage location	In a Portal Framework application, to expose the new page template in the **Assets** page of the runtime administration console, you must create the page template under the `*Application_Root*/Portal/public_html/oracle/webcenter/portalapp/pagetemplates` directory, which contains the out-of-the-box templates. Creating your page templates in this directory provides the following advantages: ■ Page templates can be packaged into resource archives, which can be imported and used in other WebCenter Portal Framework applications, or portals built with Portal Builder. You can create general purpose, reusable page templates. ■ Page templates can be managed at run time using the Administration Console. After importing a page template, you need to edit `pagetemplate-metadata.xml` to register the newly imported template for JDeveloper. For more information, see Section 9.5.1, "Enabling Runtime Administration of Portal Resources."
Runtime behavior	If you develop a page template in JDeveloper that you plan to allow authorized users to edit in Composer at runtime, follow the tips provided in Section 11.2.3, "Best Practices for Developing Page Templates That Can Be Edited at Runtime." Select the **Create Associated ADFm Page Definition** option when developing a page template so that the template can include portlets and task flows and to enable runtime switching. For more information, see Section 11.3, "Creating a Page Template." and Section 11.5.3, "How to Enable Dynamic Switching of Page Templates at Runtime in a WebCenter Portal Framework Application."
Components	For details on what different ADF layout components look like, see the ADF Faces Rich Client demo online tool (`http://jdevadf.oracle.com/adf-richclient-demo/faces/visualDesigns/index.jspx`). Select **Page** or **Page Template** from the **View Source** menu for a component to see what tags and attributes are used as well as what the component structure looks like for the page. Because a page template layout can be changed, create pages and design custom components that display properly in flowing and stretching context. For tips on customizing the appearance of components, see Section 11.2.4, "Best Practices for Customizing the Appearance of Components."
Scrolling	Add scroll bars only around flowing island content. For tips on implementing scroll bars, see Section 11.2.5, "Best Practices for Defining Scrolling in a Page Template."
Margins, borders, and padding	Due to browser CSS Box Model Rules, defining margins, borders and padding on components might be complex. For tips on resolving the complexities of defining margins, borders and padding on components, see Section 11.2.6, "Best Practices for Defining Margins, Borders, and Padding."

Table 11–2 (Cont.) Best Practices Summary for Page Templates

Considerations	Best Practices
Attributes	Consider attributes that can be set in your page templates or pages that use the page templates. For example, `showFooter` specifies whether or not to show the page footer. A page template without attributes is syntactically correct. However, page template attributes are useful when you want to use one page template for several pages where the template should render slightly differently. Information about using attributes in your page templates is provided throughout this chapter, including Section 11.2.7, "Best Practices for Hiding Content in Page Templates in a Portal Framework Application" and Section 11.3, "Creating a Page Template."
Links	To add links to page templates, copy components provided in the out-of-the-box page templates to include links navigation, menus, breadcrumbs, buttons, and images. `go` components such as `goButton` and `goLink` have little to no client side footprint since they do not carry client side functionality. They are also preferred over command components (`commandButton`, `commandLink`) for general navigation in portals because they enable URLs that are optimized for search engines.
Internationalization	To create page templates with internationalization techniques in mind, see Chapter 75, "Building Multilanguage Portals" for information about recommended practices such as storing static text in resource bundle files.
Naming page templates (display name)	The display name is exposed to users when creating a new page. For this reason, you should make the page template name something that helps users quickly identify which type of pages the template should be used for.

This section includes the following topics:

- Section 11.2.1, "Best Practices for Creating Stretching Layouts"
- Section 11.2.2, "Best Practices for Creating Flowing Layouts"
- Section 11.2.3, "Best Practices for Developing Page Templates That Can Be Edited at Runtime"
- Section 11.2.4, "Best Practices for Customizing the Appearance of Components"
- Section 11.2.5, "Best Practices for Defining Scrolling in a Page Template"
- Section 11.2.6, "Best Practices for Defining Margins, Borders, and Padding"
- Section 11.2.7, "Best Practices for Hiding Content in Page Templates in a Portal Framework Application"

11.2.1 Best Practices for Creating Stretching Layouts

If your page template is best suited to a stretching layout (see Section 11.1.2, "Understanding Page Template Layout"), follow these tips as you develop the layout:

- Build the outer structure with containers that can be stretched and can stretch their children. Inside your `document` component, use containers such as `panelGridLayout` (Figure 11–2) with rows (`gridRow`) and cells (`gridCell`), and `panelSplitter` (Figure 11–3).

> **Note:** Each layout or panel component's tag documentation identifies whether it is stretchable and how to achieve it in its "Geometry Management" documentation. Some components have attributes to determine whether children will be stretched or not. For example: `document` has a `maximized` attribute, `showDetailItem` has a `stretchChildren` attribute.

- Create flowing islands. Inside of the stretchable outer structure, create islands of flowing (non-stretched) components. To make this transition from stretching to flowing, use `panelGroupLayout` with `layout="scroll"` or `layout="vertical"` since it supports being stretched but will not stretch its children.
- On stretching components, set `dimensionsFrom="auto"` so that the stretching component (for example, `panelStretchLayout`) will only try to stretch its child if it itself is being stretched. If it is not being stretched, then it will flow (not stretch) its children.
- Do not stretch something vertically (by using a height with a percent value) when inside a flowing container.
- Do not use the `position` CSS property in an `inlineStyle`. Doing so will impede the ability to override this property with a style specified in the skin.

> **Note:** The following components are just some of the components that cannot be reliably stretched:
>
> - Most input components
> - `panelBorderLayout`
> - `panelFormLayout`
> - `panelGroupLayout` (with `layout="default"`)
> - `panelGroupLayout` (with `layout="horizontal"`)
> - `panelHeader` (with `type="flow"`)
> - `panelLabelAndMessage`
> - `panelList`
> - `panelGrid`
> - `tableLayout` (Apache MyFaces Trinidad HTML Component)

11.2.2 Best Practices for Creating Flowing Layouts

If your page template is best suited to a flowing layout (see Section 11.1.2, "Understanding Page Template Layout"), follow these tips as you develop the layout:

- Use `panelGridLayout` with rows (`gridRow`) and cells (`gridCell`) to define a structured layout that will flow.
- To avoid multiple scroll bars, do not nest scrolling `panelGroupLayout` components, instead use `layout="vertical"`.
- Most stretchable ADF components also work in flowing context with `dimensionsFrom="auto"`.

- To stretch a component horizontally, use `styleClass="AFStretchWidth"` (instead of `inlineStyle="width:100.0%"`).

Working with customizable components:

- In `panelCustomizable`, use `layout="auto"` to detect whether to stretch its children.
- To support flowing and stretching layouts, use `showDetailFrame` with `stretchChildren="auto"`.

11.2.3 Best Practices for Developing Page Templates That Can Be Edited at Runtime

To create a page template at design time (in JDeveloper) that is suited to being editable at runtime (in Composer), follow these tips:

- Add components from the Composer group in the Component Palette.
- Do not add `pageCustomizable` to a page template.
- Add at least one `panelCustomizable` component, which provides a container with horizontal or vertical layout that holds other components.
- Inside a `panelCustomizable` component, add ADF components (such as `outputText`, `richTextEditor`, or `goLink`) surrounded by a `showDetailFrame`, which provides a chrome for a component that enables you to add actions like show, hide, and move. You can edit the frame or the embedded component properties.

> **Caution:** Use this technique sparingly, as `showDetailFrame` components impact processing time. If the end user is not expected to move components around, do not wrap them in a `showDetailFrame`.

Many of the components available to add to a page at design time are also available at runtime in the resource catalog. Table 11–3 maps design time components to runtime components.

Table 11–3 Component Mapping: Design time to Runtime

Design Time (JDeveloper)	Runtime (Composer)
`panelCustomizable`	`Box`
`outputText`	`HTML Markup`
`goLink`	`Hyperlink`
`goImageLink`	`Image`
`showDetailFrame`	`Movable Box`
`richTextEditor`	`Text`
`inlineFrame`	`Web Page`

11.2.4 Best Practices for Customizing the Appearance of Components

To customize the appearance of components, follow these tips:

- For custom styling, use Cascading Style Sheets (CSS), which is easy to maintain and can be changed without changing the page template source. For example, make the background color of a page blue using the CSS code `background-color: blue`.

- Use a custom skin for consistently modified appearances if the existing skin doesn't provide all that you need.
- For instance-specific alternative styling, use the `styleClass` attribute. Keep the corresponding style definitions in an easy-to-maintain location such as in a custom skin (recommended) or in a style provided by the `af:resource` tag.
- As a last resort, use component attributes such as `inlineStyle`, `contentStyle`, and `labelStyle`. These are harder to maintain as they are scattered throughout components rather than collected in a single style sheet, contribute more to the page's raw HTML size, and may not even be needed if one or more of the above mechanisms are used. Styles are directly processed by the web browser, which gives you a great deal of power but at the cost of being error-prone.
- Browsers do not support all styles on all elements and certain combinations of styles produce non-obvious results. Here is some guidance on style configurations to avoid:
  - An `inlineStyle` with a `height` value with `%` units
  - An `inlineStyle` with a `width` value between `90%` and `100%` (use `styleClass="AFStretchWidth"` or `styleClass="AFAuxiliaryStretchWidth"` instead)
  - An `inlineStyle` with `height`, `top`, and `bottom` values
  - An `inlineStyle` with `width`, `left`, and `right` values
  - An `inlineStyle` with a `position` value
  - In a child being stretched by a parent component, an `inlineStyle` with `width` or `height` values

11.2.5 Best Practices for Defining Scrolling in a Page Template

To define scrolling in a page template, follow these tips:

- Try to avoid the need for end users to scroll horizontally by designing the page content to occupy the available screen size.
- Add scroll bars only around flowing island content. The recommended transition component for switching from a stretching outer frame into a flowing island is the `panelGroupLayout` with `layout="scroll"`. If the contents of this `panelGroupLayout` cannot fit in the space allocated, the browser will determine whether scroll bars are needed and will add them automatically.
- Do not nest scrolling `panelGroupLayout` components because this will make the user see multiple scroll bars. Also, this should only be used at transitions from stretching to flowing areas and since you should not have stretching areas inside of flowing areas, you would generally never end up with nested scroll bars. It is best to minimize the number of areas that users must scroll in order to see what they are looking to find. Take time to consider what scrolling users will need. In cases where undesired scroll bars exist, you may want to change the `layout` attribute of the `panelGroupLayout` to `vertical`.

11.2.6 Best Practices for Defining Margins, Borders, and Padding

Due to browser CSS Box Model Rules, defining margins, borders and padding on components can be complex. In many cases, to apply these kinds of styles, you need to use multiple components together:

- In a scrolling area, you can add an extra `panelGroupLayout` with `layout="vertical"` with the padding defined on it, inside of the outer `panelGroupLayout` with `layout="scroll"`.
- In a stretching area, you may need to wrap a `panelGroupLayout` component inside a `panelGridLayout` with spacers inside `gridCell` components. See Figure 11–2.

> **See Also:** Refer to the Navigation-Master-Detail, Tiled Flowing, and Tiled Stretching layout pattern examples for various mechanisms to apply padding:
>
> `http://jdevadf.oracle.com/adf-richclient-demo/faces/feature/layoutBasicTest.jspx`

11.2.7 Best Practices for Hiding Content in Page Templates in a Portal Framework Application

In a Portal Framework application, there are several special pages based on a page template that hide parts of the page template. These pages use the attributes specified in the page template to accomplish this:

- In out-of-the-box `login.jspx` and `error.jspx`: `showNavigation=false` and `showLogin=false`.
- In built-in administration pages: `isAdminPage=true`.
- When editing a template, Assets Manager sets `isEditingTemplate=true`.

Use these attributes in your custom page template if the template will be used as the default template or if you use the out-of-the-box login page.

You may allow page templates with editable components to be edited using Composer. Oracle recommends you hide the template content, except the content facet reference, when editing the page so that only the page content, not the page template, can be edited. For example, use the rendered attribute:

```
rendered = "#{!composerContext.inEditMode or attrs.isEditingTemplate}"
```

11.3 Creating a Page Template

Before you create a page template, read through Section 11.2, "Best Practices for Developing Page Templates."

This section describes how to start from scratch with a new page template of your own design. Alternatively, you can start with the two built-in page templates provided in Portal Framework applications, or the latest page templates provided with WebCenter Portal (recommended), and modify them according to your requirements. To use an existing page template as a starting place, see Section 11.4, "Editing a Page Template."

Note: Creating a page template is a complex task. Oracle recommends that you use JDeveloper to develop page templates for both Portal Framework applications and portals built with WebCenter Portal (Portal Builder). You can also develop page templates in Portal Builder, but the editing capabilities are limited.

When fully developed, you can upload page templates directly to WebCenter Portal (the portal server) for immediate use or for testing. Alternatively, you can export the page template to a file and upload the page template to WebCenter Portal later on through Portal Builder.

To create a page template:

1. In the Application Navigator, right-click the node where you want to create and store page templates (Figure 11–6) and choose **New**:

Figure 11–6 Contents of the pagetemplates Folder

   - For Portal Framework applications, the recommended directory is `/oracle/webcenter/portalapp/pagetemplates`

   Note: In a Portal Framework application, to expose the new page template in the **Assets** page of the runtime administration console, you must create the page template under the `*Application_Root*/Portal/public_html/oracle/webcenter/portalapp` directory. By default, Portal Framework applications include a separate `pagetemplates` directory, which contains the built-in page templates.

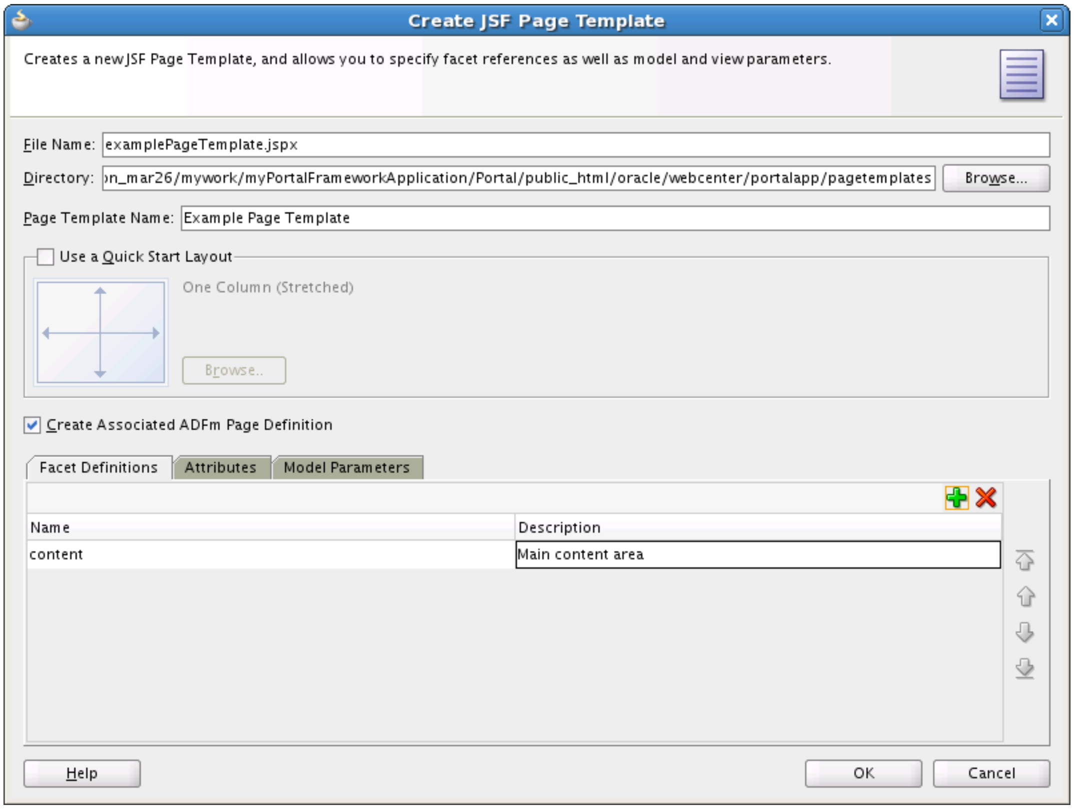
   - For page templates to be used in WebCenter Portal (Portal Builder), use the `WebCenterSpacesResource` project to select a directory for shared assets or portal assets, as described in Section 55.1, "Developing Assets for WebCenter Portal."

2. In the New Gallery, expand **Web Tier**, select **JSF** and then **JSF Page Template**, and click **OK**.

3. In the Create JSF Page Template dialog (Figure 11–7), in the **File Name** field, enter a name for the JSPX file that represents the page template (for example `myCompanyPageTemplate.jspx`).

The file name identifies the page template in the Application Navigator.

Figure 11–7 The Create JSF Page Template Dialog



Create JSF Page Template

Creates a new JSF Page Template, and allows you to specify facet references as well as model and view parameters.

File Name: examplePageTemplate.jspx

Directory: ›n_mar26/mywork/myPortalFrameworkApplication/Portal/public_html/oracle/webcenter/portalapp/pagetemplates

Page Template Name: Example Page Template

□ Use a Quick Start Layout

One Column (Stretched)

☑ Create Associated ADFm Page Definition

Name	Description
content	Main content area

4. In the **Directory** field, verify or enter the full directory path of the location under which to create the page template.

5. In the **Page Template Name** field, enter a display name for the page template that will help users quickly identify which type of pages this template should be used for.

6. If you want to use one of the predefined layouts for your page template, select **Use a Quick Start Layout**.

7. Select **Create Associated ADFm Page Definition** to use ADFm Model data bindings in the page template.

   Associating a page definition with the page template enables you to include objects that have model elements to them (for example, task flows and portlets) in the page template. It also enables users to switch to a different page template at runtime. For runtime page template switching to work, one of the following conditions must be met:

   – All page templates in the application have associated page definitions.

   – None of the page templates in the application have associated page definitions.

   Therefore, because the built-in page templates provided with Portal Framework applications have associated page definitions, for page template switching to work in Portal Framework applications, any other page templates created within the application must also have associated page definitions.

8. Click the **Facet Definitions** tab to define the areas, or *facets*, in the page template where content can be inserted.

   Facets are placeholders in the template that will be filled in by the pages using the template. An ADF page template can have any number of facets, but a Portal Framework application requires that each template have one facet called `content`. Typically Portal Framework applications do not use any other facets, since WebCenter Portal's runtime tools recognize only this facet. Other facets could be used only at design time, in JDeveloper.

   A page template that is intended for use in a WebCenter Portal application must contain at least one facet definition that must be called `content`. To create this facet definition:

   a. Click the **New** icon to add a new row to the **Facet Definitions** tab.

   b. In the **Name** field for the new facet definition, enter `content`.

   c. In the **Description** field, enter a brief description for the facet definition, for example `Main content area`.

   d. Create additional facet definitions as required.

   e. For information about how to add the facets to the required location in the page template, see Section 11.4, "Editing a Page Template."

   Example 11–1 shows the `content` facet definition in the `<af:xmlContent>` section of the `pageTemplate_globe.jspx` built-in page template.

Example 11–1 Content Facet in the Globe Built-In Page Template

```
<af:xmlContent>
  <component xmlns="http://xmlns.oracle.com/adf/faces/rich/component">
    <display-name>Globe Page Template</display-name>
    <facet>
      <description>Facet for content</description>
      <facet-name>content</facet-name>
    <facet>
    ...
  </component>
</af:xmlContent>
```

9. Click the **Attributes** tab and click the **New** icon to define attributes for passing values from pages that use the template to the template itself. These values can be used by the page template to drive what is actually displayed on individual pages that use the template.

   A page template without attributes is syntactically correct. However, page template attributes are useful when you want to use one page template for several pages where the template should render slightly differently.

   For example, the `pageTemplate_globe.jspx` built-in page template includes a link to the seeded Administration page. If the current page *is* the Administration page, then this link does not need to be displayed. The template uses an attribute, called `isAdminPage`, to identify whether the current page is the seeded Administration page. The value of this attribute, set by pages that use the template, determines whether or not to display the link to the Administration page.

   Example 11–2 shows the `isAdminPage` attribute definition in the page template.

Example 11–2 Attribute Definition in the Globe Built-In Page Template

```
<af:xmlContent>
```

```
  ...
    <attribute>
      <attribute-name>isAdminPage</attribute-name>
      <attribute-class>java.lang.Boolean</attribute-class>
      <default-value>#{false}</default-value>
    </attribute>
  ...
</af:xmlContent>
```

Example 11–3 shows how the page template uses the value of the `isAdminPage` attribute to determine whether or not to render the link to the seeded Administration page.

Example 11–3 Conditional Value for Rendering the Administration Page Link

```
<af:pageTemplateDef var="attrs">
  ...
  <af:goLink id="pt_glnk1" text="Administration"
             destination="/admin"
             rendered="#{attrs.showAdmin !attrs.isAdminPage}"
             inlineStyle="font-size:small; color:White;"/>
```

Example 11–4 shows how the seeded **Administration** page sets the `isAdminPage` attribute to `true`, ensuring that the page template does not render the link when users are viewing the **Administration** page.

Example 11–4 Setting the Value of a Page Template Attribute

```
<af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}" id="pt1">
  <f:attribute name="isAdminPage" value="#{true}"/>
```

Example 11–5 shows how the page template uses the value of the `contentWidth` attribute to set the page width. The default value is 960 pixels.

Example 11–5 contentWidth Attribute

```
<attribute>
  <attribute-name>contentWidth</attribute-name>
  <attribute-class>java.lang.String</attribute-class>
  <default-value>960px</default-value>
</attribute>
```

Example 11–6 shows how the page template uses the value of the `showNavigation` and `showLogin` attributes to show or hide the login link and the navigation bar.

10. Click **OK**.

    The page template is created and opened in the visual editor. The next step is to edit the page template to define its layout and content.

11.4 Editing a Page Template

You can edit your page template after its initial creation. You can also edit one of the built-in page templates to alter it to meet your specific requirements. Any changes you make are automatically rolled out to any pages that use the page template.

Note: Editing a page template is a complex task. Oracle recommends that you use JDeveloper to develop page templates for both Portal Framework applications and portals built with WebCenter Portal (Portal Builder). You can also develop page templates in Portal Builder, but the editing capabilities are limited.

When fully developed, you can upload page templates directly to WebCenter Portal (the portal server) for immediate use or for testing. Alternatively, you can export the page template to a file and upload the page template to WebCenter Portal later on through Portal Builder.

Before you edit a page template, read through Section 11.2, "Best Practices for Developing Page Templates."

For examples of features that you can include in your own page templates, refer to:

- The two built-in page templates in Portal Framework applications. See Section 11.1.4, "Understanding the Built-In Page Templates in a WebCenter Portal Framework Application."
- The built-in page templates provided with WebCenter Portal, specifically the latest templates that include fewer task flows and the performance-optimizing `panelGridLayout` component, which uses rows (`gridRow`) and cells (`gridCell`) to define a structured layout. See the "About Built-in Page Templates" section in *Building Portals with Oracle WebCenter Portal.*

Even if you do not intend to base your page templates on the built-in ones at all, it is still worth studying them for ideas. For example, the built-in page templates include a login form, and a good example of navigation visualization, which you can modify according to your requirements.

If iterative development is enabled, any changes that you make to page templates can be seen immediately in a running Portal Framework application. For more information about iterative development, see Section 2.3.1, "Preparing for Iterative Development in a Portal Framework Application."

To edit a page template:

1. To add WebCenter Portal-specific components to your page template, you must first add the JSP library to your project in JDeveloper. For example:

   ```
   JDev_HOME/jdeveloper/webcenter/modules/oracle.webcenter.framework_
   11.1.1/spaces-components.jar
   ```

   After adding the library to your project, you see a new component palette named `SpacesDeclarativeComponents`. You can drop components from the palette into your page template. These same built-in components are available at run time through the resource catalog, under **Template Development**.

2. In the Application Navigator, right-click the page template that you want to edit, and choose **Open**.

   - For Portal Framework applications, the recommended directory for page templates is `/oracle/webcenter/portalapp/pagetemplates`

Note: In a Portal Framework application, to expose the new page template in the **Assets** page of the runtime administration console, the page template must be stored under the `*Application_Root*/Portal/public_html/oracle/webcenter/portalapp` directory. By default, Portal Framework applications include a separate `pagetemplates` directory.

- For page templates to be used in WebCenter Portal (Portal Builder), use the `WebCenterSpacesResource` project to locate page templates for shared assets or portal assets, as described in Section 55.1, "Developing Assets for WebCenter Portal."

3. In the visual editor, make required changes to the layout and content of the page template.

   a. Drag components from the Component Palette and drop them onto the page template in the visual editor.

      Navigation visualization is a very important aspect of a page template. For information about adding navigation visualization to your page template, see Section 10.11, "Visualizing Portal Navigation."

      For information about adding other resources to your page template, such as portlets, task flows, or content, see Chapter 15, "Creating Pages and Adding Resources."

      Other features you might want to provide in your page template include a log in/log out area or a search field. The built-in page templates include an example of a login form.

      Throughout your page templates, you can use expression language (EL) expressions to specify a variable value instead of a constant value. For descriptions of common EL expressions, see Appendix G, "Expression Language Expressions."

   b. For areas on the page template where users can place their own content in pages based on the template:

      a. Drag the **FacetRef** component from the Component Palette and drop it onto the appropriate location on the page template.

      b. In the Insert Facet Ref dialog, from the **Facet Name** drop-down list, select the facet that you want to use for this area of the page template. If you enter a new facet name, JDeveloper creates a new facet definition in the page template definition file.

      Example 11–6 shows how the `content` facet is included in the `pageTemplate_globe.jspx` built-in page template.

Example 11–6 The content Facet in the Globe Built-In Page Template

```
<af:pageTemplateDef var="attrs">
  <af:panelGroupLayout id="pt_root" layout="scroll">
    <af:panelGroupLayout id="pt_pg12" layout="vertical">
      ...
      <af:facetRef facetName="content"/>
      ...
    </af:panelGroupLayout>
  </af:panelGroupLayout>
  ...
```

```
<af:pageTemplateDef>
```

c. To add new facet definitions or attributes, select the `af:pageTemplateDef` tag in the Structure window and use the Property Inspector. For examples, see the steps in Section 11.3, "Creating a Page Template."

d. For general information about JSF page templates, see the "Using Page Templates" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

4. Save the page template definition file.

11.5 Applying a Page Template to a Page

This section describes how to apply a page template to a page in a Portal Framework application.

> **Note:** If you developed a page template in JDeveloper for use in WebCenter Portal (Portal Builder), this task is performed using Portal Builder, where the page template is selected at either the application level or the portal level to define the structure and layout (header, body, navigation, and footer) of all pages in the portal. For Portal Builder, see the "Choosing a Default Page Template" section in *Administering Oracle WebCenter Portal* to configure global defaults across portals, and the "Changing the Page Template for a Portal" section in *Building Portals with Oracle WebCenter Portal* to select the default page template for the portal.

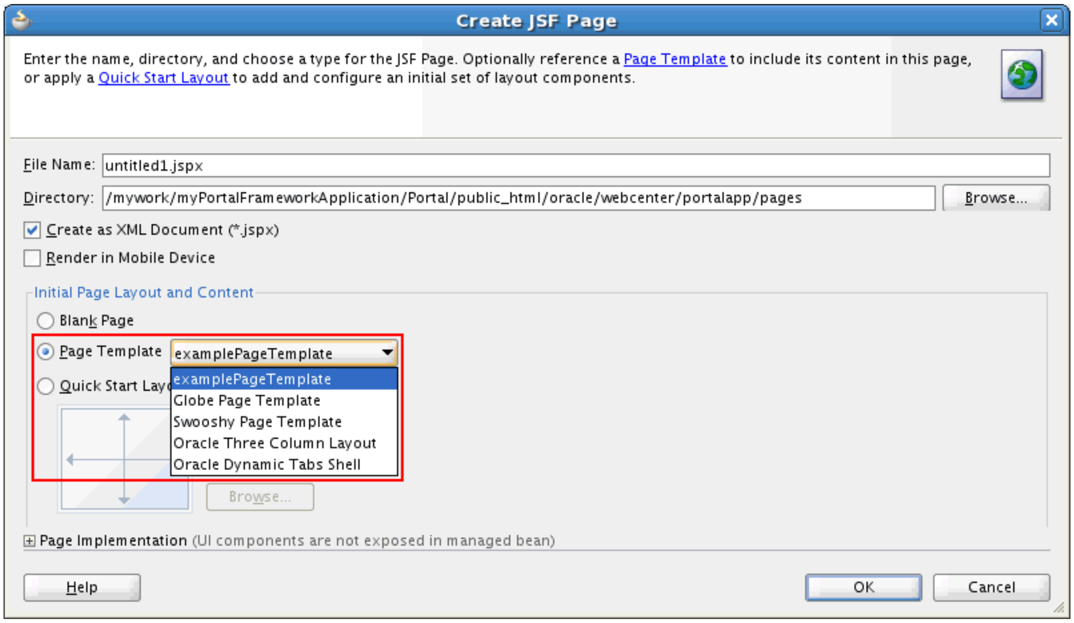
This section includes the following topics:

- Section 11.5.1, "How to Apply a Page Template During Page Creation in a WebCenter Portal Framework Application"
- Section 11.5.2, "How to Change the Page Template Applied to a Page in a WebCenter Portal Framework Application"
- Section 11.5.3, "How to Enable Dynamic Switching of Page Templates at Runtime in a WebCenter Portal Framework Application"
- Section 11.5.3.1, "What Happens at Runtime"

11.5.1 How to Apply a Page Template During Page Creation in a WebCenter Portal Framework Application

When you create a JSF page in a Portal Framework application, you can choose the page template to apply to the page in the Create JSF Page dialog, as shown in Figure 11–8.

Figure 11–8 Page Template Option in the Create JSF Page Dialog



Create JSF Page

Enter the name, directory, and choose a type for the JSF Page. Optionally reference a Page Template to include its content in this page, or apply a Quick Start Layout to add and configure an initial set of layout components.

File Name: untitled1.jspx

Directory: /mywork/myPortalFrameworkApplication/Portal/public_html/oracle/webcenter/portalapp/pages

☑ Create as XML Document (*.jspx)

□ Render in Mobile Device

Initial Page Layout and Content

○ Blank Page

● Page Template examplePageTemplate

○ Quick Start Lay

⊞ Page Implementation (UI components are not exposed in managed bean)

For more information about creating pages in Portal Framework applications, see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."

11.5.2 How to Change the Page Template Applied to a Page in a WebCenter Portal Framework Application

When you create a page, you select a specific page template to use for that page (see Section 11.5.1, "How to Apply a Page Template During Page Creation in a WebCenter Portal Framework Application"). This adds a static reference to the page template to the JSPX file for the page. Example 11–7 shows such a reference.

Example 11–7 Referencing A Page Template in a Page

```
<af:pageTemplate
    viewId="/oracle/webcenter/portalapp/pagetemplates/pageTemplate_globe.jspx"
    value="#{bindings.pageTemplateBinding}"
    id="pt1">
  <f:facet name="content"/>
</af:pageTemplate>
```

A binding of the page template is created in the page's page definition file. Example 11–8 shows such a binding.

Example 11–8 Binding a Page Template to a Page

```
<executables>
  <variableIterator id="variables"/>
  <page path="oracle.webcenter.portalapp.pagetemplates.pageTemplate_globePageDef"
        id="pageTemplateBinding" Refresh="ifNeeded"/>
</executables>
```

To apply a different page template to a page, you must change both these references.

11.5.3 How to Enable Dynamic Switching of Page Templates at Runtime in a WebCenter Portal Framework Application

You can change the references in a page's JSPX file and page definition file to use an EL expression that identifies the page template to use from the default page template setting. Users with the appropriate permissions can use the runtime administration console to switch to a different default page template.

> **Note:** You can switch between page templates at runtime only if the page template was created with an associated page definition.

To enable dynamic switching of page templates at runtime:

1. In the Application Navigator, right-click the JSPX file for the page, and choose **Open**.
2. Click the **Source** tab.
3. Replace the following code:

   ```
   <af:pageTemplate viewId="pathToPageTemplate"
                    value="#{bindings.pageTemplateBinding}"
                    id="ptId">
     <f:facet name="content"/>
   </af:pageTemplate>
   ```

   with:

   ```
   <af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}"
                    id="ptId">
     <f:facet name="content"/>
   </af:pageTemplate>
   ```

   This indicates that the page template to be used by the page is defined in the page template's page definition.
4. Right-click the JSPX file and choose **Go to Page Definition**.
5. Click the **Source** tab.
6. Replace the following code:

   ```
   <page path="pathToPageTemplatePageDef"
         id="pageTemplateBinding" Refresh="ifNeeded"/>
   ```

   with:

   ```
   <page viewId="${preferenceBean.defaultPageTemplate}"
         id="pageTemplateBinding" Refresh="ifNeeded"/>
   ```

   The `${preferenceBean.defaultPageTemplate}` EL expression retrieves the name of the page template from the default page template setting.
7. You can set the default page template, as described in Section 11.6, "Selecting the Default Page Template."

11.5.3.1 What Happens at Runtime

When users with appropriate permission select a page template in the runtime administration console, it will be used by all the pages because the expression

`#{bindings.pageTemplateBinding.templateModel}` always returns the page template set in the administration console.

> **See Also:** For information about configuring defaults for Portal Framework applications, see the "Choosing a Default Page Template" section in *Administering Oracle WebCenter Portal*.

11.6 Selecting the Default Page Template

This section describes how to set the default page template that should be used by default for all pages in a Portal Framework application.

> **Note:** If you developed a page template for use in WebCenter Portal (Portal Builder), this task is performed using Portal Builder, where the default page template is selected at either the application level or the portal level for all pages in the portal. For Portal Builder, see the "Choosing a Default Page Template" section in *Administering Oracle WebCenter Portal* to configure global defaults across portals, and the "Changing the Page Template for a Portal" section in *Building Portals with Oracle WebCenter Portal* to select the default page template for the portal.

When you first create a Portal Framework application, the `pageTemplate_globe.jspx` built-in page template is set as the application's default page template. If you subsequently create your own page template to use for the structure and layout of your application pages, you can set it as the default page template.

You can set the default page template for a Portal Framework application by editing the `oracle.webcenter.portalapp.pagetemplate.pageTemplate` preference in the `adf-config.xml` file. The preference bean `#{preferenceBean}` allows runtime access to this section in `adf-config.xml` and the configuration specified there.

To select the default page template:

1. In the Application Resources pane of the Application Navigator, right-click the **adf-config.xml** file, and choose **Open**.

   > **Tip:** To locate the `adf-config.xml` file, expand the **Descriptors** node, and then the **ADF META-INF** node.

2. Click the **Source** tab.
3. Locate the ADF preference with the following ID:

   ```
   oracle.webcenter.portalapp.pagetemplate.pageTemplate
   ```

4. Set the value attribute to the path of the page template that you want to use as the default for the application, for example:

   ```
   value="/oracle/webcenter/portalapp/pagetemplates/myPageTemplate.jspx
   ```

   Example 11–9 shows an example of the complete preference element.

Example 11–9 The Default Page Template ADF Preference

```
<preference id="oracle.webcenter.portalapp.pagetemplate.pageTemplate"
            desc="Default Page Template"
            value="/oracle/webcenter/portalapp/pagetemplates/myPageTemplate.jspx"
```

```
          resourceType="Template" display="true"/>
```

5. Save the `adf-config.xml` file.

You can now reference the default page template without having to specify its actual name. Example 11–10 shows the EL expression to include in a page's page definition file to indicate that a page should use the application's default page template, rather than an explicitly selected page template.

Example 11–10 EL Expression to Use the Application Default Page Template

```
<page viewId="${preferenceBean.defaultPageTemplate}"
      id="pageTemplateBinding" Refresh="ifNeeded"/>
```

11.7 Deleting a Page Template

This section describes how to delete a page template in a Portal Framework application.

Note: If you developed a page template for use in WebCenter Portal (Portal Builder), this task is performed using Portal Builder, where the default page template is deleted at either the application level or the portal level. For Portal Builder, see the "Deleting an Asset" section in Building Portals with Oracle WebCenter Portal.

Caution: Before you delete a page template, ensure that there are no pages that use the page template. When you delete a page template, attempting to run any page that has a direct reference to the page template will result in a runtime error.

To delete a page template in JDeveloper:

- Right-click the page template in the Application Navigator and choose **Delete** from the context menu.

For more information, see Section 9.4, "Deleting Portal Resources."

11.8 Page Templates Tutorials and Examples

The following supplementary tutorials and examples provide additional information about page templates:

- *Dissecting a Page Template*. Analyzes the details of a simple page template for an Oracle WebCenter Portal Framework application, including recommended practices.

  `http://www.oracle.com/technetwork/middleware/webcenter/portal/learnmore/dissectingapagetemplate-1926909.pdf`

- *Oracle WebCenter Portal Online Training: Creating and Using Page Templates in Oracle WebCenter Portal Applications*. Provides a recorded presentation and slides to create and use page templates for a portal in an earlier release.

  `http://www.oracle.com/technetwork/middleware/webcenter/portal/learnmore/pagetemplates-1438595.pdf`

- *Optimizing WebCenter Portal Mobile Delivery*. Identifies and analyzes some common WebCenter Portal performance bottlenecks related to page weight and describes a generic approach that can streamline a portal while improving the performance and response times. Of particular interest in the context of developing page templates is the section "Page Design and Component Choices." A sample application is available for download.

  `http://www.ateam-oracle.com/webcenter-mobile-delivery/`

- *Working with Links in WebCenter Application*. Describes considerations for using links. Pertinent to page templates are links in menus, breadcrumbs, buttons, and images.

  `http://www.ateam-oracle.com/working-with-links-in-webcenter-application/`

12

Developing Page Styles and Task Flow Styles

This chapter describes how to use Oracle JDeveloper to create and manage page styles and task flow styles for your WebCenter Portal Framework applications.

This chapter includes the following topics:

- Section 12.1, "Introduction to Styles"
- Section 12.2, "Developing Page Styles"
- Section 12.3, "Developing Task Flow Styles"

12.1 Introduction to Styles

Oracle WebCenter Portal provides several different styles to determine the layout of content within a portal:

- **Page styles** determine the layout of content in a new page that is created at runtime. For more information, see Section 12.1.1, "Introduction to Page Styles."
- **Task flow styles** determine the layout of content in a task flow that is created at runtime. Task flow styles can also include objects that can be bound to any data visualization that is added to the task flow. For more information, see Section 12.1.2, "Introduction to Task Flow Styles."
- **Content Presenter display templates** define the layout of Content Presenter content items on a page. These templates are not discussed in this chapter. For more information, see Chapter 27, "Creating Content Presenter Display Templates."

Runtime Management

Portal Framework applications support the runtime administration of styles to help users continue developing a portal even after it has been deployed. With runtime administration, authorized users can manage styles in a browser-based environment, with no requirement to install or understand JDeveloper. For more information, see Section 9.5, "Working with Portal Resources at Runtime."

Round-Trip Development

You can bring runtime-created or modified styles back into JDeveloper, to ensure that any changes are not lost when the portal is redeployed. You can also edit these styles to further enhance them if necessary, and upload them back into the deployed portal. For more information, see Section 9.6, "Working with Round-Trip Development."

Note: You cannot create Content Presenter display templates at runtime. You can create page and task flow styles at runtime only by making a copy of an existing style.

This section includes the following topics:

- Section 12.1.1, "Introduction to Page Styles"
- Section 12.1.2, "Introduction to Task Flow Styles"

12.1.1 Introduction to Page Styles

A page style is a JSPX page used for pages created at runtime. It describes the layout of a newly created page and may also dictate the type of content that the page supports.

When a user creates a page using a page style, the layout and initial content are copied from the page style to the newly created page. Unlike page templates, page styles are not reference-based, that is, if you change a page style, the change is not inherited in pages that use the style.

Typically, a page style contains components that enhance the usefulness and appearance of a given page. These include an in-place HTML text editor, images, layout boxes, hyperlinks, and so on. Content contributors can further populate the page with content. Figure 12–1 shows a sample portal page that is based on a page style.

Figure 12–1 Sample Page that Uses a Page Style

DEFINED BY THE PAGE STYLE

You create page styles in JDeveloper, but they are only used at runtime to create pages.

A user can create pages at runtime based on the available page styles. The **Create Page** option is available in the Assets page of the runtime administration console. It is also available in other application pages that contain the `Page - Create New` task flow. When a user clicks **Create Page**, the Create Page dialog displays a set of predefined styles, as shown in Figure 12–2. The user can choose a style and create a page based on that. As the layout is already in place in the new page, the user only needs to add content to different areas of the page.

Figure 12–2 Create Page Dialog

○ Text Page ○ Three Column ○ Web Page

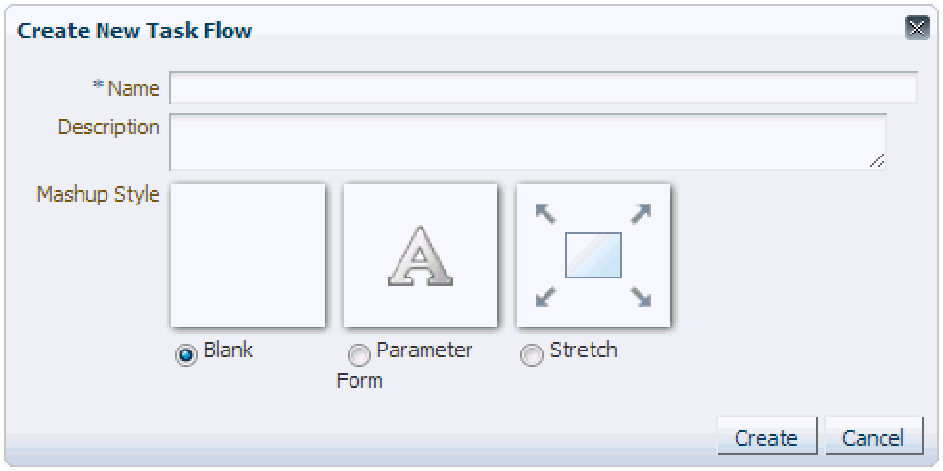
12.1.2 Introduction to Task Flow Styles

Task flow styles are very similar to page styles, except that they are used at runtime to create task flows rather than pages. Task flow styles are especially useful when creating task flows for use with Data Presenter, as they can include objects that can then be bound to any data visualization that is added to the task flow.

Task flow styles are used only when creating task flows at runtime, but they are created and published in JDeveloper.

Task flow styles are displayed in the Create New Task Flow dialog box (Figure 12–3). Users can choose a style and create a task flow based on that style. For more information, see the "Working with Task Flows" section in *Building Portals with Oracle WebCenter Portal*.

Figure 12–3 Create New Task Flow Dialog



Create New Task Flow

● Blank ○ Parameter Form ○ Stretch

12.2 Developing Page Styles

Page styles are JSPX pages that can be used as templates to create new pages at runtime.

When users create a new page at runtime, the Create Page dialog, shown in Figure 12–2, displays the available page styles.

This section includes the following topics:

- Section 12.2.1, "How to Create a Page Style"
- Section 12.2.2, "What You May Need to Know About Developing Page Styles"
- Section 12.2.3, "How to Delete a Page Style"

Note: You can develop page styles in JDeveloper for use in WebCenter Portal. For more information, see Section 9.7, "Working with WebCenter Portal Resources."

12.2.1 How to Create a Page Style

The recommended method for creating page styles is to download one of the existing page styles and import it into JDeveloper. You can then use this page style as the starting point for your new page style and then export it for uploading back into your application.

Creating a page style this way also ensures that it is available in the Create Page dialog.

To create a page style:

1. In the deployed application, download one of the existing page styles. For more information, see the "Downloading an Asset" section in *Building Portals with Oracle WebCenter Portal*.
2. Import the downloaded page style into JDeveloper. For more information, see Section 9.6.2, "How to Import a Portal Resource into JDeveloper."
3. In the Application Navigator, right-click the imported page style, and choose **Open**.

4. In the visual editor, make any changes to the layout of content of the page style, in the same way as you would edit any page.

   For information about how to define the content of the page style, see Section 17.6.1, "How to Create Templates for Pages Created at Runtime" and Section 12.2.2, "What You May Need to Know About Developing Page Styles."

   Example 12–1 shows the code for a sample page style, /oracle/webcenter/portalapp/pages/pageStyles/TemplateFlowingTwoColumn.jspx, which creates a basic page designed to flow and provide two columns that are 35 percent and 65 percent in proportion. Example 12–2 shows the associated page definition file, /oracle/webcenter/portalapp/pages/pageStyles/TemplateFlowingTwoColumnPageDef.jspx.

Example 12–1 Source Code of a Custom Page Style

```
<?xml version='1.0' encoding='utf-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"
xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"
xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"
xmlns:f="http://java.sun.com/jsf/core"
xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
xmlns:trh="http://myfaces.apache.org/trinidad/html" version="2.1">
  <jsp:directive.page deferredSyntaxAllowedAsLiteral="true"/>
  <jsp:directive.page contentType="text/html;charset=utf-8"/>
  <f:view>
    <af:document title="#{pageDocBean.title}" id="docrt">
      <af:form usesUpload="true" id="f1">
        <af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}"
        id="T">
          <f:facet name="content">
            <pe:pageCustomizable id="pcl1">
              <af:panelGroupLayout id="pgl1" layout="scroll"
              styleClass="replace_with_scheme_name"
              inlineStyle="replace_with_inline_style">
                <trh:tableLayout id="tl1" width="100%">
                  <trh:rowLayout id="rl1">
                    <trh:cellFormat id="cf1" width="35%" valign="top">
                      <cust:panelCustomizable id="hm_pnc1" layout="scroll"/>
                    </trh:cellFormat>
                    <trh:cellFormat id="cf2" width="65%" valign="top">
                      <cust:panelCustomizable id="hm_pnc2" layout="scroll"/>
                    </trh:cellFormat>
                  </trh:rowLayout>
                </trh:tableLayout>
                <trh:tableLayout id="tl2"/>
              </af:panelGroupLayout>
              <f:facet name="editor">
                <pe:pageEditorPanel id="pep1"/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:pageTemplate>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

Example 12–2 Page Definition of the Custom Page Style

```
<pageDefinition version="11.1.1.41.30" id="TemplateFlowingTwoColumnPageDef"
  Package="oracle.webcenter.siteresources.scopedMD.s8bba98ff_4cbb_40b8_beee_
296c916a23ed.pageStyle.gsr2b052c53_0eba_43fd_81e2_7f12dbb885a5">
  <parameters/>
  <executables>
    <page viewId="#{preferenceBean.defaultPageTemplate}"
          id="pageTemplateBinding" Refresh="ifNeeded"/>
    <taskFlow id="pageeditorpanel"
taskFlowId="#{pageEditorBean.pageEditorPanel}"/>
  </executables>
</pageDefinition>
```

5. Save your changes.
6. Export the page style. For more information, see Section 9.6.3, "How to Export a Portal Resource from JDeveloper."
7. Upload the exported page style into the deployed application. For more information, see the "Uploading an Asset" section in *Building Portals with Oracle WebCenter Portal*.

12.2.2 What You May Need to Know About Developing Page Styles

There are a few prerequisites for developing page styles to be exposed as portal resources.

- If a page style is based on a page template, then while designing the page style JSPX file, add the `content` facet, or any other facet defined in the page template, to contain page content.
- To make the page customizable, add a `Page Customizable` component within the content facet. As the `Page Customizable` contains a child `Panel Customizable` component by default, users can add content to the page at runtime.
- To enable dynamic selection of the page template to use for the page style, in the page style JSPX file, specify that the page template is defined in the page style's page definition, as follows:

  ```
  <af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}" id="T">
  ```

  You can then specify an EL value in the page style page definition to retrieve the name of the page template from the default page template setting, as follows:

  ```
  <page viewId="#{preferenceBean.defaultPageTemplateViewId}"
        id="pageTemplateBinding" Refresh="ifNeeded"/>
  ```

  At runtime, users with the appropriate permissions can switch to a different page template by selecting a new default page template in the runtime administration console. For more information, see the "Choosing a Default Page Template" section in *Administering Oracle WebCenter Portal*.
- You can create a managed bean that controls which page template to use, as shown in the following example:

  ```
  public class siteTemplatesManager {
      final private String templateA = "/templateA.jspx";
      final private String templateB = "/templateB.jspx";
      private String currentSiteTemplateViewId;

      public siteTemplatesManager() {
  ```

```
            super();
            currentSiteTemplateViewId = templateA;
        }
        public String gettemplateViewId() {
            return currentSiteTemplateViewId;
        }
        public void settemplateAViewId(ActionEvent ae) {
            currentSiteTemplateViewId = templateA;
        }
        public void settemplateBViewId(ActionEvent ae) {
            currentSiteTemplateViewId = templateB;
        }
    }
```

12.2.3 How to Delete a Page Style

If a page style is no longer required within your application, you can delete it.

When you delete a page style, it is no longer listed in the Create Page dialog. Deleting a page style has no impact on pages that have already been created using the page style.

To delete a page style, right-click the page style in the Application Navigator and choose **Delete** from the context menu. For more information, see Section 9.4, "Deleting Portal Resources."

12.3 Developing Task Flow Styles

Task flow styles are ADF task flows that can be used as templates to create new task flows at runtime.

You may choose to create task flow styles for the following purposes:

- To provide a specific, consistent layout for task flows.
- To seed a UI picker that can in turn be used in the task flows created from the task flow style, for example, a task flow style with a portal picker drop down. When a task flow based on this style is populated with an Activity Stream task flow, the picker drop down can be wired to an input parameter on the Activity Stream task flow. The Activity Stream task flow then displays activities specific to the selected portal.
- To provide a predefined UI that can be bound separately to data, for example, you can create a flowing data layout in the task flow style, create a task flow from it, drop a data control, then bind the flowing data layout to the data control.

When users create a new task flow at runtime, the Create New Task Flow dialog, shown in Figure 12–3, displays the available task flow styles.

This section includes the following topics:

- Section 12.3.1, "How to Create a Task Flow Style"
- Section 12.3.2, "What You May Need to Know About Developing Task Flow Styles"
- Section 12.3.3, "How to Delete a Task Flow Style"

Note: You can develop task flow styles in JDeveloper for use in WebCenter Portal. For more information, see Section 9.7, "Working with WebCenter Portal Resources."

12.3.1 How to Create a Task Flow Style

Creating a task flow style is the same as creating a task flow, but you create task flow styles only so that they can be used as templates to create task flows at runtime.

The recommended method for creating task flow styles is to download one of the existing task flow styles and import it into JDeveloper. You can then use this task flow style as the starting point for your new task flow style and then export it for uploading back into your application.

Creating a task flow style this way also ensures that it is available in the Create New Task Flow dialog.

To create a task flow style:

1. In the deployed application, download one of the existing task flow styles. For more information, see the "Downloading an Asset" section in *Building Portals with Oracle WebCenter Portal*.
2. Import the downloaded task flow style into JDeveloper. For more information, see Section 9.6.2, "How to Import a Portal Resource into JDeveloper."
3. In the Application Navigator, right-click the imported task flow style, and choose **Open**.
4. Make any changes to the code of the task flow style.
5. Save your changes.
6. Export the task flow style. For more information, see Section 9.6.3, "How to Export a Portal Resource from JDeveloper."
7. Upload the exported task flow style into the deployed application. For more information, see the "Uploading an Asset" section in *Building Portals with Oracle WebCenter Portal*.

12.3.2 What You May Need to Know About Developing Task Flow Styles

To expose a task flow style for use when creating task flows at runtime, you must consider the following requirements:

- Create *only one* view fragment for a task flow that will be used as a task flow style. The view fragment JSFF file must be created in the same location as the task flow definition XML file.
- Add a `Panel Customizable` component to the view fragment from the Composer tag library. This ensures that task flows based on this task flow style can be populated at runtime.
- Create a page definition for the view fragment, by right-clicking the JSFF file and choosing **Go to Page Definition**. The page definition for the view fragment must also be located in the same directory as the task flow definition XML file.
- If the task flow style refers to code, for example, using an EL value, then that code must be present in the deployed application.

12.3.3 How to Delete a Task Flow Style

If a task flow style is no longer required within your application, you can delete it.

When you delete a task flow style, it is no longer listed in the Create New Task Flow dialog at runtime. Deleting a task flow style has no impact on task flows that have already been created using the task flow style.

To delete a task flow style, right-click the task flow style in the Application Navigator and choose Delete from the context menu. For more information, see Section 9.4, "Deleting Portal Resources."

13 Developing Skins

This chapter describes how to use Oracle JDeveloper to create and manage skins for your WebCenter Portal Framework applications.

This chapter includes the following topics:

13.1 Introduction to Developing Skins

Skins help you define the colors, fonts, images, and some dimensional details like the height and width of your application components to represent your company's preferred look and feel.

Skins are based on the Cascading Style Sheet (CSS) specification. A skin is a CSS file containing various skin selectors that define the styles of your application components. You can adjust the look and feel of any component by changing its style-related properties. Use of a skin in an application helps you to avoid specifying styles for each component individually or inserting a style sheet on each page. Every component automatically uses the styles defined in the skin. Skins help you to change an application's appearance without changing the portal pages themselves.

ADF Faces skins drive the look and feel of Portal Framework applications. For more information about ADF Faces skins, see the "ADF Faces Skins" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

Seeded Skin

When you create a Portal Framework application, a seeded skin, `portal-skin.css`, is added to your application.

You can edit this seeded skin to meet your particular requirements, or you can create your own. If you choose to create your own skin, the seeded skin is still a useful tool for you to discover the different things you can achieve in your own skin.

Runtime Management

Portal Framework applications support the runtime administration of skins to help users continue developing a portal even after it has been deployed. With runtime administration, authorized users can manage an application's skins, and create new ones, in a browser-based environment, with no requirement to install or understand JDeveloper. For more information, see Section 9.5, "Working with Portal Resources at Runtime."

Round-Trip Development

You can bring skins that have been created or modified at runtime back into JDeveloper, to ensure that any changes are not lost if the portal is redeployed. You can also edit these skins to further enhance them if necessary, and upload them back into the deployed portal. For more information, see Section 9.6, "Working with Round-Trip Development."

13.2 Best Practices for Developing Skins

When skinning WebCenter Portal, you can look at it from coarse-grain and fine-grain standpoint. At the coarse-grain level many large elements on the page, such as the background and the center of the page, can use very basic styling techniques to impart a look and feel to particular corporate brand with very little effort. At the fine-grain level you can apply the styling to specific components and controls within the page. The most efficient way to develop your skin is to start by defining the coarse-grain elements and then use fine-grain styling to tune your overall look and feel to be inline with your corporate brand.

In many cases a hybrid model of styling works very well. Taking the coarse-grained elements (page background, main portion of the body, and so on) and using traditional CSS approaches with those, but then getting specific using the ADF skinning, will work together to generate the overall appearance for WebCenter Portal.

An example of a hybrid approach would be using technology in WebCenter Portal to generate a menu that uses unordered lists and list items, then applying traditional CSS to them. Even though you are benefiting from WebCenter Portal's navigation models, you are not doing traditional ADF skinning – but instead using standard CSS.

Expression Language (EL) allows you to access the various objects for navigation within your template design. Looping in EL is simple and coding is done inline with the page template. You can mix regular HTML directly into the looping markup.

13.2.1 Externalizing Static Assets

When using coarse-grained techniques in addition to ADF styling, it is often helpful to hold various styling assets outside of WebCenter Portal. To do this you can use WebCenter Content to manage all of the unstructured assets for WebCenter Portal. They can include things like CSS and images that you want manage within your environment and provides revision control and workflow. This is a best practice if you want to allow design teams to access and work with WebCenter Portal without involving the development team for each and every change

13.3 Creating a Skin

By default, Portal Framework applications use the `portal` skin, which is defined in the `portal-skin.css` file. You can easily edit this file to suit your requirements. However, if you want to use a custom skin in your application, you must create a CSS file and define the required skin selectors.

This section includes the following topics:

- Section 13.3.1, "How to Create a CSS File"
- Section 13.3.2, "How to Define Skin Style Selectors"
- Section 13.3.3, "What You May Need to Know About Skin-Related Artifacts"

13.3.1 How to Create a CSS File

For information about creating an ADF Faces skin, see the "How to Add a Custom Skin to an Application" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

> **Note:** When you create a CSS file, by default, JDeveloper places it under the `*Application_Root*/Portal/public_html/css` folder.
>
> However, skins created at this default location are not included on the Assets page of the runtime administration console, and thus cannot be managed at runtime.
>
> To enable authorized users to manage a skin at runtime, you must create it in the following directory:
>
> `*Application_Root*/Portal/public_html/oracle/webcenter/portalapp`
>
> By default, Portal Framework applications include a separate `skins` directory.
>
> For more information, see Section 9.5.1.2, "How to Include a Portal Resource on the Assets Page."

13.3.2 How to Define Skin Style Selectors

After creating the CSS file, you must define the required ADF Faces skin selectors for the components in your application. For example, you can use the `.AFDefaultFontFamily:alias` selector to specify the font family for your application as follows:

```
.AFDefaultFontFamily:alias {
font-family: Tahoma, Verdana, Helvetica, sans-serif;
}
```

For information about:

- ADF Faces skin selectors in general, refer to the "Skin Style Selectors" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*. Also refer to Oracle JDeveloper's online help for information about the selectors that you can use in a skin. These are documented in the "Skin Selectors for Fusion's ADF Faces Components" and "Skin Selectors for Fusion's Data Visualization Tools Components" topics in JDeveloper's online help.
- Defining ADF Faces component style selectors, see the "Defining Skin Style Properties" and "Changing the Style Properties of a Component" sections in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

13.3.3 What You May Need to Know About Skin-Related Artifacts

Oracle recommends that you store asset-related artifacts, such as images and icons, on your content server and that you create a folder structure on your content server specifically for asset artifacts so that content is easy to identify and move, if required.

13.4 Editing a Skin

You can make changes to your skin after its initial creation by editing the CSS file to edit or add style selectors. You can also edit the seeded `portal` skin by editing the `portal-skin.css` file.

To edit a skin:

1. In the Application Navigator, right-click the skin that you want to edit, for example **portal-skin.css**, and choose **Open**.
2. In the source code for the skin, define the required ADF Faces skin selectors for the components in your application. For example, to set a font size of `16px` for your application content, you can use the `.AFDefaultFont:alias` skin selector as follows:

   For more information, see Section 13.3.2, "How to Define Skin Style Selectors."
3. Save the CSS file.

13.5 Applying a Skin to Your Application

Every Portal Framework application defines a default skin that determines the appearance of all the pages within the application.

When you first create a Portal Framework application, the seeded skin, portal, is set as the application's default skin. If you subsequently create your own skin, you can set it as the default instead.

You can set the default skin for a Portal Framework application by editing the `oracle.webcenter.portalapp.skin` preference in the `adf-config.xml` file.

> **Note:** If runtime administration is enabled, authorized users can change the skin at runtime. For information, see the "Changing the Skin for a Portal" section in *Building Portals with Oracle WebCenter Portal*.

To apply a skin to your application:

1. In the Application Resources pane of the Application Navigator, right-click the **adf-config.xml** file, and choose **Open**.

   > **Tip:** To locate the `adf-config.xml` file, expand the **Descriptors** node, and then the **ADF META-INF** node.
2. Click the **Source** tab.
3. Locate the ADF preference with the following ID:

   ```
   oracle.webcenter.portalapp.skin
   ```
4. Set the value attribute to the family name of the skin that you want to apply to your application, for example:

   ```
   value="portal"
   ```

   This value must be same as the value specified for the `Skin Family` attribute in the Create Portal Resource or Update Portal Resource dialog of the skin.

5. Optionally, in the `desc` property, specify a description of the skin you want to apply. At runtime, this value shows up as the display name of the skin.
6. The `display` property specifies whether the skin is listed in the skin picker at runtime. Example 13–1 shows an example of the complete preference element.

Example 13–1 The Default Skin ADF Preference

```
<portal:preference id="oracle.webcenter.portalapp.skin"
                   desc="Default Portal Skin" value="portal"
                   resourceType="Skin" display="true"/>
```

7. Save the `adf-config.xml` file.

> **Note:** If you want to apply a skin created at a location other than `*Application_Root*/Portal/public_html/oracle/webcenter/portalapp/skins`, you must register the skin in the `trinidad-skins.xml` file and configure your application to use the skin. For information, see the "How to Register a Custom Skin" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

13.6 Conditionally Changing Skins for Users

You can assign different skins per user, page, application, and so on, without impacting the actual application logic. To conditionally set a skin, you use the `<skin-family>` entry in the `trinidad-config.xml` file.

You can use EL expressions that can be evaluated dynamically to determine the skin to display. For example, if you want to use the German skin when the user's browser is set to the German locale, and to use the English skin otherwise, use the following `<skin-family>` entry in the `trinidad-config.xml` file:

```
<skin-family>#{facesContext.viewRoot.locale.language=='de' ? 'german' :
'english'}</skin-family>
```

For more information, see the "How to Configure a Component for Changing Skins Dynamically" section in the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

> **Note:** The default value of `<skin-family>` is `#{preferenceBean.defaultTrinidadSkin}`. If you change the default value, your application users cannot set skins at runtime in the Resource Manager.

You can also use the `SkinSetting` API to set the skin for a user conditionally. Refer to the API for information about the calls you can use. The API is available here:

`http://download.oracle.com/docs/cd/E15523_01/apirefs.1111/e15995/oracle/webcenter/generalsettings/model/SkinSetting.html`

13.7 Deploying a Skin as a Separate Shared Library

Oracle WebCenter Portal provides various default skins. All Oracle WebCenter Portal skin artifacts are available in the shared library, `oracle.webcenter.skin`. The shared library is packaged as an EAR, and includes several skin JARs that contain the following types of files:

- .css file, the skin selector file
- .png, the image files
- .js, the javascript file
- trinidad-skins.xml, the skin definition file

By default, the oracle.webcenter.skin shared library is referenced by all Portal Framework applications and Portlet Producer applications. Therefore, all skins are available through the classpath. When you use a portlet in your Portal Framework application, the portlet is rendered using the skin defined for your application. Therefore, to achieve skin sharing, the same skin must be accessible through the shared library, to both the Portal Framework application and the Portlet Producer application.

However, there may be a case where you modified portal-skin.css in your Portal Framework application. So, the skin available in the shared library is not the same as the updated version available in the Portal Framework application. If the skin's version in the Portal Framework application is not identical to the skin in the shared library, skin sharing between Portal Framework application and Portlet Producer application will fail because the portlet producer can access only the original version of the skin packaged in the shared library, while the Portal Framework application uses the modified skin. The Portal Framework application renders with the latest skin changes, while the portlet within the same application renders with the original skin from the shared library. This behavior is called skin coordination.

Instead of using the default skin, you may create a new custom skin in your Portal Framework application, either as a portal resource or define it in the trinidad-skins.xml with a unique skin family ID. If your application uses a portlet, the portlet producer will not be able to find the custom skin in the shared library. This causes a skin mismatch problem, and the portlet is rendered with a bare bone, simple skin rather than the custom skin used by the Portal Framework application.

Therefore, whenever you modify a skin or create a custom skin for your Portal Framework applications, you must deploy the new or modified skin as a shared library.

To deploy a skin as a shared library:

1. Ensure that a copy of trinidad-skins.xml is available in the WEB-INF folder of your Portal Framework application. If not, create a new one.
2. Update trinidad-skins.xml to point to the newly created skin CSS file.
3. Create a new MANIFEST.MF file in the project and provide the details for the new shared library.

   The following is a sample code in a MANIFEST.MF file:

```
Manifest-Version: 1.0
 Ant-Version: Apache Ant 1.7.1
 Created-By: 1.6.0 (Sun Microsystems, Inc.)
 Extension-Name: oracle.webcenter.customskin
 Implementation-Title: oracle.webcenter.customskin
 Implementation-Version: 11.1.1
 Implementation-Vendor: Oracle
 Specification-Title: Custom WebCenter shared library
 Specification-Version: 11.1.1
```

4. Create a new deployment profile:
    a. Right-click the **Portal** project, then choose **New**.
    b. In the New Gallery dialog, choose **General** > **Deployment Profile** > **Shared Library JAR File**, and click **OK**.
    c. In the Create Deployment Profile dialog, in the **Deployment Profile Name** field, enter the profile name and click **OK**.
    d. In the Edit JAR Deployment Profile Properties dialog, ensure that **Include Manifest File** check box is selected.
    e. In the **Additional Manifest Files to Merge into MANIFEST.MF** section, use the **Add** button to add `trinidad-skins.xml` and the desired skin CSS file in the shared library.
    f. Click **OK**.
    g. In the Project Properties dialog, click **OK**.
5. Right-click the **Portal** project, choose **Deploy**, then select the JAR shared library deployment profile name.
6. In the Deploy dialog, select **Deploy to a Weblogic Application Server**, and click **Next**.
7. Select the WebLogic Server that hosts your portlet producer, and click **Next**.
8. Ensure that **Deploy as a Shared Library** is selected, then click **Finish**.
9. Update `/META-INF/weblogic-application.xml` for both the Portal Framework application and the Portlet Producer application to reference the custom skin shared library.

```
 <library-ref>
    <library-name>Custom_Library_Name</library-name>
    <specification-version>Library_Version</specification-version>
  </library-ref>
```

10. Redeploy both the Portal Framework application and the Portlet Producer application.

    The custom skin can now be shared between these applications.

Note: The custom skin shared library must be deployed, and must appear as "Active" on the WebLogic Server console before true skin sharing can be achieved. If there is any issue with the shared library JAR (like incorrect manifest or incorrect version), the deployed shared library will not show up in the WebLogic Server console as "Active".

Note: If you have multiple skin files, you can put all skin artifacts into one shared library JAR, and merge the two `trinidad-skins.xml` files into a single file. You can keep using this shared library for all your custom skins development.

13.8 Troubleshooting Problems with Skins

This section provides information to assist you in troubleshooting problems you may encounter while using skins.

Problem

Your application does not reflect skin changes made at design time.

Solution

During development, after you make changes to a skin, you can see your CSS changes without restarting the server. The CHECK_FILE_MODIFICATION context parameter requires the server to check the timestamp on a skin and reload it if the skin has changed. This setting is automatically set to true if iterative development is enabled for your application. If iterative development is not enabled, ensure that CHECK_FILE_MODIFICATION is set to true in WEB-INF/web.xml, as shown in the following example:

```
<context-param>
<param-name>org.apache.myfaces.trinidad.CHECK_FILE_MODIFICATION</param-name>
<param-value>true</param-value>
</context-param>
```

Problem

Skin selectors appear encoded and compressed when you open a skin's CSS file in a browser.

Solution

By default, class names in a CSS file are compressed to reduce the overall size of the file. So, the skin selectors you see, for example in the Firebug extension of Firefox, are encoded values bearing little relationship to the original names. For example, a CSS file may contain an entry that looks like:

```
 .x123 {color: #534741}
```

It is easier to examine a CSS file when the compression is turned off. You can disable compression by setting the value of DISABLE_CONTENT_COMPRESSION context parameter to true in WEB-INF/web.xml, as shown in the following code:

```
<context-param>
<param-name>org.apache.myfaces.trinidad.DISABLE_CONTENT_COMPRESSION</param-name>
<param-value>true</param-value>
</context-param>
```

With the compression turned off, the entry may look like:

```
.af_panelFormLayout_label-cell
{
color: #534741
}
```

For better performance, it is recommended that you turn on CSS compression in a production environment. If you turn off CSS compression, it may lead to skin mismatching, as described in the next problem scenario.

Problem

When you run a page containing a portlet, the portlet is rendered without any styles or formatting.

Solution

When your application consumes a portlet based on an ADF application, the portlet producer tries to match the skin of your application. If the skins match, the producer uses your application's skin.

Skin compression is not taken into account during skin matching. If the skin compression settings differ but the skins match, the producer returns IDs like ".x123" and expects to find these values in your application; whereas your application may return values like ".af_panelFormLayout_label-cell". Therefore, no styles are found and the portlet rendering fails.

Your application and portlet producers must use the same skin compression settings. If your application uses an uncompressed skin, your portlet producer also must use an uncompressed skin.

Problem

Style sheet files (CSS) within the MDS folder structure (`oracle/webcenter/portalapp`) do not take effect as specified in `trinidad-skins.xml`.

Solution

For style sheet files (CSS) within the MDS folder structure, prefix "`mds:`" to the path in `trinidad-skins.xml`, as shown in the following example:

```
<skin>
   <id>myskin2.desktop</id>
   <family>myskin2</family>
   <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
 <style-sheet-name>mds:/oracle/webcenter/portalapp/css/skin.css</style-sheet-name>
   <extends>fusion.desktop</extends>
</skin>
```

Problem

The weblogic log output includes the following message:

```
<SkinFactoryImpl> <getSkin> Cannot find a skin that matches family portal and
version 1.1. We will use the skin portal.desktop
```

Solution

Edit your application's `trinidad-config.xml` file and remove the `<skin-version>` element.

```
<?xml version="1.0" encoding="UTF-8"?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">
  <skin-family>#{preferenceBean.defaultTrinidadSkin}</skin-family>
  <skin-version)v1.1</skin-version>
</trinidad-config>
```

14

Developing Resource Catalogs

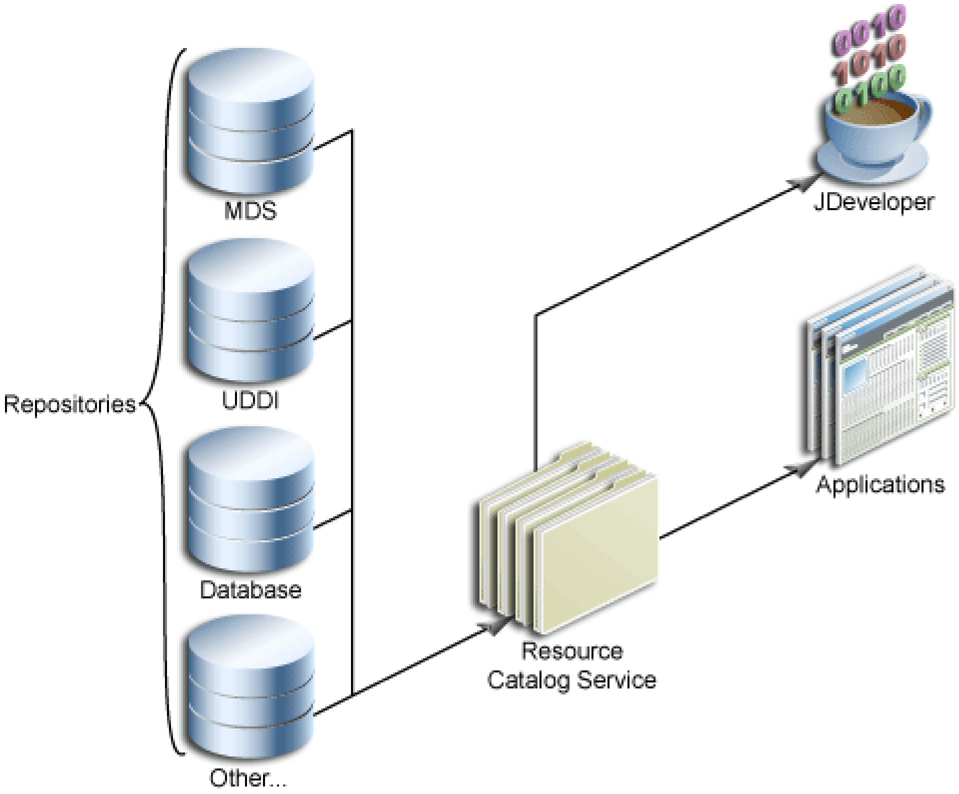
This chapter describes how to use Oracle JDeveloper to create and manage resource catalogs for your WebCenter Portal Framework applications.

This chapter includes the following topics:

14.1 Introduction to Resource Catalogs

Resource catalogs provide a consolidated view of the contents of one or more otherwise unrelated repositories in a unified search and browse user interface. They provide a mechanism for defining and organizing all the resources available for inclusion in a page, page template, or task flow. Resources originate in their source repository and are then exposed through the resource catalog as shown in Figure 14–1.

Figure 14–1 Resource Catalog Overview



When using JDeveloper, you see two types of resource catalogs—design time resource catalogs and runtime resource catalogs.

Design time resource catalogs are available in the Resource Palette and are like favorites lists for developers. The WebCenter Portal - Services Catalog is a design time catalog that is available out-of-the-box when you install the WebCenter Portal extension bundle. You can add task flows and data controls from this catalog to a Portal Framework application. In addition to the WebCenter Portal - Services Catalog, you can define connections and create catalogs to organize resources exposed by those connections. Such resources can be re-used in any application that you are developing.

See Also:

- Section 2.2.2, "Installing the WebCenter Portal Extension for JDeveloper"
- Oracle JDeveloper online Help for more information about the Resource Palette and catalogs.

  To locate this information in JDeveloper, from the **Help** menu, select **Table of Contents**. In Help Center, expand **JDeveloper Basics** and select **Working with the Resource Palette**.

In WebCenter Portal and deployed Portal Framework applications, runtime resource catalogs determine the resources available when using Composer to populate pages, task flows, and page templates.

See Also:

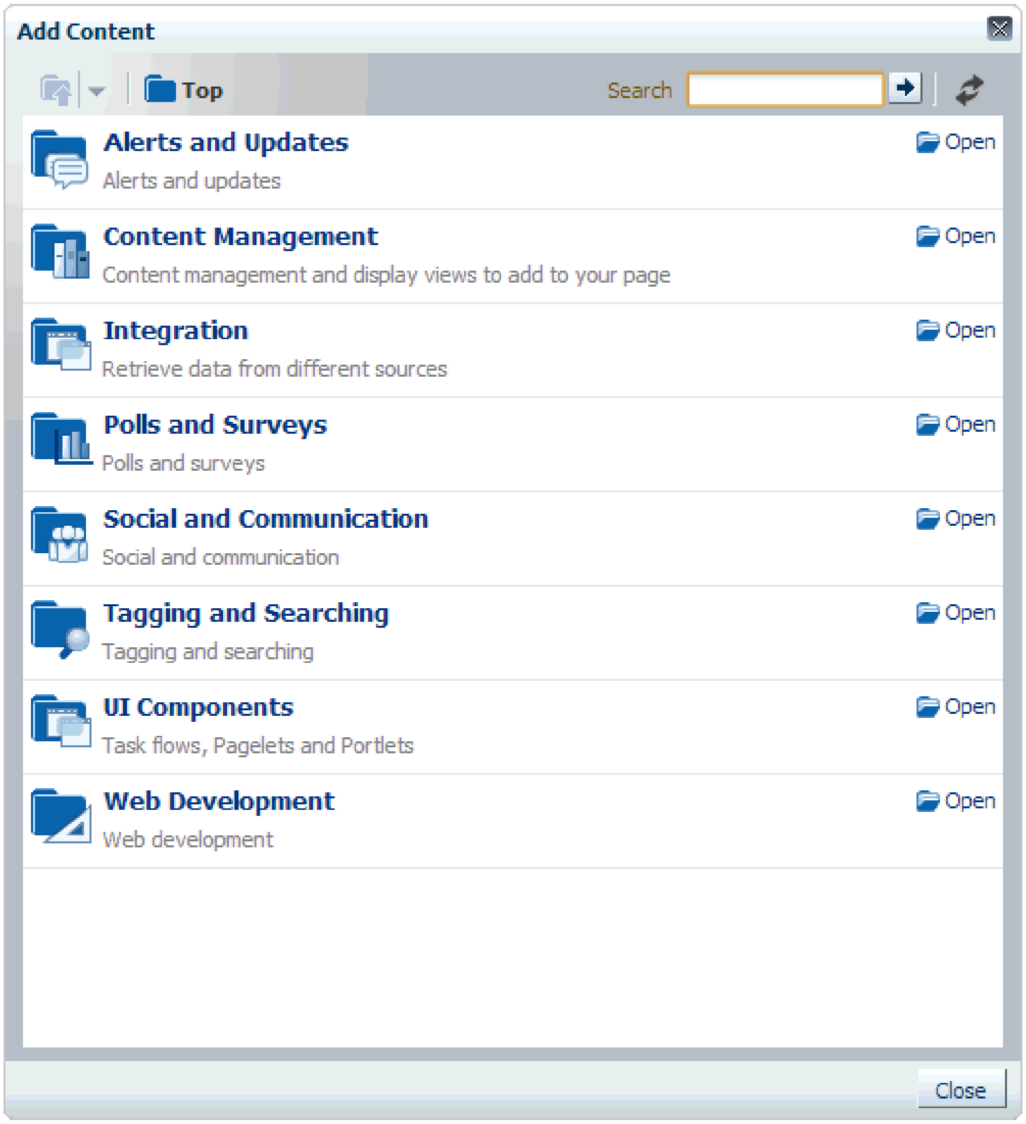
- Section 18.1, "Designing Editable Pages Using Composer Components"
- Chapter 11, "Developing Page Templates"

Seeded Resource Catalog Configuration

When you add a `Page Customizable` component to a page in your application, a seeded resource catalog with the catalog definition file, `default-catalog.xml`, is configured in the application. Depending on the type of application you created, the catalog definition file is created in one of the following folders:

- In a Portal Framework application, the `default-catalog.xml` file is located in the *`Application_Root`*`/Portal/public_html/oracle/webcenter/portalapp/catalogs` directory. The resource catalog in this case contains the folders shown in Figure 14–2.

Figure 14–2 Default Resource Catalog



Alerts and Updates — Open
Alerts and updates

Content Management — Open
Content management and display views to add to your page

Integration — Open

Tagging and Searching — Open
Tagging and searching

UI Components — Open
Task flows, Pagelets and Portlets

Web Development — Open
Web development

- In a non-Portal Framework application, the `default-catalog.xml` file is located in the *`APPLICATION_ROOT`*`/Portal/src/portal` directory. The resource catalog in this case contains the **ADF Faces Components** folder, which contains ADF Faces components that a user can add to the page.

If you have registered a portlet producer with your application, then that producer's portlets are displayed in a Portlets folder in the resource catalog. If you have not registered any producers, the Portlets folder is hidden.

You can create your own resource catalogs or modify the seeded catalog and include components relevant to your business.

Runtime Management

Portal Framework applications support the runtime administration of resource catalogs to help users continue developing a portal even after it has been deployed. With runtime administration, authorized users can create and manage resource catalogs in a browser-based environment, with no requirement to install or understand JDeveloper. For more information, see Section 9.5, "Working with Portal Resources at Runtime."

Round-Trip Development

You can bring runtime-created or modified resource catalogs back into JDeveloper, to ensure that any changes are not lost when the portal is redeployed. You can also edit these resource catalogs to further enhance them if necessary, and upload them back into the deployed portal. For more information, see Section 9.6, "Working with Round-Trip Development."

14.2 Creating a Resource Catalog

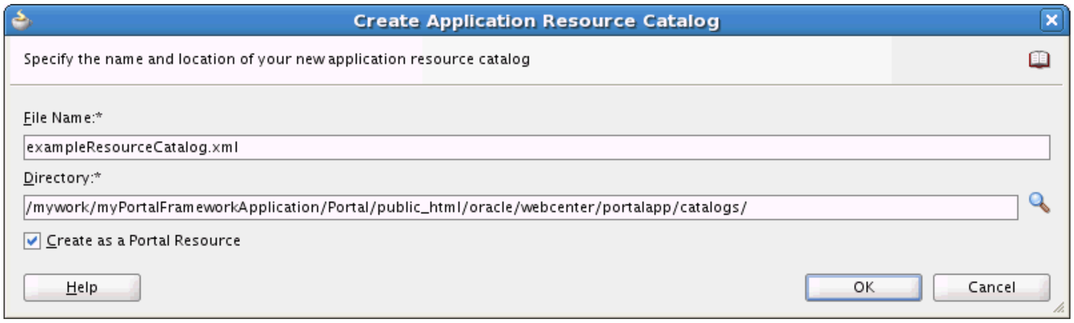
If the seeded resource catalog created for your application does not meet your requirements, or if you want to configure multiple resource catalogs, you can create your own resource catalogs with all the required resources.

> **Note:** To correctly implement resource catalogs, you must know where the application looks for the definitions and the XML schema upon which the definitions are based. See Appendix B, "Composer Component Properties and Files" for further information.

To create a resource catalog:

1. In the Application Navigator, right-click the node where you want to create the resource catalog (typically, `/oracle/webcenter/portalapp/catalogs`) and choose **New**.
2. In the New Gallery, expand **Web Tier**, select **Portal Framework** and then **Resource Catalog**, and click **OK**.
3. In Create Application Resource Catalog dialog, in the **File Name** field, enter a name for the XML file that represents the resource catalog, for example, `users-catalog.xml`.

Figure 14–3 The Create Application Resource Catalog Dialog



Create Application Resource Catalog

Specify the name and location of your new application resource catalog

File Name:*

exampleResourceCatalog.xml

Directory:*

/mywork/myPortalFrameworkApplication/Portal/public_html/oracle/webcenter/portalapp/catalogs/

☑ Create as a Portal Resource

4. In the **Directory** field, enter the full directory path of the location under which to create the resource catalog definition XML file.

> **Note:** In a Portal Framework application, to expose the new resource catalog in the Assets page of the runtime administration console, you must create the resource catalog under the `*Application_Root*/Portal/public_html/oracle/webcenter/portalapp` directory. By default, Portal Framework applications include a separate `catalogs` directory.
>
> In a non-Portal Framework application, create the resource catalog in the `*Application_Root*/Portal/src/portal directory`.

> **Tip:** If you do not select this option now, you can add the resource catalog to the runtime administration console later by right clicking it and choosing **Create Portal Resource**.

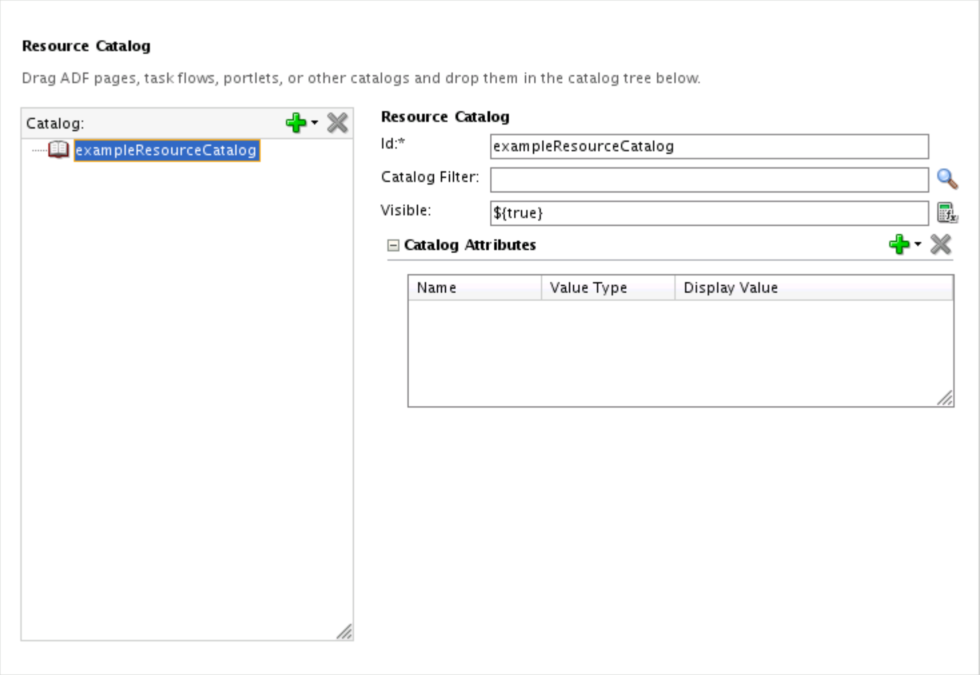
5. Select **Create as Portal Resource** to enable users with the appropriate permissions to manage the resource catalog at runtime in the Assets page of the runtime administration console.

> **Note:** This option is available in a Portal Framework application only if the directory you entered is the `*Application_Root*/Portal/public_html/oracle/webcenter/portalapp` directory or one of its subdirectories.

6. Click **OK**.

   When you create a resource catalog in a Portal Framework application, a catalog definition file (an XML file) is created for the resource catalog in the specified directory. The catalog definition file opens in Design view.

Figure 14–4 A Resource Catalog in Design View



Resource Catalog

Drag ADF pages, task flows, portlets, or other catalogs and drop them in the catalog tree below.

Catalog: exampleResourceCatalog

Resource Catalog

Id:* exampleResourceCatalog

Catalog Filter:

Visible: ${true}

Catalog Attributes

Name	Value Type	Display Value

The catalog definition file is initially empty, so you must edit it to design the structure and content of your resource catalog. For more information, see Section 14.3, "Editing a Resource Catalog."

> **Tip:** If you do not want to add resources from scratch, as a starting point, you could copy the source code of the `default-catalog.xml` file into the Source view of your new catalog definition.

If you created the resource catalog under the appropriate directory and selected the Create as a Portal Resource option, the resource catalog is automatically available for runtime management. For more information, see Section 9.5, "Working with Portal Resources at Runtime."

14.3 Editing a Resource Catalog

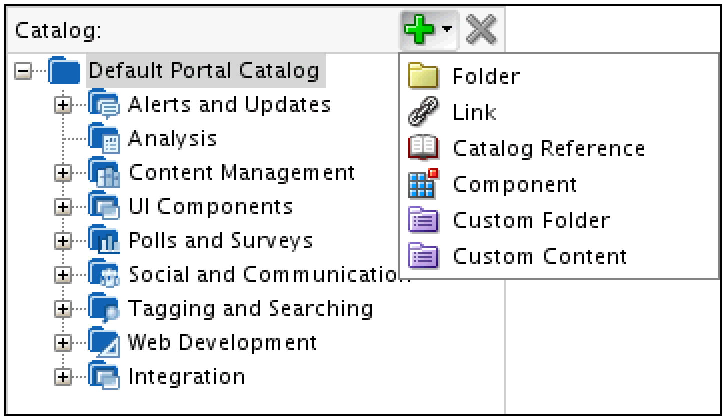
To define the content of your resource catalog you can edit the seeded resource catalog, `default-catalog.xml`, to add the resources that you want users to be able to add to the pages and task flows in your application. The seeded resource catalog is created automatically when you create an application using the WebCenter Portal Framework Application template.

You can also create your own resource catalog and edit that. For more information, see Section 14.2, "Creating a Resource Catalog."

You can add resources to a resource catalog in two ways:

- Drag and drop resources from different areas in JDeveloper onto the resource catalog in Design view.
- Use the options on the Add new node menu in the Design view for the resource catalog (Figure 14–5).

Figure 14–5 The Resource Catalog Add New Node Menu



In the Design view for a resource catalog you can also rearrange, modify, and delete existing resources.

The left half of the XML editor contains the Catalog section, which displays the hierarchical structure of components in the catalog. The right half of the page provides fields to define attributes and parameters on a selected resource.

> **Tip:** If you are creating a resource catalog from scratch, you can refer to the default catalog definition file to get an idea of how resources are included in the catalog.

> **Note:** If you are using a standalone version of Composer (that is, Composer without WebCenter Portal Framework), you can add a resource to the catalog by directly adding a `<resource>` element to the source of the catalog definition file. For more information, see Section C.3.12, "resource."

> **See Also:** For details about the catalog definition file and its attributes:
>
> - Section C.2, "XML Schema"
> - Section C.3, "Catalog Definition Attributes"

This section includes the following topics:

- Section 14.3.1, "How to Define Connections to Resources"
- Section 14.3.2, "How to Drag and Drop a Resource into a Resource Catalog"
- Section 14.3.3, "How to Add a Link to a Resource Catalog"
- Section 14.3.4, "How to Add a Folder to a Resource Catalog"
- Section 14.3.5, "How to Add a Custom Component to a Resource Catalog"
- Section 14.3.6, "How to Add a Custom Folder to a Resource Catalog"
- Section 14.3.7, "How to Add a Custom Content Provider to a Resource Catalog"
- Section 14.3.8, "How to Add a Resource Catalog to Another Resource Catalog"
- Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource"

- Section 14.3.10, "How to Rearrange Resources in a Catalog"
- Section 14.3.11, "How to Show or Hide a Resource Catalog or Resource"
- Section 14.3.12, "How to Edit a Resource in a Resource Catalog"
- Section 14.3.13, "How to Delete a Resource from a Resource Catalog"
- Section 14.3.14, "How to Expose Data Controls Created at Design Time in a Resource Catalog"
- Section 14.3.15, "How to Expose Data Controls Created at Runtime in a Resource Catalog"
- Section 14.3.16, "How to Control Visibility of Portlets in a Resource Catalog"

14.3.1 How to Define Connections to Resources

Many resources, such as WebCenter Portal tools and services and portlets, are accessed through connections defined in your application's `connections.xml` file. Therefore, you must create connections before adding such resources to the resource catalog.

You can create connections to resources in different ways. This section describes how to create a connection from the Resource Palette. For information about additional ways to create connections, see Section 4.2, "Preparing Your Framework Application for Tools and Services."

To create a connection from the Resource Palette:

1. From the Resource Palette, click the **New** icon in the upper left corner.
2. Choose **New Connection** and then the type of connection you want to create.

   The wizard for your connection type appears.
3. Step through the wizard filling in the necessary information about the connection.

   When you click **Finish**, the connection should appear in the Resource Palette under **Connections**.
4. Right click the connection in the Resource Palette and choose **Add to Application** from the context menu.

   Alternatively, you can drag and drop the connection from the Resource Palette to the Application Resources panel of the Application Navigator.

14.3.2 How to Drag and Drop a Resource into a Resource Catalog

You can add the following resources to a catalog by dragging and dropping them onto the desired location in the Design view of the catalog definition file:

- **Portlets,** from the Application Resources pane or the Resource Palette.
- **Content,** from a WebCenter Content connection in the Application Resources pane or Resource Palette.
- **Task flows,** from the Application Resources pane or the Resource Palette.

> **Note:** If you add an ADF task flow to the catalog and want to export the catalog to an already deployed application, then you must deploy the task flow as a shared library to the deployed application.
>
> For more information, see Section 15.4, "Adding Custom Task Flows to a Page."

- **Resource catalogs,** from the Application Navigator. This embeds one resource catalog inside another.

14.3.3 How to Add a Link to a Resource Catalog

You can add links to the following resources to a catalog:

- **Task Flow**: Link to a WebCenter Portal tools and services task flow (in the Resource Palette) or a custom task flow created in JDeveloper (in the Application Navigator).
- **Portlet**: Link to any registered portlet producer. See Chapter 63, "Consuming Portlets" for detailed information about registering portlet producers and adding portlets to a page.
- **Content**: Link to a file or directory from an existing WebCenter Content connection.
- **Other**: Link to a custom component that you create by providing the XML code for that component.

To add a link:

1. In the Application Navigator, right-click the resource catalog to which you want to add the link, and choose **Open**.
2. In the Design view for the resource catalog, in the Catalog section on the left side, select the node in the resource catalog under which you want to add the link.
3. Click the **Add new node** icon and choose **Link**.

   A `url` element is added to the catalog. The right side of the page displays fields to define the new link's attributes and parameters.
4. The **Id** field is automatically populated with generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the catalog definition file.
5. From the **Type** list, select the type of resource that you want to create. You can choose **Taskflow**, **Portlet**, **Content**, or **Other**.

   > **Notes:** If you add an ADF task flow to the catalog and want to export the catalog to an already deployed application, then you must deploy the task flow as a shared library to the deployed application.
   >
   > For more information, see Section 15.4, "Adding Custom Task Flows to a Page."
6. If you are adding a link to a custom resource (that is, you selected **Other** from the Type list), then specify the factory class of the component. For all other resource types, the **Factory Class** value is automatically populated with the appropriate value for the selected link type.

   The factory classes for the available resource types are as follows:

   - Task flow: `oracle.webcenter.portalframework.sitestructure.rc.TaskFlowResourceFactory`

- Portlet: oracle.webcenter.portalframework.sitestructure.rc.PortletResourceFactory
- Content: oracle.webcenter.content.model.rc.ContentUrlResourceFactory

For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

7. In the **URL** field, enter the URL to access the resource. If you do not know the location, click the **Browse Files** icon to browse for available resources. Table 14–1 provides the URL format to used for each resource type.

Table 14–1 URL Format for the Different Resource Types

Resource Type	Location in the Application	URL Format
Task Flow from an ADF Library	Resource Palette	`taskflow://`*`pathToTaskFlow/taskFlowDefinitionFilName#taskFlowId`*
Task Flow Within the Application	Application Navigator	`taskflow://`*`pathToTaskFlow/taskFlowDefinitionFileName#taskFlowId`*
Portlet	Portlet producer connection in the Application Resources pane or in the Resource Palette	`portlet://`*`producerId/portletId`*
Content	Content Repository connection in the Application Resources pane	`content://`*`contentConnectionId/documentId`*

Note: If you enter the URL for a portlet or content type resource manually, and if the connection for that resource is available only in the Resource Palette, then ensure that you first add the connection to the application.

8. In the **Visible** field, specify whether the link is listed in the resource catalog at runtime. The default value is the EL expression `#{true}`, which means the link is listed for all users at all times. Enter `false` or `#{false}` to hide the link from all users at all times, or enter an EL expression to specify the conditions under which the link is listed. If the field is empty, the value defaults to `true`.

9. Optionally, in the URL Attributes section, specify any desired display options for the link. For more information, see Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource."

10. In the URL Parameters section, enter values, as desired, for any parameters supported by the resource. You can bind these parameters to other artifacts in the application.

    Click the **Add** icon to create a row in the Parameters table.

11. Save the catalog definition file.

14.3.4 How to Add a Folder to a Resource Catalog

You can create folders to group similar resources, thereby organizing the catalog better.

To add a folder:

1. In the Application Navigator, right-click the resource catalog to which you want to add the folder, and choose **Open**.

2. In the Design view for the resource catalog, in the Catalog section on the left side, select the node in the resource catalog under which you want to add the folder.

3. Click the **Add new node** icon and choose **Folder**.

   A `folder` element is added to the catalog. The right side of the page displays fields to define the new folder's attributes and parameters.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the resource catalog.

5. In the **Visible** field, specify whether the folder is listed in the resource catalog at runtime. The default value is the EL expression `#{true}`, which means the folder is listed for all users at all times. Enter `false` or `#{false}` to hide the folder from all users at all times, or enter an EL expression to specify the conditions under which the folder is listed. If the field is empty, the value defaults to `true`.

6. Optionally, in the Folder Attributes section, specify any desired display options for the folder. For more information, see Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource."

7. In the Folder Parameters section, enter values, as desired, for any parameters supported by the folder. You can bind these parameters to other artifacts in the application.

   Click the **Add** icon to create a row in the Parameters table.

8. Save the catalog definition file.

14.3.5 How to Add a Custom Component to a Resource Catalog

You can add custom component to a resource catalog, such as simple ADF Faces components, compound objects containing two or more components, and JSF Verbatim tags that let you add arbitrary HTML content inside them. An example for arbitrary HTML that you can add to your catalog is a YouTube video.

To add a custom component:

1. In the Application Navigator, right-click the resource catalog to which you want to add the custom component, and choose **Open**.

2. In the Design view for the resource catalog, in the Catalog section on the left side, select the node in the resource catalog under which you want to add the custom component.

3. Click the **Add new node** icon and choose **Component**.

   A `component` element is added to the catalog. The right side of the page displays fields to define the new component's attributes and parameters.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the resource catalog.

5. In the **Component Factory** field, enter the name of a Java class that implements the `oracle.adf.rc.component.ComponentFactory` interface and creates an instance of the component based on a set of parameters, for example, `oracle.adf.rc.component.XmlComponentFactory`.

   As you type the name, the field auto-completes with valid factory classes from the classpath. You can also use the **Browse** icon to select a class.

For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

6. In the **Visible** field, specify whether the component is listed in the resource catalog at runtime. The default value is the EL expression `#{true}`, which means the component is listed for all users at all times. Enter `false` or `#{false}` to hide the component from all users at all times, or enter an EL expression to specify the conditions under which the component is listed. If the field is empty, the value defaults to `true`.

7. Optionally, in the Component Attributes section, specify any desired display options for the custom component. For more information, see Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource."

8. Use the Component Parameters section to add parameters that were defined when implementing the factory class.

   For example, if you are adding an XML component, click the **Add** icon in the Parameters section and select **xml**. In the new row that is displayed, specify the XML code for the component in the value field.

   > **Note:** The xml option is displayed only if you selected `oracle.adf.rc.component.XmlComponentFactory` as the component factory.

   To ensure that the component works properly, you must specify the custom component ID to be `#`, and provide the namespace, as shown in the following example:

   ```
   <cust:panelCustomizable id="#"
   xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"/>
   ```

   The `#` value ensures that a unique ID is generated dynamically for the component.

9. Save the catalog definition file.

14.3.6 How to Add a Custom Folder to a Resource Catalog

You can add a folder using a resource catalog adapter so that the folder is populated dynamically. A custom folder is not added as a folder with resources to the catalog; it contains only a reference to the factory class, which displays the resources dynamically.

To add a custom folder:

1. In the Application Navigator, right-click the resource catalog to which you want to add the custom folder, and choose **Open**.

2. In the Design view for the resource catalog, in the Catalog section on the left side, select the node in the resource catalog under which you want to add the custom folder.

3. Click the **Add new node** icon and choose **Custom Folder**.

   A `customFolder` element is added to the catalog. The right side of the page displays fields to define the new folder's attributes and parameters.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the resource catalog.

5. In the **Initial Context Factory** field, enter the name of a Java class that implements the `javax.naming.InitialContextFactory` interface and generates the folder based on a set of parameters.

   For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

6. In the **Visible** field, specify whether the folder is listed in the resource catalog at runtime. The default value is the EL expression `#{true}`, which means the folder is listed for all users at all times. Enter `false` or `#{false}` to hide the folder from all users at all times, or enter an EL expression to specify the conditions under which the folder is listed. If the field is empty, the value defaults to `true`.

7. Select **Insert Folder Contents** to display the contents of the custom folder directly in the catalog rather than displaying them under the folder.

8. Optionally, in the Custom Folder Attributes section, specify any desired display options for the folder. For more information, see Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource."

9. Use the Custom Folder Parameters section to add parameters that were defined while implementing the factory class. You can bind these parameters to other artifacts in the application.

   Click the **Add** icon in the Parameters section to create a new row in the Parameters table.

   You may see a drop-down menu on the **Add** icon if the factory class exposes parameters, for example, Content Presenter-specific factory classes provide a `templateView` parameter.

10. Save the catalog definition file.

14.3.7 How to Add a Custom Content Provider to a Resource Catalog

A custom content provider dynamically generates zero or more catalog entries at runtime. Catalog entries include folders, links, custom folders, components, and so on. When you add a custom folder, a folder is created in the catalog and is displayed at runtime even if it is empty. However, when you add a custom content element, a folder is created in the catalog, but is displayed at runtime only if it has components inside it. Except for this difference, a custom content provider is similar to a custom folder.

To add a custom content provider:

1. In the Application Navigator, right-click the resource catalog to which you want to add the custom content provider, and choose **Open**.

2. In the Design view for the resource catalog, in the Catalog section on the left side, select the node in the resource catalog under which you want to add the custom content provider.

3. Click the **Add new node** icon and choose **Custom Content**.

   A `customContent` element is added to the catalog. The right side of the page displays fields to define the new folder's attributes and parameters.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the resource catalog.

5. In the **Content Provider** field, enter the fully qualified name of a class that implements the interface `oracle.adf.rc.spi.plugin.catalog.CustomContentProviderV2`.

   You can use the **Browse** icon to see a list of classes that implement this interface. Also, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

6. In the **Visible** field, specify whether the folder is listed in the resource catalog at runtime. The default value is the EL expression `#{true}`, which means the folder is listed for all users at all times. Enter `false` or `#{false}` to hide the folder from all users at all times, or enter an EL expression to specify the conditions under which the folder is listed. If the field is empty, the value defaults to `true`.

7. Optionally, in the Custom Content Attributes section, specify any desired display options for the folder. For more information, see Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource."

8. Use the Custom Content Parameters section to define parameters on the folder. The parameters you define here are passed to and interpreted by the `CustomContentProviderV2` implementation.

   Click the **Add** icon in the Parameters section to create a new row in the Parameters table.

9. Save the catalog definition file.

14.3.8 How to Add a Resource Catalog to Another Resource Catalog

You can include another resource catalog inside the selected catalog. When you add another catalog, only a pointer to this catalog is included in the catalog definition file. The actual catalog contents are inserted only at runtime.

To add a resource catalog to another resource catalog:

1. In the Application Navigator, right-click the resource catalog to which you want to add the resource catalog, and choose **Open**.

2. In the Design view for the resource catalog, in the Catalog section on the left side, select the node in the resource catalog under which you want to add the resource catalog.

3. Click the **Add new node** icon and choose **Catalog Reference**.

   A `catalog` element is added to the catalog. The right side of the page displays fields to define the resource catalog's attributes and parameters.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something more descriptive. The ID must be unique within the resource catalog.

5. In the **Path** field, enter the MDS path to the catalog definition file, for example, `\oracle\webcenter\portalapp\catalogs\custom-catalog.xml`.

   You can use the **Browse** icon to browse application folders and select the catalog definition file.

6. In the **Visible** field, specify whether the folder is listed in the resource catalog at runtime. The default value is the EL expression `#{true}`, which means the folder is listed for all users at all times. Enter `false` or `#{false}` to hide the folder from all users at all times, or enter an EL expression to specify the conditions under which the folder is listed. If the field is empty, the value defaults to `true`.

7. Optionally, in the Catalog Attributes section, specify any desired display options for the resource catalog. For more information, see Section 14.3.9, "How to Set Display Options for a Resource Catalog or Resource."

8. Save the catalog definition file.

14.3.9 How to Set Display Options for a Resource Catalog or Resource

You can specify various display options for a resource catalog or any of its resources to determine their appearance and behavior. The display options available depend on the type of the resource.

- **Title**: A label to be used for the resource in the catalog. This attribute is defined by default. You can change its value, if required.
- **Description**: A description of this resource.
- **Subject**: Keywords to facilitate keyword searching of the resource catalog.
- **ToolTip**: The tool tip to be displayed when you move the mouse over this resource name in the catalog.
- **IconURI**: The location of the icon to display next to the resource name in the catalog.

To set display options for a resource catalog or resource:

1. In the Application Navigator, right-click the resource catalog and choose **Open**.

2. In the Design view for the resource catalog, in the Catalog column on the left side, select the resource for which you want to set display options.

   To set display options for the resource catalog, select the root node.

3. In the resource's Attributes panel, click the **Add** icon and choose the attribute that you want to set. Table 14–2

Table 14–2 Resource Catalog Display Options

Attribute	Description
Title	The title displayed for the resource in the resource catalog.
Description	A description of the resource.
Subject	Keywords to facilitate searching of the node.
ToolTip	Text that displays to provide additional information about the resource when users hover the mouse over the Title.
IconURI	An icon to visually represent the resource. This is displayed next to the Title in the resource catalog.

4. From the **Value Type** drop-down list, choose:
   - **Literal String—**to specify a string as the value for the attribute.
   - **Resource Bundle—**to use a resource bundle to provide localized values for the attribute.

5. In the **Display Value** field, enter the value for the attribute. If you are using a resource bundle, click the **Browse** icon to select the resource bundle to search for the localized value.

6. Save the catalog definition file.

14.3.10 How to Rearrange Resources in a Catalog

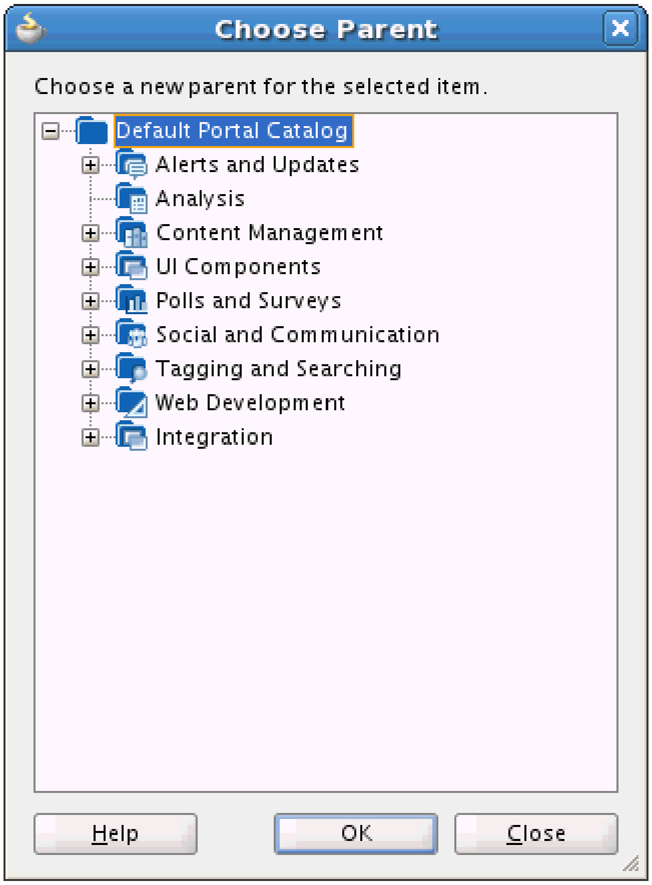
You can move resources to different folders within a resource catalog after you have added them. You can rearrange resources in the following ways:

- Drag and drop a resource from one folder into another.
- Use the **Change Parent** context menu option to move a resource to a different folder.

To rearrange a resource using the Change Parent option:

1. In the Application Navigator, right-click the resource catalog and choose **Open**.
2. In the Design view for the resource catalog, in the Catalog column on the left side, right-click the resource and choose **Change Parent** from the context menu.
3. In the Choose Parent dialog (Figure 14–6), select the folder in which to include the resource and click **OK**.

Figure 14–6 The Change Parent Dialog



Choose Parent

Choose a new parent for the selected item.

- Default Portal Catalog
  - Alerts and Updates
  - Analysis
  - Content Management
  - UI Components
  - Polls and Surveys
  - Social and Communication
  - Tagging and Searching
  - Web Development
  - Integration

Note: The **OK** button is enabled only when you select a valid location for the resource.

---

4. Save the navigation model definition file.

14.3.11 How to Show or Hide a Resource Catalog or Resource

You can specify whether or not a resource catalog or one of its resources is visible at runtime.

> **Tip:** As well as specifying an absolute true or false value, you can also dynamically determine whether or not the resource catalog or resource is available by using an EL expression to specify the conditions under which it is visible.

To show or hide a resource catalog or resource:

1. In the Application Navigator, right-click the resource catalog and choose **Open**.
2. In the Design view for the resource catalog, in the Catalog column on the left side, select the resource for which you want to set the visibility.

   To set the visibility of the navigation model resource catalog, select the root node.
3. In the **Visible** field, specify whether the resource catalog or resource is available for use in the application. This field takes an EL value. The default is `#{true}`, which means the resource catalog or resource is visible. Enter `false` or `#{false}` to hide the resource catalog or resource, or enter an EL expression to specify the conditions under which it is available. If the field is empty, the value defaults to `true`.
4. Save the navigation model definition file.

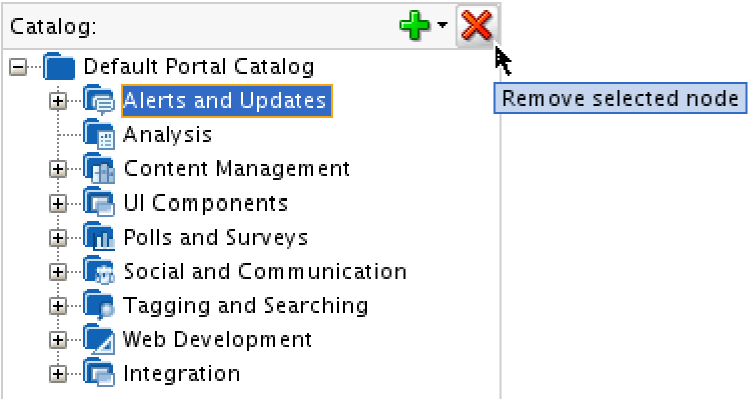
14.3.12 How to Edit a Resource in a Resource Catalog

To edit a resource, select it in the Catalog section of the catalog definition file. The resource's attributes and parameters are displayed in the right half of the page. You can edit values for these attributes and parameters and save the catalog definition file. For details about a resource's attributes and parameters, see the appropriate section earlier in this chapter.

14.3.13 How to Delete a Resource from a Resource Catalog

To delete a resource, select it in the Catalog section of the catalog definition file and click the **Remove selected node** icon (Figure 14–7).

Figure 14–7 Delete Option in the Resource Catalog Design View



14.3.14 How to Expose Data Controls Created at Design Time in a Resource Catalog

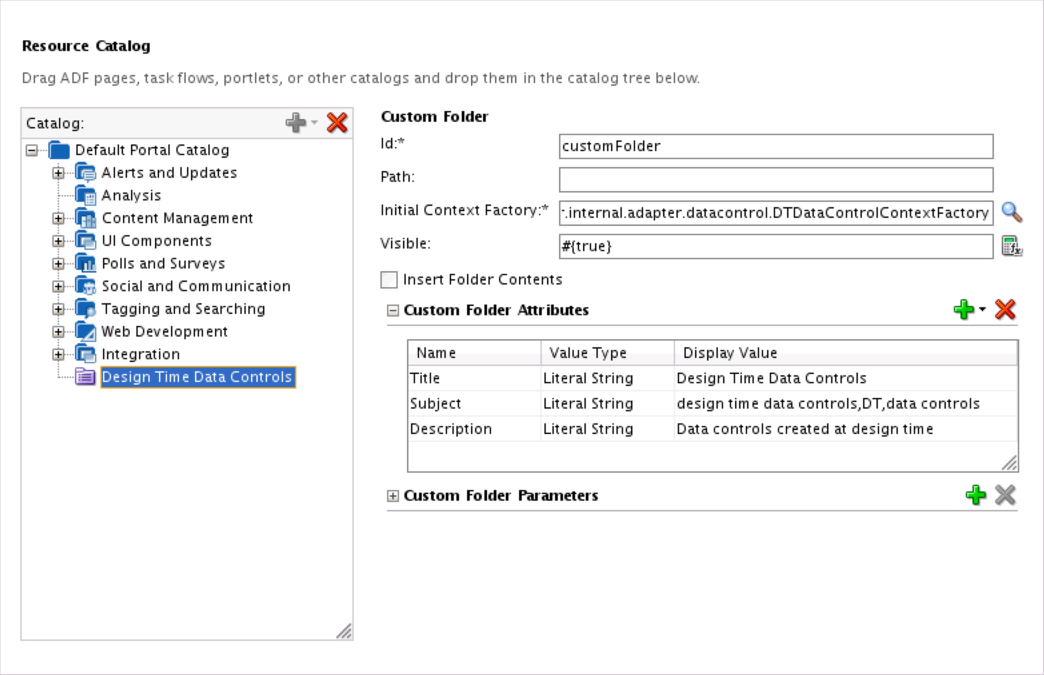
Oracle WebCenter Portal exposes a large number of service data controls that can be added to application pages and task flows. In addition, you may have created your own SQL or Web Services data controls in JDeveloper. To enable users to add these data controls to pages and task flows, you must expose the data controls in the resource catalog. For this, you must add a `customFolder` entry in your catalog definition file, as shown in Example 14–1 and Figure 14–8:

Example 14–1 Custom Folder for Design Time Created Data Controls

```
<customFolder id="dtDataControls"

factoryClass="oracle.webcenter.datacomposer.internal.adapter.datacontrol.DTDataCon
trolContextFactory">
  <attributes>
    <attribute value="Design Time Data Controls" attributeId="Title"/>
    <attribute value="Data controls created at design time"
attributeId="Description"/>
    <attribute value="design time data controls,DT, data controls"
attributeId="Subject"/>
    <attribute value="/adf/webcenter/folderlists_qualifier.png"
attributeId="IconURI"/>
  </attributes>
</customFolder>
```

Figure 14–8 Design Time Data Controls Folder



Resource Catalog

Drag ADF pages, task flows, portlets, or other catalogs and drop them in the catalog tree below.

Custom Folder

Id:* customFolder

Path:

Initial Context Factory:* ·.internal.adapter.datacontrol.DTDataControlContextFactory

Visible: #{true}

□ Insert Folder Contents

Custom Folder Attributes

Name	Value Type	Display Value
Title	Literal String	Design Time Data Controls
Subject	Literal String	design time data controls,DT,data controls
Description	Literal String	Data controls created at design time

Custom Folder Parameters

To expose the `customFolder` as a translatable resource in the catalog, the folder's string attributes must be stored as resource strings in a resource bundle. For this, the catalog definition file must have a `resourceBundle` attribute and each translatable attribute must have an `isKey` attribute. Then the attribute value is saved in a resource bundle, as shown in the following example:

The `resourceBundle` attribute on the catalog definition:

```
<catalogDefinition id="DefaultCatalog" visible="#{true}"

resourceBundle="oracle.webcenter.portalapp.catalogs.DefaultCatalogBundle"
                    definitionFilter="portal.catalog.DefaultCatalogFilter"
                    xmlns="http://xmlns.oracle.com/adf/rcs/catalog">
```

The `isKey` attribute defined on the attributes of a translatable resource:

```
<customFolder id="dtDataControls"

factoryClass="oracle.webcenter.datacomposer.internal.adapter.datacontrol.DTDataCon
trolContextFactory">
  <attributes>
    <attribute value="DATACONTROL_FOLDER.TITLE" isKey="true" attributeId="Title"/>
    <attribute value="DATACONTROL_FOLDER.DESCRIPTION" attributeId="Description"
isKey="true"/>
    <attribute value="DATACONTROL_FOLDER.KEYWORDS" attributeId="Subject"
isKey="true"/>
    <attribute value="/adf/webcenter/folderlists_qualifier.png" isKey="false"
attributeId="IconURI"/>
  </attributes>
</customFolder>
```

For more information about using resource bundles, see Section 20.12, "Configuring Runtime Resource String Editing."

At runtime, the resource catalog displays a folder titled **Design Time Data Controls** irrespective of whether the application has any design-time data controls.

In a deployed application, the Assets page of the runtime administration console allows you to add design-time data controls individually to custom catalogs. Out-of-the-box catalogs cannot be edited at runtime. For more information, see the "Adding a Resource to a Resource Catalog" section in *Building Portals with Oracle WebCenter Portal*.

Exposing Custom Data Controls in an Already Deployed Application

If you created a SQL or web service data control in your application, and want to expose them in an already deployed application, you must perform the following steps:

- Package the application into an ADF shared library.
- Deploy the application to the WebLogic Server instance. For more information, see Section 55.2.5, "Deploying Extensions to the WebCenter Portal Shared Library (extend.spaces.webapp.war)."

When you perform this configuration, the deployed data controls are available in the Design Time Data Controls folder in the runtime Resource Registry. Users can add the data controls from the registry to any custom resource catalog, from where they can be consumed in pages and task flows.

14.3.15 How to Expose Data Controls Created at Runtime in a Resource Catalog

Users can create data controls at runtime in the Assets page of the runtime administration console. If you want your resource catalog to dynamically display data controls created at runtime, add a `customFolder` entry in your catalog definition file, as shown in Example 14–2.

Example 14–2 Custom Folder for Runtime Created Data Controls

```
<customFolder id="rtDataControls"

factoryClass="oracle.webcenter.datacomposer.internal.adapter.datacontrol.DataContr
olContextFactory">
  <attributes>
    <attribute value="Runtime Data Controls" attributeId="Title"/>
    <attribute value="Data controls created at runtime"
attributeId="Description"/>
    <attribute value="runtime data controls,RT,data controls"
attributeId="Subject"/>
    <attribute value="/adf/webcenter/folderlists_qualifier.png"
attributeId="IconURI"/>
  </attributes>
</customFolder>
```

To expose this folder as a translatable resource, the folder's string attributes must be stored as resource strings in a resource bundle. See Section 14.3.14, "How to Expose Data Controls Created at Design Time in a Resource Catalog" for an example of how to create translatable resources.

At runtime, the catalog displays a folder titled **Runtime Data Controls** irrespective of whether the folder has any data controls.

14.3.16 How to Control Visibility of Portlets in a Resource Catalog

Out-of-the-box, a resource catalog displays portlets from all the available producers irrespective of whether the portlets are secured or not. As a result, users are allowed to consume even secured portlets to which they do not have access. When a user adds such a portlet to a page, the portlet component is added, but it does not display any content. To ensure that users view and consume only those portlets that they can access, you can control the visibility of portlets in the resource catalog. Implement the `PortletItemSecurityHelper` interface to display portlets conditionally in the resource catalog, based on the user's permissions.

To control visibility of portlets in a resource catalog:

1. Implement the `PortletItemSecurityHelper` interface in your own item security helper class, for example, `CustomPortletSecurityHelper.java`.

   Example 14–3 shows a sample implementation of the `PortletItemSecurityHelper` interface. The following assumptions are made for the purpose of this example:

   - Grants are defined for each portlet to control who can see it.
   - A permission class, `PortletVisibilityPermission`, is defined to check a user's permissions on the portlet.

Example 14–3 Sample Implementation of PortletItemSecurityHelper

```
public class CustomPortletSecurityHelper extends PortletItemSecurityHelper
{
    public boolean canView(String producerId, String portletId)
    {
        String permissionPath = producerId + '/' + portletId;
        PortletVisibilityPermission permission = new PortletVisibilityPermission
(permissionPath, VIEW_ACTION);
        try
        {
          // throws AccessControlException if the permission is not granted
          JpsAuth.checkPermission(permission);
          canView = true;
          sLogger.logp(Level.FINE, SOURCE_CLASS, method,
                       "PortletVisibilityPermission check passed. Producer={0},
Portlet={1} Action=view",
                       new Object[]{producerId, portletId});
        }
        catch(AccessControlException ace)
        {
          canView = false;
          sLogger.logp(Level.FINE, SOURCE_CLASS, method,
                       "PortletVisibilityPermission check passed. Producer={0},
Portlet={1} Action=view",
                       new Object[]{producerId, portletId});
        }
        return canView;
    }
}
```

2. Create an `rc_ext.xml` file in the application's `META-INF` directory, and add the following code to register the implementation with the resource catalog:

```
<extension xmlns:="http://xmlns.oracle.com/adf/rc/extension"
           id="your.extension.id"
           name="Your Extension Name"
           version="11.1.1.4.0">
  <item-security-helper class="your.implementation.class.name"/>
</extension>
```

At runtime, when a user clicks **Add Content** in Composer, the resource catalog displays only those portlets on which the user has permissions.

14.4 Selecting the Default Resource Catalog

You can configure the default catalog at the application and page levels. You can also use different resource catalogs depending on different criteria.

This section includes the following subsections:

- Section 14.4.1, "How to Select the Default Resource Catalog for an Application"
- Section 14.4.2, "How to Configure Multiple Resource Catalogs"
- Section 14.4.3, "How to Select the Default Resource Catalog for a Page"

14.4.1 How to Select the Default Resource Catalog for an Application

Every Portal Framework application defines a default resource catalog that is used when users add content to a page, task flow, or page template.

When you first create a Portal Framework application, the seeded resource catalog, default-catalog.xml, is set as the application's default resource catalog. If you subsequently create your own resource catalog, you can set that as the default.

You can set the default resource catalog for a Portal Framework application in the application's `adf-config.xml` file. For more

To select the default resource catalog for an application:

1. Open the application's `adf-config.xml` file.
2. Change the `catalog-name` attribute value in the `<rcv:rcv-config>` element and specify the custom catalog name, as shown in the following example:

```
<rcv:rcv-config>
  <rcv:default-catalog
catalog-name="/oracle/webcenter/portalapp/catalogs/myCustomCatalog.xml"/>
</rcv:rcv-config>
```

The `catalog-name` attribute identifies the catalog to be used as the default one.

The path you specify is relative to the resource catalog root directory, for example, if you saved your new catalog definition as `C:\JDeveloper\mywork\RCSampleApp\Portal\Public_Html\oracle\webcenter\portalapp\catalogs\myCustomCatalog.xml`, then the `catalog-name` value would be `/oracle/webcenter/portalapp/catalogs/myCustomCatalog.xml`. The name uses the `/` separator because it represents a part of an MDS path.

> **Note:** For information about the resource catalog-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

3. Save the `adf-config.xml` file.

14.4.2 How to Configure Multiple Resource Catalogs

Most businesses require that users and groups have access to only those resources that they can add to a page. To address this need, you can configure multiple resource catalogs in your application. You can expose different catalogs to different users based on specific criteria, such as the page being edited, the user, or the user role. This section describes how to associate multiple resource catalogs with your application. It contains the following subsections:

To use multiple catalogs, you must implement the `ResourceCatalogSelector` API to select the appropriate catalog for the user and the page being edited. You must include the `catalog-selector` entry in your application's `adf-config.xml` file to specify the name of your `ResourceCatalogSelector` class. If you do not specify a `catalog-selector`, the default catalog is used for all editable pages and all users see the same content. If you specify a `catalog-selector`, the default catalog is used only when the specified selector returns null.

To configure multiple resource catalogs:

1. Create your custom catalogs by performing the steps outlined in Section 14.2, "Creating a Resource Catalog" and Section 14.3, "Editing a Resource Catalog."
2. Implement the `oracle.adf.rc.model.config.ResourceCatalogSelector` interface in your own resource catalog selector class, for example, `CatalogSelector.java`.

   Example 14–4 shows a catalog selector implementation where a custom resource catalog, `admin-catalog.xml`, is shown to `ahunold` who has administrator privileges, and `users-catalog.xml` is shown to users `sking` and `jdoe`. If there is a problem with rendering either of these catalogs, then the default catalog is shown to users.

Example 14–4 Sample ResourceCatalogSelector Showing Entries for Multiple Resource Catalogs

```
package webcenter;
```

```
import javax.faces.context.FacesContext;

import java.util.Map;

import javax.faces.component.UIViewRoot;
import javax.faces.context.FacesContext;
import javax.faces.context.ExternalContext;

import oracle.adf.rc.model.config.ResourceCatalogSelector;
import oracle.adf.rc.model.dc.RCVContext;

import oracle.adf.rc.model.config.ResourceCatalogSelector;

/**
 * CatalogSelector is a sample implementation of the ResourceCatalogSelector
 * interface.
 *
 * This implementation is based on the authenticated user
 */
public class CatalogSelector implements ResourceCatalogSelector {
  public CatalogSelector() {
  }

  /**
   * Returns the Id of the catalog that must be used for the current
   * user.
   *
   * @param context a Map cont
   * @return id of the catalog to be used for the current user or
   *         null if the default catalog must be used.
   */
  public String getCatalogName(Map context) {
    // if no catalog is selected, return null & ensure that the Composer uses the
    // default catalog defined in the rcv-config
    String retval = null;

    // get information about the current user.
    FacesContext fctx = FacesContext.getCurrentInstance();
    ExternalContext ectx = fctx.getExternalContext();
    String user = ectx.getRemoteUser();

    if (user == null || user.length() == 0) {
      // user name is not available so use the default catalog
      retval = null;

    }
    else if (user.equals("jdoe") || user.equals("sking")  ) {
      // return users-catalog for users jdoe and sking
      retval = "users-catalog";

    }
    else if (user.equals("ahunold")) {
      // return admin-catalog for user ahunold
      retval = "admin-catalog";

    }

    return retval;
    }
}
```

3. In your `adf-config.xml` file, enter the name of the class you created for selecting a resource catalog with the `<rcv:catalog-selector>` tag as show in the following example:

```
<rcv:rcv-config>
<rcv:default-catalog
catalog-name="/oracle/webcenter/portalapp/catalogs/default-catalog.xml"/>
<rcv:catalog-selector class-name="webcenter.CatalogSelector"/>
</rcv:rcv-config>
```

   The value for `catalog-name` corresponds to the default catalog definition file with the MDS path.

> **Note:** For information about the resource catalog-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

14.4.3 How to Select the Default Resource Catalog for a Page

If your application page contains Composer components, then you can specify the catalog name in the `catalog` attribute on the `Page Customizable` component. You can specify a static or EL value. For more information, see Section B.1.1, "Page Customizable Component."

14.5 Filtering Items in a Resource Catalog

If you want to arrange catalog content so that it is essentially the same for all users, but displays different subsets of the content to different users, then you can configure your resource catalog to filter out selected items based on specific criteria.

For example, if two users `A` and `B` have different privileges on a page, you can configure your application to display the entire catalog to user `A` and only a subset of items in the catalog to user `B`.

To apply a filter on the catalog, you must implement the `oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter` interface. Additionally, you must associate this filter with the resource catalog.

> **Tip:** You can conditionally hide individual resources in a catalog by specifying an EL expression in the **Visible** field for the resource. For more information, see Section 14.3.11, "How to Show or Hide a Resource Catalog or Resource."

To filter items in a resource catalog:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, and then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, enter a name for the class, for example, `CatalogFilter`.
4. Under the Optional Attributes section, add the `oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter` interface.

5. Click **OK**.
6. Specify the logic for filtering items.

> **Note:** When implementing the filter logic it is common to want information about the current user and current page. This information can be obtained from the FacesContext.

Example 14–5 shows a sample CatalogDefinitionFilter implementation. It is configured to hide the Discussions folder (forumsFolder) for user jdoe from the custom catalog, users-catalog.xml. The entire catalog, with the ADF Faces Components and Discussions folders, is shown to all other users.

Example 14–5 Sample Showing CatalogDefinitionFilter Implementation

```
package webcenter;

import oracle.adf.rc.catalog.CatalogElement;
import oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter;

import java.util.Hashtable;

import javax.faces.context.ExternalContext;
import javax.faces.context.FacesContext;

public class CatalogFilter implements CatalogDefinitionFilter {

  public boolean includeInCatalog(CatalogElement element, Hashtable env) {

    ExternalContext ectx =
FacesContext.getCurrentInstance().getExternalContext();

    if ("jdoe".equals(ectx.getRemoteUser()) &&
"forumsFolder".equals(element.getId()))
      return false;
    else
      return true;
  }

}
```

7. In the Application Navigator, right-click the resource catalog and choose **Open**.
8. In the Design view for the resource catalog, in the Catalog panel on the left side, select the root node of the resource catalog
9. In the **Catalog Filter** field, enter the name of the Java class you created, for example, webcenter.CatalogFilter.

   This adds a definitionFilter attribute in Source view of the file.
10. Save the catalog definition file.

14.6 Deleting a Resource Catalog

If a resource catalog is no longer required within your application, you can delete it.

To delete a resource catalog, right-click the catalog in the Application Navigator and choose **Delete** from the context menu. For more information, see Section 9.4, "Deleting Portal Resources."

14.7 Defining Task Flow Parameters and Attributes of the Enclosing Show Detail Frames for Task Flows

At runtime, when you add a task flow from the resource catalog to your application page in Composer, the task flow is automatically enclosed in a `Show Detail Frame` component. You can initialize attributes, such as the title, height, or width, associated with the enclosing `Show Detail Frame` by defining those attributes in the catalog definition file that contains the task flow. To differentiate the task flow's properties from the enclosing `Show Detail Frame`'s properties, you must use `attr.` as a prefix for `Show Detail Frame` properties.

For example, if a user adds a task flow to a page with a dark background setting, the task flow continues to use the background setting of the enclosing `Show Detail Frame` component. This may not be the look the user wants. To enable the user to change the `Show Detail Frame`'s background property, you must initialize and expose the background attribute in the resource catalog. At runtime, while editing the task flow's properties, a user can also change the `Show Detail Frame`'s background attribute.

Similarly, you can also initialize task flow parameters. You can define such parameters in the catalog definition file using an EL expression. At runtime, while editing the task flow's properties, a user can also change values for the exposed parameters. To differentiate the task flow's properties from the initialized parameters, you must use `parameter.` as a prefix for such parameters.

To initialize task flow parameters and `Show Detail Frame` properties:

1. Open the catalog definition file that contains the task flow.
2. Within the task flow's `<url>` or `<resource>` element, add an `<attribute>` entry for each parameter and `Show Detail Frame` attribute you want to define.

   The `attributeId` for a parameter must contain the parameter name along with a prefix of `parameter.`; the `attributeId` for a `Show Detail Frame` attribute must contain the attribute name along with a prefix of `attr.` as shown in the following example:

```
<url visible="#{true}"
factoryClass="oracle.webcenter.portalframework.sitestructure.rc.TaskFlowResourc
eFactory"
     id="wallMiniView"

url="taskflow://oracle/webcenter/peopleconnections/wall/controller/taskflows/Wa
llViewer.xml#WallViewer">
  <attributes>
    <attribute value="WALL_MINIVIEW.TITLE" attributeId="Title" isKey="true"/>
    <attribute value="WALL_MINIVIEW.DESCRIPTION" attributeId="Description"
isKey="true"/>
    <attribute value="#{securityContext.userName}"
attributeId="parameter.userName"/>
    <attribute value="false" attributeId="attr.stretchContent"/>
    <attribute value="never" attributeId="attr.showResizer"/>
  </attributes>
  <contents/>
</url>
```

> **Note:** Include the `isKey` attribute and set it to `true` only if the value is coming from a resource bundle. If not included, the `isKey` value defaults to `false`.

3. Save the catalog definition file.

14.8 Troubleshooting Problems with Resource Catalogs

This section provides information to assist you in troubleshooting problems you may encounter while using resource catalogs.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

Resource catalog is empty.

Solution

The default catalog is not available to MDS. Ensure that the deployment profile contains the necessary entries to copy the default catalog file. Also, ensure that in the MDS section of `adf-config.xml`, a namespace entry points to the default catalog file.

Problem

A project task flow does not appear in the resource catalog.

Solution

The task flow must be packaged as an ADF Library (JAR file) and added to the project. You must also ensure that the task flow ID is given in the following format:

```
taskflow://Path_to_Task_Flow/Task_Flow_Definition_File_Name#Task_Flow_ID
```

For example:

```
taskflow://oracle/webcenter/peopleconnections/wall/controller/taskflows/WallViewer
.xml#WallViewer
```

15

Creating Pages and Adding Resources

This chapter describes how to create pages in your Portal Framework applications. It also discusses the different resources you can add to those pages to build up the content of your application.

This chapter includes the following topics:

15.1 Introduction to Pages

Pages are the fundamental building blocks of a Portal Framework application. You use the pages in a Portal Framework application to expose the different kinds of content you want to provide to your users. For more information, see Section 5.3.2, "Understanding Pages, Page Templates, and the Portal Page Hierarchy."

Pages can include content from various resources, such as:

- Portlets and pagelets
- WebCenter Portal task flows and custom task flows
- Content from UCM
- External applications
- Data controls

Adding content to the pages in your application is no different from adding content to any other web application.

15.2 Creating Pages in a WebCenter Portal Framework Application

The WebCenter Portal Framework Application template populates a new Portal Framework application with several default pages. You must add your own pages to develop your application beyond this initial framework.

Note: Always create Portal Framework application pages in JDeveloper as JSP *documents* (JSPX files) rather than JSP *pages* (JSP files). For page customizations to be stored, the page must be represented in XML. By choosing to create an XML representation of the JSP document, you ensure that customizations are always possible for the Portal Framework application page.

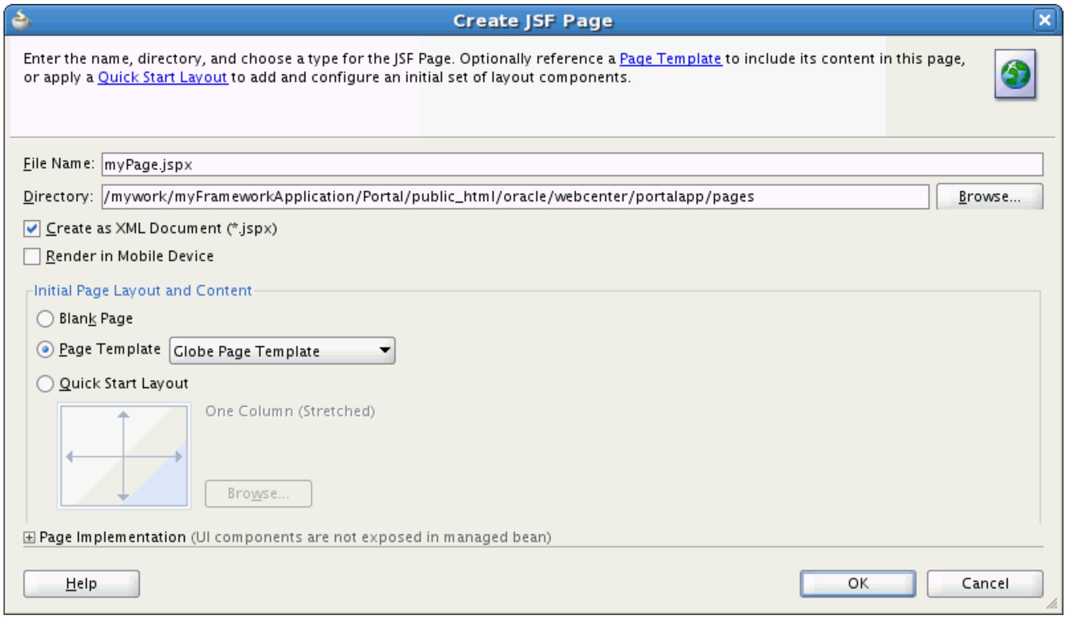
---

1. In the Application Navigator, right-click the **pages** folder (`/oracle/webcenter/portalapp/pages`) in your application project and choose **New**.

   Tip: For pages to be used in the page hierarchy, they must be located under `oracle/webcenter/portalapp`. For more information, see Section 5.3.2, "Understanding Pages, Page Templates, and the Portal Page Hierarchy."

2. In the New Gallery, expand **Web Tier,** select **JSF** and then **JSF Page,** and click **OK.**
3. In the Create JSF Page dialog (Figure 15–1), in the **File Name** field, enter a file name for the page.

Figure 15–1 The Create JSF Page Dialog



Create JSF Page

Enter the name, directory, and choose a type for the JSF Page. Optionally reference a Page Template to include its content in this page, or apply a Quick Start Layout to add and configure an initial set of layout components.

File Name: myPage.jspx

Directory: /mywork/myFrameworkApplication/Portal/public_html/oracle/webcenter/portalapp/pages

☑ Create as XML Document (*.jspx)

☐ Render in Mobile Device

Initial Page Layout and Content

○ Blank Page

● Page Template: Globe Page Template

○ Quick Start Layout

One Column (Stretched)

⊞ Page Implementation (UI components are not exposed in managed bean)

4. Select **Create as XML Document (*.jspx).**
5. In the Initial Page Layout and Content section, select **Page Template** and select the page template that you want to use to define the layout and structure of the page. For more information on page templates, see Chapter 11, "Developing Page Templates."

After you have created the page, you can edit the code to enable dynamic selection of the page template. For more information, see Section 11.5.3, "How to Enable Dynamic Switching of Page Templates at Runtime in a WebCenter Portal Framework Application."

6. Click **OK**.

For information about the other settings in this dialog that are not specific to Portal Framework application pages, see the "Creating a View Page" section in *Web User Interface Developer's Guide for Oracle Application Development Framework*.

For information about how to add general components, such as layout components, to the page, see the "How to Add ADF Faces Components to JSF Pages" section in *Web User Interface Developer's Guide for Oracle Application Development Framework*.

To enable users to edit your application's pages at runtime, you must add Composer components to it. For more information, see Chapter 18, "Enabling Runtime Editing of Pages Using Composer."

15.3 Adding WebCenter Portal Tools and Services Task Flows to a Page

WebCenter Portal tools and services enrich applications with enterprise 2.0 capabilities, including social computing services, personal productivity services, online awareness and communications, content integration, and web analytics. WebCenter Portal tools and services expose their functionality through task flows. For more information about WebCenter Portal tools and services, see Chapter 4, "Preparing Your Application for WebCenter Portal Tools and Services."

If you create your application using the WebCenter Portal Framework Application template, all the appropriate WebCenter Portal tools and services connection wizards and tag libraries are readily visible and available in the New Gallery and Component Palette. When you consume a WebCenter Portal tools and services task flow or component, the necessary libraries are automatically added to the project. Depending on the tool or service you plan to consume, your application must meet certain prerequisites. For example, if the service must know the identity of users, then your application must provide some level of security with user authentication. For more information, see Chapter 4, "Preparing Your Application for WebCenter Portal Tools and Services."

For more information about the individual WebCenter Portal tools and services and their task flows, see Table 15–1.

Table 15–1 WebCenter Portal Tools and Services - More Information

WebCenter Portal Tools and Services	More Information
Activity Graph	Chapter 46, "Integrating the Activity Graph"
Analytics	Chapter 47, "Integrating Analytics"
Announcements	Chapter 32, "Integrating Announcements"
Blogs	Section 30.4, "Integrating Blogs"
Discussions	Chapter 33, "Integrating Discussions"
Documents	Chapter 28, "Integrating Documents"
Events	Chapter 48, "Integrating Events"
Instant Messaging and Presence (IMP)	Chapter 34, "Integrating Instant Messaging and Presence"

Table 15–1 (Cont.) WebCenter Portal Tools and Services - More Information

WebCenter Portal Tools and Services	More Information
Links	Chapter 43, "Integrating Links"
Lists	Chapter 49, "Integrating Lists"
Mail	Chapter 35, "Integrating Mail"
Notifications	Chapter 50, "Integrating Notifications"
People Connections	Part VI, "Working with People Connections"
Polls	Chapter 36, "Integrating Polls"
Recent Activities	Chapter 51, "Integrating Recent Activities"
RSS	Chapter 52, "Integrating RSS"
Search	Chapter 45, "Integrating Search"
Tags	Chapter 44, "Integrating Tags"
Wikis	Section 30.3, "Integrating Wikis"
Worklists	Chapter 41, "Integrating Worklists"

> **Note:** If the WebCenter Portal tools and services task flows do not quite meet your requirements, you can customize them to change their look and feel or functionality. For example, you can add text, change labels, remove regions or components, or show additional attributes. For more information, see Chapter 23, "Customizing WebCenter Portal Tools and Services Task Flows."

15.4 Adding Custom Task Flows to a Page

Task flows, like pages, are containers in which you can add components such as portlets, content, and other task flows. You can add task flows to pages or other task flows. Task flows created in JDeveloper can be included in resource catalogs so that users can add them to pages or other task flows at runtime.

You can drag and drop a custom task flow into a resource catalog so that it is available for users to add to pages or task flows at runtime. For more information, see Section 14.3.2, "How to Drag and Drop a Resource into a Resource Catalog." When you deploy the application, the task flow is also deployed to the target instance.

For detailed information about creating different types of ADF task flows, see the "Creating ADF Task Flows" part in *Fusion Developer's Guide for Oracle Application Development Framework*.

You cannot directly upload a task flow created in and exported from JDeveloper into an already deployed application, but you can import a task flow created at runtime into JDeveloper, modify it, and export it back to the deployed application.

Exposing Task Flows Created in JDeveloper to a Deployed Application

If you create a custom task flow in JDeveloper and want to expose it in an already deployed application, you must deploy the project containing the task flow as an ADF shared library to the runtime application. Once the library containing the task flow is accessible to the application, it is included in the runtime Resource Registry and can be added to custom resource catalogs from there.

Note: Permissions to view or edit a task flow are not provisioned by default when you create the task flow. To ensure that a task flow is visible at runtime, prior to deploying as a shared library, you must grant at least the View privilege on the task flow. For more information, see Section 22.6.1, "Granting Permissions on Task Flows."

For the steps to deploy an application to a Portal Framework application as a shared library, see the "Deploying the Application to a WebLogic Managed Server" section in *Administering Oracle WebCenter Portal*. However, while running the Install Application Assistant, on the Choose targeting style page, select **Install this deployment as a library**.

For the steps to deploy an application to a WebCenter Portal instance, see Section 55.2.5, "Deploying Extensions to the WebCenter Portal Shared Library (extend.spaces.webapp.war)."

15.5 Adding Content from WebCenter Content to a Page

To provide access to the content in your WebCenter Content content repository, you must create a connection to the WebCenter Content. For more information, see Section 25.2.1, "Creating a Content Repository Connection Based on the Oracle Content Server Adapter."

With a connection to WebCenter Content established, you can provider users with a user-friendly interface to manage, display, and search documents at runtime. For more information, see Chapter 28, "Integrating Documents."

Next, add one of the content task flows or document components to your page to expose the content from WebCenter Content. Content task flows include Content Presenter and the documents task flows:

- Content Presenter
- Document Explorer
- Document List Viewer
- Document Manager
- Document Navigator
- Folder Viewer
- Recent Documents
- Document Viewer
- Document Mini Properties
- Document Properties
- Rich Text Editor
- Document Upload
- Document Version History
- AutoVue

Document components include:

- Document Link

- Document Inline Frame
- Document Image

For more information about the Content Presenter task flow, see Section 29.1, "Understanding the Content Presenter Task Flow." For more information about the documents task flows, see Section 29.2, "Understanding the Documents Task Flows." For more information about document components, see Section 29.3, "Understanding Document Components."

If you use the Content Presenter task flow, you may also want to create your own Content Presenter display templates. Content Presenter display templates define how content repository items should be rendered on a page. For more information, see Chapter 27, "Creating Content Presenter Display Templates."

15.6 Adding Portlets to a Page

A portlet is a reusable web component that can draw content from many different sources. Portlets provide a way of presenting data from multiple sources in a meaningful and related way. For more information about portlets, see Chapter 57, "Introduction to Portlets."

To add a portlet to your application, you must first register the portlet's producer with the Portal Framework application. For more information, see Section 63.2, "Registering Portlet Producers with a WebCenter Portal Framework Application."

After you have registered the portlet producer, you can then drag and drop any portlets that you want to include in your application onto the appropriate page. For more information, see Section 63.5, "Adding Portlets to a Page."

15.7 Adding Pagelets to a Page

A pagelet is similar to a portlet, but while portlets were designed specifically for portals, pagelets can be run on any web page, including within a portal or other web application. Pagelets can be used to expose platform-specific portlets in other web environments.

For more information about adding pagelets to your pages, see Section 62.7, "Using Pagelets in Web Applications."

15.8 Adding Data Controls to a Page

Data controls are used to retrieve information from different data sources and create user interface (UI) components within your Portal Framework application. A data control provides you with easy-to-use methods that you can drag and drop onto JSF pages to publish content as ADF components, such as URLs, files, and folders. To add content from a data source to a JSF page, you must first create a connection to the data source, then use the connection to create a data control based on the repository.

You can create custom data controls to connect to different data sources and add them to your application pages or task flows. For detailed information about data controls, see the *Fusion Developer's Guide for Oracle Application Development Framework*.

You cannot directly upload a data control created in and exported from JDeveloper into an already deployed application. Neither can you import a data control created at runtime into JDeveloper.

Some WebCenter Portal tools and services provide data controls for creating customized visualizations of the tool or service. For information about consuming these data controls in your application, see Section 4.1.3, "Using WebCenter Portal Data Controls."

Exposing Data Controls for Consumption in an Already Deployed Application

The runtime Resource Registry in a Portal Framework application contains a `Design Time Data Controls` folder by default. This folder exposes the seeded WebCenter Portal tools and services data controls and any other data controls that were added to the application before it was deployed. To expose a new data control in an already deployed Portal Framework application, you must deploy the project containing the data control as an ADF shared library to the runtime application. Once the library containing the data control is accessible to the application, it is displayed in the runtime Resource Registry and can be added to custom resource catalogs from there.

For the steps to deploy an application to a Portal Framework application as a shared library, see the "Deploying Applications Using the WLS Administration Console" section in *Administering Oracle WebCenter Portal*. However, while running the Install Application Assistant, on the Choose targeting style page, select **Install this deployment as a library**.

For the steps to deploy an application to a WebCenter Portal instance, see Section 55.2.5, "Deploying Extensions to the WebCenter Portal Shared Library (extend.spaces.webapp.war)."

15.9 Using External Applications

If the resources you add to your pages require access to applications that define their own authentication processes, you can add external applications to replicate a single sign-on experience for users.

For example, your page might include portlets that point to applications that require a separate login. Or, if your page includes the Mail task flow, you must identify an external application to map the mail server user to the application user so that the user does not have to log in separately every time.

The first time a user accesses the external application, he or she is prompted for a user name and password for the external application. These credentials are then mapped to the user and stored securely in a credential store. The credential store subsequently supplies these credentials during authentication to the external application. Unless the external application's credentials change, the user supplies the credentials only once as the mapped information is read from the credential store for future requests.

For more information, see Section 74.13, "Working with External Applications."

Part III

Customizing Your Application and Extending Customization Options

Part III contains the following chapters:

- Chapter 16, "Using WebCenter Portal Composer"
- Chapter 17, "Enabling Runtime Creation and Management of Pages"
- Chapter 18, "Enabling Runtime Editing of Pages Using Composer"
- Chapter 19, "Extending Runtime Editing Capabilities Using Composer"
- Chapter 20, "Performing Advanced Composer Configurations"
- Chapter 21, "Performing Composer-Specific MDS Configurations"
- Chapter 22, "Modifying Default Security Behavior of Composer Components"
- Chapter 23, "Customizing WebCenter Portal Tools and Services Task Flows"

16

Using WebCenter Portal Composer

This chapter introduces Oracle WebCenter Portal's Composer and describes the various tasks it supports at runtime.

This chapter contains the following topics:

16.1 Introduction to Composer

Composer is a fully-integrated page editor for adding and editing page content at application runtime. To understand the functions of Composer, let us first look at a typical application development lifecycle, which comprises the following stages:

- Application developers create applications at *design time*.

  Design time traditionally represents an integrated development environment (IDE) for creating or editing applications. For Oracle WebCenter Portal, Oracle JDeveloper provides the design-time environment.

- Application administrators deploy these applications to managed servers.
- End users access the deployed applications at *runtime*.

  Runtime represents a browser-based environment used for accessing web applications.

You can see that each stage involves different categories of users. Many times, some or all of these users may want to modify pages at runtime. For example, consider a dashboard-like application that displays information pertaining to the logged-in user, for example a worklist and a mail task flow. The page developer creates the dashboard page and populates it with the required components and task flows. An application administrator deploys the application to a customer site. At the customer site, people at different levels in the organization view the dashboard and make the following requests:

- Department administrators want to add a "Department News" task flow.
- Line of business (LOB) administrators want to add an "Expense Incurred by Self/Directs" task flow.

  Line of business capabilities are administration capabilities that can be done by a business analyst or equivalent position. LOB administrators are able to perform administrative tasks that do not require top-level administration capabilities to complete.
- The country site administrator wants to add a task flow displaying the respective country's operations or rules.

In addition, content contributors, moderators, and end users may want to add, delete, or modify page artifacts based on the business needs. In a typical application development environment, these requests are passed on to the page developer. The developer modifies the application in the development environment and redeploys it to the customer site.

Rather than pushing simple modifications back to the developer, Composer, in conjunction with Metadata Services (MDS), provides an editing tool that enables business users to edit application pages at runtime. Changes made at runtime are saved as metadata, separate from the base application definitions. This concept of editing application pages at runtime is referred to as *design time at runtime*. It minimizes the need to modify the application at design time and redeploy it.

Composer provides components for controlling an application's design time at runtime behavior. This chapter describes the basic concepts and terminology you'll need to use Composer effectively.

16.2 Understanding Application and User Customizations

When a user modifies a page at runtime, the changes are typically available only to that user. You can configure your application to make runtime modifications available to all or a subset of users accessing the page. Consider an example of a dashboard page displaying details about the expenses incurred by LOB members. If the LOB administrator modifies the page and adds some expensing guidelines, the changes must be visible to all members. To address such requirements, Composer enables you to edit pages in different modes so that changes are saved as *user customizations* (that affect only the individual user's view of the page) or *application customizations* (that affect everyone's view of the page).

To save changes as either user customizations or application customizations requires that they be saved separately at the back end. In the metadata domain, MDS allows for the saving of customizations in separate layers on top of the base application definitions. Depending on the business requirement, you can save changes in a single layer or in multiple layers.

In a single-layer configuration, changes are saved as application customizations to a common layer that is accessible to all users. In this case, you cannot allow for changes to be saved as user customizations.

In a multiple-layer configuration, changes are saved at separate locations based on specified criteria such as the mode in which the page is edited, the user editing the page, or the user role. In this type of configuration, each customization layer is insulated from the other, but the layers can be stacked over each other to provide flexibility during upgrades. For example, a user may want to change the default theme of the page being viewed. It is expected that this change be saved only for this user, without affecting others' view of the page. Therefore, you can set up things so that changes made by end users who have Personalize privilege on the page are saved as user customizations, and changes made by logged-in users with customization-level privileges are saved as application customizations. You can decide which tasks are available to users with Personalize and Customize/Edit privileges respectively.

For more information about MDS and customization layers, see Section 21.1, "Introduction to MDS."

16.3 Understanding the Edit Mode and View Mode of a Page

When a user opens an application page in a browser, the page opens in *View mode*. Composer provides access to another mode called *Edit mode* to enable users with appropriate privileges to edit application pages. These modes are described in detail:

- **Edit mode**: The mode typically available to authenticated users with access privileges to edit page content. In addition to the standard tasks that can be performed in View mode, Composer provides controls for switching to Edit mode and performing tasks such as adding components, deleting components, and editing component properties. Typically, changes made to the page in Edit mode are saved as application customizations and are available for all users accessing the page.
- **View mode**: The default view of a page when opened in a browser. In this mode, users can perform tasks such as rearranging components, collapsing and expanding components, and changing the layout. Typically, changes made to a page in View mode are available for that user alone and are saved as user customizations.

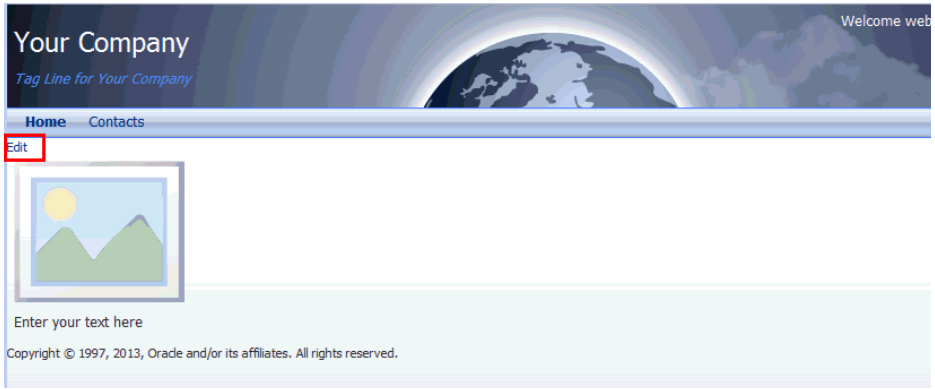
16.3.1 About Edit Mode

Composer's Edit mode provides a wide range of application customization capabilities. In Edit mode, users can add content, edit page and component properties, delete components, rearrange components, change the page layout, and so on.

You can provide the capabilities described in this chapter to your application by adding the following Composer design-time components to a page: `Change Mode Link` or `Change Mode Button`, `Page Customizable`, `Panel Customizable`, `Show Detail Frame`, `Custom Actions`, and `Layout Customizable`. For more information about these components, see Section 16.7, "Composer Components."

When you add the `Change Mode Link` or `Change Mode Button` component to a page that can be customized, an Edit link appears in View mode of the page in Composer. When users click the Edit link or button, the page opens in Edit mode of Composer. Figure 16–1 shows an Edit link on a page in View mode.

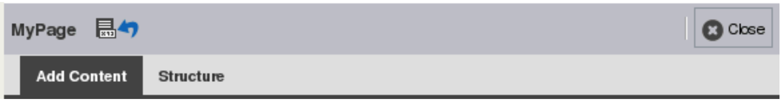
Figure 16–1 Edit Link While in View Mode



Copyright © 1997, 2013, Oracle and/or its affiliates. All rights reserved.

In Edit mode, the default Composer toolbar displays the title of the page being edited, **Page Properties** icon, **Reset Page** icon, and the **Close** button (Figure 16–2).

Figure 16–2 Composer Toolbar



By default, the page Edit mode provides two views: Add Content and Structure. However, you can configure your pages to display any or all of the following views: Design, Add Content, Structure, Select, and Preview. You use the `DesignViews` attribute to specify the views to display in Edit mode. If you specify the value as `all`, all the views become available in Edit mode except Add Content view.

For enhanced functionality, it is recommended that you configure your pages to display all the views in Composer. For information about the `DesignViews` attribute used for specifying the views to display in Edit mode, see Table B–1, " Attributes of a Page Customizable Component".

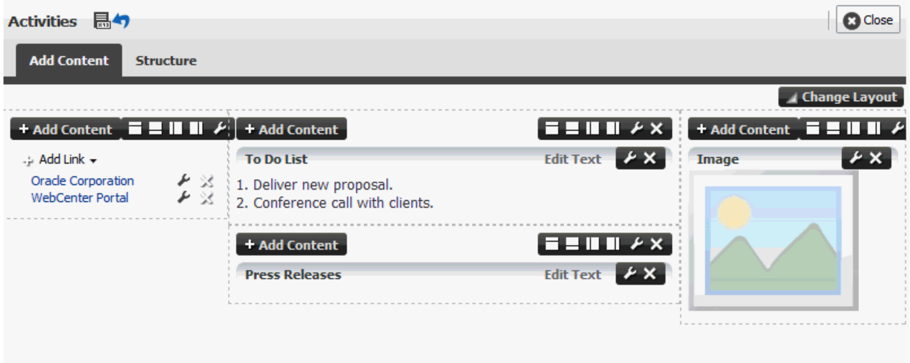
This section contains the following subsections:

- Section 16.3.1.1, "About Add Content View in Edit Mode"
- Section 16.3.1.2, "About Structure View in Edit Mode"
- Section 16.3.1.3, "About Design View in Edit Mode"
- Section 16.3.1.4, "About Select View in Edit Mode"
- Section 16.3.1.5, "About Preview View in Edit Mode"

16.3.1.1 About Add Content View in Edit Mode

The *Add Content view* is the default view when you open a page in Composer. It provides a WYSIWYG rendering of the page and its content, where controls are directly selectable on each component.

Figure 16–3 Add Content View of Composer



1. Deliver new proposal.
2. Conference call with clients.

16.3.1.2 About Structure View in Edit Mode

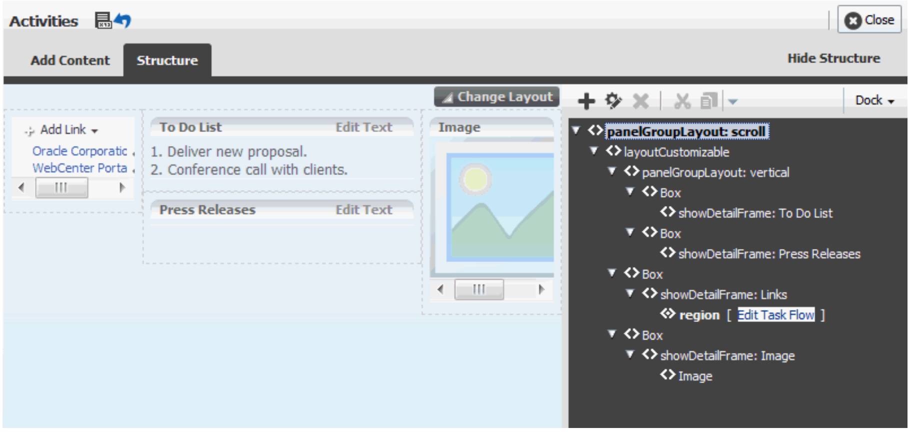
The *Structure view* provides a combined WYSIWYG and hierarchical rendering of page components, where controls are available in the toolbar of the page structure pane to add, edit, delete, hide, and rearrange page components (Figure 16–4).

Note: The `childCreation` attribute determines whether the children of popup dialogs can be viewed in Composer. By default, this attribute is set to `deferred` and users are unable to see the children of popup dialogs. Setting the value to `immediate` allows users to view the children of popup dialogs.

There is a performance impact by setting the `childrenCreation` attribute to `immediate`. If you do not need to use the popup on the page, using the default setting of `deferred` will avoid the penalty of CPU and memory usage when it is not needed. Note that the popup will be shown non-modally, thus, the application must be able to handle that fact without error.

For more information, see Section G.13, "EL Expressions Relevant to Composer" in Chapter G, "Expression Language Expressions."

Figure 16–4 Structure View of Page Edit Mode



1. Deliver new proposal.
2. Conference call with clients.

16.3.1.3 About Design View in Edit Mode

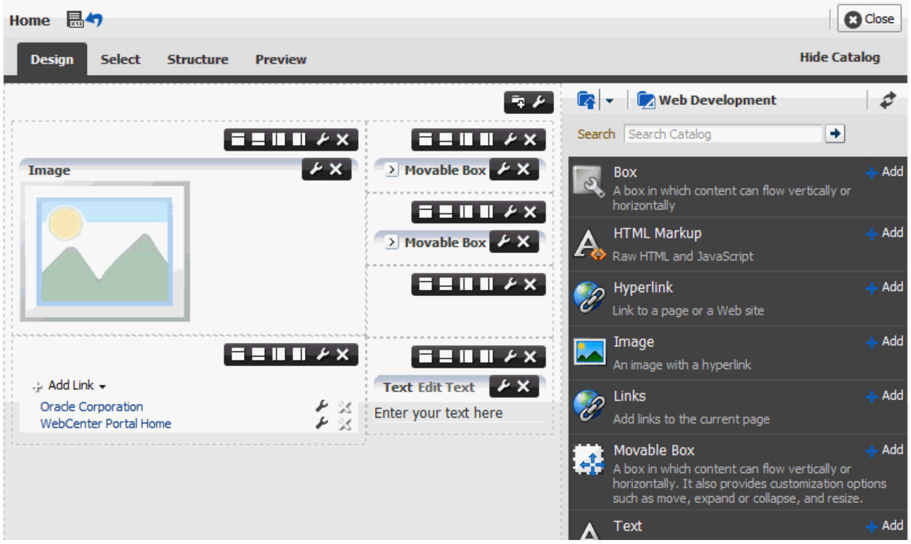
The *Design view* provides a WYSIWYG rendering of the page and its content, where controls are directly selectable on each component. The resource catalog displays inline on the right side of the page, where you can select components to add to the page (Figure 16–5).

You can choose to hide the inline resource catalog, and instead show each area of the page with an **Add Content** button to help you identify where you can add components.

Design view is not available in Edit mode by default. You can enable it by setting the value of the `DesignViews` attribute of the `Page Customizable` component to `design` or `all`. For information, see Appendix B.1.1, "Page Customizable Component."

If you choose to display Design view, it is rendered as the default view, and Add Content view is not displayed in Edit mode.

Figure 16–5 Design View of Composer



Box — A box in which content can flow vertically or horizontally — Add

HTML Markup — Raw HTML and JavaScript — Add

Hyperlink — Link to a page or a Web site — Add

Image — An image with a hyperlink — Add

Links — Add links to the current page — Add

Movable Box — A box in which content can flow vertically or horizontally. It also provides customization options such as move, expand or collapse, and resize. — Add

Text — Add

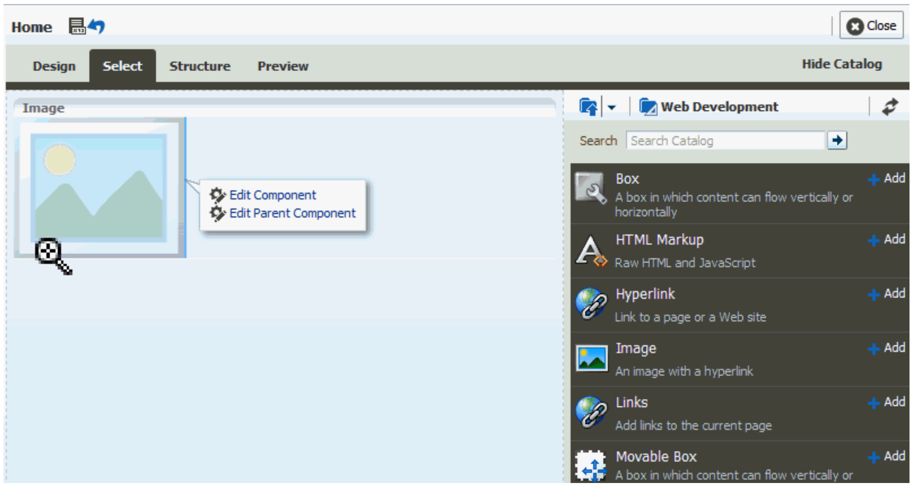
16.3.1.4 About Select View in Edit Mode

The *Select view* provides a WYSIWYG rendering of the page and its content, where you can select a component for quick access to its properties or the properties of its parent component. You cannot delete a component in Select view.

Just like Design view, the resource catalog displays inline on the right side of the page, where you can select components to add to the page (Figure 16–6).

In Edit mode, Select view is not available by default. You can enable it by setting the value of the `DesignViews` attribute of the `Page Customizable` component to `select` or `all`. For information, see Appendix B.1.1, "Page Customizable Component."

Figure 16–6 Select View of Page Edit Mode



16.3.1.5 About Preview View in Edit Mode

The *Preview view* displays a preview of the published page, as it will appear in your application.

In Edit mode, Preview view is not available by default. You can enable it by setting the value of the `DesignViews` attribute of the `Page Customizable` component to `preview` or `all`. For information, see Appendix B.1.1, "Page Customizable Component."

16.4 Customizing Capabilities in Page View Mode

Composer enables users to customize pages in View and Edit modes. This section provides an overview of user customization tasks you can enable for users in page View mode. Such tasks include rearranging components, collapsing and expanding components, and changing the page layout. You can enable the capabilities described in this section by adding the following Composer design-time components to a page: `Panel Customizable`, `Show Detail Frame`, `Custom Actions`, and `Layout Customizable`. For information about these components, see Section 16.7, "Composer Components." Changes made to a page in View mode are available only to the user making these changes.

This section contains the following subsections:

- Section 16.4.1, "Rearrange Components"
- Section 16.4.2, "Change the Layout"
- Section 16.4.3, "Expand and Collapse Components"

Note: For a detailed description of the editing tasks that you can perform on a page, see the "Creating and Editing a Portal Page" chapter in *Building Portals with Oracle WebCenter Portal*.

16.4.1 Rearrange Components

This capability allows users to organize page components so that the content most useful to them displays at the top of the page. Users can rearrange components in two ways:

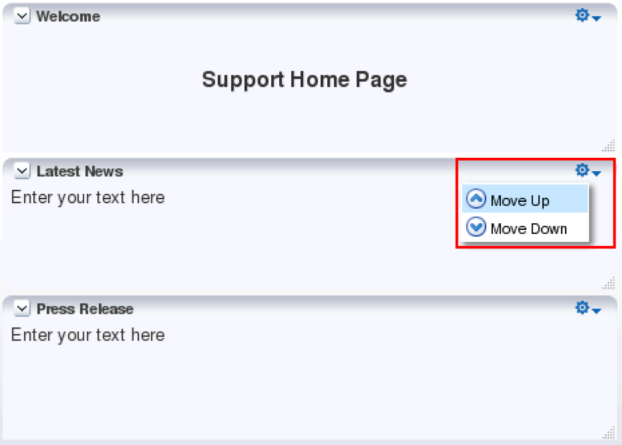
- Dragging and dropping

Users can rearrange components by dragging and dropping them within the Panel Customizable component or across Panel Customizable components on the page. As it is difficult to identify a Panel Customizable component in View mode, users can simply drag the component over the spot they want to place it. A solid box indicates a receptive drop location.

- Using the **Actions** menu

  The Move actions on a Show Detail Frame or portlet component enable users to move these components within a parent Panel Customizable component. If a Panel Customizable has multiple child components, then a child Show Detail Frame or portlet can be moved to the left and right or above and below, relative to the position of other child components. Figure 16–7 shows a sample Show Detail Frame component with Move Up and Move Down actions. In this example, selecting **Move Down** moves the Latest News component immediately below the Press Release component.

Figure 16–7 Actions Menu on a Show Detail Frame



16.4.2 Change the Layout

This capability allows users to switch between a set of predefined layouts provided by Composer. Through the use of the **Change Layout** icon, users can choose among eight different layouts to suit their needs and preferences. The Layout Customizable component in the Composer library enables the display of a **Change Layout** icon on the page, as shown in Figure 16–8.

Figure 16–8 Change Layout Icon

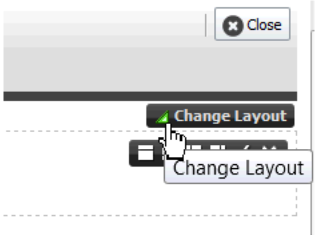


Figure 16–9 shows the layout options available with the Layout Customizable component. A gray colored border highlights the layout currently applied to the page or area.

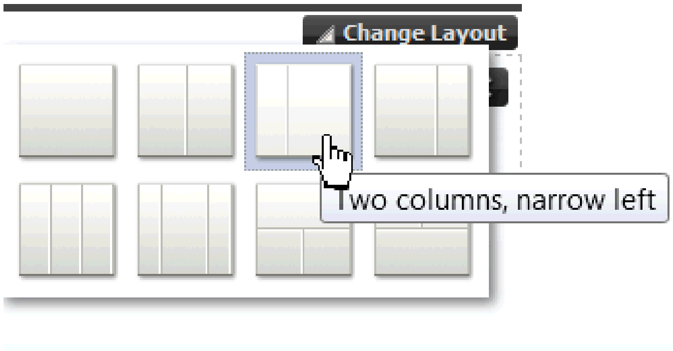
Figure 16–9 Layout Options

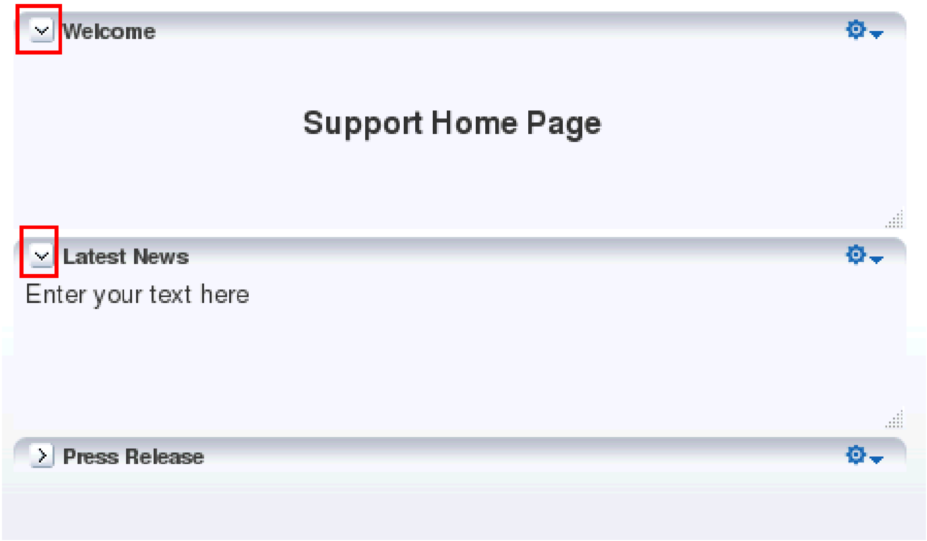


16.4.3 Expand and Collapse Components

By enabling expand and collapse components on a page, you can include more detailed information on a page without cluttering its visual appearance. Users can collapse and expand the components as desired.

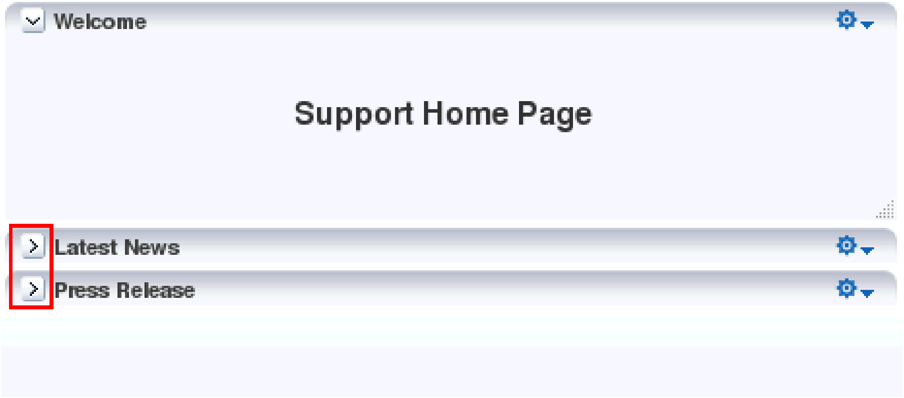
A **Collapse** icon on the header of a `Show Detail Frame` or portlet enables users to collapse such a component and display only its header. Figure 16–10 shows the **Collapse** icons on `Show Detail Frame` components.

Figure 16–10 Collapse Icon on a Show Detail Frame



The **Expand** icon on a collapsed component enables users to disclose the component so that it displays the header and content. Figure 16–11 shows the **Expand** icons on two collapsed `Show Detail Frame` components.

Figure 16–11 Expand Icon on a Show Detail Frame



16.5 Editing Capabilities in Design View and Add Content View in Page Edit Mode

This section describes the editing capabilities that Composer provides in page Edit mode. It contains the following subsections:

- Section 16.5.1, "Add Content"
- Section 16.5.2, "Rearrange Page Content"
- Section 16.5.3, "Edit Component Properties and Parameters"
- Section 16.5.4, "Reset and Override Component Properties in the Current Layer"
- Section 16.5.5, "Edit Resource Strings"
- Section 16.5.6, "Show or Hide Components"
- Section 16.5.7, "Delete Components"
- Section 16.5.8, "Change the Layout"
- Section 16.5.9, "Edit Page Properties"
- Section 16.5.10, "Wire Components to Page Parameters"
- Section 16.5.11, "Reset Page"
- Section 16.5.12, "Reset Application Customizations on Detecting Errors"
- Section 16.5.13, "Customize the Display Name of Child Components"
- Section 16.5.14, "Create Labels On Saving Application Customizations"
- Section 16.5.15, "Manage Application Customizations"

Note: You can restrict users from performing all or some of these tasks by securing the application and applying customization restrictions on components. For more information, see Section 16.8, "Security and Composer."

For a detailed description of the runtime editing tasks that users can perform on a page, see the "Editing a Page" section in *Building Portals with Oracle WebCenter Portal*.

16.5.1 Add Content

Authorized users may want to add custom content to the page, such as a portlet displaying news, for example, or stock updates. Composer enables users to add content within any container in Edit mode. Oracle WebCenter Portal's resource catalog, also known as *Oracle Business Dictionary*, contains resources that users can add to a page. These include documents, Oracle ADF components, portlets, and task flows. The catalog can be invoked in the following ways in Edit mode of a page:

- In Add Content and Design views, by clicking the **Add Content** button on any container component on the page.

  In Design view, by default an inline resource catalog is available, but you can hide it to show each area of the page with an Add Content button to help you identify where you can add components.

- In Structure view, by selecting a container component and clicking the **Add content into the selected component** icon in the Structure view toolbar.

> **Notes:** If you restrict customization on a container component, then users cannot add components inside it at runtime. See Section 22.1, "Applying Component-Level Restrictions by Defining Customization Policies" for more information.

Figure 16–12 shows the Add Content dialog in a Portal Framework application.

UI Components
Task flows, Pagelets and Portlets

Web Development
Web development

The Add Content dialog contains folders and components. An **Open** link next to an item in the catalog indicates that the item is a folder. Authorized users can drill down into the folder by clicking this link. An **Add** link next to an item indicates that the item can be added to the page. An Add link can appear next to a component or a folder. The component is added as the first child in the container on which the Add Content link was clicked.

Note: The **Top** icon in the dialog enables users to return to a top-level folder.

If you configure drop handlers for adding resources to the page, the Add link shows a context menu with different options for adding the component to the page. For more information, see Section 19.6, "Configuring Event Handlers for Composer UI Events."

Depending on its configuration, the dialog exposes all or a subset of the following components to authorized users:

Note: For information, see Chapter 14, "Developing Resource Catalogs."

- ADF Faces Components

  The Web Development folder provides `Box` and `Movable Box` components that are analogous to the JDeveloper design time components `Panel Customizable` and `Show Detail Frame`. In JDeveloper, these components are available in the Composer tag library.

  > **Note:** `Panel Customizable` and `Show Detail Frame` components added to the page at design time continue to be called the same. These components are not denoted as `Box` and `Movable Box` components respectively at runtime.

  This folder also provides `HTML Markup`, `Hyperlink`, `Image`, `Text`, and `Web Page` components that are analogous to the JDeveloper design time components `Output Text`, `Go Link`, `Go Image Link`, `Rich Text Editor`, and `Inline Frame` respectively. In JDeveloper, these components are available in the ADF Faces tag library.

  The **Web Development** folder in the catalog contains these components, as shown in Figure 16–13.

Figure 16–13 ADF Faces Components You Can Add to a Page

Movable Box — A box in which content can flow vertically or horizontally. It also provides customization options such as move, expand or collapse, and resize. — + Add

Text — Formatted text — + Add

Web Page — Includes another Web page — + Add

Close

- Task Flows

Authorized users can add custom task flows and out-of-the-box WebCenter Portal tools and service task flows to the page. A task flow added to a page is automatically enclosed in a `Movable Box` component. As a result, the task flow displays a header with options to move or delete the component.

> **Note:** The `Movable Box` component surrounding a task flow is displayed only if the task flow is displayed on the page. That is, if you do not grant even View permission on a task flow, the Movable Box surrounding it is also not displayed on the page.

- Portlets

  The **Portlets** folder lists all the registered producers. Authorized users can navigate to the required portlet and add it to the page. The Portlets folder exposes portlets from any Java-PDK or WSRP producer that was registered in Oracle JDeveloper. For information about registering portlet producers, see Chapter 63, "Consuming Portlets."

- Documents

  The **Content Management** folder lists documents and folders that users can add to the page.

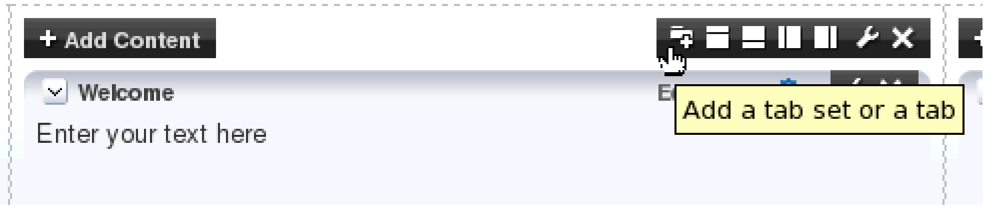
For more information, see the "Working with Web Development Components on a Page" section in *Building Portals with Oracle WebCenter Portal*.

16.5.1.1 Add a Tab Set or a Tab to a Box Component

The toolbar on the `Box` component provides an option (Figure 16–14) to add a tab or a set of tabs to the `Box` component. Use tabs to add content regions as separate layers on the page. Each new tab is placed as a layer below the currently selected tab and contains a region that can be populated with content.

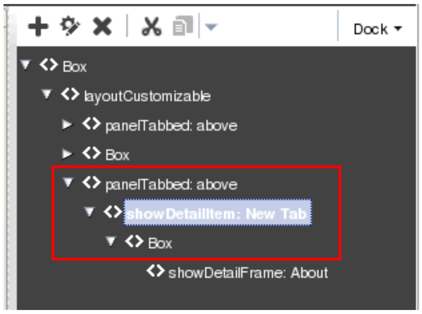
The **Add a tab set or a tab** icon is available when the `showTabAction` attribute of a `Panel Customizable` component is set to `true`.

Figure 16–14 Add Tab Set or a Tab Icon on a Box Component



When a user clicks the **Add a tab set or a tab** icon on the `Box` component, Composer adds a tab around the `Box` component. In Structure view, the `Box` component is nested inside a `Show Detail Item` component, which in turn is nested inside a `Panel Tabbed` component, as shown in Figure 16–15. Users can add any number of tabs in this way.

Figure 16–15 Tab Component in Structure View



```
▼ <> Box
  ▼ <> layoutCustomizable
    ► <> panelTabbed: above
    ► <> Box
    ▼ <> panelTabbed: above
      ▼ <> showDetailItem: New Tab
        ▼ <> Box
            <> showDetailFrame: About
```

The first tab that a user adds will surround the selected `Box` component. Each subsequent tab will contain a new `Box` component inside it.

Authorized users can delete a tab by clicking the **Delete** icon on a tab in Add Content or Design view. On deleting the last tab, the `Panel Tabbed` component is deleted from the page. Alternatively, the tab set can be deleted by deleting the `Panel Tabbed` component in Structure view. To delete only the tab without deleting the `Box` inside it, users must move (cut and paste) the `Box` outside the `Panel Tabbed` component first and then delete the `Panel Tabbed` component.

16.5.1.2 Add Box Components Adjacent to Existing Ones

A toolbar on the `Box` component in Add Content and Design view provides options to add another `Box` component before or after the component. This capability enables users to modify the layout of components on the page.

When a user clicks an **Add** icon on the `Box` component, Composer adds another `Box` component before or after it and surrounds both `Box` components with a `Panel Group Layout`. Depending on the icon used, the new `Box` component is added to the left, right, above, or below the original `Box` component, and the `layout` attribute on the parent `Panel Group Layout` component is set to `horizontal` or `vertical`. Users can add many contiguous `Box` components in this way. Every time the orientation changes for new a `Box` component, a new `Panel Group Layout` with the appropriate layout setting (horizontal or vertical) is added around the new and the existing `Box` components.

Note: The Add icons are not rendered on the component if:

- The `allowAction` attribute on the `Panel Customizable` component is set to `false`
- The `Panel Customizable` is stretched
- The `Panel Customizable` component is restricted

For more information, see Chapter 22, "Modifying Default Security Behavior of Composer Components."

Users can delete `Box` components that they added using the Add icons, in Add Content, Design, and Structure views.

Note: If the `Panel Group Layout` has only two `Box` components and you delete one of them, then the `Panel Group Layout` is also deleted.

The Box component toolbar contains the following Add Box icons in addition to the Edit icon:

- Add Box Above
- Add Box Below
- Add Box Left
- Add Box Right

16.5.1.2.1 Add Box Above Clicking the **Add box above** icon (Figure 16–16) adds a Box component above the selected Box component. The layout attribute on the Panel Group Layout is set to vertical.

Figure 16–16 Add Box Above Icon on a Box Component

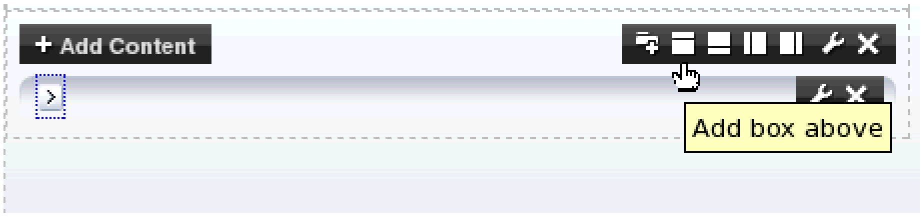


Figure 16–17 shows how the Box component appears in Structure view before adding another Box component adjacent to it.

Figure 16–17 Box Component Before Adding Another One Adjacent to It

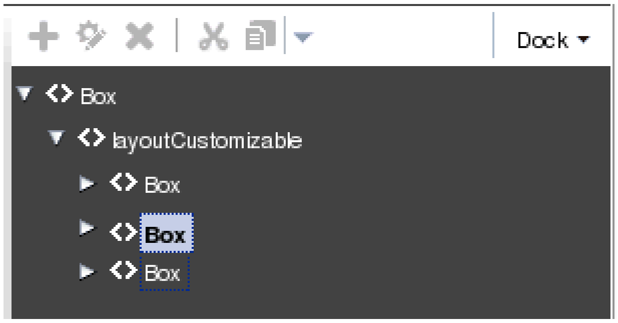

Figure 16–18 shows the two Box components vertically aligned in the component navigator.

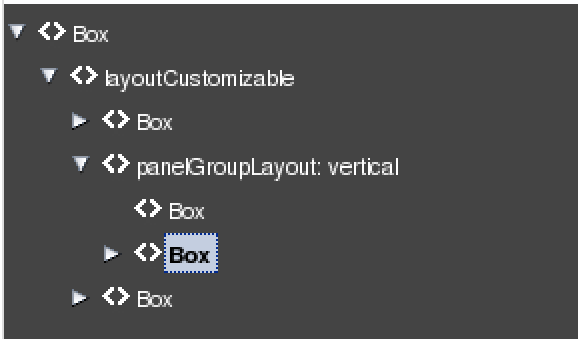
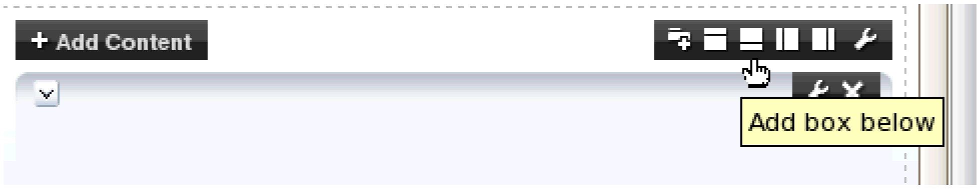
Figure 16–18 Box Component Added Above



Users can click the **Add box above** icon repeatedly to add many contiguous Box components vertically within the same parent Panel Group Layout.

16.5.1.2.2 Add Box Below Clicking the **Add box below** icon (Figure 16–19) adds a Box component below the selected Box component. The layout attribute on the Panel Group Layout is set to vertical.

Figure 16–19 Add Box Below Icon on a Box Component



Users can click the **Add box below** icon repeatedly to add many contiguous Box components vertically within the same parent Panel Group Layout.

16.5.1.2.3 Add Box Left Clicking the **Add box left** icon (Figure 16–20) adds another Box component to the left of the selected Box component. The layout attribute on the Panel Group Layout is set to horizontal.

Figure 16–20 Add Box Left Icon on a Box Component

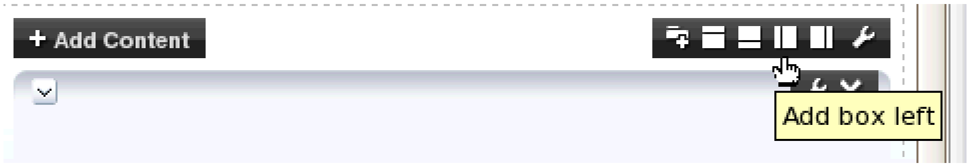


Figure 16–21 shows the two Box components horizontally aligned in the component navigator.

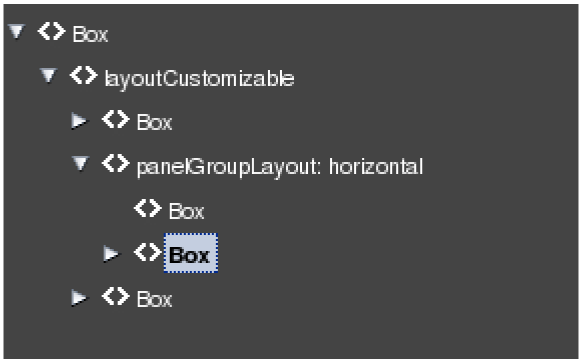
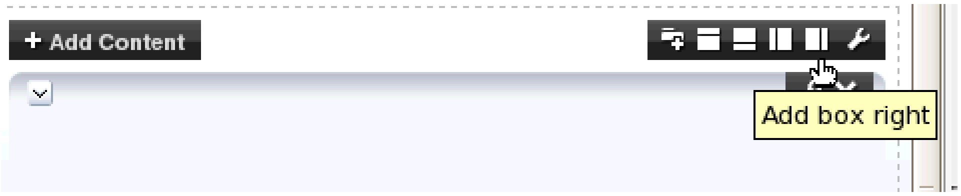
Figure 16–21 Box Component Added to the Left



Users can click the **Add Box Left** icon repeatedly to add many contiguous Box components horizontally within the same parent Panel Group Layout.

16.5.1.2.4 Add Box Right Clicking the **Add box right** icon (Figure 16–22) adds another Box component to the right of the selected Box component. The layout attribute on the Panel Group Layout is set to horizontal.

Figure 16–22 Add Box Right Icon on a Box Component



Users can click the **Add box right** icon repeatedly to add many contiguous `Box` components horizontally within the same parent `Panel Group Layout`.

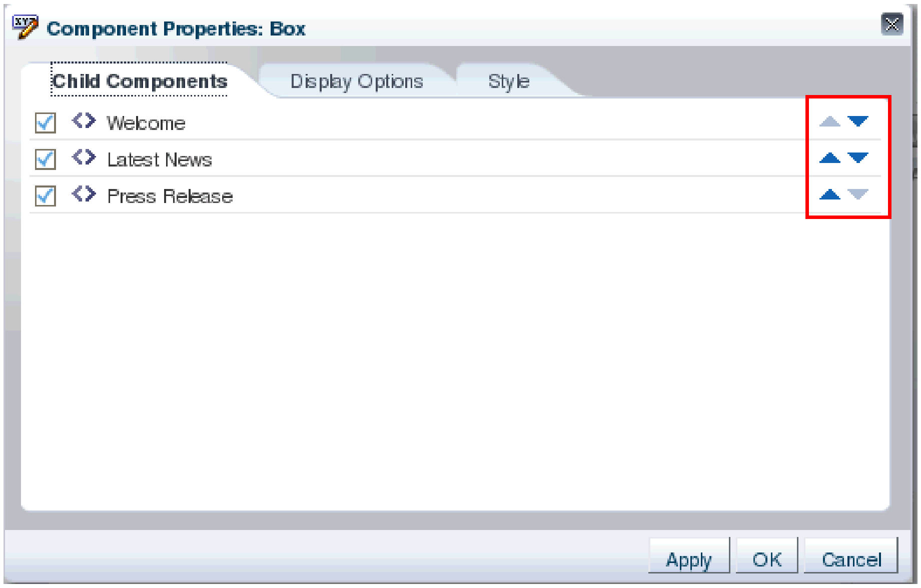
16.5.2 Rearrange Page Content

This capability allows users to organize page components based on where they are easiest to use; for example, users can move content most useful to them to the top of the page. In Add Content and Design views, users can rearrange content on the page in the following ways:

- Drag and drop a component within the same `Panel Customizable` component or across `Panel Customizable` (or `Box`) components on the page.
- Use the Move actions on the Actions menu of a `Show Detail Frame` or portlet to move it within the parent `Panel Customizable` component. Depending on the number of child components in the `Panel Customizable` and how these components are oriented, a component can be moved to the left and right, or up and down.
- To resequence components within a container, in the Component Properties dialog for the container, click the Child Components tab and use the up and down arrows shown against each child component (Figure 16–23).

> **Notes:** A component on which customization is restricted, can be rearranged inside its parent container if the parent is customizable.
>
> The Child Components tab displays a list of direct child components at the top (Components list) of the tab, followed by a list of all facets defined for the component (Fixed Components list). There are no up and down arrows against facet components as these components cannot be rearranged. The Fixed Components list is displayed only if the component contains facets.

Figure 16–23 Resequencing Options on the Child Components Tab of a Container



16.5.3 Edit Component Properties and Parameters

The Component Properties dialog enables users to edit component properties and the parameters associated with components, such as portlets and task flows.

Note: A component cannot be edited if:

- The `Id` attribute was not set for the component at design time
- The component or any of its attributes have been restricted

  For information about restricting customization, see Chapter 22, "Modifying Default Security Behavior of Composer Components."
- It is a component from the ADF Faces library

In Add Content and Design views, clicking the **Edit** icon on a component displays the Component Properties dialog, shown in Figure 16–24.

Customized in the current context

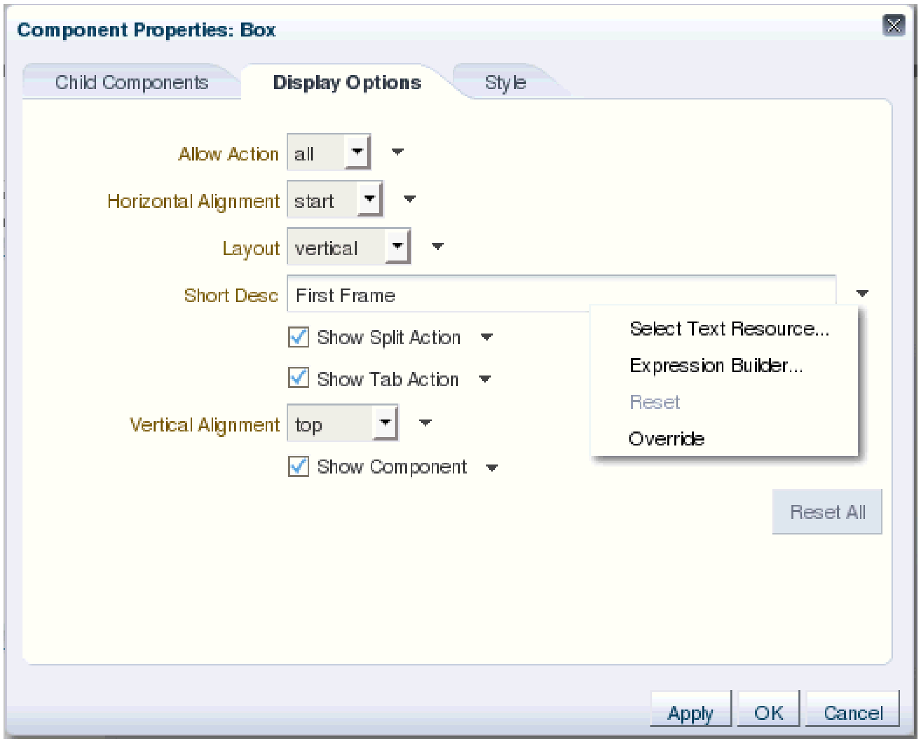
The Component Properties dialog also enables users to reset visual properties in the current context. For more information, see Section 16.5.4, "Reset and Override Component Properties in the Current Layer."

16.5.4 Reset and Override Component Properties in the Current Layer

Users can reset and override application customizations made to a component's properties in the current layer. The Component Properties dialog provides options to reset a particular property or all properties on that panel in the Component Properties dialog.

An **Override** option on the context menu for a property (Figure 16–27) enables users to use a value from another layer as a fixed value for the current layer. For example, a user edits the `Short Desc` property on a `Movable Box` component in layer `X` and sets it to `First Frame`. A user editing this component in another layer, `Y`, can choose `First Frame` as the fixed value for `Short Desc` in layer `Y`. All users that are accessing the component in layer `Y` will see this value henceforth. The value for `Short Desc` does not change in layer `Y` even if it is changed in layer `X`. When a user enters a value for a property, the Override option for that property is grayed out.

Figure 16–27 Reset and Override Options in the Component Properties Dialog



Allow Action: all

Horizontal Alignment: start

Layout: vertical

☑ Show Component

A **Reset** option on the context menu for a property enables users to reset that property to its original state. The Reset option is grayed out when the property has not yet been edited in that layer, or when the user has chosen to override the property with the displayed value, which comes from another layer.

A **Reset All** button enables users to reset all properties on the Display Options tab. Users can reset only application customizations applied to visual properties, which are rendered on the Display Options tab.

Note: The Reset option and the Reset All button are not available if the component was created newly or none of the attributes were modified in the current layer.

16.5.5 Edit Resource Strings

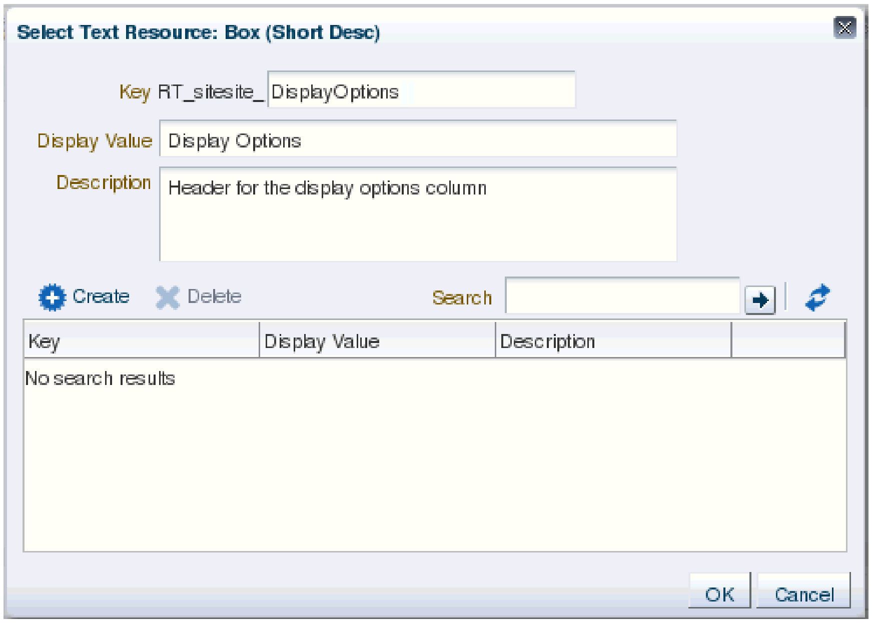
Component properties edited in Composer are available only in the current language. For example, if you add a task flow to your page, the task flow title you enter in Composer is available only in the current language. As a result, users in different locales do not see the translated values for such properties. To provide language support for component properties edited at runtime, Composer enables users to edit resource strings for properties that take String values. This is similar to the resource string editor feature provided by JDeveloper. Changes made to resource strings in Composer are saved into an application override bundle. This bundle is sent for translation and the translated versions are imported back into the application. This way, users are able to see the property values in their language.

For more information about the override bundle and configuring resource string editing in existing (release 11.1.1) Portal Framework applications, see Section 20.12, "Configuring Runtime Resource String Editing."

At runtime, for component display options that can take String values, the Edit menu next to the property field provides a Select Text Resource option, as shown in Figure 16–27. Users can select this option to edit resource strings for properties.

The Select Text Resource dialog (Figure 16–28) provides options to search existing resources, edit or delete resource keys, and add new resource key/value pairs.

Figure 16–28 Select Text Resource Dialog



Select Text Resource: Box (Short Desc)

Key RT_sitesite_ DisplayOptions

Display Value: Display Options

Description: Header for the display options column

Key	Display Value	Description
No search results		

The Select Text Resource dialog displays the following:

- **Key field**: For specifying a new key name or modifying the existing name. This is a String value used for uniquely identifying a locale-specific object in the resource bundle.

  The key name is automatically prefixed with the MDS layer to which the resource belongs. The prefix helps distinguish keys created at runtime from those created at design time.

  The **Edit** and **New key/value** icons (Figure 16–29), displayed for existing keys, enable users to perform the following tasks:

  – **Edit**: Modify the key value for an existing resource string. The string with new values is saved into the override bundle.

  – **New key/value**: Create key and value pairs in the application override bundle.

Figure 16–29 Icons for Creating and Editing Resource String Keys

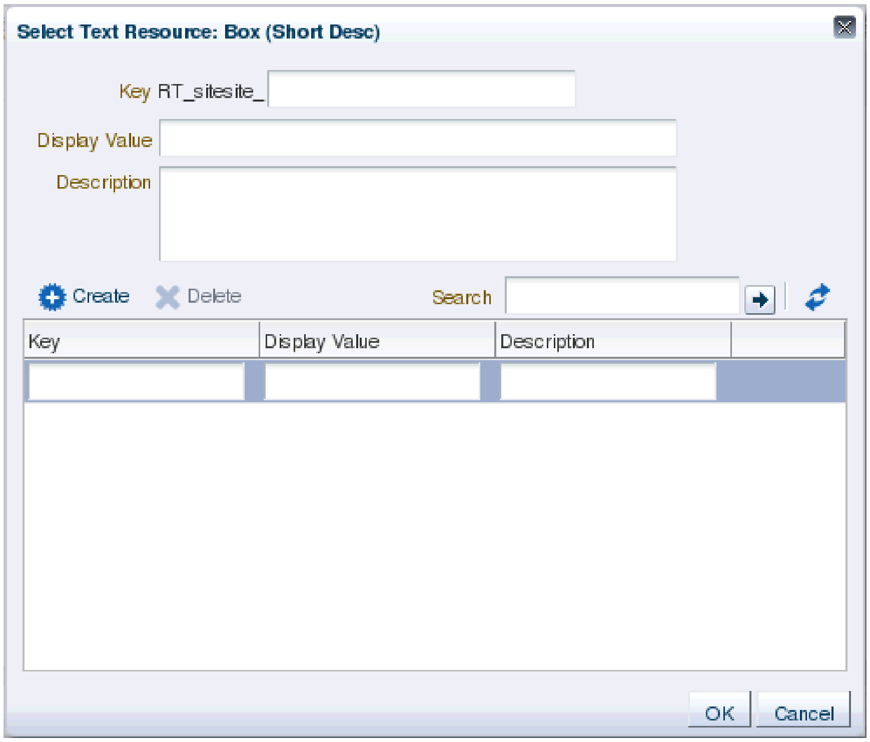
Search

Users can edit only strings that were created in the same MDS layer. Other strings appear as read-only.

> **Note:** When you try to override the default content in the resource bundle by directly entering values in the Select Text Resource dialog, the changes do not take effect and the page may appear blank.
>
> Therefore, it is recommended that you create a new resource string instead of directly entering values in the Select Text Resource dialog.

- Display Value field: For specifying a resource string to translate for display in the UI or modifying an existing string.
- Description field: For specifying a translatable description of the resource or modifying an existing description.
- Create button: For creating a new resource string. On clicking the **Create** button, the search results table provides a new row with input fields for creating a new resource. Users can double click inside the row (Figure 16–30) and create a new string by specifying values for the Key, Display Value, and Description, and then click **OK**.

Figure 16–30 Fields for Creating a New Resource String in the Search Results Table



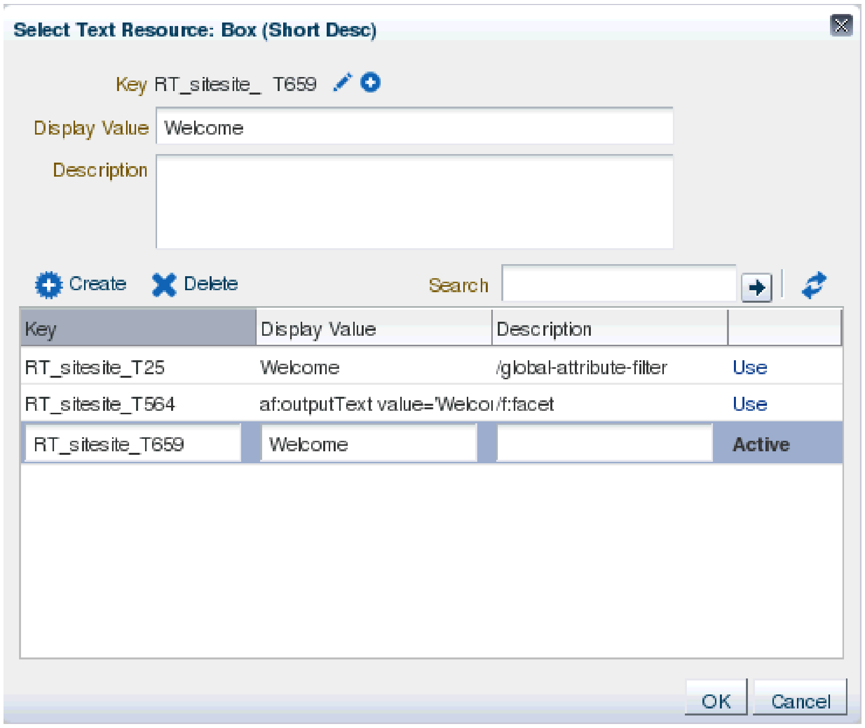
Users can just create inactive strings that get saved to the override bundle. Clicking the **Use** button in the last column selects a string for use as the current property value.

- Delete button: For deleting a selected resource from the search results table.
- Search field: For searching existing resources. Users can search for strings that were created in the same layer, in a different MDS layer, or resource bundles defined and used in a JSPX file at design time.
- Refresh: For refreshing the search results table.
- Search results table: For displaying search results, editing strings, and specifying values for new strings.

  Users can edit strings that were created in the same layer. Other strings created at design time or in a different MDS layer can only be used for the property, but not edited.

  A link or a status indicator toggle displays in the last column and enables users to promote a string to be the active, to-be-translated resource or identifies a string as the active resource (Figure 16–31).

Figure 16–31 Active Status on a Resource String



Select Text Resource: Box (Short Desc)

Key RT_sitesite_ T659

Display Value Welcome

Description

Key	Display Value	Description	
RT_sitesite_T25	Welcome	/global-attribute-filter	Use
RT_sitesite_T564	af:outputText value='Welco	/f:facet	Use
RT_sitesite_T659	Welcome		Active

Note: When searching for resource strings created at design time, Composer searches for the `c:set` tag that is used when specifying resource strings in JSPX files.

The following example shows the `c:set` element used for defining the `ComposerBundle` in a JSPX page:

```
<c:set var="portalBundle"
        value="#{compBundle['test.resource.ComposerBundle']}"/>
```

Notes

- Composer supports creation of around 500 resource strings at runtime. Beyond this number, application performance slows down.
- The search criteria in the resource string editor is case-sensitive.
- To search for the description of a resource string, the user must provide the complete string value in the search criteria.
- The resource string editor does not display string descriptions for entries created in Properties bundle or List Resource bundle formats in JDeveloper.
- The option to edit resource strings is disabled for properties on the Parameters and Events tabs.

  If the EL value for an ADF resource is referenced in a page definition parameter such as page parameter, task flow parameter, or portlet parameter, then the binding EL returns an empty value. Users must avoid referencing ADF resource EL values in page definition parameters.

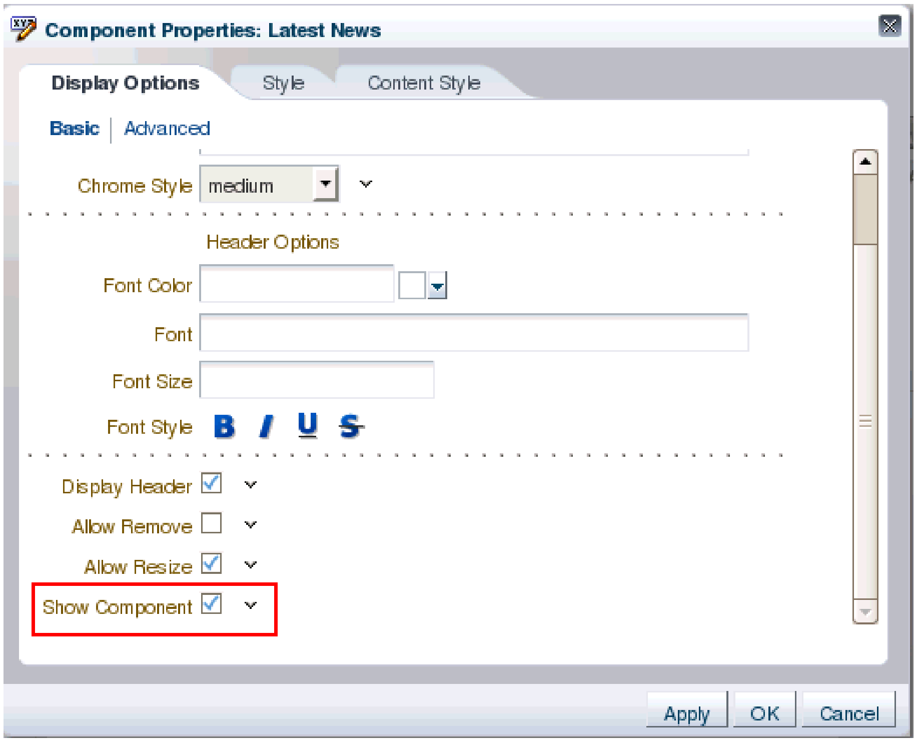
16.5.6 Show or Hide Components

Users can choose to show and hide components selectively on the page using various options. Users can hide or show a component in the following ways:

> **Note:** Show or hide behavior is tied to the component's `rendered` property. When a user hides a component, its `rendered` property is set to `false` and vice versa. If the `rendered` attribute on a component has an EL value, then that value is lost on using the show or hide option. The value is set to `true` or `false`.

- Click the **Edit** icon on the component. In the Component Properties dialog, deselect the Show Component check box (Figure 16–32).

Figure 16–32 Show Component Option in the Component Properties Dialog



Chrome Style: medium

Font Color:

Font:

Font Size:

Display Header ☑

Allow Remove □

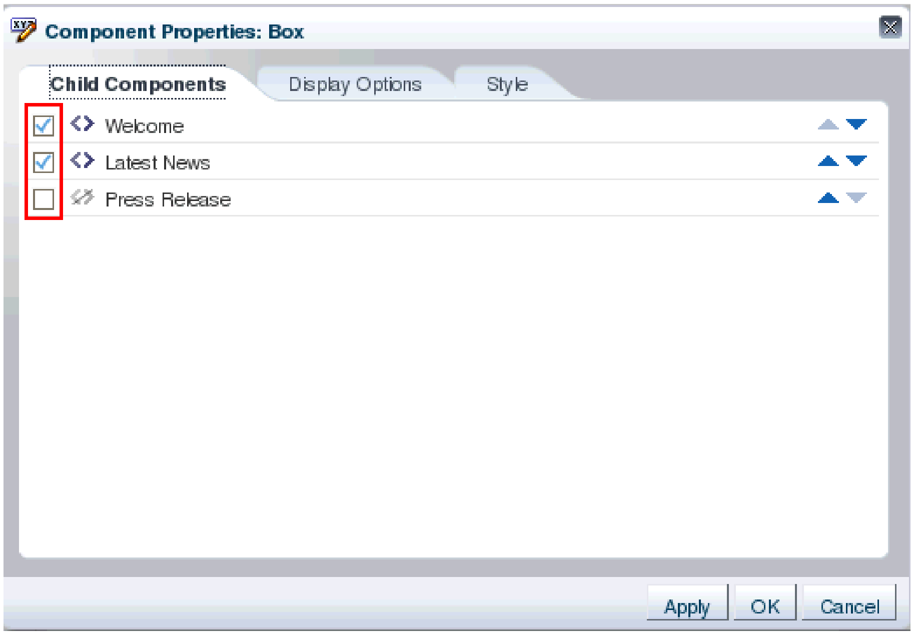
Allow Resize ☑

Show Component ☑

Deselecting the Show Component check box and clicking Apply or OK in the dialog renders the component on the page again.

- Click the **Edit** icon on the component's container. On the Child Components tab in the Component Properties dialog, deselect the check box shown against the component name to hide a component. (Figure 16–33)

Figure 16–33 Hide Component Link in a Container's Component Properties Dialog



☑ Welcome
☑ Latest News
□ Press Release

16.5.7 Delete Components

Users can delete a component from the page by clicking the **Delete** icon on its header.

A Delete dialog prompts users to confirm deletion.

Note: If you defined customization restrictions on a component, then the **Delete** icon is disabled for the component at runtime. For more information, see Section 22.1.1, "How to Define Type-Level Customization Policies."

16.5.8 Change the Layout

The **Change Layout** icon enables users to select a layout from a set of eight predefined layouts. The default page layout is `threeColumn`.

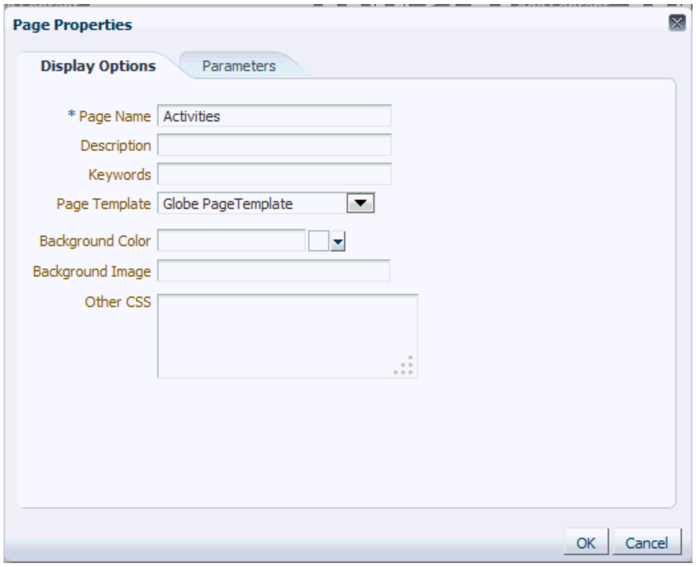
In Structure view, users can select the `Layout Customizable` component and view its properties. The layout options are displayed in the Component Properties dialog. Users can select any predefined layout and click Apply or OK.

Note: Predefined layout options are available to users only if you have added a `Layout Customizable` component to the page at design time. For more information, see Section 16.7.5, "Layout Customizable."

16.5.9 Edit Page Properties

In the **Page Properties** dialog, users can create or edit a page's parameters and display properties. Figure 16–34 shows the Security tab in the Page Properties dialog.

Figure 16–34 Page Properties Dialog



Page Properties

* Page Name: Activities

Description:

Keywords:

Page Template: Globe PageTemplate

Background Color:

Background Image:

Other CSS:

On the Parameters tab, users can create page parameters that can be linked to component properties, thereby enabling any component on the page to adapt to the page context. For example, suppose that a page has a parameter called `SYMBOL` with the default value `ORCL`. This page contains the Stock Chart, Stock Price, and Company Info task flows. The task flows can be linked with the page parameter so that all the task flows respond to a change in the value of `SYMBOL` and are updated accordingly.

16.5.10 Wire Components to Page Parameters

Composer enables users to link portlets and task flows with page parameters so that these components can read the page parameters and change their behavior accordingly.

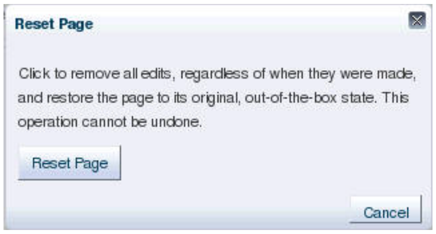
Users can wire portlet and task flow parameters to page parameters using the Component Properties dialog. For more information, see the "Wiring Pages, Task Flows, Portlets, and ADF Components" chapter in *Building Portals with Oracle WebCenter Portal*.

In addition to wiring components and page parameters, Composer also enables users to pass values for display options and parameters through page URLs. For more information, see the "Passing Parameter Values Through the Page URL" section in *Building Portals with Oracle WebCenter Portal*.

16.5.11 Reset Page

The **Reset Page** icon is available on the page in Edit mode. This icon invokes the Reset Page dialog that provides options to remove edits made to a page in the current layer or top layer and reset it to a previously saved version or its original, out-of-the-box state.

Figure 16–35 Reset Page Dialog



Reset Page

Click to remove all edits, regardless of when they were made, and restore the page to its original, out-of-the-box state. This operation cannot be undone.

Note: The **Reset Page** icon is a default add-on rendered on the Composer toolbar. You can disable this icon if you do not want users to reset the page. For information, see Section 19.2.5, "How to Selectively Display Add-Ons."

Roll Back to a Specific Label

If your application is configured to use a database store, a new version of the page is generated each time a user saves application customizations. If a sandbox is configured for your application, by creating a label with the `SAVE_LABEL_%` convention you can ensure that Composer resets the page as follows:

- If there is only one label name following the `SAVE_LABEL_%` convention, then Composer resets the page to its state in that label.
- If there is no label name following the `SAVE_LABEL_%` convention, then Composer resets the page to its original, out-of-the-box state.
- If there are multiple labels following the `SAVE_LABEL_%` convention, then Composer resets the page to its state in the latest label among these.

To roll back to a specific label, you must have configured your application to use a sandbox. Specifically, the namespace of the page being customized must be defined in the `<metadata-namespaces>` section in the application's `adf-config.xml` file. For more information, see Section 21.2.1, "How to Enable Composer Sandbox Creation."

Rolling back to a specific label is useful if your application has dependencies on the customization metadata and resetting the page to its original state can cause issues.

Notes:

- Users can only reset application customizations done on a page. Components defined in the base page or a shared component's page are left intact.
- When a user resets a page, components added to the page at runtime are removed. However, if the page uses a template, then components added inside `Panel Customizable` components on the template are not removed.

Example 16–1 shows the sample code to create a label with a `SAVE_LABEL_` prefix.

*Example 16–1 Code to Create a Label Prefixed with SAVE_LABEL_*

```
import oracle.mds.versioning.VersionHelper;
import oracle.mds.naming.Namespace;

....
```

```
long labelNumber = (long)(Math.random() * 1000000000);
String savedlabel = "SAVE_LABEL_" + labelNumber;

MDSInstance mdsInstance =
(MDSInstance)ADFContext.getCurrent().getMDSInstanceAsObject();

VersionHelper vh = VersionHelper.get(mdsInstance);

Namespace[] validNamespaces = new Namespace[1];
Namespace pageNamespace = Namespace.create(<pagePath or taskflow path>,
NamespaceRestriction.CUSTOMIZATIONS);

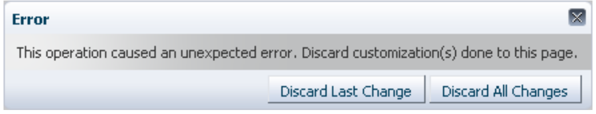
validNamespaces[0] = pageNamespace;
vh.createLabel(savedlabel, null, validNamespaces);
```

16.5.12 Reset Application Customizations on Detecting Errors

Composer provides a mechanism to alert users to customization errors that may cause a page to break. Users are alerted about errors in the following ways:

- If the change is saved to MDS, an Error dialog, shown in Figure 16–36, provides the option to roll back only the last change or all changes that users made in the current context.

Figure 16–36 Error Dialog Prompting Users to Discard Changes

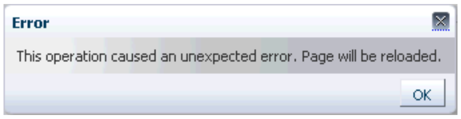


Error

This operation caused an unexpected error. Discard customization(s) done to this page.

- If the change is not yet saved to MDS, an Error dialog, shown in Figure 16–37, simply informs users that an error occurred and the page will be reloaded.

Figure 16–37 Error Dialog Informing Users About Page Reload



Error

This operation caused an unexpected error. Page will be reloaded.

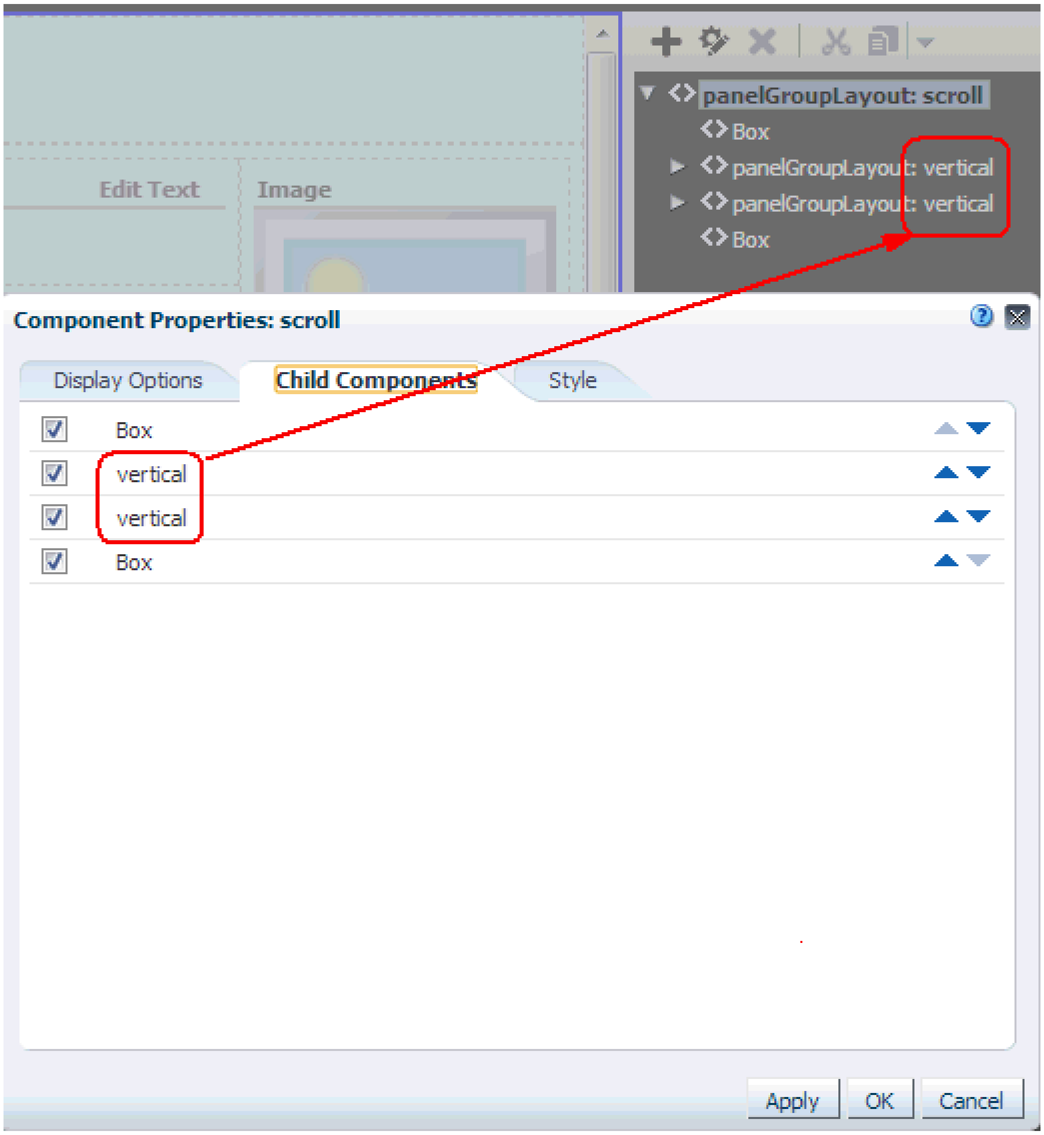
Errors occurring while performing the following operations may cause the page to break:

- Pasting a component at the wrong position while using the Cut and Paste options; for example, pasting a table column outside the table.
- Adding components or task flows; for example, adding a task flow that calls a Web service, which in turn gives an error.
- Moving `Show Detail Frame` components on the page using the drag-and-drop method.

16.5.13 Customize the Display Name of Child Components

On a page, a component may be a parent to a number of child components. When you view the properties of the parent component, you can find its child components listed on the **Child Components** tab of the Component Properties dialog. When multiple child components are of the same type, they may be indistinguishable from each other in the list of child components. For example, a `panelGroupLayout` component uses the value of its `layout` attribute (for example, `vertical`) as the display name, so multiple `panelGroupLayout` components may all have the same name in the list of child components, as illustrated in Figure 16–38 in Structure view.

Figure 16–38 Child Component Names: Structure View and Component Properties Dialog



☑ Box
☑ vertical
☑ vertical
☑ Box

If you need to identify and work with a specific child component, you can edit the source code of a page to specify a unique display name for any component to make it easily distinguishable. This display name is shown in hint text and the Component Properties dialog. The custom attribute that implements this functionality is `composer_name_hint`, which you can specify using `<f:attribute>`, as follows:

Syntax:

```
<f:attribute name="composer_name_hint" value="display_name"/>
```

Example:

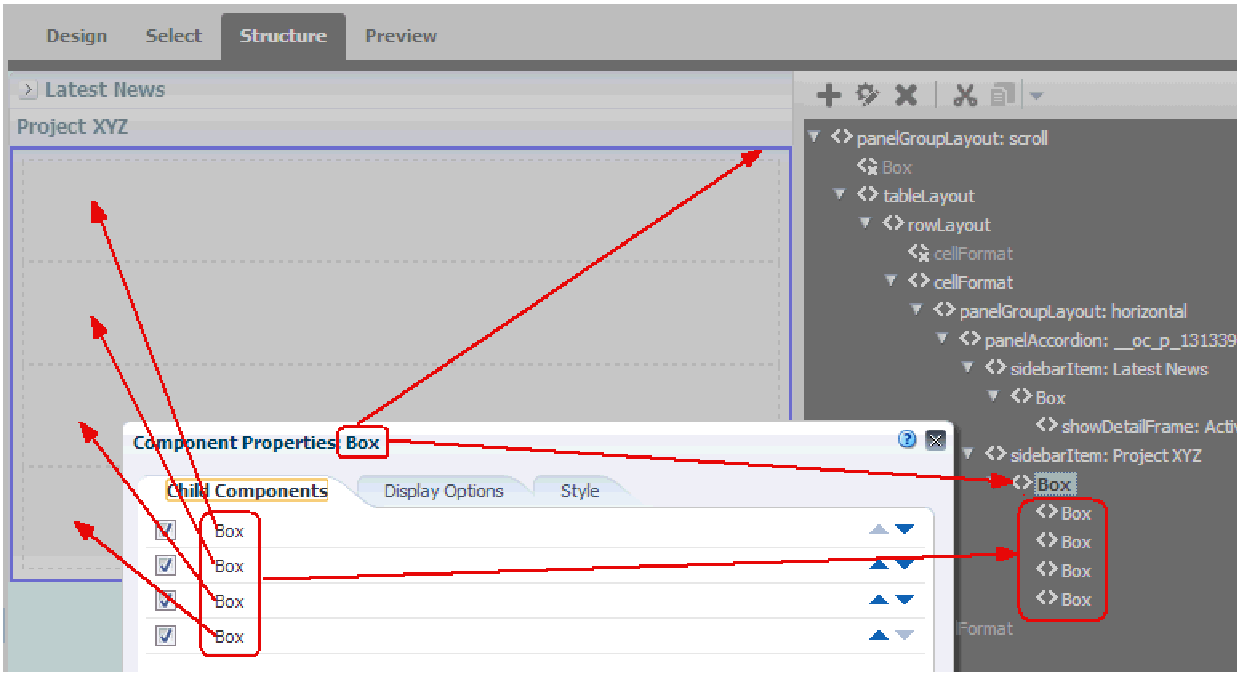
```
<af:panelGroupLayout id="pgl1" layout="scroll" inlineStyle="">
```

```
  <f:attribute name="composer_name_hint" value="Main Area"/>
</ af:panelGroupLayout>
```

Figure 16–39 shows the **Child Components** tab of the Component Properties dialog for a parent `panelCustomizable` (Box) component that includes four `panelCustomizable` (Box) child components.

Notice that the display name `Box` is used for the parent component and the four child components, making them indistinguishable.

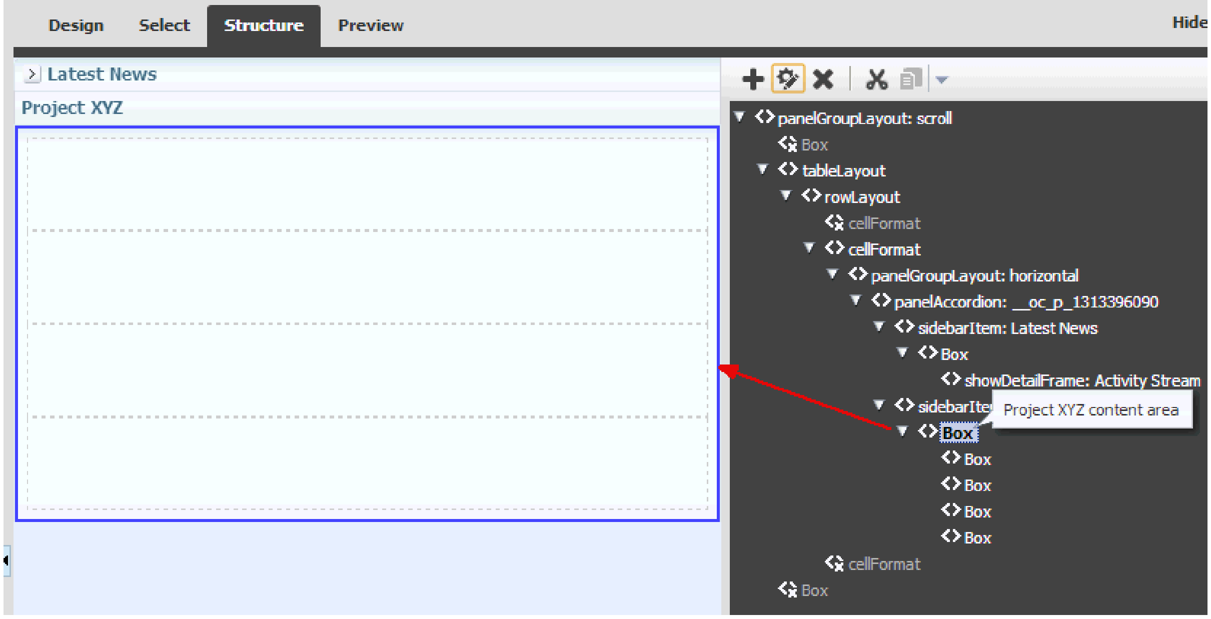
Figure 16–39 Components Without composer_name_hint Defined: Structure View and Component Properties Dialog



To customize the display name of these components, you can edit the source code to add a `composer_name_hint` attribute to each component. The `composer_name_hint` value is exposed in the following locations:

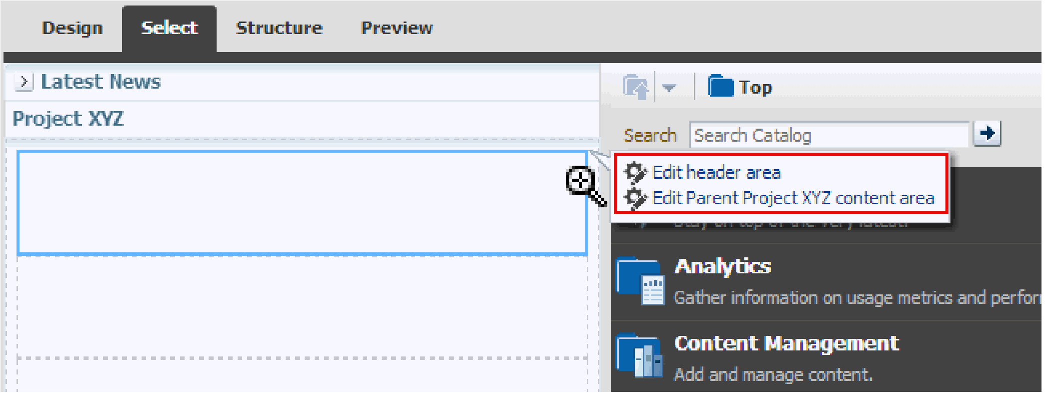
- In Structure view, the `composer_name_hint` value shows as hint text for the component (Figure 16–40).

Figure 16–40 Components With composer_name_hint Defined: Structure View Hint Text



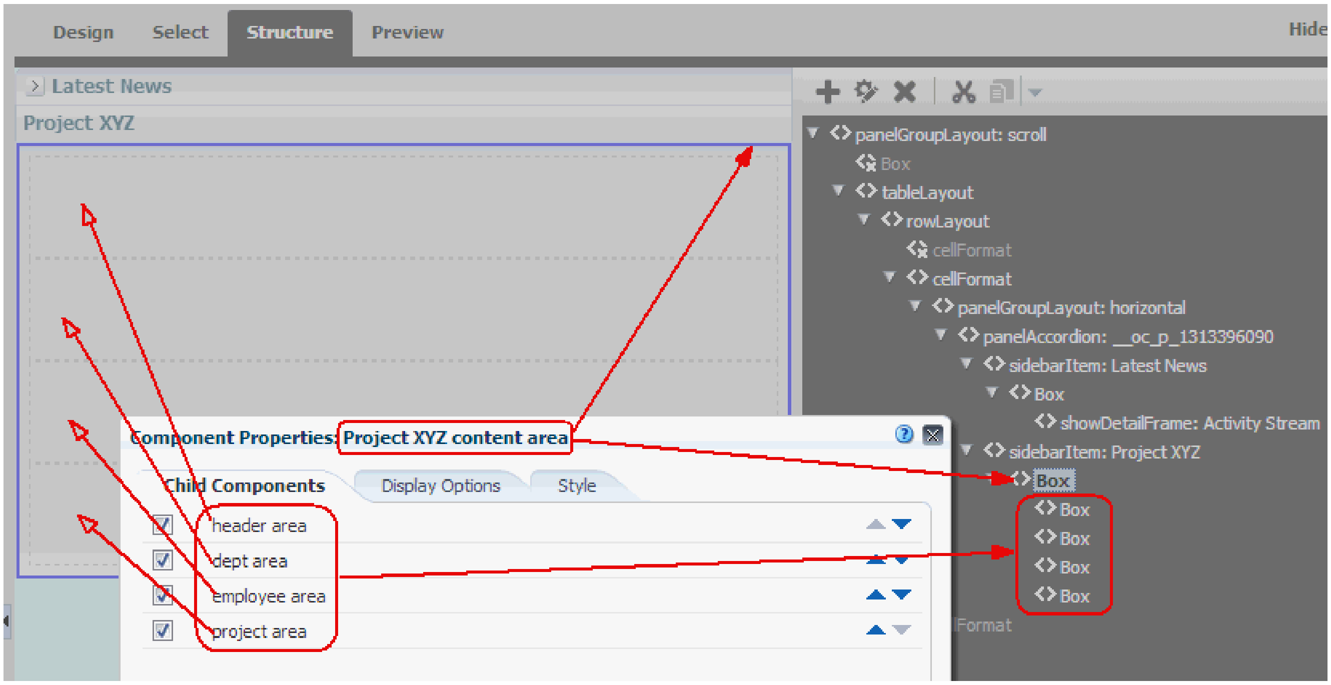
- In Select view, right-clicking on a selected component displays a context menu showing the `composer_name_hint` value for the component and/or its parent component (Figure 16–41).

Figure 16–41 Components With composer_name_hint Defined: Select View Hint Text



- The Component Properties dialog for the component includes the `composer_name_hint` value in its title (Figure 16–42).
- In the parent component's Component Properties dialog, the **Child Components** tab lists each child component using its `composer_name_hint` value as the display name (Figure 16–42).

Figure 16–42 Components With <f:attribute> Defined: Component Properties Dialog



The page source code for the parent Box (`panelCustomizable`) component and its four child Box components shown in Figure 16–42 looks like this:

```
<af:showDetailItem id="82127" text="Project XYZ"
xmlns:af="http://xmlns.server.com/adf/faces/rich" disclosed="true"
inflexibleHeight="100">
   <cust:panelCustomizable id="45399" layout="scroll"
xmlns:cust="http://xmlns.server.com/adf/faces/customizable">
      <f:attribute name="composer_name_hint" value="Project XYZ content area"/>
      <cust:panelCustomizable id="273"
xmlns:cust="http://xmlns.server.com/adf/faces/customizable">
         <f:attribute name="composer_name_hint" value="header area"/>
      </cust:panelCustomizable>
      <cust:panelCustomizable id="959"
xmlns:cust="http://xmlns.server.com/adf/faces/customizable">
         <f:attribute name="composer_name_hint" value="dept area"/>
      </cust:panelCustomizable>
      <cust:panelCustomizable id="393"
xmlns:cust="http://xmlns.server.com/adf/faces/customizable">
         <f:attribute name="composer_name_hint" value="employee area"/>
      </cust:panelCustomizable>
      <cust:panelCustomizable id="941"
xmlns:cust="http://xmlns.server.com/adf/faces/customizable">
         <f:attribute name="composer_name_hint" value="project area"/>
      </cust:panelCustomizable>
   </cust:panelCustomizable>
</af:showDetailItem>
```

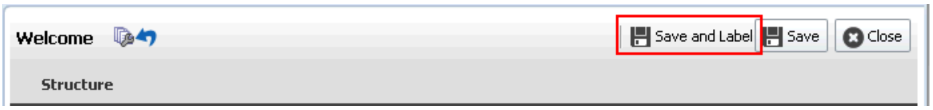
16.5.14 Create Labels On Saving Application Customizations

A Save and Label button on the Composer toolbar, shown in Figure 16–43, enables users to save their application customizations in a new label. Labels created in Composer are stored with a prefix of `composer_`, that is, a label created with the name `myLabel` is stored as `composer_myLabel`.

Creating labels enables users to reset customizations on a selected object to those from a selected label. This can be achieved using the Promote link in Customization Manager. For more information, see the section titled Promote Customization Metadata.

> **Note:** The Save and Label button is displayed only if you have configured a sandbox with an MDS database store for your application and set the `allowLabel` attribute on the `Page Customizable` component to `true`. For more information about this attribute, see Section B.1.1, "Page Customizable Component."

Figure 16–43 Save and Label Button on the Composer Toolbar

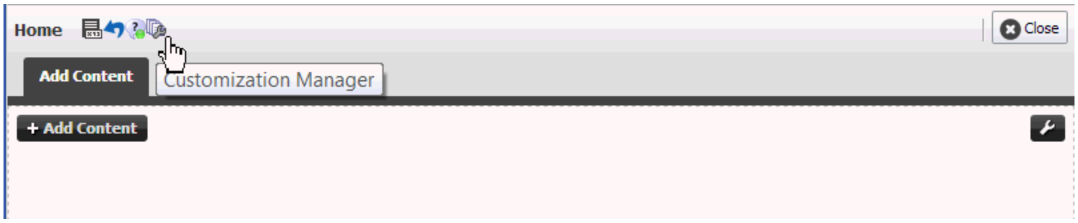


16.5.15 Manage Application Customizations

The Customization Manager is a Composer add-on panel that enables users to manage customization metadata for objects such as XML documents, pages, page fragments, and task flows on the page. It displays a list of all such objects on the page, and provides details about the layers in which these objects are customized. Users can download customization metadata for a selected object, edit it, and upload the revised metadata file. Additionally, the Customization Manager also provides options to delete customizations and promote customizations from a previously saved label.

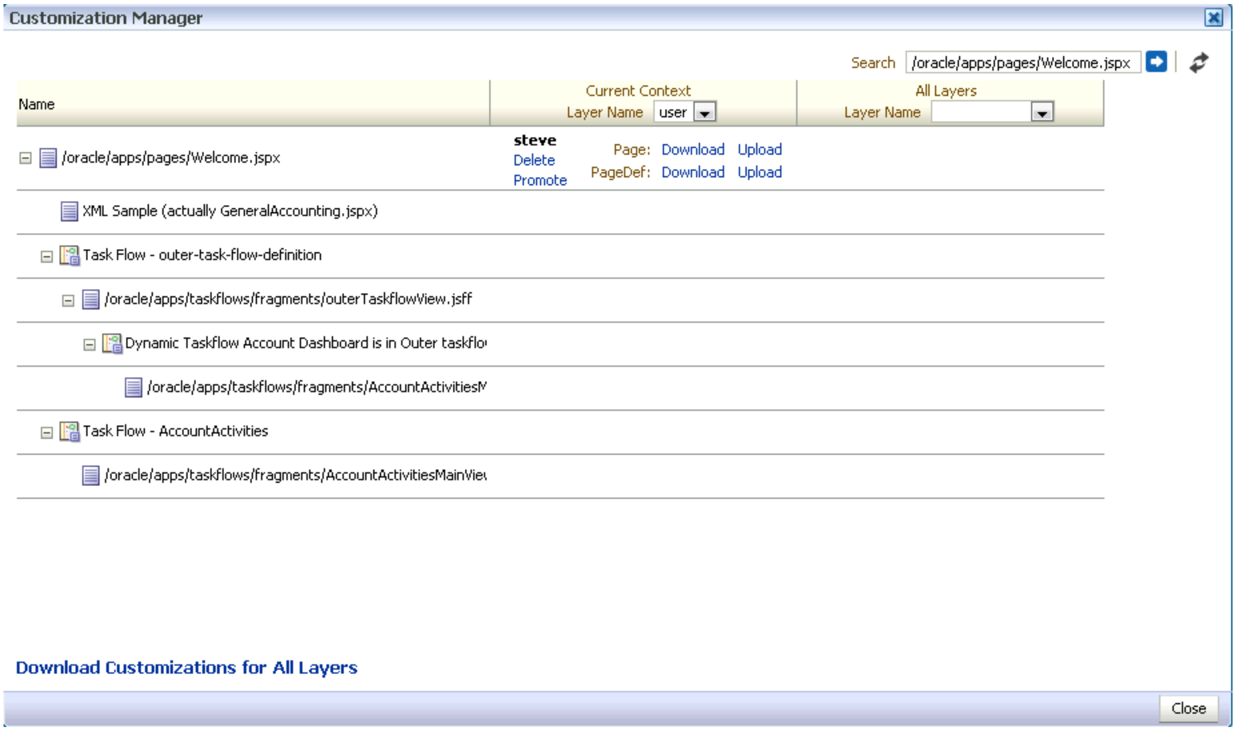
The Customization Manager is not available by default in your custom application. You can enable it by performing certain configurations. For more information, see Section 19.2.4, "How to Display the Customization Manager Add-On." If you configure your application to display the Customization Manager add-on, the Composer toolbar displays the **Customization Manager** icon, as shown in Figure 16–44.

Figure 16–44 Customization Manager Button



Clicking the Customization Manager button invokes the Customization Manager dialog, shown in Figure 16–45.

Figure 16–45 Customization Manager Dialog



Customization Manager

Search /oracle/apps/pages/Welcome.jspx

Name	Current Context Layer Name user		All Layers Layer Name
/oracle/apps/pages/Welcome.jspx	steve Delete Promote	Page: Download Upload PageDef: Download Upload	
XML Sample (actually GeneralAccounting.jspx)			
Task Flow - outer-task-flow-definition			
/oracle/apps/taskflows/fragments/outerTaskflowView.jsff			
Dynamic Taskflow Account Dashboard is in Outer taskflo			
/oracle/apps/taskflows/fragments/AccountActivitiesM			
Task Flow - AccountActivities			
/oracle/apps/taskflows/fragments/AccountActivitiesMainVie			

Download Customizations for All Layers

The Customization Manager displays Delete, Promote, Download, and Upload links against each customized page, fragment, or XML document in each layer. Users can specify a JSPX, JSFF, or XML file name in the search field to view customization details about objects in that file and manage those customizations. To search for a file, you must specify the absolute path to the file, for example, `/oracle/webcenter/portalapp/pages/home.jspx`.

Note: In case of a deeply nested task flow or a task flow with a cyclic dependency, Customization Manager displays a maximum depth of ten task flows.

Users can manage customizations in the current MDS context in which the application is running. The Current Context column displays options to manage customizations in the selected layer. The drop-down menu lists the layers in which the page or fragment was customized. This column is useful for all users who want to manage customizations they have made. The All Layers column displays options to manage customizations in all layers in the application. This column is useful for administrators who want to manage customizations made in all layers.

Notes:

- If you have configured a sandbox for your application, all Customization Manager operations are performed in the sandbox; for example, when a user uploads a customization document, it is stored in the sandbox until the user saves or discards changes made during that session.
- You can customize the Customization Manager to only display options of your choice. For example, you can show or hide the Download, Delete, or Upload links. Further, you can choose to show details for the current context only or for all layers only.

  You can make these settings using parameters on the Customization Manager task flow. By enabling parameter support on the task flow, you can enable users also to customize the Customization Manager at runtime. For more information, see Section 19.8, "Defining Property Filters."

This section describes the capabilities provided by the Customization Manager. It contains the following subsections:

- Download Customization Metadata
- Download Customization Metadata for All Customized Objects
- Upload Customization Metadata
- Delete Customization Metadata
- Promote Customization Metadata

Download Customization Metadata

A Download link enables users to download the customization document for the selected page, fragment, or XML document from the selected layer. This is useful if a user wants to edit customization metadata for a component or inspect the customization metadata. For example, if a page displays errors, the user can download the customizations, review them, and send them to Oracle Support Services, if required. This helps in diagnosing any customization issues on the page.

The Save dialog lets users select a location for saving the document. Users can edit this file locally and upload it to the site again. For information about uploading files, see Upload Customization Metadata.

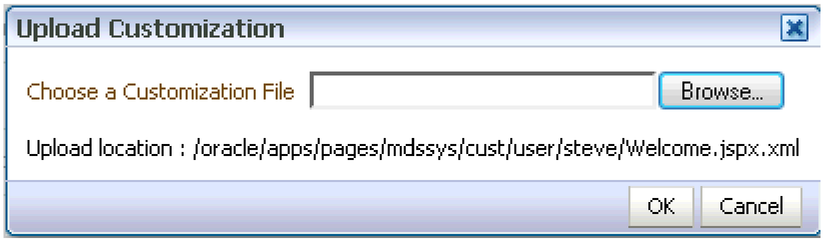
Download Customization Metadata for All Customized Objects

The Download Customizations for All Layers link at the bottom of the page enables users to download a ZIP file containing all customization documents shown in the Customization Manager.

Upload Customization Metadata

An Upload link enables users to upload a customization document for the selected artifact, such as page, fragment or XML document, in a specific layer. Figure 16–46 shows the Upload Customization dialog that lets users select the file they want uploaded.

Figure 16–46 Upload Customization Dialog



Upload location : /oracle/apps/pages/mdssys/cust/user/steve/Welcome.jspx.xml

The artifact is then customized based on the metadata in the uploaded document.

Note: The `usesUpload` attribute on the `Form` tag on the page controls the display of Upload links in Customization Manager. If you set `usesUpload` to `false`, the Upload links will not work.

Delete Customization Metadata

A Delete link enables users to delete the customization document for the selected artifact from a specific layer.

Promote Customization Metadata

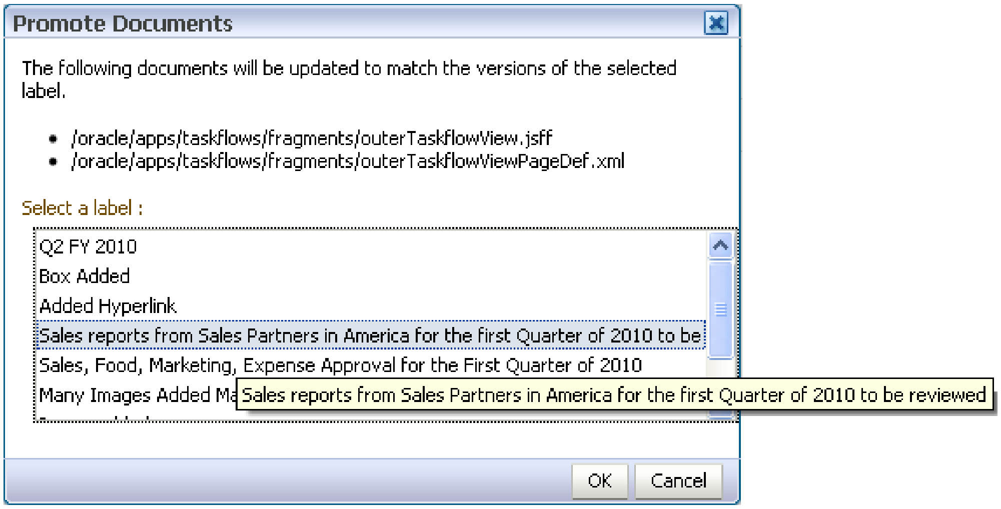
While customizing a page, users can save application customizations at any point and create a new label to save those customizations. A Promote link in the Customization Manager enables users to select a label and reset application customizations on the selected page or task flow to those from the label.

Notes: The Promote option is available only in sandbox-enabled applications.

For more information about the Save and Label option in Composer, see Section 16.5.14, "Create Labels On Saving Application Customizations."

The Promote link invokes the Promote Documents dialog, which lists all available labels and the files that will be promoted, as shown in Figure 16–47.

Figure 16–47 Select a Label Dialog



Promote Documents

The following documents will be updated to match the versions of the selected label.

- /oracle/apps/taskflows/fragments/outerTaskflowView.jsff
- /oracle/apps/taskflows/fragments/outerTaskflowViewPageDef.xml

Select a label :

Q2 FY 2010
Box Added
Added Hyperlink
Sales reports from Sales Partners in America for the first Quarter of 2010 to be
Sales, Food, Marketing, Expense Approval for the First Quarter of 2010
Many Images Added Ma

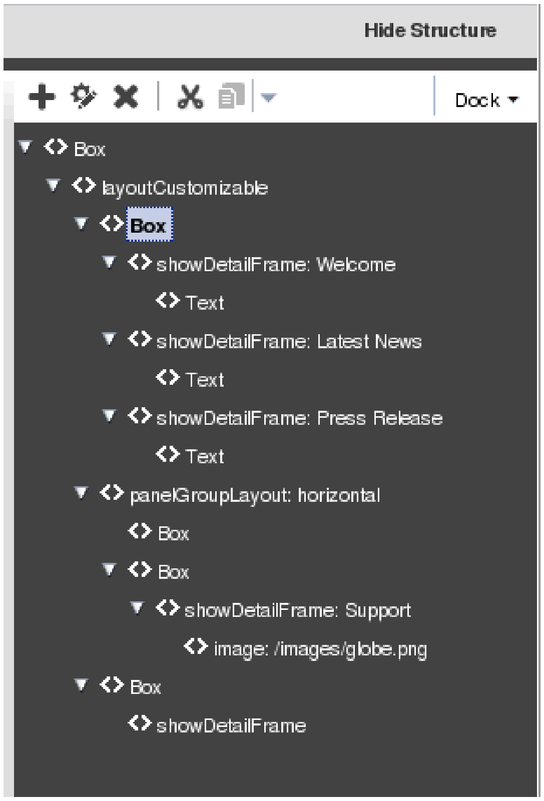
Sales reports from Sales Partners in America for the first Quarter of 2010 to be reviewed

Users can select a label and promote that label to the sandbox for the selected artifact. This means that application customizations for the selected artifact are reset to those from the specified label. If a task flow is selected, then all page fragments and page definitions are promoted. If a page or fragment is selected, then the page or fragment and its page definition are promoted. Users can select a label from any available layer and promote customizations from that label. For example, if an application has layers MCOOPER, JDOE, and SITE, and a user working in the MCOOPER layer clicks the Promote link for a page, the Promote dialog lists all labels available in all three layers.

16.6 Editing Capabilities in Structure View in Page Edit Mode

Structure view (Figure 16–48) provides a WYSIWYG and a hierarchical rendering of page components in a component navigator. Add Content, Switch, Delete, Cut, and Paste controls are available on Structure view toolbar provide specific operations in Composer. In Structure view, users can access and modify properties of components that are not otherwise selectable in Design or Add Content view. For example, many ADF Faces components can be edited only in Structure view. Users can also edit components within a task flow.

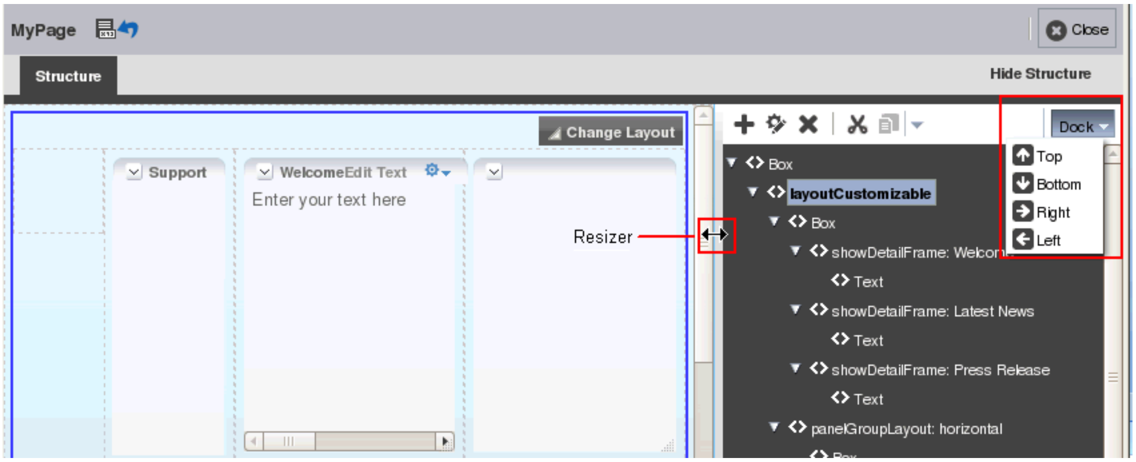
Figure 16–48 Structure View of a Page



```
Box
  layoutCustomizable
    Box
      showDetailFrame: Welcome
        Text
      showDetailFrame: Latest News
        Text
      showDetailFrame: Press Release
        Text
    panelGroupLayout: horizontal
      Box
      Box
        showDetailFrame: Support
          image: /images/globe.png
    Box
      showDetailFrame
```

By default, the component navigator displays on the right side of the page in Composer. Users can choose to display it at the top, bottom, or left, using the **Dock** menu (Figure 16–49). Users can also drag the border on the edge of the component navigator to alter its height or width.

Figure 16–49 Structure Position Option and Resizer



At the root of the component navigator is the direct child of the `Page Customizable` component at design time. When a node is selected in the component navigator, the corresponding component is selected on the page. Similarly, when a component is selected directly on the page, the corresponding node is selected in the component navigator.

A gray area located at the bottom of the page displays a bread crumb trail for the selected component (Figure 16–50). The bread crumb trail shows how the component is nested on the page. When no component is selected, the bread crumb bar displays just the page name. The container names are links that when clicked highlight the selected component.

Figure 16–50 Bread Crumbs for a Component Selected in Page Structure View

Box
showDetailFrame: Support
image: /images/globe.png
Box
MyPage > Box > layoutCustomizable > Box > showDetailFrame: Welcome

Task flows that can be edited have Edit Task Flow links next to them. On clicking an Edit Task Flow link, the component navigator displays the hierarchy of components within the task flow's page or fragment. Users can edit this page or fragment and click Close to zoom out of the task flow. For more information, see Section 16.6.2, "Edit Content Inside a Task Flow." Similarly, declarative components display Open links that enable users to edit components inside the selected declarative component's facets.

Similar to Design and Add Content view, in Structure view also users can perform such tasks as adding components, editing page and component properties, changing page layout, and deleting components. Users can select a component on the page or in the component navigator and click the buttons on the Structure view toolbar to perform these tasks. To edit or delete a component, users can also select options on the context menu for the component. In addition to these tasks, users can perform the following tasks in page Structure view:

- Section 16.6.1, "Rearrange Page Content Using Cut and Paste Options"
- Section 16.6.2, "Edit Content Inside a Task Flow"
- Section 16.6.3, "Edit Content Inside a Declarative Component"
- Section 16.6.4, "Show or Hide Components"

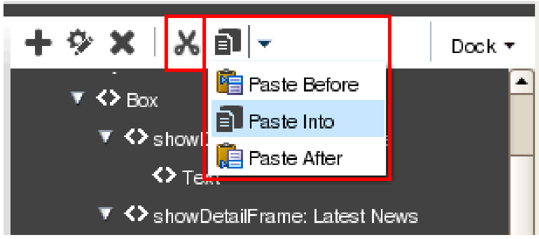
Notes:

- The **Save** button is provided on the Composer toolbar only if the application is configured to use a sandbox. For more information about sandboxes, see Section 21.2, "Using Composer Sandbox."
- You can restrict users from performing all or some of these tasks by securing the application and applying customization restrictions on components. For more information, see Section 16.8, "Security and Composer."

16.6.1 Rearrange Page Content Using Cut and Paste Options

Users can rearrange components on a page using the Cut and Paste options on the Structure view toolbar (Figure 16–51). A Paste menu enables users to paste a component into, before, or after any other component in the component navigator.

Figure 16–51 Cut and Paste Options on Structure View Toolbar



The Cut and Paste buttons are grayed out if the user selects a component that does not support a cut or paste operation. Cut and paste operations are not supported under the following conditions:

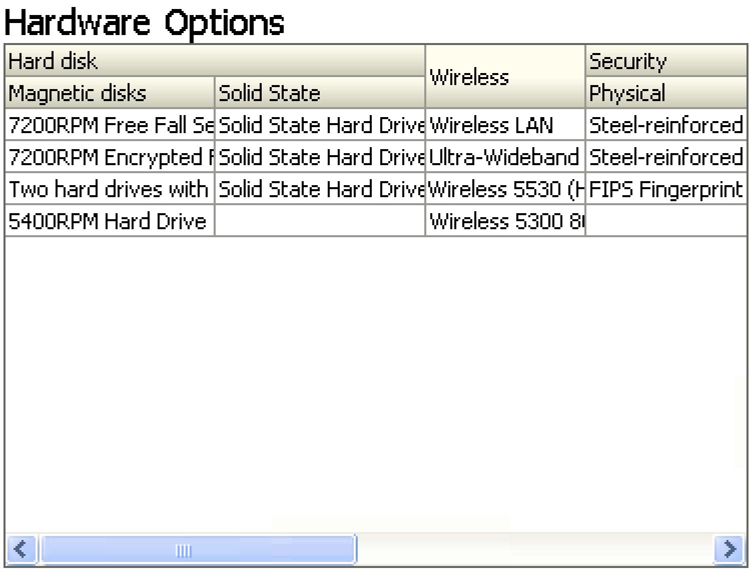
- The target component is not on the same page as the cut component.
- The target component is nested inside the cut component.
- The target component is located before or after a faceted component, that is, a component inside a facet.
- The parent of the target component is not customizable.
- The parent of the cut component is not customizable.

Notes: A component on which customization is restricted can be rearranged inside its parent container if the parent is customizable.

Example

If your customizable page contains an ADF Faces `Table` component, then in Composer's Structure view, users can resequence or move columns within or across tables and column groups. Consider a sample application created for selling computer accessories. The application home page has two tables containing details about the software and hardware offerings. The Hardware Options table contains three columns. The Hard disk column in turn contains the Magnetic disks and Solid State columns inside a column group, as shown in Figure 16–52.

Figure 16–52 Table in the Sample Application



Hardware Options

Hard disk		Wireless	Security
Magnetic disks	Solid State		Physical
7200RPM Free Fall Se	Solid State Hard Drive	Wireless LAN	Steel-reinforced
7200RPM Encrypted F	Solid State Hard Drive	Ultra-Wideband	Steel-reinforced
Two hard drives with	Solid State Hard Drive	Wireless 5530 (H	FIPS Fingerprint
5400RPM Hard Drive		Wireless 5300 8	

Users can switch to Structure view and resequence the Magnetic disks and Solid State columns within the Hard disk column or move them out of the column group and paste them next to any other column (the Wireless column, for example).

Users can select a column and click **Cut**, then select another column and click **Paste Before** or **Paste After**.

16.6.2 Edit Content Inside a Task Flow

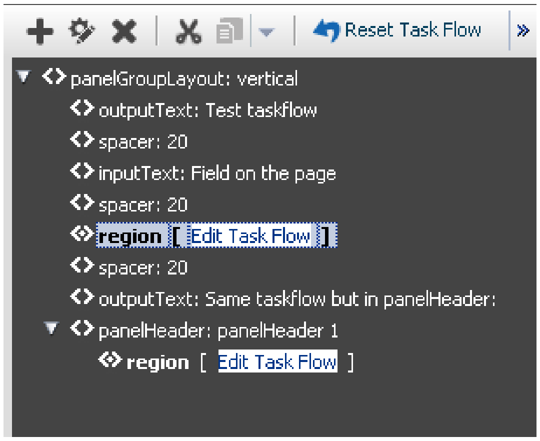
Oracle ADF Task flows consist of one or more views and each view in a task flow is associated with a page or page fragment. When you add a task flow to your page, the content on the fragment associated with the current view is displayed on the page. Composer enables users to edit components on the page or fragment used for the current view of a task flow. Since changes are made to the task flow's page or fragment, they are reflected in all places where the task flow's page or fragment is used.

Structure view provides an option to open a task flow and display only components on its page or fragment in the component navigator. Users can edit the page or fragment and close the task flow to navigate back to the page containing the task flow.

Users with Customize permission on a task flow can edit its page or fragment.

Each task flow in the component navigator displays an **Edit Task Flow** link next to it, as shown in Figure 16–53.

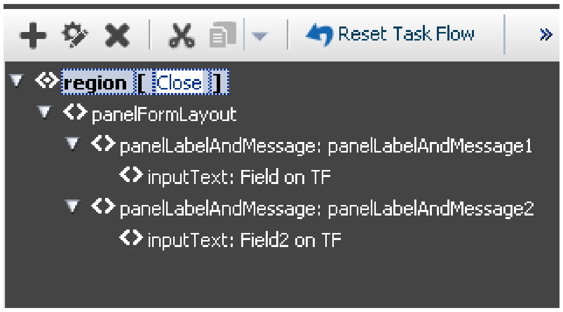
Figure 16–53 Edit Task Flow Link on a Task Flow



panelGroupLayout: vertical
outputText: Test taskflow
spacer: 20
inputText: Field on the page
spacer: 20
region [Edit Task Flow]
spacer: 20
outputText: Same taskflow but in panelHeader:
panelHeader: panelHeader 1
region [Edit Task Flow]

Clicking the **Edit Task Flow** link results in Structure view zooming in to display the task flow's page and its components, as shown in Figure 16–54.

Figure 16–54 Components Within a Task Flow



region [Close]
panelFormLayout
panelLabelAndMessage: panelLabelAndMessage1
inputText: Field on TF
panelLabelAndMessage: panelLabelAndMessage2
inputText: Field2 on TF

Users can select components on the task flow's page and edit them in Composer just like editing any other page components. However, Composer does not support moving components from one task flow to another.

If multiple users attempt to edit the same task flow at the same time, a concurrency warning appears in Composer that alerts each user to the others. However, this warning is displayed only if a sandbox is configured in the application. For information about how changes are saved in such cases, see "What Happens During Concurrent Edits".

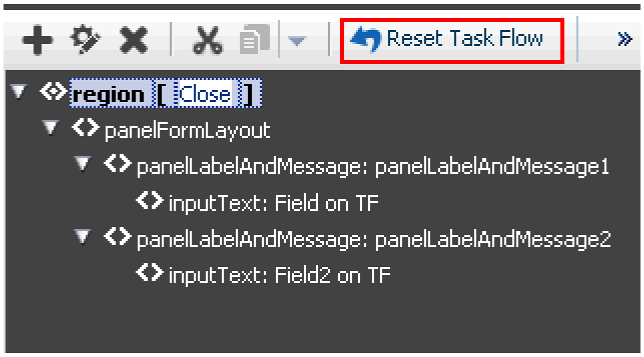
Clicking the **Close** link next to an open task flow results in the component navigator displaying the page containing the task flow.

16.6.2.1 Reset Task Flow

The **Reset Task Flow** button on the Structure view toolbar (Figure 16–55) invokes the Reset Task Flow dialog that provides options to remove application customizations made to a task flow and reset it to a previously-saved version or to its original out-of-the-box state. You can ensure that the task flow is reset to its state in a previously-saved label only if your application is configured to use a database store. The **Reset Task Flow** button is rendered only on zooming into a task flow.

Note: If you disable the **Reset Page** button in your application, the **Reset Task Flow** button is also disabled. Users cannot reset task flows after they make changes. For more information, see Section 16.5.11, "Reset Page."

Figure 16–55 Reset Task Flow Button



Roll Back to a Specific Label

If your application is configured to use a database store, a new version of the task flow is generated each time a user saves application customizations. If a sandbox is configured for your application, by creating a label with the `SAVED_LABEL_%` convention you can ensure that Composer resets the task flow as follows:

- If there is only one label name following the `SAVED_LABEL_%` convention, then Composer resets the task flow to its state in that label.
- If there is no label name following the `SAVED_LABEL_%` convention, then Composer resets the task flow to its original, out-of-the-box state.
- If there are multiple labels following the `SAVED_LABEL_%` convention, then Composer resets the task flow to its state in the latest label among these.

To roll back to a specific label, you must have configured your application to use a sandbox. Specifically, the namespace of the task flow being customized must be defined in the `<metadata-namespaces>` section in the application's `adf-config.xml` file. For more information, see Section 21.2.1, "How to Enable Composer Sandbox Creation."

Rolling back to a specific label is useful if your application has dependencies on the customization metadata and resetting the task flow to its original state may cause issues.

When a user resets a task flow, the following changes occur:

- Only the currently selected fragment is reset. Other fragments of the task flow are not reset.
- Nested task flows are not affected by the reset operation.
- When a task flow is reset, changes are reflected on all pages consuming this task flow.
- Components added to the task flow at runtime are removed. However, if the task flow's page or fragment uses a template, then components added inside `Panel Customizable` components on the template are not removed.

Example 16–2 shows the sample code to create a label with a `SAVE_LABEL_` prefix.

*Example 16–2 Code to Create a Label Prefixed with SAVE_LABEL_*

```
import oracle.mds.versioning.VersionHelper;
import oracle.mds.naming.Namespace;

. . .
long labelNumber = (long)(Math.random() * 1000000000);
String savedlabel = "SAVE_LABEL_" + labelNumber;

MDSInstance mdsInstance =
(MDSInstance)ADFContext.getCurrent().getMDSInstanceAsObject();

VersionHelper vh = VersionHelper.get(mdsInstance);

Namespace[] validNamespaces = new Namespace[1];
Namespace pageNamespace = Namespace.create(<pagePath or taskflow path>,
NamespaceRestriction.CUSTOMIZATIONS);

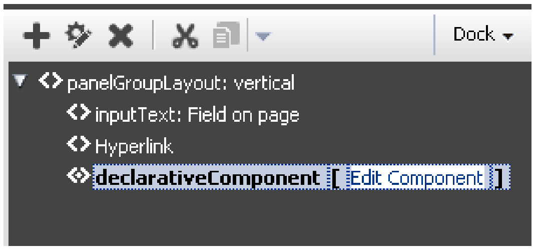
validNamespaces[0] = pageNamespace;
vh.createLabel(savedlabel, null, validNamespaces);
```

16.6.3 Edit Content Inside a Declarative Component

If the application page contains declarative components, users can edit these components in Composer. Editing declarative components is similar to editing task flows. For more information, see Section 16.6.2, "Edit Content Inside a Task Flow."

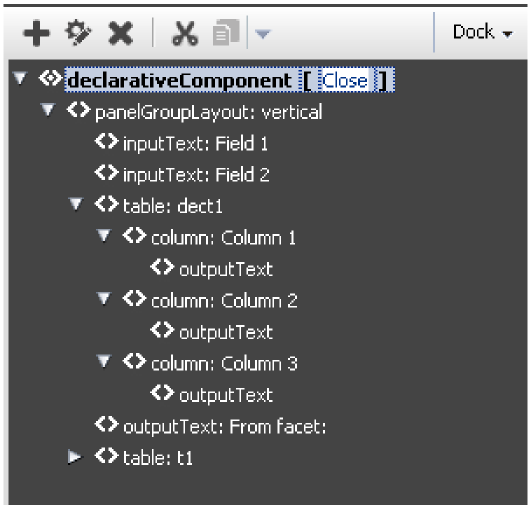
Figure 16–56 and Figure 16–57 show the Edit Component and Close options available on declarative components.

Figure 16–56 Edit Option On a Declarative Component



Dock
panelGroupLayout: vertical
inputText: Field on page
Hyperlink
declarativeComponent [Edit Component]

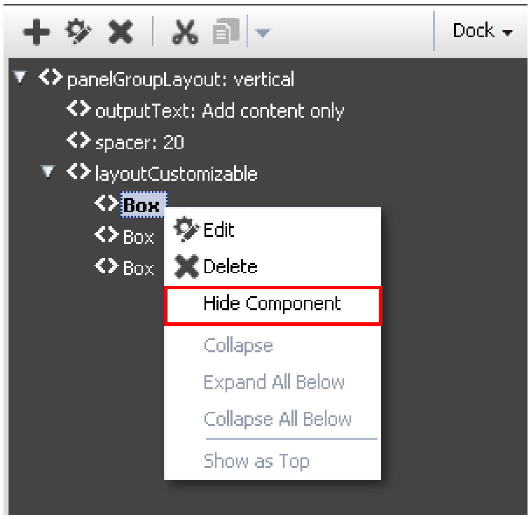
Figure 16–57 Close Option Displayed While Editing a Declarative Component



16.6.4 Show or Hide Components

To hide a component, right-click the component in the component navigator or on the page and choose Hide Component on the context menu (Figure 16–58).

Figure 16–58 Hide Component Option in Structure View of the Page



A hidden component is not displayed on the page, but appears grayed out in the component navigator. The context menu for a hidden component displays a Show Component option. Choosing this option renders the component on the page again.

Note: Show or hide behavior is tied to the component's `rendered` property. When a user hides a component, its `rendered` property is set to `false` and vice versa. If the `rendered` attribute on a component has an EL value, then that value is lost on using the show or hide option. The value is set to `true` or `false`.

16.7 Composer Components

To make any JSPX document (`*.jspx`) editable at runtime, you must add Composer components to your page in Oracle JDeveloper at application design time.

> **Note:** Composer works only with JSPX pages and ADF Faces. You cannot add these components to JSP pages. For information about adding Composer components to your page, see Section 18.1, "Designing Editable Pages Using Composer Components."

The Composer tag library in JDeveloper (Figure 16–59) is available from the Component Palette and provides components that you can add to make a page editable.

Figure 16–59 Composer Tag Library in the Component Palette

Layout Customizable

Panel Customizable

Show Detail Frame

Operations

Custom Action

ShowProperty

This section provides an overview of the Composer components that are used to enable page editing. It contains the following subsections:

- Section 16.7.1, "Page Customizable"
- Section 16.7.2, "Change Mode Link and Change Mode Button"
- Section 16.7.3, "Panel Customizable"
- Section 16.7.4, "Show Detail Frame"
- Section 16.7.5, "Layout Customizable"

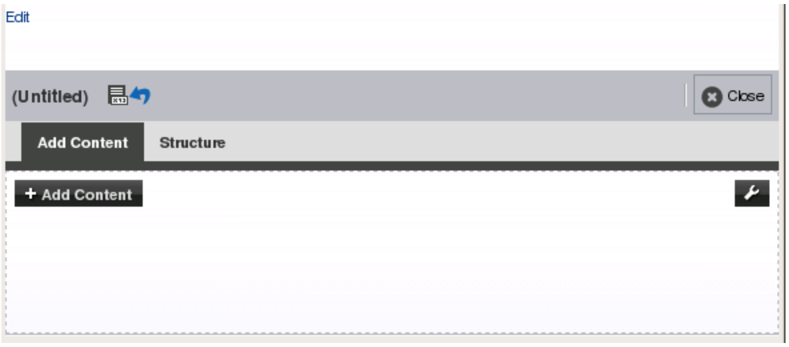
For more information about these components and other Composer components such as `Custom Action`, see Appendix B, "Composer Component Properties and Files."

16.7.1 Page Customizable

The `Page Customizable` component defines the editable area of a page. Within this area, you can edit component properties, add content to the page, arrange content, and so on.

Adding a `Page Customizable` component enables the runtime inclusion of Composer on the page. Users can edit pages in Composer using page-related controls available across the top of the page, **Add Content** buttons on components, and **Edit** icons on each editable page component (Figure 16–60).

Figure 16–60 Page Customizable Component



To enable runtime editing for multiple application pages in one operation, add a Page Customizable component to the ADF page template used for those pages. This avoids the need to manually add a Page Customizable to each page. For more information about adding the Page Customizable component, see Section 18.1.2, "How to Enable Runtime Customization Using a Page Customizable Component."

16.7.2 Change Mode Link and Change Mode Button

The Change Mode Link or Change Mode Button component provides an easy way to switch from View mode of the page to Edit mode. Figure 16–61 shows a Change Mode Link component on the page.

Figure 16–61 Change Mode Link Component

Enter your text here
Copyright © 1997, 2013, Oracle and/or its affiliates. All rights reserved.

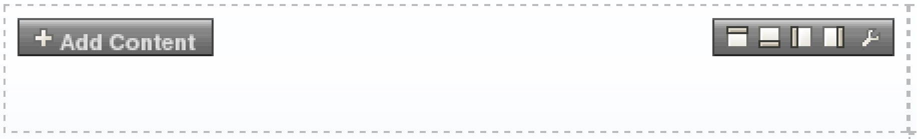
For more information about using Change Mode Link or Change Mode Button, see Section 18.1.3, "How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button."

16.7.3 Panel Customizable

A Panel Customizable defines an area of the page onto which users can add components at runtime. Users can move or minimize Show Detail Frame components and portlets that are added as child components of a Panel Customizable. Users can also drag and drop these components into another Panel Customizable component on the page.

In Edit mode, the Panel Customizable component is rendered as a box with dotted lines. In fact, a Panel Customizable is referred to as a Box in the runtime resource catalog. An **Add Content** button appears on each Panel Customizable component on the page, as shown in Figure 16–62. You can use this button to open the resource catalog Viewer and add components within the Panel Customizable.

Figure 16–62 Panel Customizable Component

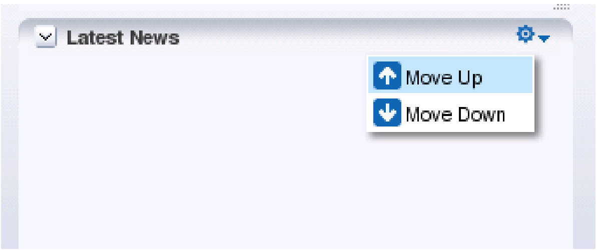


For more information, see Section 18.1.4, "How to Define Editable Areas of a Page Using Panel Customizable Components."

16.7.4 Show Detail Frame

A Show Detail Frame component renders a border or chrome around its child component along with a header that contains icons to enable users to perform some operations. The actions available on this menu enable users to move the component, along with its content, to new positions on the page (Figure 16–63). Users can also drag and drop Show Detail Frame components from one Panel Customizable component to another on the page. Note that a Show Detail Frame must be included inside a Panel Customizable component for it to be movable.

Figure 16–63 Show Detail Frame Component



A Show Detail Frame component enables the following actions:

- Collapse and expand the component
- Move content to different positions on the page
- If you add a task flow as a child component, then along with custom actions it enables task flow navigation using the Actions menu.
- If you add an ADF Faces Rich Text Editor as a child component, then it enables end users to edit and save text in the Rich Text Editor.

You can add your own UI controls to further customize the display of content by using facets of the Show Detail Frame. For information about using these facets, see Section 20.1, "Enabling Custom Actions on a Show Detail Frame Component by Using Facets."

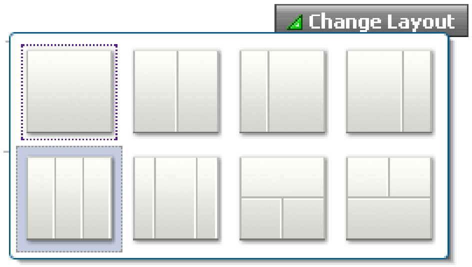
For information about adding this component to a page, see Section 18.1.6, "How to Enable Component Customization Using Show Detail Frame Components."

16.7.5 Layout Customizable

The `Layout Customizable` component is a container that enables end users to lay out its child components in several predefined ways (for example, two column, three column, and so on). You can design your page in such a way that all components on the page are enclosed in a `Layout Customizable` component. In such a case, the layout is applied to the entire page.

Access predefined layouts using the layout changer. By default, the layout changer displays both in page View mode and page Edit mode. By using the `Layout Customizable` component attributes you can choose to display the layout changer as an icon, text, or icon and text. In addition, you can decide whether to show or hide the layout changer in View mode. Figure 16–64 shows a `Layout Customizable` component and the predefined layouts that display when users click the layout changer.

Figure 16–64 Layout Customizable Component



For more information, see Section 18.1.5, "How to Enable Layout Customization for a Page Using a Layout Customizable Component."

16.8 Security and Composer

In an application that is accessed by end users, application developers, and administrators, it may not be advisable to allow all users to perform all editing tasks. For example, you may want to allow end users to only customize their view of the page by performing tasks like rearranging components or hiding areas they do not want to see. On the other hand, application developers must be allowed to update content on the page, component properties, and so on. The ability to customize a page, component, or component attribute is inherited from security definitions at the tag, page, component, and attribute levels. However, you can override the default security definitions at various levels in keeping with your business requirement.

You can define application security on many levels, including on a page, an operation, a component, or a component attribute. There are several ways in which one can restrict application customizations on a component. Composer determines if a component can be customized by honoring these rules. For example, before users can customize components, the components' sources of security restrictions are queried to determine if application customization is allowed. If a component does not permit application customization, Composer considers it restricted; that is, Composer treats the component as if it were explicitly secured. Table 16–1 describes Composer behavior to reflect application customization restrictions.

Table 16–1 Customization Restrictions on Composer Components

Restriction	Behavior
The page (and its contents) is open for all customizations	Composer allows editing of components without restrictions.

Table 16–1 (Cont.) Customization Restrictions on Composer Components

Restriction	Behavior
The page is restricted	Composer displays but none of the options, for example **Page Properties** and **Edit** icons, are accessible.
Some operations are restricted	Composer displays but the options corresponding to the restricted operations are disabled.
A component is restricted	The **Edit** icon is not rendered on the component and its properties cannot be edited.
A component's attributes are restricted	The restricted attributes are not displayed in Composer. Composer's API enables the developer to determine if a component's attributes are restricted or not.

Depending on the privileges granted while implementing security, users can perform different user and application customization tasks when they log in to the application.

> **Note:** In a secured application, it is recommended that you check all users' privileges and enable the Edit link or button on the page only for privileged users. Unauthenticated users who stumble into page Edit mode can change component properties.
>
> You can enable the Edit link or button for selected users by specifying an EL value for the `rendered` attribute on the `Change Mode Link` or `Change Mode Button` component. For more information, see Section B.1.2, "Change Mode Link and Change Mode Button."

This section describes the default security behavior of Composer components. It contains the following subsections:

- Section 16.8.1, "Page and Task Flow Security"
- Section 16.8.2, "MDS Customization Restrictions"
- Section 16.8.3, "Component Action-Level Security"

For information about overriding default security behavior, see Chapter 22, "Modifying Default Security Behavior of Composer Components."

16.8.1 Page and Task Flow Security

The application's `jazn-data.xml` file is the repository for page-level and task flow-level security information. Composer references this file and enables editing capabilities based on a user's privileges:

- A user with the Personalize privilege on a page or task flow can perform only the user customizations described in Section 16.4, "Customizing Capabilities in Page View Mode."
- A user with the Edit or Customize privilege can perform all runtime editing tasks such as adding content, editing component properties, and deleting components. Composer and Oracle WebCenter Portal Customizable Components do not differentiate between Edit and Customize privileges.

Notes: Composer and Oracle WebCenter Portal Customizable Components support cascading of privileges with Grant being a super set of all privileges. A user with Grant privilege on a page or task flow is considered to have Edit, Personalize, and View privileges. A user with Personalize privilege is considered to additionally have the View privilege.

Table 16–2 explains Composer behavior based on page- and task flow-level privileges. Only those privileges that are relevant to Composer and Oracle WebCenter Portal Customizable Components are listed in this table. The Grant privilege is not listed as it is a super set of all privileges. Users with the Grant privilege can perform all editing tasks.

Table 16–2 Mapping of Page or Task Flow Privileges to Composer Behavior

Privilege	Composer Behavior
Edit or Customize	Users can switch to Edit mode of the page, where Composer is invoked, and edit the page. Users with either the Edit or Customize privilege can perform all runtime editing tasks. With the Edit or Customize privilege on a page or task flow, users can: ■ Add content ■ Edit component properties ■ Rearrange content ■ Delete components in Composer ■ Personalize or customize a portlet ■ Move a portlet or task flow in View mode. This is persisted as a user customization. ■ Expand and collapse a task flow or portlet in View mode. This is persisted as a user customization. ■ Resize a column of a table in a task flow. This is persisted as a user customization. ■ Reset the page to its original state ■ Delete components in View mode Note: You can perform all or some of these tasks depending on whether you have page-level or task flow-level privileges. If users do not have the Edit or Customize privilege on a page but try to edit it, a message appears stating that they do not have permission to do so. If users do not have the Edit or Customize privilege on a task flow, the Edit option is not displayed for the task flow in Structure view.

Table 16–2 (Cont.) Mapping of Page or Task Flow Privileges to Composer Behavior

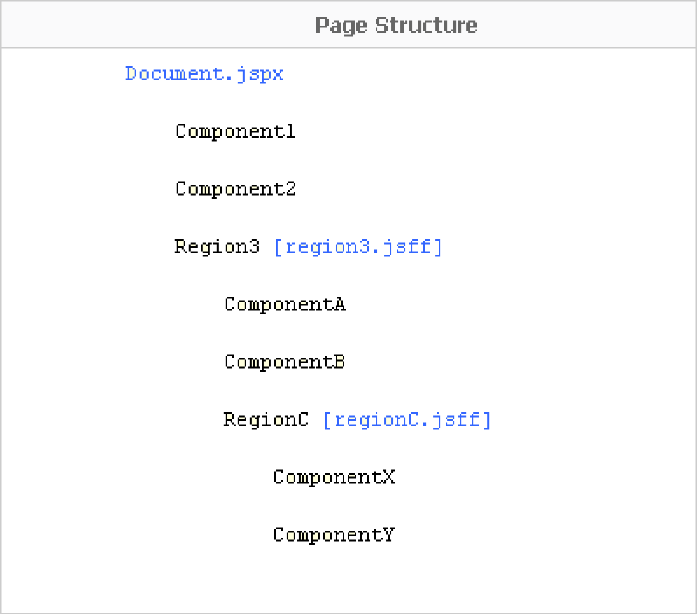
Privilege	Composer Behavior
Personalize	In View mode, users with a Personalize privilege on the page can: ■ Rearrange content ■ Personalize a portlet ■ Move a portlet or task flow in View mode. This is persisted as a user customization. ■ Expand and collapse a task flow or portlet in View mode. This is persisted as a user customization. ■ Resize a column of a table in a task flow. This is persisted as a user customization. ■ Delete components in View mode **Note**: Having Personalize permission does not enable users to perform portlet customizations. If users without Personalize, Edit, or Customize permission try to edit a page, a message appears stating that they do not have permission to do so.
View	Users with the View privilege can only view the page or task flow, but not perform user or application customizations.

16.8.1.1 Task Flow Security

When you add a task flow to a customizable page, Composer provides options for editing the task flow and components on the task flow's page. In a secured application, Composer provides editing capabilities based on the privileges provisioned on the customizable page and the task flow. For more information about task flow privileges and Composer's behavior, see Table 16–2.

On an application page, components can be located directly on the JSPX page or on page fragments inside shared components such as task flows. Restrictions on components inside a task flow are derived from the page fragment. To understand task flow security better, consider an example of a page containing a task flow, which in turn contains another task flow, as shown in Figure 16–65.

Figure 16–65 Structure of a Page Containing Nested Task Flows



```
Page Structure

Document.jspx
    Component1
    Component2
    Region3 [region3.jsff]
        ComponentA
        ComponentB
        RegionC [regionC.jsff]
            ComponentX
            ComponentY
```

Components on this page inherit security as follows:

- `Component1`, `Component2`, and `Region3` inherit security definitions from `Document.jspx`.
- `ComponentA`, `ComponentB`, and `RegionC` inherit security definitions from `region3.jsff`.
- `ComponentX` and `ComponentY` inherit security definitions from `regionC.jsff`.

Task flows do not support cascading of permissions. That is, page permissions are not inherited by components inside a task flow. However, users who do not have Edit or Customize permission on the page cannot customize task flows on the page.

For example, if you grant Edit or Customize permission on `Document.jspx` and `regionC.jsff` but not on `region3.jsff`, then users can customize `Component1`, `Component2`, `RegionC`, `ComponentX`, and `ComponentY`, but not `ComponentA`, `ComponentB`, and `RegionC`.

In a secured application, task flow permissions are stored in the application's `jazn-data.xml` file. The list of available actions for a task flow is defined by the task flow permission class, `oracle.adf.controller.security.TaskFlowPermission`. The permission class defines task flow-specific actions that it maps to the task flow's operations. By default, only View permission is provisioned on task flows. To enable users to edit a task flow at runtime, you must ensure that Customize permission is granted on the task flow. For more information, see Section 18.3.1.1, "Considerations for Adding Task Flows" and Section 22.6, "Implementing Task Flow Security."

For more information about task flows and their security behavior, see *Fusion Developer's Guide for Oracle Application Development Framework*.

16.8.2 MDS Customization Restrictions

Portal Framework applications have a default MDS configuration that restricts application customization on all application objects. To enable runtime page editing, you must make this default restriction inactive by adding a `Page Customizable` component to the page. A `Page Customizable` component enables application customization on all components under it. However, it does not enable customization on components of a nested page or fragment. For example, if the `Page Customizable` is used in a page template and has a `Facet Ref` inside it, then customization is not enabled by default on the components inside the `Facet Ref`.

You can enable application customization on a set of attributes for the component using MDS type-level restrictions or instance-level restrictions. Type-level restrictions are applicable to a specified component type across instances. At runtime, attributes for which you have enabled customization are shown as editable properties in Composer, and restricted attributes are not displayed in the Component Properties dialog for the selected component. For information, see Section 22.1, "Applying Component-Level Restrictions by Defining Customization Policies."

16.8.3 Component Action-Level Security

The `Panel Customizable` and `Show Detail Frame` components enable the placement of restrictions on individual supported actions. For example, one can specify a restriction on whether the current user is allowed to minimize the `Show Detail Frame`.

It is left to you to enforce restrictions on the actions on a component. You can specify restriction on component actions in `adf-config.xml`. If a restriction is specified and applicable to the current user, the `Panel Customizable` or `Show Detail Frame` does not render the action.

For information about applying action-level restrictions, see Section 22.5, "Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions."

17

Enabling Runtime Creation and Management of Pages

This chapter describes how to create and manage pages at runtime and also provides advanced information on managing pages.

This chapter contains the following topics:

17.1 Introduction to Page Creation and Management

You can create new pages and task flows in your application at runtime. You can base your pages on default or custom styles and templates. You can create them with either the Page - Create New task flow or the page APIs.

After you create pages or task flows, users can view and manage them with either the page data control or the page APIs. The APIs provide a means of defining a work area within the application, called a scope. Scopes are useful for categorizing custom pages that are of interest to a specific team or community (similar to a portal in WebCenter Portal).

Table 17–1 describes the page developer tools.

Table 17–1 Page Developer Tools

Tool	Description
Page - Create New	A task flow for creating pages or task flows at runtime.

Table 17–1 (Cont.) Page Developer Tools

Tool	Description
Page Data Control	A data control for viewing or deleting information about listed pages and task flows at runtime. Page Data Control is available at design time after you add the page libraries to your application. By default, the page libraries are added to the application when you use the WebCenter Portal Application template or when you add the Page - Create New task flow.
Page APIs	APIs for creating and managing pages and task flows at runtime.

Pages are integrated with many WebCenter Portal tools and services, such as links, search, and tags. You can track the most recent changes in pages with Recent Activities. Because it is preconfigured to work with Recent Activities, pages automatically produce the information that Recent Activities uses to display the most recent additions, changes, or deletions in pages.

17.2 Creating Pages and Task Flows

You can create pages and task flows at runtime with either the Page - Create New task flow or the page APIs.

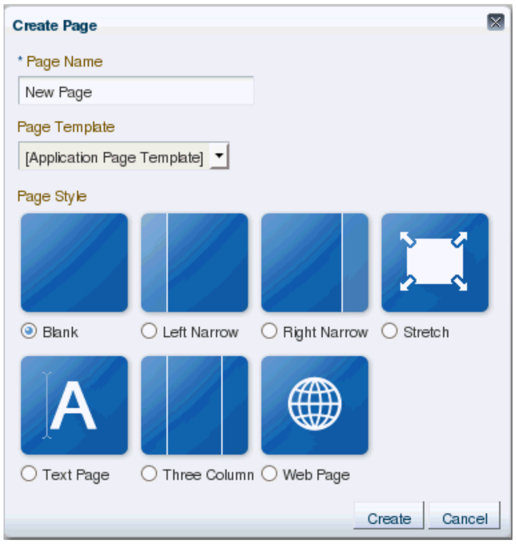
> **Note:** The Page - Create New task flow provides a means of creating pages and task flows and editing task flow parameters. To execute operations, such as copy, rename, create scope, and so on, you must use the page APIs along with the Page - Create New task flow. The page APIs provide the flexibility of customization within the pages.

The Page - Create New task flow enables you to invoke the Create Page dialog at runtime. The Create Page dialog in turn enables users to create pages based on predefined styles and templates.

Page styles and templates provide both a default page structure that describes the areas where you can place content (that is, the page layout) and a background color and image that contribute to a page's look and feel. You can select the page style and template when you create a page. You can additionally enhance the usefulness and presentability of a page using page layout components. These include an in-place HTML text editor, images, layout boxes, hyperlinks, and so on.

Figure 17–1 shows the Create Page dialog at runtime.

Figure 17–1 Create Page Dialog with Default Styles



Create Page

* Page Name

New Page

Page Template

[Application Page Template]

Page Style

● Blank ○ Left Narrow ○ Right Narrow ○ Stretch

○ Text Page ○ Three Column ○ Web Page

Some page styles include properties that suggest a particular use for the page. For example, the Web Page style includes a configurable property for specifying a URL. Among its many uses, the Web Page style provides a means of embedding wiki or blog pages and exposing external Web content within your application.

In many cases, you can switch the page layout when you revise a page. You can also start with a blank page and create layout, look, and feel from the start.

At runtime, you can view a list of pages created through the Page - Create New task flow and create, copy, update or delete those pages.

For more information, see the "Editing a Page" section in *Building Portals with Oracle WebCenter Portal*.

17.2.1 How to Create Pages

This section describes how to add the Page - Create New task flow to your application to enable the creation of pages at runtime. It contains the following subsections:

- Section 17.2.1.1, "How to Add the Page - Create New Task Flow"
- Section 17.2.1.2, "Setting Security for Pages in JDeveloper"
- Section 17.2.1.3, "How to Create Pages at Runtime"
- Section 17.2.1.4, "Structure of Pages Created at Runtime"
- Section 17.2.1.5, "How to Access Pages Created at Runtime"

17.2.1.1 How to Add the Page - Create New Task Flow

To add the Page - Create New task flow to your Portal Framework application:

1. Create a page. Follow the steps described in Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."
2. Open the customizable page to which you want to add the task flow.
3. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
4. Drag and drop the **Page - Create New** task flow onto your page.

5. When prompted, select **Region** as the way to create the task flow.
6. Click **OK**.
7. Save your page.
8. Run your application to see that the Create Page button appears on the page.
9. Click **Create Page**.

   The Create Page dialog opens (see Figure 17–1).
10. Enter a page name, then select the page template and the page style.
11. Click **Create**.

    A page is created based on the selected information. For more details on where the page is created, see Section 17.2.1.4, "Structure of Pages Created at Runtime."

> **Note:** After you add the task flow, you can edit task flow parameters. For information about Page - Create New task flow parameters, see Section 17.3, "Defining Values for the Page - Create New Task Flow Parameters."
>
> For detailed information about pages, such as how to delete pages created at runtime, see Section 17.5, "Managing Pages."

17.2.1.2 Setting Security for Pages in JDeveloper

Pages do not require their own, specific configuration of ADF security. They follow the security set up for the Portal Framework application. In a non-secured application, all pages created in the Create Page dialog appear in the data control, viewable by everyone. In a secured application, users see only the pages they create or the pages to which they are granted privileges.

To secure your application and the Page - Create New task flow:

1. Follow the steps in Section 4.2.1.1, "Implementing Security for Tools and Services."
2. After you add the **Page - Create New** task flow to a page, locate the `jazn-data.xml` file in Application Resources, and double-click its name.
3. Click **Resource Grants**, then select **Task Flow** from the **Resource Type** drop-down list.
4. Select the **Show task flows imported from ADF libraries** check box.
5. In the **Resources** column, select the **page-create-page** task flow.
6. In the **Granted To** column, click the **Add** icon to add a role to which to grant task flow access privileges.
7. Select the required role, and click **OK**.

   The newly added role is displayed in the Granted To list.
8. In the **Actions** column, select the privileges to grant to the selected role (Figure 17–2).

Figure 17–2 Adding Privileges for the Page - Create New Task Flow

9. From Resource Type, select **Web Page** to apply security to the page on which you added the Page - Create New task flow.

   Follow the same procedure outlined in steps 5 through 8: select a page, add roles, and apply privileges.

Note: The **Page Data Control** data control does not require any security setting for a secure or non-secure application.

17.2.1.3 How to Create Pages at Runtime

For detailed information, see the "Creating and Editing a Portal Page" chapter in *Building Portals with Oracle WebCenter Portal*.

17.2.1.4 Structure of Pages Created at Runtime

The pages you create at runtime using the Page - Create New task flow or the page APIs are stored in the `mds` folder, located under your application root. Table 17–2 provides examples of the default formats used for page and task flow file names.

Table 17–2 Default File Name Formats

File Type	Format
Page	`Page<N>.jspx` (value of N starts from 1) For example: `Page1.jspx`, `Page2.jspx`, `Page<N>.jspx`
Page Definition	`Page1PageDef.xml`, `Page2PageDef.xml`, `Page<N>PageDef.xml`
Task Flow View pages	`Page1.jsff`, `Page2.jsff`, `PageN.jsff`
Task Flow View Page Definitions	`Page1PageDef.xml`, `Page2PageDef.xml`, `Page<N>PageDef.xml`
Task Flow Definitions	`Page1.xml`, `Page2.xml`, `Page<N>.xml`

When you use the page APIs to create pages, you can provide a custom value for the file name format. For example: `myPage<`*N*`>.jspx` (value of N starts from 1)

The following examples show the structure of a page (`Page1.jspx`) and its associated page definition (`Page1PageDef.xml`) created at runtime by the user `user1`.

Example 17–1 Page Created Under a Default Scope

```
mds\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1.jspx
```

Example 17–2 Page Definition Created Under a Default Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1PageDef.xml
```

Example 17–3 Page Created Under a Custom Scope

```
mds\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1.jspx
```

Example 17–4 Page Definition Created Under a Custom Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1PageDef.xml
```

In Example 17–4, the `scopeGUID` is a unique ID assigned to a specific scope by pages.

Example 17–5 Task Flow View Page Created Under a Default Scope

```
mds\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1.jspx
```

Example 17–6 Task Flow Definition Created Under a Default Scope

```
mds\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1.xml
```

Example 17–7 Task Flow View Page Definition Created Under a Default Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1PageDef.xml
```

Example 17–8 Task Flow View Page Created Under a Custom Scope

```
mds\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1.jspx
```

Example 17–9 Task Flow Definition Created Under a Custom Scope

```
mds\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1.xml
```

Example 17–10 Task Flow Page Definition Created Under a Custom Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1PageDef.xml
```

In Example 17–10, the `scopeGUID` is a unique ID assigned to a specific scope by the pages.

17.2.1.5 How to Access Pages Created at Runtime

To access pages with a default scope, enter the following URL:

```
http://<server>:<port>/<app name>/faces/oracle/webcenter/page/scopedMD/s8bba98ff_
4cbb_40b8_beee_296c916a23ed/user/<user guid>/Page1.jspx
```

To access pages with a custom scope, enter the following URL:

```
http://<server>:<port>/<app name>/faces/oracle/webcenter/page/scopedMD/<scope
guid>/Page1.jspx
```

17.3 Defining Values for the Page - Create New Task Flow Parameters

This section describes how to access and define values for the Page - Create New task flow parameters. It contains the following subsections:

- Section 17.3.1, "How to Access Page - Create New Task Flow Parameters"
- Section 17.3.2, "Setting Scope in a Page - Create New Task Flow"
- Section 17.3.3, "Setting an Outcome Parameter"
- Section 17.3.4, "Specifying Styles"
- Section 17.3.5, "Specifying an ADF Template"
- Section 17.3.6, "Showing a Command Link"
- Section 17.3.7, "Displaying an Image"
- Section 17.3.8, "Customizing the Label"

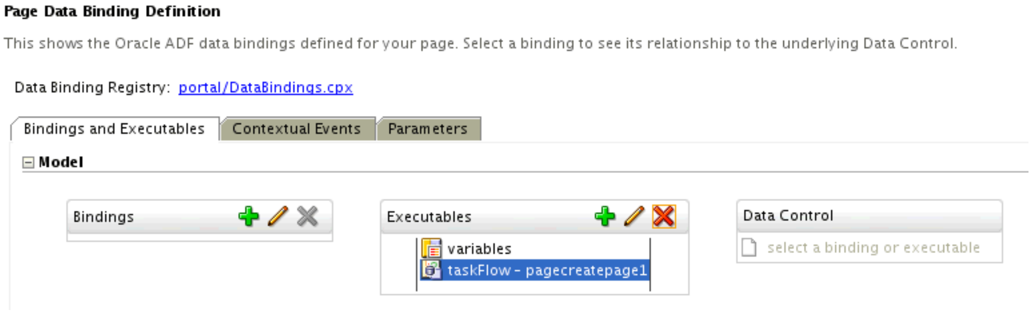
17.3.1 How to Access Page - Create New Task Flow Parameters

To access Page - Create New task flow parameters:

1. Go to the Application Navigator and right-click the `.jspx` page with the Page - Create New task flow, then select **Go to Page Definition**.
2. In the Executables section, scroll to select the **pagecreatepage** task flow.
3. Click the **Edit** (pencil) icon to edit any of the parameters.

   The Page Data Binding Definition in the design view is shown in Figure 17–3.

Figure 17–3 Page Data Binding Definition



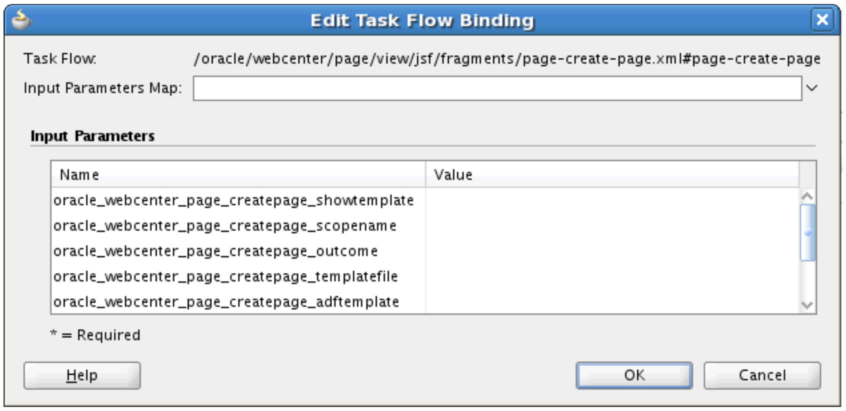
Page Data Binding Definition

This shows the Oracle ADF data bindings defined for your page. Select a binding to see its relationship to the underlying Data Control.

Data Binding Registry: portal/DataBindings.cpx

The **Edit Task Flow Binding** dialog opens, as shown in Figure 17–4.

Figure 17–4 Edit Task Flow Binding for the Page - Create New Task Flow



Task Flow: /oracle/webcenter/page/view/jsf/fragments/page-create-page.xml#page-create-page

Input Parameters Map:

Input Parameters

Name	Value
oracle_webcenter_page_createpage_showtemplate	
oracle_webcenter_page_createpage_scopename	
oracle_webcenter_page_createpage_outcome	
oracle_webcenter_page_createpage_templatefile	
oracle_webcenter_page_createpage_adftemplate	

* = Required

The following optional Page - Create New parameters are available:

- `showtemplate`

  By default, the Page Template drop-down list appears in the Create Page task flow at application runtime. You can choose to hide the page templates option by setting `showtemplate` to `false`.

- `scopename`

  For information, see Section 17.3.2, "Setting Scope in a Page - Create New Task Flow."

- `outcome`

  For information, see Section 17.3.3, "Setting an Outcome Parameter."

- `templatefile`

  For information, see Section 17.3.4, "Specifying Styles."

- `adftemplate`

  For information, see Section 17.3.5, "Specifying an ADF Template."

- `uitype`

  For information, see Section 17.3.6, "Showing a Command Link."

- `icon`

  For information, see Section 17.3.7, "Displaying an Image."

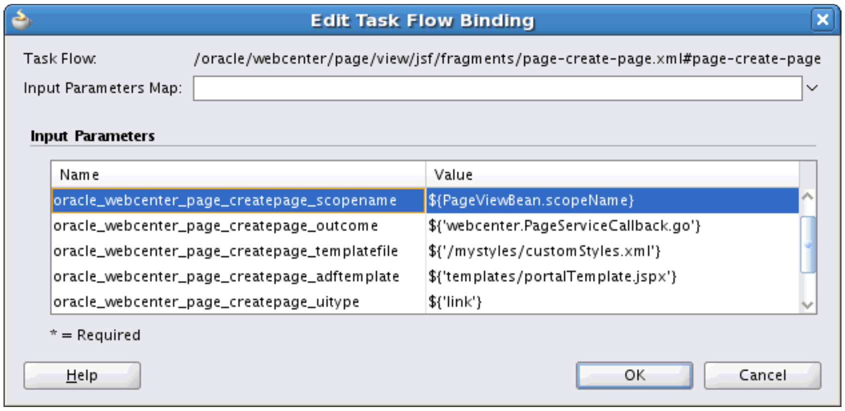
- `label`

  For information, see Section 17.3.8, "Customizing the Label."

17.3.2 Setting Scope in a Page - Create New Task Flow

By default, the pages and task flows you create using the Page - Create New task flow are stored in the default scope. To assign a specific scope to the Page - Create New task flow, the scope name must be assigned to the `oracle_webcenter_page_createpage_scopename` parameter, as shown in Figure 17–5.

Figure 17–5 oracle_webcenter_page_createpage_scopename Parameter



Edit Task Flow Binding

Task Flow: /oracle/webcenter/page/view/jsf/fragments/page-create-page.xml#page-create-page

Input Parameters Map:

Input Parameters

Name	Value
oracle_webcenter_page_createpage_scopename	${PageViewBean.scopeName}
oracle_webcenter_page_createpage_outcome	${'webcenter.PageServiceCallback.go'}
oracle_webcenter_page_createpage_templatefile	${'/mystyles/customStyles.xml'}
oracle_webcenter_page_createpage_adftemplate	${'templates/portalTemplate.jspx'}
oracle_webcenter_page_createpage_uitype	${'link'}

* = Required

In Figure 17–5, `PageViewBean` is a custom managed bean that is invoking the `getScopeName()` method to fetch the value of `scopeName`. It uses the page API. By doing this, the Page - Create New task flow creates all pages and task flows under the specified scope, rather than the default scope.

The following example code highlights only the creation of scope. If a scope already exists, then users can get the scope name from the `Scope` object.

Example 17–11 Creating a Scope for Application Pages

```
import oracle.webcenter.framework.service.Scope;
import oracle.webcenter.framework.service.ScopeAlreadyExistsException;
import oracle.webcenter.framework.service.ServiceContext;

public class PageViewBean {
    private String scopeName;

    public String getScopeName() {
        String scopeName = "MyScope";
        ServiceContext sContext = ServiceContext.getContext();
        try {
            Scope scope =
                sContext.createScope(scopeName); // Creates a new scope
            this.scopeName = scope.getName(); // Returns the scope name
            sContext.setScope(scope); // Setting the Scope. This step is
important.
        } catch (ScopeAlreadyExistsException scopeExistsException) {
            System.out.println("Scope Already Exists...");
        }
        return this.scopeName;
    }

    public void setScopeName(String scopeName) {
        this.scopeName = scopeName;
    }

}
```

17.3.3 Setting an Outcome Parameter

The outcome parameter defines a Java method that is called after the page is created. In this method, you can add dynamic content to the page, refresh the user interface that calls up the dialog to confirm creation of a new page, or initiate browser navigation to the newly created page. To specify a Java method to invoke after page creation (that is, it is called after users click the **Create** button in the Create Page dialog), enter the following in the Edit Task Flow Binding dialog:

```
oracle_webcenter_page_createpage_outcome = ${'view.MyTestClass.go'}
```

You can define the method either with a String parameter or with no parameter. The String parameter value is the new page's name with full path. If the method is defined both ways, then the one with a parameter is invoked.

In the following example, the method `go(String newPagePath)` is invoked. This method redirects users to the newly created page with the Java class `MyTestClass.java`. The value of `newPagepath` is passed by pages.

```
package view;

import javax.faces.context.ExternalContext;
import javax.faces.context.FacesContext;
import javax.faces.event.ActionEvent;

public class MyTestClass {
    public MyTestClass() {
    }

    /*
       This method is executed only when there is no other go(String newPagePath)
method with a String argument .
    */
    public void go() {
        System.out.println("go() method without parameters executed.");
    }

    /*
       This method is prioritized and executed even when there are other go()
methods without arguments.
    */
    public void go(String newPagePath) {
        System.out.println("go(String newPagePath) method with parameter
executed.");
        try {
            FacesContext context = FacesContext.getCurrentInstance();
            String viewID = context.getViewRoot().getViewId();
            System.out.println("ViewID=" + viewID);

            ExternalContext extCtx = context.getExternalContext();
            String targetURI =
                extCtx.getRequestContextPath() + "/faces" + viewID;
            System.out.println("Navigate to: " + targetURI);
            extCtx.redirect(targetURI);
            context.responseComplete();
        } catch (Exception ee) {
            System.out.println("Error: " + ee.toString());
        }

    }
}
```

17.3.4 Specifying Styles

Pages provide out-of-the-box styles that are packaged within the page libraries. You can use these styles or create your own custom styles.

This section describes how to apply out-of-the-box styles and custom styles. It contains the following subsections:

- Section 17.3.4.1, "Out-of-the-Box Styles"
- Section 17.3.4.2, "Custom Styles"

> **Note:** For more information about styles, see Section 17.6, "Introduction to Custom Styles and Templates."

17.3.4.1 Out-of-the-Box Styles

The following out-of-the-box-styles are provided (see Figure 17–1):

- Blank
- Left Narrow
- Right Narrow
- Stretch
- Text Page
- Three Column
- Web Page

To associate out-of-the-box styles with the Page - Create New task flow, use the optional parameter `oracle_webcenter_page_createpage_templatefile`. Use the parameter value to specify the location of the file that contains the list of out-of-the-box styles.

To associate out-of-the-box styles with the Page - Create New task flow:

1. Create a folder named `mystyles` under your Portal Framework application's `public_html` folder.
2. Within `mystyles`, create a file named `default_pageservice_styles.xml`.
3. Add entries for all the out-of-the-box styles using the `templateDef` element.

   The `templateDef` element takes the following attributes:

   - `name`: This attribute specifies the path to the `.jspx` page that defines a page style. When you use the default styles, you must specify the path to the page that defines the style you intend to use. The default page style page files are located within the page libraries. For example:

     ```
     name="/oracle/webcenter/page/pstemplates/TemplateThreeColumn.jspx"
     ```

     `TemplateThreeColumn.jspx` is the page within the page library that defines the Three Column Template style.
   - `title`: The value you enter for `title` is used as the name for the style in the Create Page dialog. You can modify the title of an out-of-the-box style to any name. For example: `title="Three Column Layout"` or `title="Sales Standard"`.
   - `icon`: This attribute specifies an image icon for a style.

For out-of-the-box styles, if you do not specify an icon for a style, the default icons assigned to each out-of-the-box style are used.

Example 17–12 shows the content of a sample `default_pageservice_styles.xml` file that lists the other out-of-the-box styles:

Example 17–12 Sample default_pageservice_styles.xml File

```
<?xml version="1.0" encoding="UTF-8" ?>
 <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateThreeColumn.jspx"
title="Three Column Layout" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateText.jspx"
title="Text Page" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateStretch.jspx"
title="Stretch" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateWeb.jspx"
title="Web Page" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateBlank.jspx"
title="Blank" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateNarrowLeft.jspx"
title="Left Narrow Column Layout" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateNarrowRight.jspx"
title="Right Narrow Column Layout" />
 </templatesDef>
```

4. Open the Edit Task Flow Binding dialog as described in Section 17.3.1, "How to Access Page - Create New Task Flow Parameters."

5. Set the `oracle_webcenter_page_createpage_templatefile` parameter value to `${'/mystyles/default_pageservice_style.xml'}`.

   For example:

   ```
   oracle_webcenter_page_createpage_templatefile = ${'/mystyles/default_
   pageservice_style.xml'}
   ```

6. Click **OK**.

17.3.4.2 Custom Styles

In this example, you associate a custom style, labeled **News**, with the Page - Create New task flow.

To associate a custom style with the Page - Create New task flow:

1. Define your custom style in a `.jspx` file (for example, `NewsTemplate.jspx`).

   > **Note:** For information about how to create ADF templates, see Section 17.6, "Introduction to Custom Styles and Templates."

2. Add an entry for the custom style in an XML file (for example, `custom_pageservice_style.xml`).

   For example:

   ```
   <?xml version="1.0" encoding="UTF-8" ?>
     <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
       <templateDef name="NewsTemplate.jspx" title="News" icon="/images/news.png"
   />
     </templatesDef>
   ```

Note: For more information about the syntax to use for `templateDef` element and the style-related `.xml` file, see Section 17.3.4.1, "Out-of-the-Box Styles."

---

3. Save the `custom_pageservice_style.xml` under a folder in your application's `public_html` folder.

   For example:

   ```
   …/public_html/mystyles/custom_pageservice_style.xml
   ```

4. The following files must be placed in the same folder as `custom_pageservice_style.xml`:

   - The file that defines the custom style, for example, `NewsTemplate.jspx`.
   - The page definition file of the custom style file, for example, `NewTemplatePageDef.xml`.
   - The ADF Template (for example, `defaultTemplate.jspx`) on which the custom style file is based. This step is applicable only if you are using ADF templates.

   Note: If you specify the location of an ADF template using the `oracle_webcenter_page_createpage_adftemplate`, then you *do not* need to put this file (`defaultTemplate.jspx`) under the `mystyles` folder. You can specify a different location for the file by following Section 17.3.5, "Specifying an ADF Template."

   ---

5. Open the Edit Task Flow Binding dialog as described in Section 17.3.1, "How to Access Page - Create New Task Flow Parameters."

6. Set the `oracle_webcenter_page_createpage_templatefile` parameter to `${'/mystyles/custom_pageservice_style.xml'}`, where `mystyles` is a folder under the `public_html` folder of your application.

   For example:

   ```
   oracle_webcenter_page_createpage_templatefile = ${'/mystyles/custom_
   pageservice_style.xml'}
   ```

17.3.5 Specifying an ADF Template

When you want to use the same template for both design time and runtime pages, you can use an ADF template. All that is required is to point the Page - Create New task flow to the template location.

To associate an ADF template with the Page - Create New task flow:

1. Open the Edit Task Flow Binding dialog as described in Section 17.3.1, "How to Access Page - Create New Task Flow Parameters."

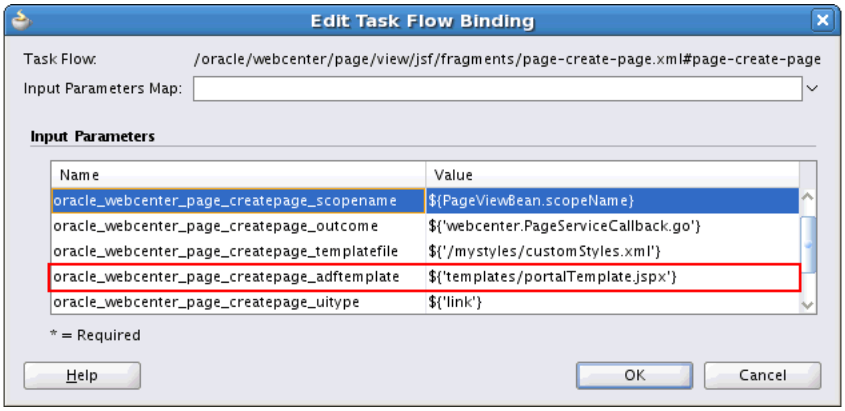
2. In the Value column next to the `oracle_webcenter_page_creatpage_adftemplate` parameter, enter the path to the ADF template.

   For example:

   ```
   ${'templates/portalTemplate.jspx'}
   ```

In Figure 17–6, an ADF template called `portalTemplate.jspx` is used.

Figure 17–6 oracle_webcenter_page_createpage_adftemplate Parameter



Task Flow: /oracle/webcenter/page/view/jsf/fragments/page-create-page.xml#page-create-page

Input Parameters Map:

Input Parameters

Name	Value
oracle_webcenter_page_createpage_scopename	${PageViewBean.scopeName}
oracle_webcenter_page_createpage_outcome	${'webcenter.PageServiceCallback.go'}
oracle_webcenter_page_createpage_templatefile	${'/mystyles/customStyles.xml'}
oracle_webcenter_page_createpage_adftemplate	${'templates/portalTemplate.jspx'}
oracle_webcenter_page_createpage_uitype	${'link'}

* = Required

ADF templates can be in your application's `public_html` folder. In this case, the path of `portalTemplate.jspx` is `../public_html/templates/portalTemplate.jspx`.

3. Click **OK**.

17.3.6 Showing a Command Link

By default, the Page - Create New task flow is rendered as a command *button* (Figure 17–7). You can instead specify that it is rendered as a command *link* (Figure 17–8).

Figure 17–7 Command Button

Figure 17–8 Command Link

To render the Page - Create New task flow as a command link:

1. Open the Edit Task Flow Binding dialog as described in Section 17.3.1, "How to Access Page - Create New Task Flow Parameters."

2. Revise the `oracle_webcenter_page_createpage_uitype` parameter to the following value: `${'link'}`.

   For example:

   ```
   oracle_webcenter_page_createpage_uitype = ${'link'}
   ```

3. Click **OK**.

17.3.7 Displaying an Image

You can associate an icon with the Page - Create New task flow button or link.

To specify an icon for the Page - Create New task flow button or link:

1. Open the Edit Task Flow Binding dialog as described in Section 17.3.1, "How to Access Page - Create New Task Flow Parameters."
2. Revise the `oracle_webcenter_page_createpage_icon` parameter to the required value.

   For example:

   ```
   oracle_webcenter_page_createpage_icon = ${'/images/page.jpg'}
   ```

3. Click **OK**.

17.3.8 Customizing the Label

By default, the label for the Page - Create New task flow command button or link is **Create Page**. You can provide your own value using the `oracle_webcenter_page_createpage_label` parameter value.

Figure 17–9 shows the task flow rendered as a command button with a custom label.

Figure 17–9 Custom Label

To change the command button or link label:

1. Open the Edit Task Flow Binding dialog as described in Section 17.3.1, "How to Access Page - Create New Task Flow Parameters."
2. Revise the `oracle_webcenter_page_createpage_label` parameter to your preferred string value.

   For example:

   ```
   oracle_webcenter_page_createpage_label = ${'Create New Page'}
   ```

3. Click **OK**.

17.4 How to Create Task Flow View Pages

The following types of objects are required for the creation of a task flow view page:

- Task flow view page (JSFF file)
- Page definition of view page
- Task flow definition XML file, which defines the task flow

To enable the creation of task flow view pages through the Page - Create New task flow:

1. At design time, add a **Page - Create New** task flow to your page (`home.jspx`).
2. Open the Edit Task Flow Binding dialog as described in Section 17.3.1, "How to Access Page - Create New Task Flow Parameters."
3. Change the label on the Create Page button or link by revising the value specified for the `oracle_webcenter_page_createpage_label` parameter.

   For example:

   ```
   oracle_webcenter_page_createpage_label = ${'Create Task Flow'}
   ```

4. Click **OK**.

5. Create an XML file (for example, custom_taskflow_styles.xml) to contain entries for all the task flow styles.

   For example:

   ```
   <?xml version='1.0' encoding="UTF-8"?>
   <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
     <templateDef name="mytaskflow_view.jsff" title="News"
   icon="/images/news.png" type="taskflow"/>
   </templatesDef>
   ```

   The element templateDef in the XML file contains the following attributes:

   - name: to specify the name of the task flow view page
   - title: to specify the label to associate with the task flow view page style in the Create Page dialog.
   - icon: to specify the image icon for the task flow

   Note: For sample attribute syntaxes, see step 3 in Section 17.3.4.1, "Out-of-the-Box Styles."

6. Under your application's public_html folder, create a folder (for example, mystyles) and add the custom_taskflow_styles.xml file to it.

7. Make sure that the following files are also under the mystyles folder:

   - mytaskflow_view.jsff (task flow view page)
   - mytaskflow_viewPageDef.xml (task flow view page definition)
   - mytaskflow_view.xml (task flow definition)

8. Open the Edit Task Flow Binding dialog again, and provide the path to the XML file you created in step 5, for the oracle_webcenter_page_createpage_templatefile parameter.

   For example:

   ```
   oracle_webcenter_page_createpage_templatefile=${'/mystyles/custom_taskflow_
   styles.xml' }
   ```

   In this example, mystyles is a folder under the public_html folder of your application.

9. Run the home.jspx page, and then click the **Create Task Flow** button.

10. Enter the title of the task flow, select the **News** style (that you created in Section 17.3.4.2, "Custom Styles"), and then click **Create**.

    The new task flow view page is rendered.

For information about where the task flows are created, see Section 17.2.1.4, "Structure of Pages Created at Runtime."

17.5 Managing Pages

You can manage pages using either the Page data control or the page APIs. This section contains the following subsections:

- Section 17.5.1, "Using the Page Data Control to Manage Pages"
- Section 17.5.2, "Using the Page APIs to Manage Pages and Task Flows"

17.5.1 Using the Page Data Control to Manage Pages

You can customize page views with the Page data control. The data control enables you to view information about existing pages at runtime and delete any of the listed pages. The Page data control, `Page Data Control`, is included in page libraries and is available at design time after you add the libraries to the application.

For more information about the Page data control, see Section 17.8.2, "Using the Page Data Control."

17.5.2 Using the Page APIs to Manage Pages and Task Flows

You can use APIs to manage pages and task flows. These include APIs to delete pages and task flows, change the hidden status, change the page scheme (name, background color, background image), and copy pages.

For more information about page APIs, see Section 17.8.1, "Using the Page Java APIs."

17.6 Introduction to Custom Styles and Templates

At runtime, when users click the Create Page option, the Create Page dialog displays a set of predefined styles for creating the page (see Figure 17–1). Users select one of these page styles to create a page based on the associated style template. The *style* provides a special look and feel to your pages. The *template* provides the page layout. Templates are the ADF pages on which runtime pages are based. Pages can be based on default or custom styles and templates.

To provide custom selections for the Create Page dialog, you must define them, for example, in `/mytemplates/templates.xml`. Place the directory `/mytemplates` under the web content root.

If you choose *not* to use the default options available with the Create Page dialog, then you can use the following types of custom templates in your application:

- Page and page fragment templates for use with runtime pages
- ADF templates for use as the base for page and page fragment templates
- Templates to be used by the Create Page dialog itself

This section explains how to customize the Page - Create New task flow to use different templates for the Create Page dialog and for the new pages that you create at runtime. It contains the following subsections:

- Section 17.6.1, "How to Create Templates for Pages Created at Runtime"
- Section 17.6.2, "Using ADF Templates"
- Section 17.6.3, "Creating Styles for the Create Page Dialog"

> **Note:** For more information about the `templates.xml` file, see Section 17.3.4, "Specifying Styles."

17.6.1 How to Create Templates for Pages Created at Runtime

You can create custom page templates according to your design requirements and associate page styles with these templates. If you want to restrict the style options in the Create Page dialog or provide a different set of styles, then you must perform the following high-level tasks:

- Create pages or page fragments to be used as templates for the different page styles.
- Edit the Create Page dialog parameter to specify new page styles.

This section steps you through both procedures. It contains the following subsections:

- Section 17.6.1.1, "How to Create a Page or Page Fragment Style"
- Section 17.6.1.2, "How to Edit Create Page Dialog Styles"

17.6.1.1 How to Create a Page or Page Fragment Style

To create a page or page fragment style:

1. In Oracle JDeveloper, create a JSF template with all necessary information, such as header, welcome message, login/logout links, and so on.
2. When creating pages, create a page (JSPX) based on that template.

   When creating task flows, create a page fragment (JSFF) based on that template.

   When creating a page based on a template, the template is copied and a new page is created based on it.
3. Put all the necessary content in the JSPX or JSFF file.

   For example, if there is a facet where you would like to display content, you can drop a Page Customizable component from Composer around it to make the page editable at runtime. Make sure you set the correct values for the `document title`, `styleClass`, and `inlineStyle` attributes.

   > **Note:** If this page or page fragment will be used as a template for pages that can be customized at runtime, then you must ensure that the `ID` attribute on all components on this page or fragment is set to a unique value.

   Example 17–13 shows the sample code of a page fragment style, `pstemplateview.jsff`.

Example 17–13 Sample Code of a New Page Style

```
<?xml version='1.0' encoding='utf-8'?>

```
         <af:form usesUpload="true" id="f1">
           <af:pageTemplate
viewId="/oracle/webcenter/page/pstemplates/defaultTemplate.jspx" id="T">
             <f:facet name="content">
               <pe:pageCustomizable id="pcl1">
                 <af:panelStretchLayout id="psl2"
                                        styleClass="replace_with_scheme_name"
                                        inlineStyle="replace_with_inline_style">
                   <f:facet name="center">
                     <af:panelGroupLayout id="pgl1"
                                          layout="scroll">
                       <pe:layoutCustomizable id="lc1"
                                 showLayoutChanger="#{pageServiceBean.isEditMode}"
                                 text="Change Layout"
                                 showIcon="false"
                                 type="threeColumnNarrow"
                                 shortDesc="Layout Changer">
                         <cust:panelCustomizable id="mainC"/>
                         <f:facet name="contentA">
                           <cust:panelCustomizable id="cnta"/>
                         </f:facet>
                         <f:facet name="contentB">
                           <cust:panelCustomizable id="cntb"/>
                         </f:facet>
                       </pe:layoutCustomizable>
                     </af:panelGroupLayout>
                   </f:facet>
                 </af:panelStretchLayout>
                 <f:facet name="editor">
                   <pe:pageEditorPanel id="pep1"/>
                 </f:facet>
               </pe:pageCustomizable>
             </f:facet>
           </af:pageTemplate>
         </af:form>
       </af:document>
```

Note: The page definition file of the JSPX page, which defines the style, must contain the following syntax for the `id` and `Package` attributes. These values are replaced with the relevant values when a page is created based on a custom style.

```
<?xml version="1.0" encoding="UTF-8" ?>
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel"
                version="11.1.1.41.30"
                id="ps_pagedefusage"
                Package="ps_package">
```

Alternatively, the JSPX or JSFF template file that you are creating can be based on an ADF template.

Example 17–14 shows the sample code of an ADF template.

Note: If you choose to design your own ADF templates and want to set page style, then you must have a `Panel Group Layout` or `Panel Stretch Layout` component as a direct child of the `Page Customizable`. Additionally, you must set the placeholder for `styleClass` and `inlineStyle`, as shown in **bold** below. The page style values replace the placeholder text.

Example 17–14 Sample Code of a Page Style that uses an ADF Template

```
<?xml version='1.0' encoding='utf-8'?>
<!-- Copyright (c) 2006, 2008, Oracle and/or its affiliates.

<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"
          xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <jsp:directive.page deferredSyntaxAllowedAsLiteral="true"/>
  <jsp:directive.page contentType="text/html;charset=utf-8"/>
  <f:view>
    <af:document title="#{pageDocBean.title}" id="docrt">
      <af:form usesUpload="true" id="f1">
        <af:pageTemplate

viewId="/oracle/webcenter/webcenterapp/view/templates/WebCenterAppShellTemplate.js
px"
                value="#{bindings.shellTemplateBinding}" id="T">
          <f:facet name="content">
            <pe:pageCustomizable id="pcl1">
              <af:panelStretchLayout id="psl2"
                                     styleClass="replace_with_scheme_name"
                                     inlineStyle="replace_with_inline_style">
                <f:facet name="center">
                  <af:panelGroupLayout id="pgl1"
                                       layout="scroll">
                    <pe:layoutCustomizable id="lc1"

showLayoutChanger="#{pageServiceBean.isEditMode}"
                                           text="#{uib_o_w_w_r_WebCenter.LABEL_
CHANGE_LAYOUT}"
                                           showIcon="false" type="oneColumn"
                                           shortDesc="#{uib_o_w_w_r_
WebCenter.LABEL_CHANGE_LAYOUT}">
                      <cust:panelCustomizable id="mainC"/>
                      <f:facet name="contentA">
                        <cust:panelCustomizable id="cnta"/>
                      </f:facet>
                      <f:facet name="contentB">
                        <cust:panelCustomizable id="cntb"/>
                      </f:facet>
                    </pe:layoutCustomizable>
                  </af:panelGroupLayout>
                </f:facet>
              </af:panelStretchLayout>
              <f:facet name="editor">
                <pe:pageEditorPanel id="pep1"/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:pageTemplate>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

Example 17–15 shows the sample code of a page style, `NewsTemplate.jspx`, that is based on an ADF template, `portalTemplate.jspx`. The `viewId` attribute of the `af:pageTemplate` tag provides the name of the ADF template used.

For information about using ADF templates, see *Web User Interface Developer's Guide for Oracle Application Development Framework*.

Example 17–15 Sample Code of a Page Style Based on an ADF Template

```
<?xml version='1.0' encoding='utf-8'?>
<!-- Copyright (c) 2006, 2008, Oracle and/or its affiliates.

                        showLayoutChanger="#{pageServiceBean.isEditMode}"
                                     text="#{res['TEMPLATE.CHANGE_LAYOUT']}"
                                     showIcon="false" type="oneColumn"
                                     shortDesc="#{res['TEMPLATE.CHANGE_LAYOUT']}">
                      <cust:panelCustomizable id="mainC">
                        <cust:showDetailFrame id="sdf2"
                                              showMinimizeAction="none"
                                              showMoveAction="none"
                                              showRemoveAction="none"
                                              displayHeader="false"
                                              displayShadow="false"
                                              stretchContent="false"
                                              shortDesc="#{null}"
                                              background="light"
                                              showResizer="never"
                                              text="Text">
                          <af:richTextEditor id="rtepc" clientComponent="true"
                                             simple="true" label="#{null}"
                                             rows="20" readOnly="false"
                                             contentStyle="width:100%;"/>
                        </cust:showDetailFrame>
                      </cust:panelCustomizable>
                      <f:facet name="contentA">
                        <cust:panelCustomizable id="cnta"/>
                      </f:facet>
                      <f:facet name="contentB">
                        <cust:panelCustomizable id="cntb"/>
                      </f:facet>
                    </pe:layoutCustomizable>
                  </af:panelGroupLayout>
                </f:facet>
              </af:panelStretchLayout>
              <f:facet name="editor">
                <pe:pageEditorPanel/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:pageTemplate>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

To display a different style or use a different template for a style, you must define it, for example, in `/mytemplates/templates.xml`. Place the directory `/mytemplates` under the web content root. For more information about the `templates.xml` file, see Section 17.3.4, "Specifying Styles."

Example 17–16 shows a sample `templates.xml` file.

Example 17–16 templates.xml File

```
<?xml version='1.0' encoding="UTF-8"?>
<templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
  <templateDef name="TemplateBlank.jspx"
               title="Blank"/>
  <templateDef name="TemplateNarrowLeft.jspx"
               title="Left Narrow Column Layout"/>
  <templateDef name="TemplateNarrowRight.jspx"
               title="Right Narrow Column Layout"/>
  <templateDef name="TemplateThreeColumn.jspx"
               title="Three Column Layout"/>
  <templateDef name="TemplateStretch.jspx"
               title="Stretch"/>
  <templateDef name="TemplateText.jspx"
               title="Text"/>
  <templateDef name="TemplateWeb.jspx"
               title="Web"/>
  <templateDef name="NewsTemplate.jspx"
               title="News"/>
</templatesDef>
```

17.6.1.2 How to Edit Create Page Dialog Styles

To edit the styles for the Create Page dialog and add a reference to the new page style:

1. Create the `/mytemplates/templates.xml` file, commenting out `templateDef` entries for any default page styles that you do not want to display.
2. In the `templateDef` entry for the style that you want to associate with a different template, edit the `name` and `type` attributes, as shown in the following example:

```
<templateDef name="pstemplateview.jsff"
             title="News"
             icon="/images/news.png"
             type="taskflow"/>
```

where

- name is the name of the page style that you want to use.
- title is the label displayed for the style in the Create Page dialog.
- type is the type of page style. It can take the value page or task flow. The default value page, creates a page based on the style's associated template. The value task flow creates a task flow view of a page based on the style's associated template.

3. If you want to add a new style to the Create Page dialog, add a templateDef entry, as shown in the following example:

```
<templateDef name="pstemplateview3.jsff"
             title="Rich Text"
             type="taskflow"
             forGroupSpace="false"/>
```

4. Save the XML file.

At runtime, the Create Page dialog displays the styles you specified. The pages and task flow page views users create using those styles are based on the JSPX or JSFF templates you defined.

17.6.2 Using ADF Templates

If your page template is based on an ADF template, you can configure the page creation task flow to use a different ADF template depending on different criteria, such as user or scope.

You can specify the ADF template to use for runtime page creation in either of the following ways:

- By using the oracle_webcenter_page_createpage_adftemplate parameter in the page creation task flow (see Section 17.3.4, "Specifying Styles").
- By using the ADFTemplateViewID parameter in the createPage() and createTaskflow() APIs.

Any JSPX page template that is based on an ADF template contains an af:pageTemplate tag with the viewId attribute. The viewId attribute contains the name of the ADF template. Example 17–15 shows a page template that is based on the ADF template portalTemplate.jspx.

When you specify an ADF template name for use during page creation, the af:pageTemplate tag in the page template is searched and the viewId attribute is updated with the value you provided.

This section describes how to specify which ADF template to use under a given circumstance. It contains the following subsections:

- Section 17.6.2.1, "How to Specify the ADF Template Name Using the Task Flow Parameter"
- Section 17.6.2.2, "How to Specify the ADF Template Name Using API Parameters"

17.6.2.1 How to Specify the ADF Template Name Using the Task Flow Parameter

To specify the ADF template name using the task flow parameter:

1. Open the JSPX file containing the Page - Create New task flow.
2. Right-click the page name and select **Go to Page Definition**.
3. In the page definition file, under Executables, select the Create Page task flow, and click the **Edit** icon on the header.
4. The Edit Task Flow Binding dialog opens with the list of input parameters supported by the task flow.
5. Set the `oracle_webcenter_page_createpage_adftemplate` parameter.

   If you define a constant value, for example `${'/mytemplates/defaultTemplate2.jspx'}`, then this ADF template is used for all pages created using the create page task flow.

   However, by providing an EL value for the parameter, you can ensure that a different ADF template is used based on different criteria, such as user or scope.

   For example, assume you have two users, `user1` and `user2`, and want to use a different ADF template for pages created by each user. You must enter the value `${MyClass.ADFTemplate}` for the `oracle_webcenter_page_createpage_adftemplate` parameter and define the method `MyClass.getADFTemplate()` so that it returns different ADF templates based on which user has logged in.
6. Click **OK**.

17.6.2.2 How to Specify the ADF Template Name Using API Parameters

To specify the ADF template name using API parameters:

1. Create a page or a task flow, and specify the ID of the ADF template view activity.

   The page or task flow is subsequently created based on that ADF template.

   To create a page:

   ```
   PageService.createPage(
        String pageType, String nameFormat, String title,
        String pageTemplate, String pageTemplatePath,
        String ADFTemplateViewID,
        String cssStyle, String schemeBGImage, String schemeBGColor)
   ```

   where `ADFTemplateViewID` is the ID of the ADF template view activity.

   To create a task flow:

   ```
   PageService.createTaskflow(
        String nameFormat, String title,
        String pageTemplate, String pageTemplatePath,
        String ADFTemplateViewID,
        String cssStyle, String schemeBGImage, String schemeBGColor)
   ```

   where `ADFTemplateViewID` is the ID of the ADF page template view activity.

17.6.3 Creating Styles for the Create Page Dialog

To use your own page styles, define them in `/mytemplates.templates.xml` file. If you want to maintain a separate XML file with a different set of page styles, you can create an XML file and reference that from the Page - Create New task flow. For example, to display two different options to two users with different privileges, you must create two XML files and define different styles in each XML file. You can then ensure that the Create Page dialog displays the respective options to each user.

This section describes how to create and reference a new style for the runtime Create Page dialog. It contains the following subsections:

- Section 17.6.3.1, "How to Create a Style for the Create Page Dialog"
- Section 17.6.3.2, "How to Reference a New Style from the Page - Create New Task Flow"

17.6.3.1 How to Create a Style for the Create Page Dialog

To create a style for the Create Page dialog:

1. In the `/mytemplates` directory, create an XML file, for example `templates2.xml`.
2. Add a `templatesDef` element, and within that add a `templateDef` entry for each style that you want to include in the Create Page dialog.

   Example 17–17 shows the code entered into sample XML file `templates2.xml` that references the `pstemplateview.jsff` fragment you created in Section 17.6.1.1, "How to Create a Page or Page Fragment Style."

Example 17–17 Sample Code for the Create Page Dialog Style

```
<?xml version="1.0" encoding="UTF-8" ?>
- <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
<templateDef name="pstemplateview.jsff" title="News" icon="/images/news.png"
             type="taskflow" />
  </templatesDef>
```

   where

   - `name` is the name of the page or page fragment to use as a template.
   - `title` is the label for the style in the Create Page dialog.
   - `type` is the type of template. It can take that value `page` or `taskflow`. The default value `page` creates a page based on the style's associated template. The value `taskflow` creates a task flow view of a page based on the style's associated template.

3. Save the XML file.

17.6.3.2 How to Reference a New Style from the Page - Create New Task Flow

To reference the new XML file from the Page - Create New task flow:

1. Open the JSPX page that contains the Page - Create New task flow.
2. Right-click the JSPX page, and select **Go to Page Definition**.
3. In the page definition file, under Executables, select the Create Page task flow, and click the **Edit** icon on the header.

   The Edit Task Flow Binding dialog opens with the list of input parameters supported by the task flow.

4. Provide the template file name for the `oracle_webcenter_page_createpage_templatefile` parameter.

   If you define a constant value, for example `${'/mytemplates/templates2.xml'}`, then this template is used for the Create Page dialog always.

However, by providing an EL value for the parameter, you can ensure that a different template is used for the dialog based on different criteria, such as user or scope.

For example, assume you have two users, `user1` and `user2`, and want to display a different page style to each user. In this case, you must have two templates for the Create page dialog. Let us say you have created a new template, `templates2.xml`, and updated the default template, `templates.xml`. You can then specify `${TemplateBean.template}` for the `oracle_webcenter_page_createpage_templatefile` parameter.

To use this value, you must first create the managed bean, `TemplateBean.java`, with method `getTemplate()`, which returns `templates.xml` for `user1` and `templates2.xml` for `user2`. At runtime, user1 and user2 are each shown different options in the Create Page dialog.

5. Click **OK**.

6. Click **Save All** to save your work.

17.7 Customizing Page Views

This section describes various ways to customize page views. It contains the following subsections:

- Section 17.7.1, "Rendering Pages with ADF Faces Components"
- Section 17.7.2, "Managing User Security on Pages and Task Flows"

17.7.1 Rendering Pages with ADF Faces Components

You can use ADF Faces components to render runtime pages. For example, you can use ADF Faces components to render pages as tabs, links, and image links—or thumbnail views of pages. This section provides some examples of the types of pages you can create using ADF Faces components. It contains the following subsections:

- Section 17.7.1.1, "Rendering Pages as Tabs Using ADF Faces Components"
- Section 17.7.1.2, "Rendering Pages as Links Using ADF Faces Components"
- Section 17.7.1.3, "Rendering Pages as Image Links Using ADF Faces Components"

17.7.1.1 Rendering Pages as Tabs Using ADF Faces Components

When you design your application to render pages as tabs, you can use a range of ADF Faces components to accomplish this. This section provides information about the ADF Faces components that support rendering of pages as tabs. It contains the following subsections:

- Section 17.7.1.1.1, "Rendering Pages as Tabs Using af:navigationPane"
- Section 17.7.1.1.2, "Rendering Pages as Tabs Using af:panelTabbed"

17.7.1.1.1 Rendering Pages as Tabs Using af:navigationPane Example 17–18 illustrates how pages can be rendered as tabs using `navigationPane` components.

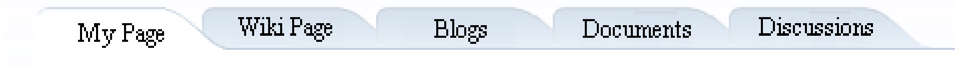
Here a method called `pages` from a custom bean (`MyPageServiceBean`) is used to get the list of pages. For more information about getting the list of pages with the page API, see the `getPages()` method in page API section.

Example 17–18 Rendering Pages as Tabs Using af:navigationPane

```
      <af:navigationPane id="tabs">
        <af:forEach var="tab" items="#{MyPageServiceBean.pages}">
          <af:commandNavigationItem text="#{tab.title}"  id="cni1"/>
          </af:forEach>
        </af:navigationPane>
```

The output of the code depicted in Figure 17–18 renders as a series of tabs (Figure 17–10).

Figure 17–10 Render Pages as Tabs



17.7.1.1.2 Rendering Pages as Tabs Using af:panelTabbed Example 17–19 illustrates how pages can be rendered as tabs using `panelTabbed` components.

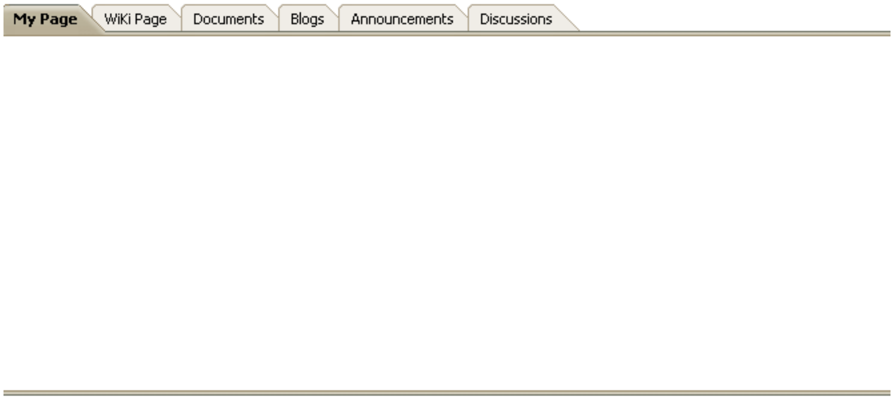
Here a method called `pages` from a custom bean (`MyPageServiceBean`) is used to get the list of pages.

Example 17–19 Rendering Pages as Tabs Using af:panelTabbed

```
<af:panelTabbed id="pt1" >
    <af:forEach var="tab" items="#{ MyPageServiceBean.pages}">
        <af:showDetailItem text="#{tab.title}" id="sdi1"/>
     </af:forEach>
   </af:panelTabbed>
```

The output of the code in Example 17–19 renders as a series of tabs (Figure 17–11).

Figure 17–11 Render Pages as af:panelTabbed Component



17.7.1.2 Rendering Pages as Links Using ADF Faces Components

This section provides examples of using ADF Faces Components to render pages as different types of links. It contains the following subsections:

- Section 17.7.1.2.1, "Rendering Pages as Links Using af:commandLink"
- Section 17.7.1.2.2, "Rendering Pages as Links Using af:goLink"

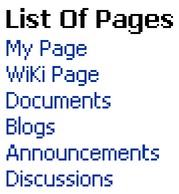
17.7.1.2.1 Rendering Pages as Links Using af:commandLink Example 17–20 illustrates how pages can be rendered as links using `af:commandLink`.

Example 17–20 Rendering Pages as Links Using af:commandLink

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:forEach var="tab" items="#{MyPageServiceBean.pages}">
     <af:commandLink text="#{tab.title}" id="cl1"/>
   </af:forEach>
</af:panelGroupLayout>
```

The output of the code depicted in Example 17–20 renders as a list of links (Figure 17–12).

Figure 17–12 Render Pages as Links



List Of Pages
My Page
WiKi Page
Documents
Blogs
Announcements
Discussions

17.7.1.2.2 Rendering Pages as Links Using af:goLink Example 17–21 illustrates how pages can be rendered as links using `af:goLink`.

Example 17–21 Rendering Pages as Links Using af:goLink

```
<af:panelGroupLayout id="pgl2" layout="vertical">
     <af:activeOutputText value="List Of Pages" id="aot2"
                             inlineStyle="font-weight:bold; font-size:small;"/>
      <af:forEach var="tab" items="#{pageServiceBean.pages}">
         <af:goLink text="#{tab.title}" id="gl1"/>
      </af:forEach>
    </af:panelGroupLayout>
```

The output of the code depicted in Example 17–21 renders as a list of links (Figure 17–12).

17.7.1.3 Rendering Pages as Image Links Using ADF Faces Components

Image links are linked thumbnail views of a page that users click to access the full page view. Example 17–22 illustrates how pages can be rendered as image links.

Example 17–22 Rendering Thumbnail Views of Pages

```
  <af:panelGroupLayout id="pg1_11" layout="scroll">
          <af:panelGroupLayout id="pg11" layout="horizontal" halign="center"
                               valign="middle">
            <h:panelGrid id="ds" columns="4" cellpadding="10" cellspacing="5"
                         style="text-align: center;" rowClasses="bottomAlign">
              <af:forEach varStatus="stat" begin="0"
end="#{MyPageServiceBean.pageCount}">
                <af:panelGroupLayout id="sdsd" layout="vertical"
                                     halign="center">
                  <af:commandImageLink text="" id="cil1"
                                       icon="/<image_name>}"/>
                  <af:activeOutputText value="Page Title" id="aot3"/>
                </af:panelGroupLayout>
              </af:forEach>
            </h:panelGrid>
          </af:panelGroupLayout>
```

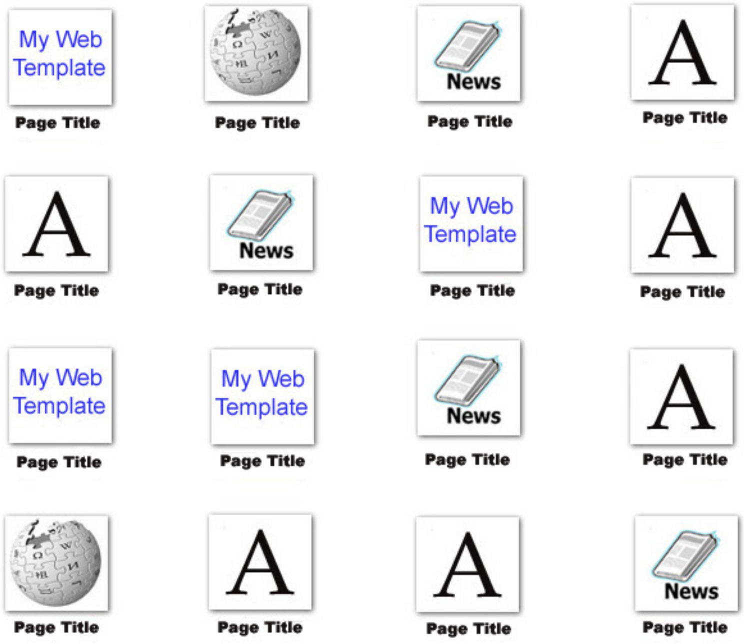
```
        </af:panelGroupLayout>
```

In Example 17–22, `pageCount` is a method from a custom bean (`MyPageServiceBean`) that gets the number of pages in the current scope. Users must write this method on their own using the other methods from page APIs.

In Example 17–22, `<image_name>` is the name of the image with which you associate your page.

The output of the code in Example 17–22 is rendered as a linked series of thumbnail views of a page (Figure 17–13).

Figure 17–13 Render Pages as Image Links



17.7.2 Managing User Security on Pages and Task Flows

You can manage access to pages and task flows either through the Security Panel, which is a part of Composer, or through page APIs.

For more information about runtime security, see the "Setting Page Security" section in *Building Portals with Oracle WebCenter Portal*.

For more information about setting page access with the page APIs, see *Java API Reference for Oracle WebCenter Portal*.

17.8 Advanced Information for Managing Pages

This section describes the APIs and data controls available for working with pages. It contains the following sections:

- Section 17.8.1, "Using the Page Java APIs"
- Section 17.8.2, "Using the Page Data Control"

17.8.1 Using the Page Java APIs

This section provides information about page Java APIs. It includes information about the location of these APIs, how to make your application ready to use them, and how to use them to create pages. It contains the following subsections:

- Section 17.8.1.1, "Configuration Settings Required for Using Page APIs"
- Section 17.8.1.2, "Introduction to the Page APIs"
- Section 17.8.1.3, "How to Set Up Your Application to Use the Page APIs"
- Section 17.8.1.4, "Example: How to Create a Page"

17.8.1.1 Configuration Settings Required for Using Page APIs

To use the page APIs, you must perform the following steps:

1. Confirm that you have the following entries in your `adf-config.xml` file:

```
<namespace path="/oracle/webcenter/page/scopedMD"
metadata-store-usage="WebCenterFileMetadataStore"/>
<namespace path="/pageDefs"
metadata-store-usage="WebCenterFileMetadataStore"/>
<namespace path="/mytemplates"
metadata-store-usage="WebCenterFileMetadataStore"/>
```

   If these entries do not exist in `adf-config.xml`, add them using a text editor.

2. Configure the `.cpx` file to use dynamic page mapping:

```
<Application xmlns="http://xmlns.oracle.com/adfm/application"
             version="11.1.1.51.35" id="DataBindings" SeparateXMLFiles="false"
             Package="view" ClientType="Generic"
             PageMapClass="oracle.jbo.uicli.mom.DynamicPageMapImpl"
             BasePageDefPackageName="pageDefs">
  <definitionFactories>
    <factory nameSpace="http://xmlns.oracle.com/adf/controller/binding"

className="oracle.adf.controller.internal.binding.TaskFlowBindingDefFactoryImpl
"/>
    <dtfactory
className="oracle.adf.controller.internal.dtrt.binding.BindingDTObjectFactory"/
>
  </definitionFactories>
  <pageMap/>
    <page path="/page1.jspx" usageId="view_page1PageDef"/>
  </pageMap>
  <pageDefinitionUsages/>
    <page id="view_page1PageDef" path="view.pageDefs.page1PageDef"/>
  </pageDefinitionUsages>
  <dataControlUsages>
    <dc id="PageServiceDC"
        path="oracle.webcenter.page.internal.model.PageServiceDC"/>
  </dataControlUsages>
</Application>
```

   If these entries do not exist in your `.cpx` file, add them using a text editor.

17.8.1.2 Introduction to the Page APIs

The page APIs are located in the `oracle.webcenter.page.model.PageService` class.

The following APIs are available for pages:

- createPage - see Section 17.8.1.4, "Example: How to Create a Page"
- deletePage
- createTaskflow - see Example 17–23, "Using Page APIs to Create a Task Flow View Page"
- deleteTaskflow
- createScope
- deleteScope
- copyPage
- getPageList - see Example 17–24, "Using Page APIs to Get a List of Pages"
- setPageTitle - see Example 17–25, "Using Page APIs to Set the Page Title"
- changeHiddenStatus
- changePageScheme - see Example 17–26, "Using Page APIs to Set the Page Scheme"
- setPageAccess

For more information about the page APIs, see *Java API Reference for Oracle WebCenter Portal*.

Example 17–23 Using Page APIs to Create a Task Flow View Page

```
PageDef createTaskflow(String nameFormat, String title, String pageTemplate,
  String pageTemplatePath, String cssStyle, String schemeBGImage, String
schemeBGColor)
  throws DuplicateNameException, InvalidNameException, LockUnavailableException;
```

where

- `nameFormat` is the name format of the task flow; it can contain a subpath, such as `users/UserA/taskflow{0}.jspx`.
- `title` is the title of the task flow.
- `pageTemplate` is the template used for the task flow.
- `pageTemplatePath` is the path for the task flow template.
- `cssStyle` is the cascading style sheet file for this task flow.
- `schemeBGImage` is the background image for the custom scheme.
- `schemeBGColor` is the background color for the custom scheme.

It returns the `PageDef` of the newly created task flow and throws the following:

- `InvalidNameException` if the name supplied cannot be used for update.
- `DuplicateNameException` if the page with the same name already exists.
- `LockUnavailableException` if another page or task flow operation is in progress.

Example 17–24 Using Page APIs to Get a List of Pages

```
PageDef getPageList(String path)
```

where

- `path` is the path under which you want to see a list of all page that the user can view. If you do not specify a path, it returns a list of all pages that the user can view in the current scope.

It returns the list of all pages that are not hidden in the current scope or under a specific path.

Example 17–25 Using Page APIs to Set the Page Title

```
setPageTitle(String pagepath, String title)
  throws InvalidNameException, ObjectChangedException, LockUnavailableException,
oracle.webcenter.framework.translations.exception.TranslationsException;
```

where

- `pagepath` is the path of the page for which you want to change the title.
- `title` is the new name of the page.

It updates the name of the page and throws the following:

- `InvalidNameException` if the name supplied cannot be used for update.
- `ObjectChangedException` if the page has changed since it was last retrieved.
- `LockUnavailableException` if another page operation is in progress.

Example 17–26 Using Page APIs to Set the Page Scheme

```
setPageScheme(String pagepath, String schemeName, String schemeBGImage, String
schemeBGColor, String otherCSS)
```

where

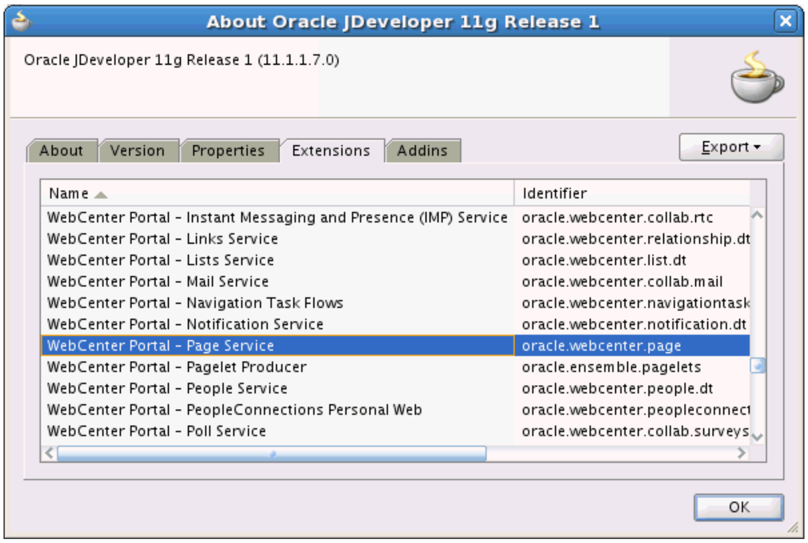
- `pagepath` is the path of the page for which you want to change the scheme.
- `schemeName` is the name of the CSS for the page.
- `schemeBGImage` is the background image for the custom scheme.
- `schemeBGColor` is the background color for the custom scheme.
- `otherCSS` refers to any other CSS attributes you want to specify.

It updates the page's scheme properties in the JSPX page.

17.8.1.3 How to Set Up Your Application to Use the Page APIs

To use the page APIs, Oracle WebCenter Portal's page extension must be present in your JDeveloper application. In JDeveloper, go to the **Help - About** menu, and click the **Extensions** tab. Look for the WebCenter Portal - Page Service, as shown in Figure 17–14.

Figure 17–14 JDeveloper Extensions



Oracle JDeveloper 11g Release 1 (11.1.1.7.0)

Name	Identifier
WebCenter Portal - Instant Messaging and Presence (IMP) Service	oracle.webcenter.collab.rtc
WebCenter Portal - Links Service	oracle.webcenter.relationship.dt
WebCenter Portal - Lists Service	oracle.webcenter.list.dt
WebCenter Portal - Mail Service	oracle.webcenter.collab.mail
WebCenter Portal - Navigation Task Flows	oracle.webcenter.navigationtask
WebCenter Portal - Notification Service	oracle.webcenter.notification.dt
WebCenter Portal - Page Service	oracle.webcenter.page
WebCenter Portal - Pagelet Producer	oracle.ensemble.pagelets
WebCenter Portal - People Service	oracle.webcenter.people.dt
WebCenter Portal - PeopleConnections Personal Web	oracle.webcenter.peopleconnect
WebCenter Portal - Poll Service	oracle.webcenter.collab.surveys

---

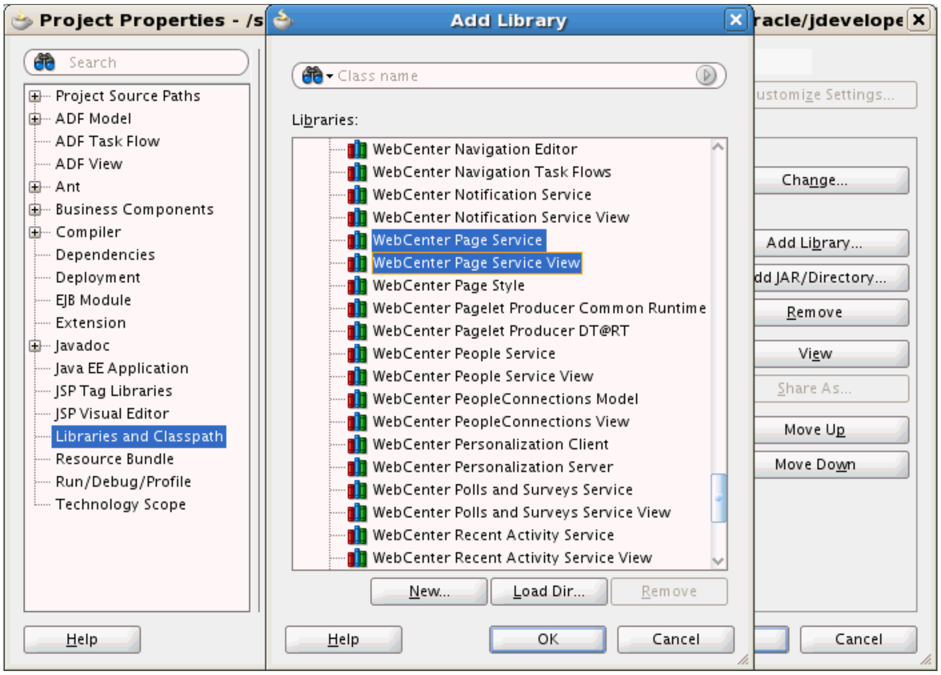
Note: For information about adding Oracle WebCenter Portal's extensions, see Chapter 2, "Setting Up Your Development Environment."

After confirming that WebCenter Portal - Page Service is included with Oracle WebCenter Portal's extensions, you must add the page libraries to the project.

To add page libraries to your project:

1. Right-click the **Portal** project and select **Project Properties** and then **Libraries and Classpath**.
2. Click **Add Library**.
3. Select the **WebCenter Page Service** and **WebCenter Page Service View** libraries, as shown in Figure 17–15.

Figure 17–15 Adding Page Libraries



4. Click **OK**.

If you do not want to use JDeveloper as the code editor, then you can set `CLASSPATH` to the following jar files:

- `Jdev_Home/jdeveloper/webcenter/jlib/pagem.jar`
- `Jdev_Home/jdeveloper/webcenter/jlib/pages.jar`
- `Jdev_Home/jdeveloper/webcenter/jlib/page-service-view.jar`
- `Jdev_Home/jdeveloper/webcenter/jlib/page-service-skin.jar`

17.8.1.4 Example: How to Create a Page

This section provides an example of how to create a page using the page APIs. Your requirements may call for different methods. Use the way the `createPage` method is invoked in this sample code as a model for invoking the methods you require on the `PageService` object.

Typically, pages created using page APIs are based on templates. Before you start creating pages using the APIs, you must ensure that each template file, for example `MyPageTemplate1.jspx`, has a page definition file, in this case `MyPageTemplate1PageDef.xml`, in the same directory as the JSPX page.

Example 17–27 shows how to use the `createPage() API` to create a scope named `MyScope`, create an MDS session instance, instantiate the page class with this new scope, and then create a page within this scope. The new page is created based on the `MyPageTemplate1.jspx` template.

Example 17–27 Sample Showing How to Create a Page

```
...

public void createMyPage
{
    try
    {
      MDSSession mdsSess =
(MDSSession)ADFContext.getCurrent().getMDSSessionAsObject();
      PageServiceConfig config = new PageServiceConfig(mdsSess, "defaultScope");
      mPageService = PageServiceFactory.createInstance(config);

      String pageNameFormat ="Page{0}.jspx";
      String pageTitle ="New Page";

      //
      // The template used to create the new page is
/mytemplates/MyPageTemplate1.jspx
      // path "/mytemplates" should be defined as a MDS namespace.
      // Also MyPageTemplate1.jspx should have a pageDef called
"MyPageTemplate1PageDef.xml and
      // it has the same path as the jspx file.

      PageDef newPage = mPageService.createPage(
        "personaluserpage", pageNameFormat, pageTitle,
        "MyPageTemplate1.jspx",
        "/mytemplates/",
        null, null, null);

    }
    catch(Exception e)
    {
      // Handle exception
    }
}

...
```

> **Note:** Pages and task flows created using page APIs do not have permissions granted by default. You must explicitly define permissions on the page.

For more information about the page APIs, see *Java API Reference for Oracle WebCenter Portal*.

17.8.2 Using the Page Data Control

The page data control enables you to view information about existing pages at runtime and delete any of the listed pages.

This section describes how to add a Page data control to a project and how to use it to view, edit, and delete pages. It contains the following subsections:

- Section 17.8.2.1, "How to Add the Page Data Control"
- Section 17.8.2.2, "How to View, Edit, and Delete Pages at Runtime"

17.8.2.1 How to Add the Page Data Control

This section provides an example of adding the Page data control at design time.

To add a Page data control to your project:

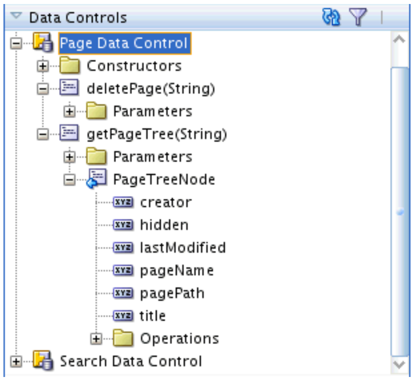
1. Ensure that Page Data Control is visible in the Data Controls panel of the Application Navigator.

The Page Data Control appears in the Application Navigator after you have performed either of the following actions:

- Added the **Page - Create New** task flow to your project (see Section 17.2.1.1, "How to Add the Page - Create New Task Flow").
- Added the **Page Data Control** as described in Section 4.1.3, "Using WebCenter Portal Data Controls.".

2. In the Data Controls panel of the Application Navigator, expand **Page Data Control**, as shown in Figure 17–16.

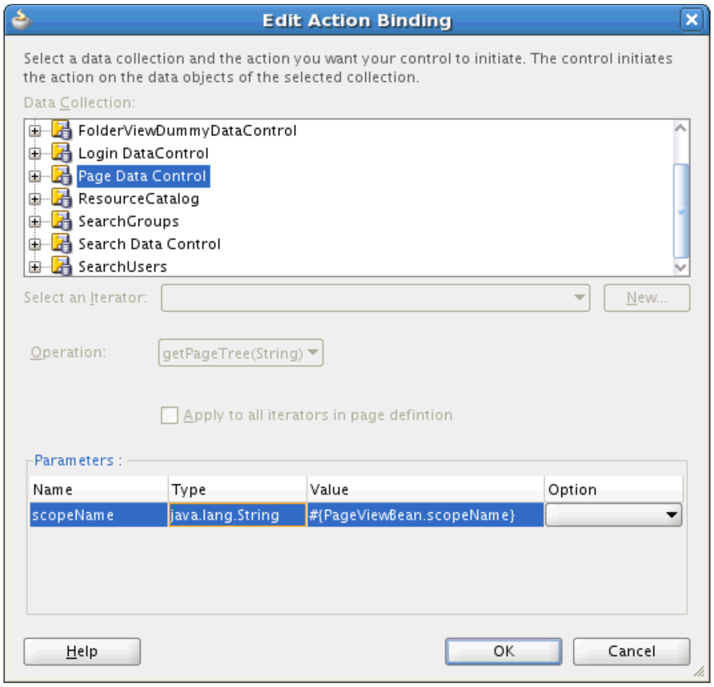
Figure 17–16 Page Data Control



3. Under **getPageTree()**, drag **PageTreeNode** and drop it on the page.
4. From the **Create** menu, select **Table**, and then select **ADF Read-only Table**.
5. In the Edit Table Columns dialog, click **OK**.
6. In the Edit Action Binding dialog, enter the `scopeName` parameter to view all the pages listed under the specified scope. Click **OK**.

   If you do not enter any value, the data control takes the default scope. In Figure 17–17, the scope value is fetched from a custom managed bean.

Figure 17–17 scopeName Parameter



Edit Action Binding

Select a data collection and the action you want your control to initiate. The control initiates the action on the data objects of the selected collection.

Data Collection:

- FolderViewDummyDataControl
- Login DataControl
- Page Data Control
- ResourceCatalog
- SearchGroups
- Search Data Control
- SearchUsers

Select an Iterator: New...

Operation: getPageTree(String)

□ Apply to all iterators in page defintion

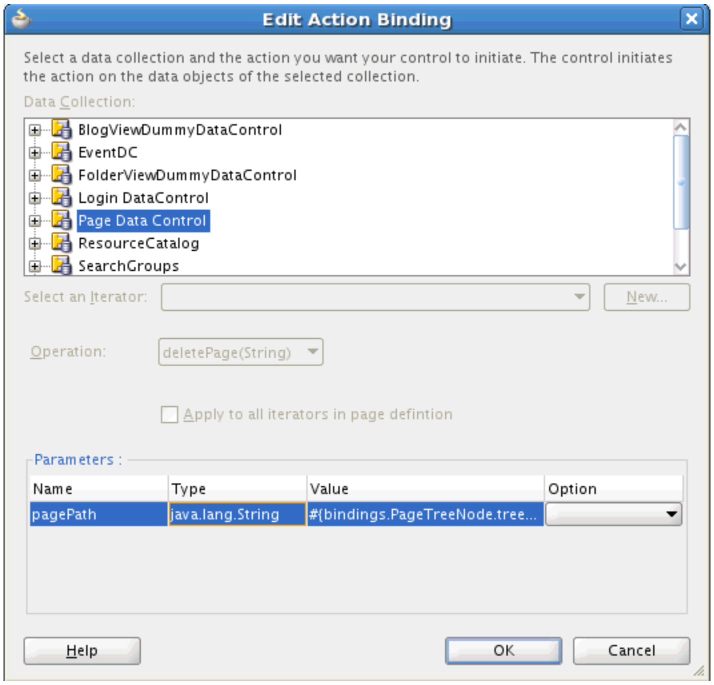
Parameters :

Name	Type	Value	Option
scopeName	java.lang.String	#{PageViewBean.scopeName}	

7. Add a new column to the table you created in step 4.
8. To add a column for deleting pages at runtime, drag the **deletePage(string)** method and drop it in the new column.
9. From the **Create** menu, select **Method**, and then select **ADF Link**.
10. In the Parameters section of the Edit Action Binding dialog, shown in Figure 17–18, specify the following value for the `pagePath` parameter:

```
#{bindings.PageTreeNode.treeModel.rowData.pagePath}
```

Figure 17–18 Edit Action Binding Dialog



Edit Action Binding

Select a data collection and the action you want your control to initiate. The control initiates the action on the data objects of the selected collection.

Data Collection:

- BlogViewDummyDataControl
- EventDC
- FolderViewDummyDataControl
- Login DataControl
- Page Data Control
- ResourceCatalog
- SearchGroups

Select an Iterator:

Operation: deletePage(String)

☐ Apply to all iterators in page defintion

Parameters :

Name	Type	Value	Option
pagePath	java.lang.String	#{bindings.PageTreeNode.tree...	

11. Click **OK**.
12. From the Data Controls panel, expand **Page Data Control**, **getPageTree()**, **PageTreeNode**, and then **Operations**.
13. Drag **Execute** and drop it on the page as an **ADF Button**.
14. In the Property Inspector, set the button's `Text` attribute to `Refresh`.

    This provides a refresh feature on the list of pages to enable users to refresh the list after they have added a page or deleted one from the list.

15. Optionally, to display pages as links that invoke page Edit mode, view the page source and replace the `outputText` element in the table's page path column with a `goLink` as follows:

    Replace

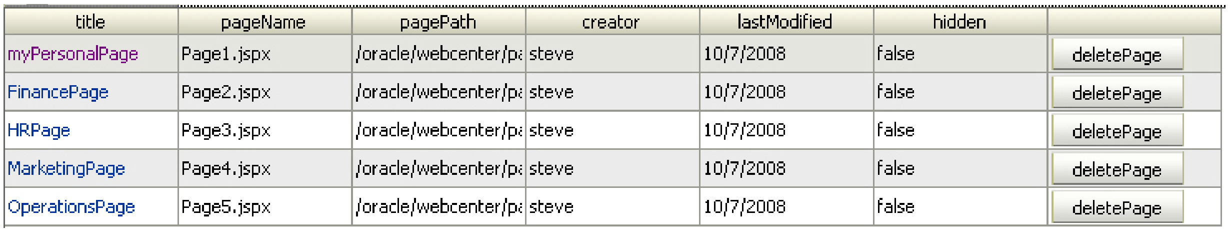
    ```
    <af:outputText value="#{row.pagePath}"/>
    ```

    with

    ```
    <af:goLink destination="/faces#{row.pagePath}" text="#{row.title}"
    targetFrame="_top"/>
    ```

16. Save your page, and run it to your browser.
17. The created data control table should look something like Figure 17–19.

Figure 17–19 Sample Data Control Table



title	pageName	pagePath	creator	lastModified	hidden	
myPersonalPage	Page1.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
FinancePage	Page2.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
HRPage	Page3.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
MarketingPage	Page4.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
OperationsPage	Page5.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage

17.8.2.2 How to View, Edit, and Delete Pages at Runtime

To view a page at runtime, follow the link generated from step 16 in Section 17.2.1.1, "How to Add the Page - Create New Task Flow." If the application has been secured properly, then an edit link should render on the page at runtime.

To delete a page, click the **deletePage** button in the row of the relevant page. This button was generated from step 8 in Section 17.2.1.1, "How to Add the Page - Create New Task Flow." Click the Refresh button for the table to remove the deleted page row from the table.

For detailed information about how to view, edit, and delete pages at runtime, see the "Working with Portal Pages" part in *Building Portals with Oracle WebCenter Portal*.

18 Enabling Runtime Editing of Pages Using Composer

This chapter describes how to add Composer components to your Portal Framework application pages to enable runtime editing of the pages.

This chapter contains the following topics:

- Section 18.1, "Designing Editable Pages Using Composer Components"
- Section 18.2, "Designing Editable Pages Using Composer Components: Example"
- Section 18.3, "Populating Pages with Content"
- Section 18.4, "Troubleshooting Composer Problems"

18.1 Designing Editable Pages Using Composer Components

The Composer tag library provides design-time components that you can add to a page in Oracle JDeveloper to enable page editing at runtime. When you create a page with Composer components at design time, at runtime Composer provides options for entering page edit mode and modifying the page according to your requirements.

You can enable customizations in Portal Framework applications and non-Portal Framework applications. Within an application, you can enable customization of the following types of pages:

- A regular JSPX page, not based on a page template
- A JSPX template page
- A JSPX page based on a page template

For more information about Composer components and their attributes, see Section 16.7, "Composer Components."

This section explains how to add Composer components to a page at design time to make it editable at runtime. It contains the following subsections:

- Section 18.1.1, "How to Create a Customizable Page"
- Section 18.1.2, "How to Enable Runtime Customization Using a Page Customizable Component"
- Section 18.1.3, "How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button"
- Section 18.1.4, "How to Define Editable Areas of a Page Using Panel Customizable Components"

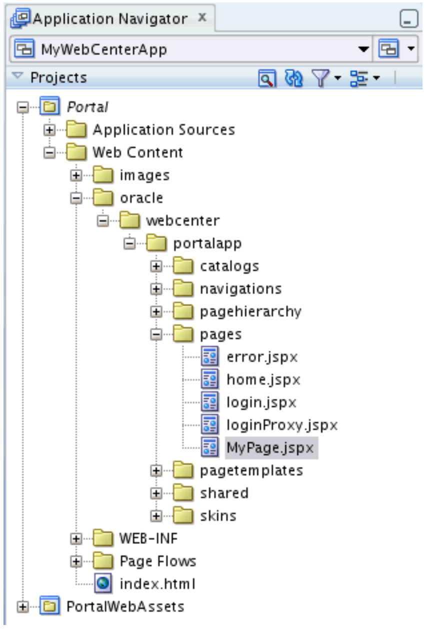
- Section 18.1.5, "How to Enable Layout Customization for a Page Using a Layout Customizable Component"
- Section 18.1.6, "How to Enable Component Customization Using Show Detail Frame Components"
- Section 18.1.7, "How to Create a Page Template for Creating Customizable Pages"
- Section 18.1.8, "How to Enable Customization in a Populated Page"
- Section 18.1.9, "What Happens When You Add Composer Components"
- Section 18.1.10, "What Happens at Runtime"
- Section 18.1.11, "What You May Need to Know When Designing Editable Pages"

18.1.1 How to Create a Customizable Page

For information about creating a customizable JSPX page in your Portal Framework application, see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."

When you create a new page in JDeveloper, it is listed in the Application Navigator under **Web Content** as shown in Figure 18–1. Additionally, the page is opened in the editor and becomes the active editor panel.

Figure 18–1 A Customizable JSPX Page in the Application Navigator



Security Considerations

By default, a Portal Framework application is configured with ADF security. A default user name and password (weblogic/weblogic1) are created automatically for you.

To enable users to edit a page in a secured application, you must grant Edit or Customize privileges on the page to the required users or roles. For more information about granting permissions, see Section 74.4, "Using the Role Manager Task Flow."

If ADF security is not enabled in your application, you can test how user privileges impact runtime customization capabilities by implementing security and configuring your application to authenticate users so that they have distinct identities. For the steps to implement a basic security model in your application, see Section 74.3, "Configuring ADF Security."

18.1.2 How to Enable Runtime Customization Using a Page Customizable Component

Adding a `Page Customizable` component to the page ensures that Composer is invoked when users switch to Edit mode of the page. When you add a `Page Customizable` component, some configuration files are updated automatically with the default Composer-specific settings. For more information, see Section 18.1.9, "What Happens When You Add Composer Components."

> **Note:** For considerations you must make before adding `Page Customizable` to a page, see Section 18.1.11, "What You May Need to Know When Designing Editable Pages."

To add a Page Customizable component to a page:

1. Open a customizable JSPX page.
2. In the Component Palette, select **ADF Faces** from the drop-down list and drag the **Panel Stretch Layout** component onto the page.

   > **Notes:** The `Panel Stretch Layout` component stretches the child in the `center` facet to fill all of the available space. This holds true when users resize the browser.

3. In the Component Palette, select **Composer** from the drop-down list.
4. Add a **Page Customizable** component to the `center` facet of `Panel Stretch Layout`.

   You must ensure that `Page Customizable` is nested inside an `af:form` element. `Page Customizable` is a rich client component that requires the rich client framework to function properly.

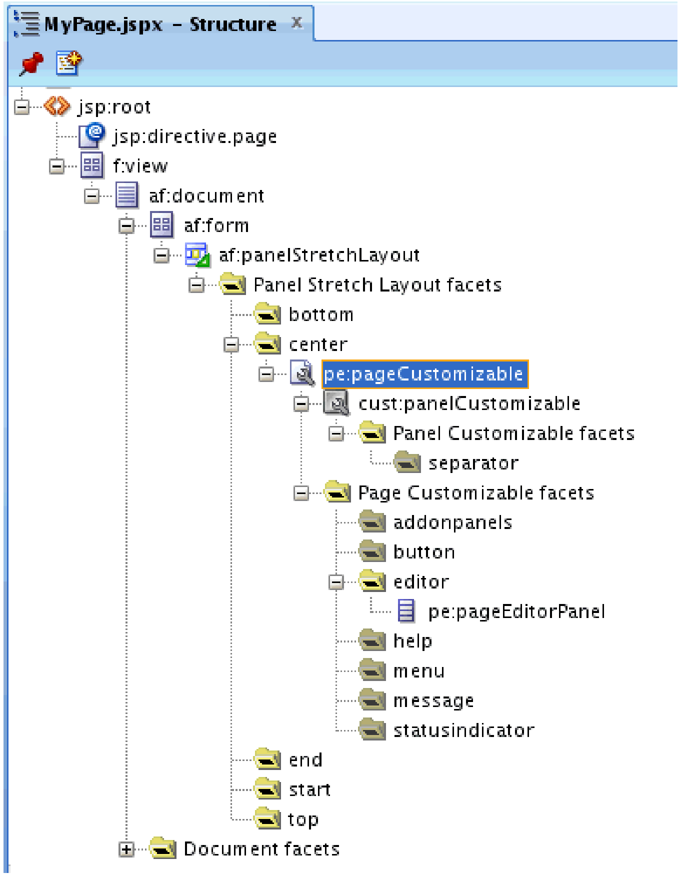
5. The required attributes for a `Page Customizable` component are populated with default values when you add the component to the page.

   For information about defining or modifying attribute values , see Section B.1.1, "Page Customizable Component."

6. Save the page.

   Under the `Page Customizable` component, by default, a `Panel Customizable` component is added as a child component and `Page Editor Panel` and various other facets are added, as shown in Figure 18–2.

Figure 18–2 Page Customizable Component



Example 18–1 shows the `pe:pageCustomizable` tag in the page source view.

Example 18–1 Page Customizable Component in the Page Source View

```
<pe:pageCustomizable id="pageCustomizable1"
  <cust:panelCustomizable id="panelcustomizable1"
                          layout="scroll"/>
  <f:facet name="editor">
    <pe:pageEditor id="pep1"/>
  </f:facet>
</pe:pageCustomizable>
```

18.1.3 How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button

To enable users to switch to Edit mode of a page easily, you must add a `Change Mode Link` or `Change Mode Button` component to the page.

Note: An alternative way to enable switching to Edit mode is by using the Change Mode API. For more information about this API, see *Java API Reference for Oracle WebCenter Portal*.

For things you should consider before adding a `Page Customizable` component to a page, see Section 18.1.11, "What You May Need to Know When Designing Editable Pages."

To add a Change Mode Link or Change Mode Button component:

1. From the Component Palette, select **Composer**.
2. In the Structure window, within the `top` facet of the `Panel Stretch Layout` that you added in the previous section, drag a **Change Mode Link** or **Change Mode Button** component from the Component Palette.

   You must ensure that `Change Mode Link` or `Change Mode Button` is nested in an `af:form` element. The `Change Mode Link` or `Change Mode Button` component is a rich client component that requires the rich client framework to function properly.

   Notes:

   - If you have not used `Panel Stretch Layout` on your page, then add the `Change Mode Link` or `Change Mode Button` component above the `Page Customizable` component in the Structure window. This ensures that `Change Mode Link` or `Change Mode Button` is displayed properly at runtime.
   - Use a `Change Mode Link` or `Change Mode Button` only when you have a `Page Customizable` on the page. You may have problems running a page that contains `Change Mode Link` or `Change Mode Button` but no `Page Customizable` component.

3. The required attributes for a `Change Mode Link` or `Change Mode Button` component are set by default when you add the component to the page.

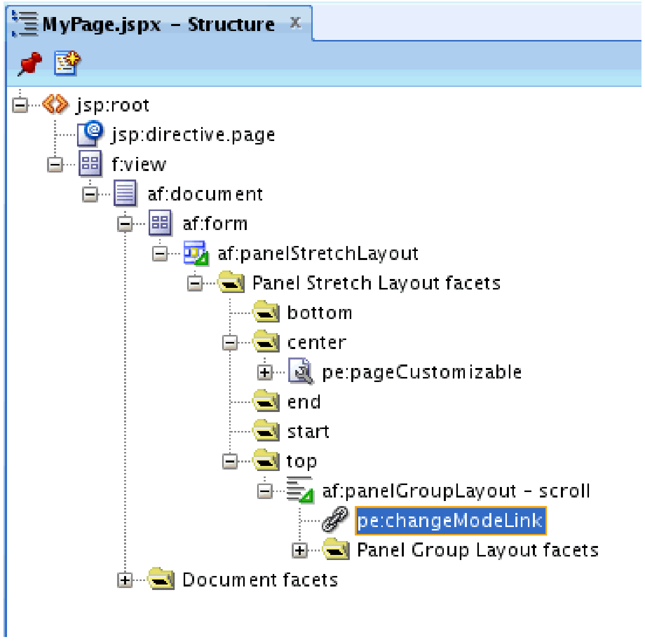
   Optionally, you can set any other attributes by referring to Table B–2 in Section B.1, "Composer Component Properties."

   Note: In a secured application, it is recommended that you check all users' privileges and enable the Edit link or button on the page only for privileged users. Unauthenticated users who stumble into page Edit mode can change component properties, though the changes will not be saved.

   You can enable the Edit link or button for selected users by specifying an EL value for the `rendered` attribute on the `Change Mode Link` or `Change Mode Button` component. For more information, see Section B.1.2, "Change Mode Link and Change Mode Button."

   The `pe:changeModeLink` or `pe:changeModeButton` tag displays within the `af:form` tag in the Structure window, as shown in Figure 18–3.

Figure 18–3 Change Mode Link

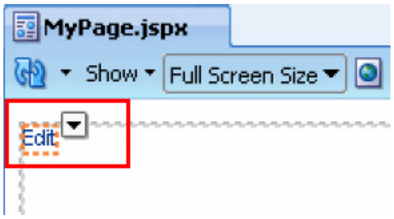


MyPage.jspx – Structure

```
jsp:root
    jsp:directive.page
    f:view
        af:document
            af:form
                af:panelStretchLayout
                    Panel Stretch Layout facets
                        bottom
                        center
                            pe:pageCustomizable
                        end
                        start
                        top
                            af:panelGroupLayout - scroll
                                pe:changeModeLink
                                Panel Group Layout facets
            Document facets
```

Figure 18–4 shows the `Change Mode Link` in the Design view of the page in JDeveloper.

Figure 18–4 Change Mode Link in Design View



18.1.4 How to Define Editable Areas of a Page Using Panel Customizable Components

The `Panel Customizable` component is required for page composition or content management tasks, such as adding, arranging, or removing portlets or regions. By default, one `Panel Customizable` component is automatically added as a direct child of the `Page Customizable` component. You can add more `Panel Customizable` components within this `Panel Customizable` component according to your requirements.

It is only within a `Panel Customizable` component that you can drag and drop components at runtime.

Note: For considerations you must make before adding `Page Customizable` to a page, see Section 18.1.11, "What You May Need to Know When Designing Editable Pages."

To add a `Panel Customizable` component to the page:

1. From the Component Palette, select **Composer** from the drop-down list.

2. Drag a **Panel Customizable** component from the Component Palette to the Structure window and drop it at any suitable location within the form.

   You must ensure that Panel Customizable is nested in an af:form element. The Panel Customizable component is a rich client component that requires the rich client framework to function properly.

   Notes:

   - A Page Customizable component contains one direct child Panel Customizable component by default. Do not add another Panel Customizable as a direct child component of the Page Customizable. If the Page Customizable has multiple child components, only the first child component is picked up while running the page.
   - Ensure that you do not delete the root Panel Customizable component on the page, because at runtime you can drop components *only* inside a Panel Customizable component.

3. The required attributes for a Panel Customizable component are set by default when you add the component to the page.

   Optionally, you can set any other attributes by referring to Table B–6 in Section B.1, "Composer Component Properties."

   Notes: If you select the stretch layout for the Panel Customizable, then the first child component is stretched to fill up available space in the Panel Customizable component. Any other child components are ignored, though they are not removed from the page.

18.1.5 How to Enable Layout Customization for a Page Using a Layout Customizable Component

Use the Layout Customizable component to enable the runtime definition or modification of the layout of components on a page or an area of a page. Use this component only if you want to allow users to customize the layout at runtime. For static layouts, use an alternative component, such as a Panel Group Layout or Panel Stretch Layout.

To add a Layout Customizable component:

1. From the Component Palette, select **Composer** from the drop-down list.
2. Drag a **Layout Customizable** component to the Structure window and drop it inside the Panel Customizable component.

   The target Panel Customizable component must be a child of the Page Customizable component.

   Ensure that Layout Customizable is nested in an af:form element. The Layout Customizable component is a rich client component and requires the rich client framework to function properly.

Note: You can delete the direct child Panel Customizable in the Page Customizable and add the Layout Customizable as a direct child of the Page Customizable. However, you must ensure that the Page Customizable has only one direct child component.

3. The required attributes for a Layout Customizable component are set by default when you add the component to the page.

   Optionally, you can set any other attributes by referring to Table B–3 in Section B.1, "Composer Component Properties."

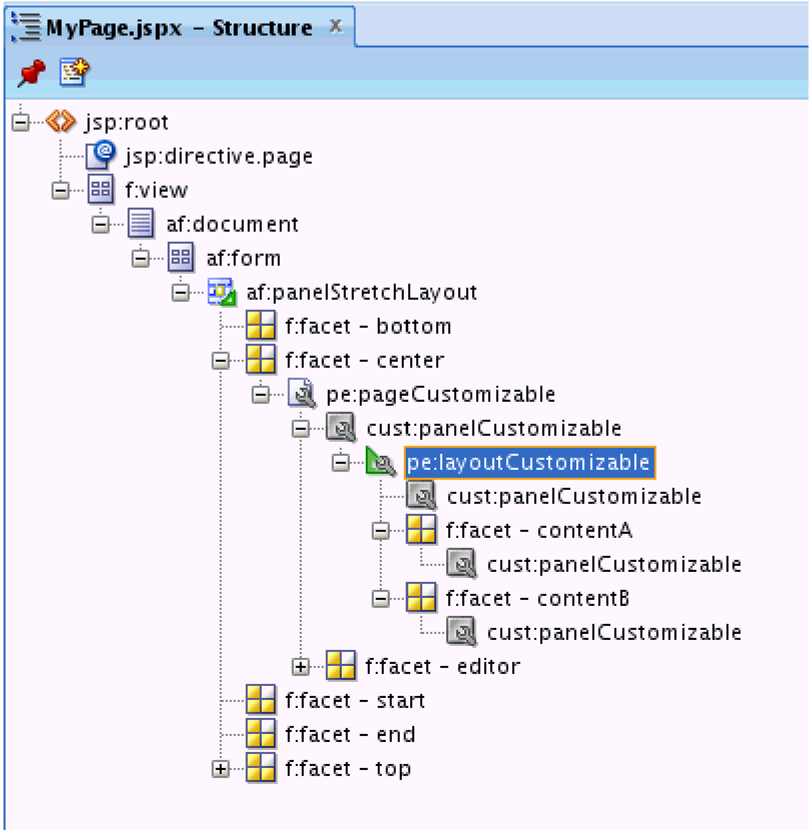
Note: To ensure that the Layout Customizable component is clearly visible on the page at runtime, provide a descriptive label for the component by using the Text attribute.

The pe:layoutCustomizable tag is located inside a cust:panelCustomizable tag in the Structure window as shown in Figure 18–5. A child Panel Customizable component is added by default in the Layout Customizable component. Additionally, a Panel Customizable component is added within each facet of the Layout Customizable component. These Panel Customizable components enable you to add content inside the Layout Customizable component at runtime.

The Panel Customizable added as a direct child provides the main area—the central area in a layout at runtime. The Panel Customizable components added within the two default Layout Customizable facets provide the two content areas, A and B. When you select a predefined layout at runtime, these three areas are arranged to display content in the selected pattern. See Predefined Layout Types for more information about how the content is laid out for each layout type.

Note: In a oneColumn layout, A and B are rendered only if the Panel Customizable component contain child components.

Figure 18–5 Layout Customizable Component



```
MyPage.jspx – Structure
jsp:root
    jsp:directive.page
    f:view
        af:document
            af:form
                af:panelStretchLayout
                    f:facet - bottom
                    f:facet - center
                        pe:pageCustomizable
                            cust:panelCustomizable
                                pe:layoutCustomizable
                                    cust:panelCustomizable
                                    f:facet - contentA
                                        cust:panelCustomizable
                                    f:facet - contentB
                                        cust:panelCustomizable
                            f:facet - editor
                    f:facet - start
                    f:facet - end
                    f:facet - top
```

18.1.6 How to Enable Component Customization Using Show Detail Frame Components

When you want to enable customizations such as property editing, moving, minimizing, or removing components, you can drop a `Show Detail Frame` component inside a `Panel Customizable` component on the page. You can then add a component inside the `Show Detail Frame`.

Note: Each `Show Detail Frame` component should have only one direct child component. If you add multiple child components, then only the first one is rendered. The other direct child components are not rendered at design time or runtime.

If multiple components must be enclosed in a `Show Detail Frame`, then add a grouping component like `Panel Group Layout` or `Panel Customizable` to the `Show Detail Frame` component and then include the ADF Faces components or other content within this grouping component.

Use the `Show Detail Frame` component to enable customizations in View and Edit modes of the page. Changes made in View mode are available to that user only, and changes made in Edit mode are available to all application users.

To add a Show Detail Frame component to the page:

1. From the Component Palette, select **Composer**.

2. Drag a **Show Detail Frame** component to the Structure window and drop it inside a `Panel Customizable` component.

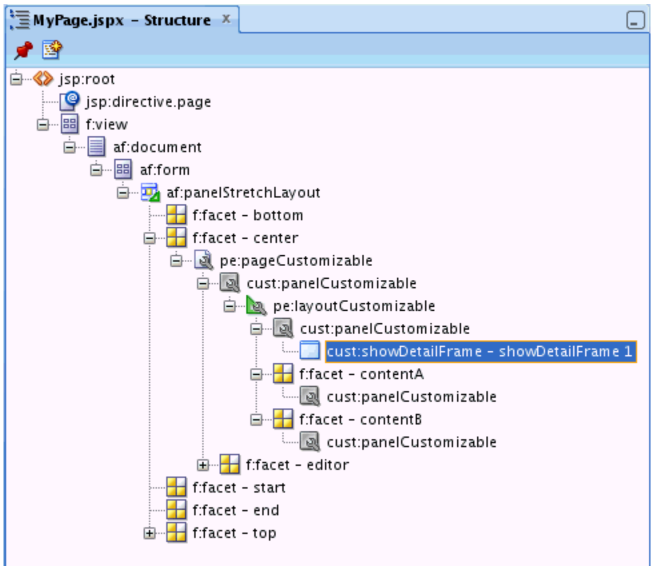
   The `Show Detail Frame` component should be nested in a `Panel Customizable` component on the page.

3. The required attributes for a `Show Detail Frame` component are set by default when you add the component to the page.

   Optionally, you can set any other attributes by referring to Table B–7 in Section B.1, "Composer Component Properties."

   The `cust:showDetailFrame` tag is added inside the `cust:panelCustomizable` tag as show in Figure 18–6.

Figure 18–6 Show Detail Frame Component



```
MyPage.jspx - Structure
jsp:root
  jsp:directive.page
  f:view
    af:document
      af:form
        af:panelStretchLayout
          f:facet - bottom
          f:facet - center
            pe:pageCustomizable
              cust:panelCustomizable
                pe:layoutCustomizable
                  cust:panelCustomizable
                    cust:showDetailFrame - showDetailFrame 1
                  f:facet - contentA
                    cust:panelCustomizable
                  f:facet - contentB
                    cust:panelCustomizable
              f:facet - editor
          f:facet - start
          f:facet - end
          f:facet - top
```

For a better understanding of this type of task, see Section 18.2, "Designing Editable Pages Using Composer Components: Example."

18.1.7 How to Create a Page Template for Creating Customizable Pages

If you plan to create many customizable pages in your application, you can base the pages on an ADF page template in which you have enabled customization. By adding Composer components to the template itself, you can save the effort required to add these components to each customizable page.

To create a page template and enable customization on it:

1. In the Application Navigator in JDeveloper, go to the Portal project of the application in which you want to create the template, right-click the **Portal** project, and choose **New**.
2. In the New Gallery, expand **Web Tier,** select **JSF** and then **JSF Page Template**, and click **OK.**
3. In the Create JSF Page Template dialog, enter a file name for the template, select a layout, and declare a new facet.
4. Click **OK**.

5. In the template, from the Composer tag library, add a **Change Mode Link** or **Change Mode Button** component above the `Panel Stretch Layout` component.

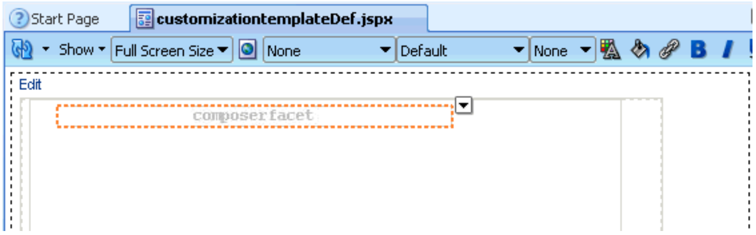
6. Add a **Page Customizable** component within the `center` facet of the `Panel Stretch Layout` component.

7. Delete the child `Panel Customizable` component from `Page Customizable` and add a `Panel Group Layout` component in its place.

8. Set the `layout` attribute on the `Panel Group Layout` to `scroll`.

9. Add a `Facet Ref` component inside the `Panel Group Layout` and specify the same name that you used to declare the facet in step 3. The template displays the facet as shown in Figure 18–7.

Figure 18–7 New Page Template File



10. Save the template file.

You can now create customizable pages based on this template. Once you create a page, you can add a `Panel Customizable` or `Layout Customizable` component inside the facet displayed on the new page. You can then add page content within the `Panel Customizable` or `Layout Customizable` component.

18.1.8 How to Enable Customization in a Populated Page

When you have an existing ADF application with JSPX pages that are populated with content, and you want to enable customization, you can do so by moving all content inside a `Page Customizable` component.

You must first add the `Page Customizable`, then a `Layout Customizable`, and then the required hierarchy of `Panel Customizable` and `Show Detail Frame` components. Drag each of the existing components and drop them onto suitable locations inside the `Page Customizable`.

Notes:

- Ensure that the `Page Customizable` component has only one direct child component.

  When you add multiple direct child components, only the first child component is rendered at runtime. The first child component is stretched to fit the page. All other direct child components are ignored and not rendered on the page.

- Use a `Layout Customizable` component only if you want to allow users to customize the layout at runtime. For static layouts, use an alternative component, such as a `Panel Group Layout` or `Panel Stretch Layout` component.
- For best results, move components using the Structure window and *not* by editing the source code.

18.1.9 What Happens When You Add Composer Components

When you add a `Page Customizable` component to the page, the following configurations are performed automatically:

- A default resource catalog definition file, `default-catalog.xml`, is configured in the application. The `default-catalog.xml` file is located in the *`Application_Root`*`/Portal/src/portal` directory. To add components to the default resource catalog available to end users of your application, see Chapter 14, "Developing Resource Catalogs."

  In a Portal Framework application, the `default-catalog.xml` file is located in the *`Application_Root`*`/Portal/public_html/oracle/webcenter/portalapp/catalogs` directory out-of-the-box, even without creating a page and adding a `Page Customizable` component.

- A resource catalog Viewer is configured for the application. At runtime, Composer provides users the option to add resources from this viewer to the page.
- The `web.xml` file available in the *`Application_Root`*`/`*`Project_Name`*`/public_html/WEB-INF` directory is updated to configure the MDS JSP provider.
- The `ComposerChangeManager` is configured in the application's `web.xml` file. For more information, see Section 20.11, "Configuring the Persistence Change Manager."
- When you create an application, a minimal `adf-config.xml` file is also created. When you add a `Page Customizable` component to an application page, the required configuration is added to the `adf-config.xml` file. For example, change persistence is configured in the `adf-faces-config` section in this file. For more information, see Section 20.11, "Configuring the Persistence Change Manager."
- The `DataBindings.cpx` file in the *`Application_Root`*`/Portal/adfmsrc/portal` directory is updated to enable the presence of task flows on the page.
- The page definition file is updated with the binding for the Composer task flow, which is available as part of the Oracle WebCenter Portal extension JAR file. Example 18–2 shows the code in the page definition file after a `Page Customizable` component is added to an application page.

Example 18–2 Page Definition File After Adding Page Customizable Component

```
<?xml version="1.0" encoding="UTF-8" ?>
```

```
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel"
                version="11.1.1.57.95" id="rcpagePageDef"
                Package="portal.pageDefs">
  <parameters/>
  <executables>
    <variableIterator id="variables"/>
    <taskFlow id="pageeditorpanel"
              taskFlowId="#{pageEditorBean.pageEditorPanel}"
              xmlns="http://xmlns.oracle.com/adf/controller/binding"/>
  </executables>
  <bindings/>
</pageDefinition>
```

See Also: Section B.2, "Composer-Specific Files and Configurations" for information about files that are created or modified when you add Composer components.

18.1.10 What Happens at Runtime

At runtime, users can perform all the tasks described in Section 16.4, "Customizing Capabilities in Page View Mode" and Section 16.5, "Editing Capabilities in Design View and Add Content View in Page Edit Mode."

Each Composer component provides runtime capabilities that are described in Section 16.7, "Composer Components."

Note: Runtime customizations that you perform on a page are not carried over when you deploy the application to a target server.

18.1.11 What You May Need to Know When Designing Editable Pages

When adding Composer components to your customizable page, consider the following:

- To enable users to edit a page in a secured application, you must explicitly grant Edit or Customize privileges on the page to the required users or roles. For more information about granting permissions, see Section 74.4, "Using the Role Manager Task Flow."
- To enable runtime customization of components, add only one `Page Customizable` component to a page.

Note: Do *not* add a second `Page Customizable` component to your page. Only the first `Page Customizable` component is picked up when you run the page.

- Ensure that the `Page Customizable` component has only one direct child component.

  When you add multiple direct child components, only the first one is rendered at runtime. The first child component is stretched to fit the page. All other direct child components are ignored.
- Place all components you want to be customizable within the `Page Customizable` component.

- To enable runtime editing, you *must* ensure that the ID attribute is defined on all components on the page. Runtime editing of components that have no ID value is not supported in Composer.

  If your page includes components with no ID value, then you may encounter problems while editing the page in Composer.
- To enable View mode user customization, place a Show Detail Frame component within a Panel Customizable component.
- Use a Show Detail Frame to enclose a single child only. If you must enclose multiple components in a Show Detail Frame, then place a grouping component, such as a Panel Group Layout or Panel Customizable, within the Show Detail Frame component and then place the ADF Faces components or other content within this grouping component.
- Portlets need not be placed within Show Detail Frame components. Portlets come equipped with a header and display options that are similar to Show Detail Frame components.

18.2 Designing Editable Pages Using Composer Components: Example

In this example, assume you want to create a page that is customizable at runtime. The page is named MyPage.jspx in a Portal Framework application named MyWebCenterApp.

To create a customizable page:

1. Create a Portal Framework application named MyWebCenterApp by performing the steps in Chapter 6, "Creating WebCenter Portal Framework Applications."
2. Create a JSPX page named MyPage.jspx by performing the steps described in Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."
3. Add a Panel Stretch Layout from the ADF Faces tag library to MyPage.jspx.

   Note: The Panel Stretch Layout component stretches the child in the center facet to fill all the available space in the browser. This is true even if you resize the browser. Therefore, by placing your components within this child component, you can ensure that the customizable portion of your page occupies the complete browser area.

4. Add Page Customizable from the Composer tag library to the center facet by following the steps in Section 18.1.2, "How to Enable Runtime Customization Using a Page Customizable Component."
5. Set the border color of Page Customizable to blue to differentiate the editable area from other noneditable areas.

   Under the Style category in the Property Inspector for Page Customizable, click the Box tab and set the Border Color attribute to Blue.
6. Set the border color of child Panel Customizable to red.

   Under the Style category in the Property Inspector for Panel Customizable, click the Box tab and set the Border Color attribute to Red.
7. Add a Change Mode Link component to the top facet of the Panel Stretch Layout by performing the steps in Section 18.1.3, "How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button."

8. In the center facet, in the `Panel Customizable` that is a direct child of the `Page Customizable`, add a `Layout Customizable` component by following the steps in Section 18.1.5, "How to Enable Layout Customization for a Page Using a Layout Customizable Component."

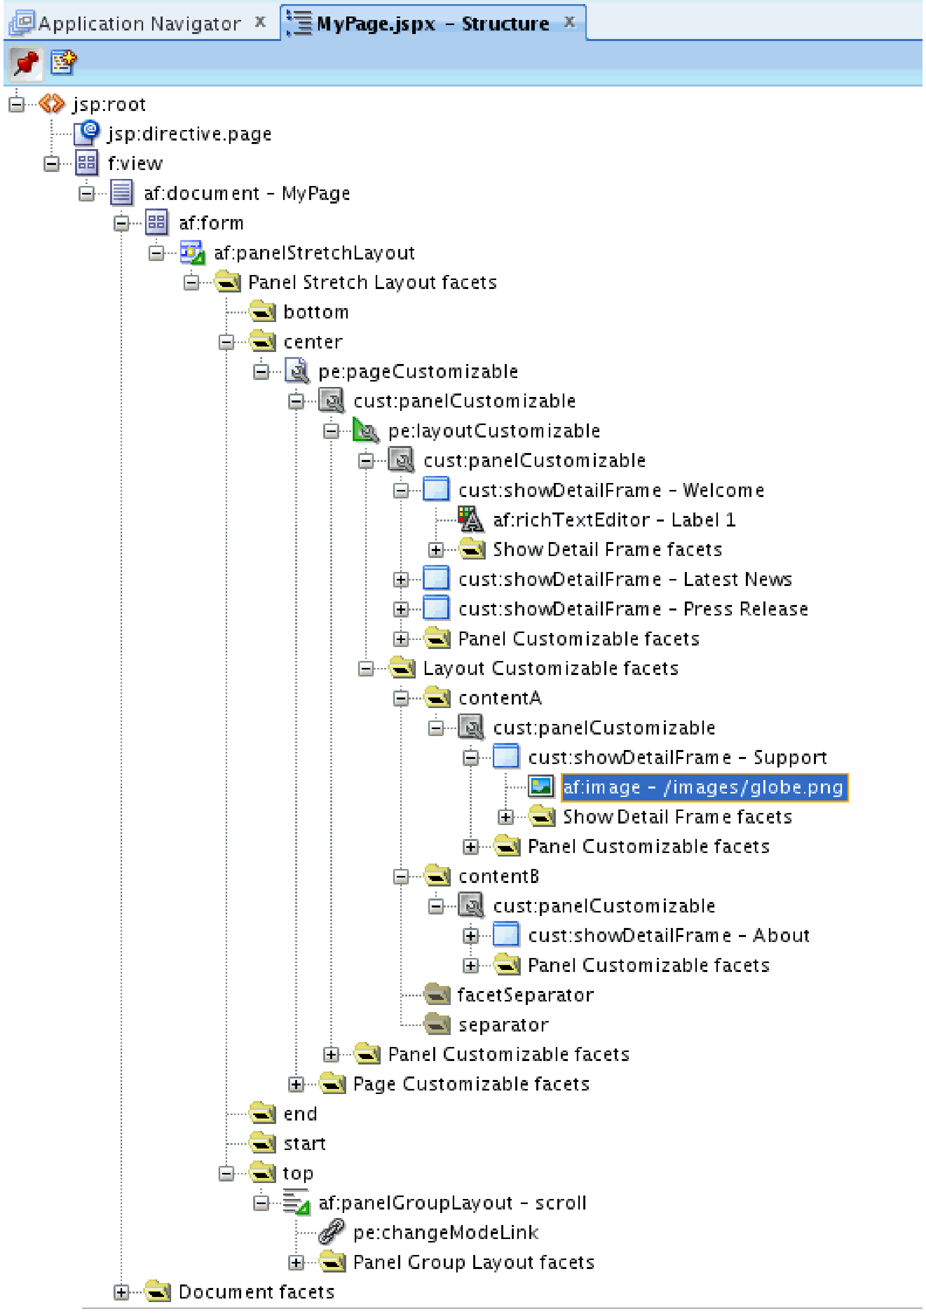
9. Add `Show Detail Frame` components inside each `Panel Customizable` on the page by performing the steps in Section 18.1.6, "How to Enable Component Customization Using Show Detail Frame Components."

   Figure 18–8 shows `Show Detail Frame` components inside `Panel Customizable` that is a direct child of `Layout Customizable`, and inside `Panel Customizable` components that are direct children of the `ContentA` and `ContentB` facets.

10. For the sake of this example, add a `Rich Text Editor` and an `Image` component inside two of the `Show Detail Frame` components nested in the `Layout Customizable`. Drag and drop each of these components from the **ADF Faces** tag library to the required location on the page.

    The hierarchy of components on the page is as shown in Figure 18–8.

Figure 18–8 Component Hierarchy in MyPage.JSPX



```
jsp:root
  jsp:directive.page
  f:view
    af:document - MyPage
      af:form
        af:panelStretchLayout
          Panel Stretch Layout facets
            bottom
            center
              pe:pageCustomizable
                cust:panelCustomizable
                  pe:layoutCustomizable
                    cust:panelCustomizable
                      cust:showDetailFrame - Welcome
                        af:richTextEditor - Label 1
                        Show Detail Frame facets
                      cust:showDetailFrame - Latest News
                      cust:showDetailFrame - Press Release
                      Panel Customizable facets
                    Layout Customizable facets
                      contentA
                        cust:panelCustomizable
                          cust:showDetailFrame - Support
                            af:image - /images/globe.png
                            Show Detail Frame facets
                          Panel Customizable facets
                      contentB
                        cust:panelCustomizable
                          cust:showDetailFrame - About
                          Panel Customizable facets
                      facetSeparator
                      separator
                  Panel Customizable facets
                Page Customizable facets
            end
            start
            top
              af:panelGroupLayout - scroll
                pe:changeModeLink
                Panel Group Layout facets
      Document facets
```

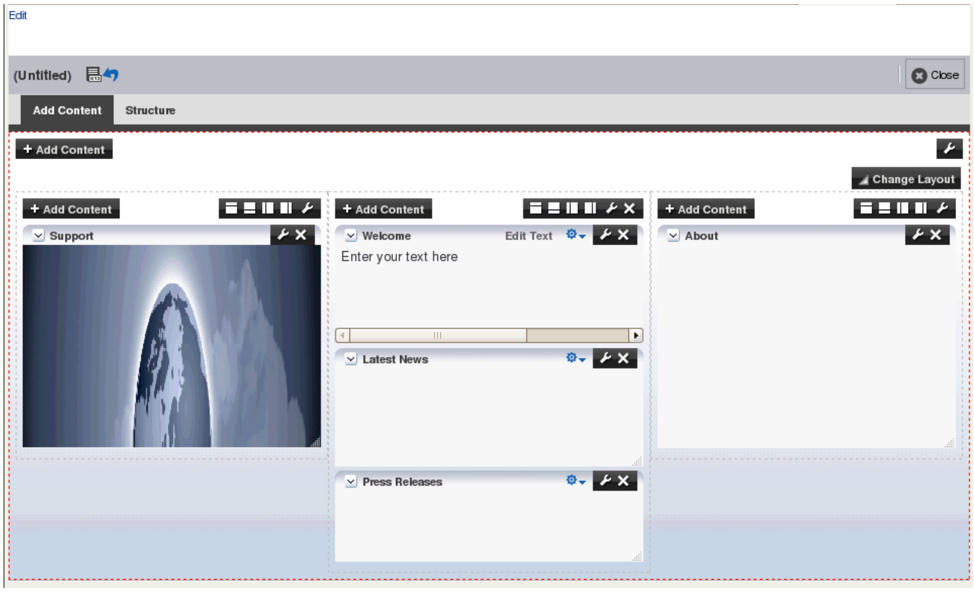
11. Grant Edit or Customize permission on the page to the required users and roles. For more information about granting permissions, see Section 74.4, "Using the Role Manager Task Flow."

12. Run `MyPage.jspx`.

    The page opens in View mode. Click the **Edit** link on the page to enter Edit mode. The page opens in Composer. In Composer, you can perform all editing tasks described in Section 16.5, "Editing Capabilities in Design View and Add Content View in Page Edit Mode."

    Figure 18–9 shows how the page appears in Edit mode at runtime.

Figure 18–9 MyPage Opened in Composer



If your application is not configured with ADF security, then to use this sample page in other examples in this guide, configure ADF security on the application.

To configure security in your application:

1. Configure ADF Security with form-based authentication, generating a default login page.

   For more information, see Section 74.3, "Configuring ADF Security."

2. Create three users `ahunold`, `sking`, and `jdoe`.

   For the detailed procedure, see Section 74.2, "Creating an Application Role."

When you run `MyPage.jspx`, a login screen is displayed. You can log in with any of the three user names that you created.

18.3 Populating Pages with Content

After you create an editable page with the required Composer components, you can populate the page with content just like a regular JSPX page. However, there are certain limitations and recommendations that you must be aware of when adding content to your Composer-enabled page.

Populating editable pages at design time is like populating any other ADF Faces page. You can drag and drop components from different areas of the IDE onto the page. You can add components like portlets, task flows, and ADF Faces components.

When you drag and drop a component anywhere inside a `Page Customizable` component, the `Id` attribute is set to a unique value. The `Id` attribute is required for editing a component and persisting its changed state. When you add a component to a page at runtime, the `Id` attribute is set automatically.

18.3.1 What You May Need to Know When Adding Content to a Page

Consider the following when adding content to your editable page:

- Add components inside `Panel Customizable` components that are nested in the `Page Customizable` component. This ensures that the components can be edited at runtime.
- You can include any Oracle ADF Faces component or task flow as child component of a `Show Detail Frame` component. However, portlets contain headers similar to those provided by `Show Detail Frame` components and can be added to `Panel Customizable` components directly. There are no additional benefits to including portlets in `Show Detail Frame` components.
- For components that you want to make selectable in Structure view in Composer, ensure that the component is compliant with rich client framework and generates a client-side component.
- If your page has the ADF Faces components `Output Text` and `Output Formatted` nested inside a `Page Customizable` component, then ensure that you set the `clientComponent` attribute value. If this attribute value is not set, then you may encounter errors while trying to move or rearrange components on the page at runtime.
- To consume portlets in your editable page, you must first register the portlet producers with your application. For information, see Chapter 63, "Consuming Portlets."

18.3.1.1 Considerations for Adding Task Flows

Users can personalize, customize, and edit task flows that are added to a customizable page. In a secured application, users with Customize permission on the task flow can also edit components on the task flow's page.

Consider the following points when adding task flows to your customizable page:

- To provide a consistent user experience in terms of look and feel, layout design, and interaction, and to avoid problems, such as too much white space, too many scroll bars, or slow, jerky, and unpredictable responses when displaying large data sets, ensure that the task flows are created by following the guidelines in Appendix D, "Guidelines for Creating Task Flows to Be Used in Composer-Enabled Pages."
- In a secured application, to enable users to view task flow content in Composer, ensure that the task flow has a `TaskFlowPermission` grant in the application's `jazn-data.xml` file, with at least `View` action provisioned. You must set this explicitly as it is not enabled by default.
- In a secured application, to enable users to edit components on the task flow's page, ensure that the task flow has a `TaskFlowPermission` grant in the application's `jazn-data.xml` file, with `Customize` action provisioned. You must set this explicitly as it is not enabled by default.
- Ensure that you specify valid values for all required parameters on the task flow.

For more information, see Chapter 22.6, "Implementing Task Flow Security"

18.4 Troubleshooting Composer Problems

This section provides information to assist you in troubleshooting problems you may encounter while using Composer.

Configuring ADF Logging for Composer

While creating your applications in JDeveloper, you can use the JDeveloper debugging tools to easily find errors in your web pages or page definition files. You can also set up the Java logger to display Java diagnostic messages. For detailed information about configuring logging, see the "Testing and Debugging ADF Components" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*. To configure logging for Composer, perform the tasks in that guide and ensure that the `oracle.adf.view.page.editor` and `oracle.adfinternal.view.page.editor` packages are configured in the `logging.xml` file, with the desired logging level.

Problem

When you run a page, the following error displays:

```
java.lang.IllegalStateException: The expression
"#{bindings.pageeditorpanel.regionModel}"
(that was specified for the RegionModel "value" attribute of the region component
with id "pePanel")
evaluated to null. This is typically due to an error in the configuration of the
objects referenced by this expression. If it helps, the expression
"#{bindings.pageeditorpanel}" evaluates to "null". If it helps, the expression
"#{bindings}" evaluates to "view_untitled1PageDef". Now using an empty RegionModel
instead.
```

Solution

This error occurs if a page containing the `Page Customizable` component does not have the required task flow binding in its page definition file. Ensure that the page definition file contains the following valid entry under the `<executables>` node:

```
<taskFlow id="pageeditorpanel"
taskFlowId="#{pageEditorBean.pageEditorPanel}"xmlns="http://xmlns.oracle.com/adf/c
ontroller/binding"/>
```

This error may also occur if your page is based on a page template and that page template contains the `Page Customizable` component. In such a case, the `af:pageTemplate` tag does not contain the `value="#{bindings.pageTemplateBinding}"` attribute.

Ensure that the page definition file has the following entry under the `<executables>` node:

```
<page path="view.pageDefs.templateDef1PageDef" id="pageTemplateBinding"
Refresh="ifNeeded"/>
```

Problem

Users cannot switch to Edit mode. The Edit link (`Change Mode Link` or `Change Mode Button`) appears disabled.

Solution

The user may have only view privilege on the page. Ensure that the user has the edit privilege on the page. For the page template on which the page is based, it is sufficient to have only view privilege.

Problem

Users encounter an exception while wiring events in the Component Properties dialog in Composer.

Solution

This error occurs if your application page includes both ADF Data Visualization components and Composer components.

Register the `DvtElementObjectFactory` class with the Oracle ADF `FactoryManager` object by adding the following code to the application class that gets loaded the earliest:

```
...
import oracle.adfdt.model.dvt.objects.DvtElementObjectFactory;
import oracle.adfdt.model.managers.FactoryManager;
...
static
{
FactoryManager.getInstance().registerFactory(new DvtElementObjectFactory());
}
```

19

Extending Runtime Editing Capabilities Using Composer

This chapter describes how to use Composer's declarative and programmable extensibility mechanism to customize runtime capabilities to suit your business needs.

This chapter contains the following topics:

19.1 Overview of Extensibility Options

Composer provides a framework on which to build customizable application pages. In addition to its default capabilities, you can extend the Composer framework to augment the runtime capabilities available to end users. You must configure the extensions in your application's `adf-config.xml` file and the Composer extension file, `pe_ext.xml`. For information about these files, see Section 19.1.8, "Configuration Files."

This section describes the options available for extending Composer runtime capabilities declaratively. It contains the following subsections:

- Section 19.1.1, "Composer Add-Ons"
- Section 19.1.2, "Composer Custom Property Panels"
- Section 19.1.3, "Composer Events Handlers"
- Section 19.1.4, "Drop Handlers."

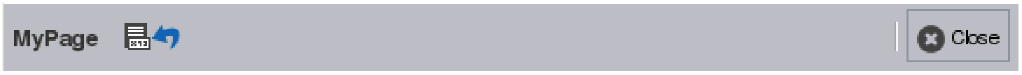
- Section 19.1.5, "Component Property Filters"
- Section 19.1.6, "Customization Manager"
- Section 19.1.7, "Composer Toolbar Customization"

19.1.1 Composer Add-Ons

The default Composer toolbar (Figure 19–1) includes the following:

- Page title: Shows the title of the page opened in Edit mode.
- **Page Properties** icon: Opens the Page Properties dialog, allowing the user to edit metadata for the host page.
- **Reset Page** icon: Reverts any changes made to the page in the current edit session.
- **Close** button: Exits Edit mode and returns the user to the standard UI.

Figure 19–1 Default Add-Ons on the Composer Toolbar



The Page Properties and Reset Page icons are examples of add-ons. Click these icons to display panels for editing page properties and resetting page customizations. Typically, add-ons are custom task flows that are rendered as icons on the Composer toolbar in page Edit mode. You can create add-ons that appear along with the Page Properties and Reset Page add-ons. For example, you can create an add-on to display page revision history so that it displays a Revisions icon on the Composer toolbar. Clicking this icon would display the page's revision history. You can also replace the Page Properties and Reset Page add-ons with custom add-ons that you create.

The process of configuring custom add-ons includes creating the task flows, packaging them into JAR files, and defining them in the Composer extension file. For more information, see Section 19.2, "Creating Composer Add-Ons."

19.1.2 Composer Custom Property Panels

The Component Properties dialog displays categories of attributes on different tabs. Each tab can be referred to as a property panel. The default Component Properties dialog in Composer is analogous to the Oracle JDeveloper Property Inspector. You can create and register custom property panels for a component, populate them with component properties, and display them as tabs along with the default tabs in the Component Properties dialog.

The process of configuring custom property panels includes creating them as task flows, packaging them into JAR files, and defining them in the Composer extension file. For more information, see Section 19.3, "Creating Custom Property Panels."

19.1.3 Composer Events Handlers

Composer provides an intuitive user interface for editing pages at runtime. This includes such UI components as the Save, Close, and Delete buttons. When a user clicks a button or icon in Composer, an event handler ensures that a specific action is performed. An event handler is the code that is called back by Composer when a Composer event is invoked. Each UI event in Composer is associated with an event handler. Sometimes it may be necessary to augment Composer's innate capabilities by performing a different action or multiple actions on invoking an event. For example, when a user clicks Save, in addition to the save operation that Composer provides by default, you might want to configure the application to perform additional tasks such as cleaning up cached information and connections to resources. You can accomplish this with event handlers. For more information, see Section 19.6, "Configuring Event Handlers for Composer UI Events."

19.1.4 Drop Handlers

The resource catalog provides resources that users can add to their pages. An Add link next to a resource name enables users to add it to the page. Composer provides *drop handler*s to handle the add operation in the catalog. By default, a drop handler is configured for each resource in the catalog. If you want to provide complete control of the drop action to the resource, you can create additional drop handlers for that resource. The Add link then displays a context menu with different options for adding the resource to the page. You can create one or more drop handlers to handle different flavors for resources in your catalog.

You can add the following types of drop handlers:

- Java classes registered with Composer and called when users click an Add link in the resource catalog. In this case, the resource is added to the page based on the data flavor selected.
- Task flows registered with Composer and called when users click an Add link in the resource catalog. In this case, a task flow is invoked, which enables users to decide what information from the resource must be displayed on the page.

For more information, see Section 19.7, "Configuring Drop Handlers in the Resource Catalog."

19.1.5 Component Property Filters

The Component Properties dialog displays properties of a selected component. By default, Composer filters certain component properties and displays a subset of properties to users. You can define filters declaratively to further hide properties that the user need not see, or to show properties that are hidden. For more information, see Section 19.8, "Defining Property Filters."

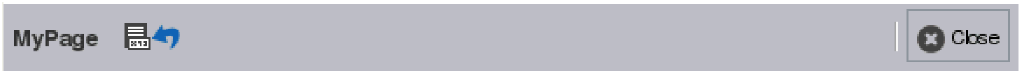
19.1.6 Customization Manager

Customization Manager is a task flow that enables users to download, upload, reset, and delete application customizations on objects like pages and task flows. You can configure the Customization Manager either in Composer or outside of it, on some administrative page. For information about configuring and using Customization Manager, see Section 19.9, "Enabling Parameter Support on the Customization Manager Task Flow."

19.1.7 Composer Toolbar Customization

The default Composer toolbar displays the following elements: page name, Page Properties and Reset Page icons, and the Close button, as shown in Figure 19–2.

Figure 19–2 Composer Toolbar with Default Elements



You can customize the toolbar by adding, deleting, or rearranging elements. You can also override existing elements with custom elements. For example, you can remove the message showing the page name if you do not want users to see the name of the page they are editing.

For information about customizing the Composer toolbar, see Section 19.10, "Customizing the Composer Toolbar."

19.1.8 Configuration Files

Before you start with the extensibility configurations described in this chapter, there are two important configuration files that you must know about. Most of the extensions discussed in this chapter are defined in these files:

- Composer extension file (`pe_ext.xml`)

  The Composer extension file, `pe_ext.xml`, enables you to extend the editing capabilities provided by Composer. Within this file you can add elements to register new Composer add-ons and custom property panels, selectively render panels, register event handlers, and define property filters. The `pe_ext.xml` file is not available in your application by default. You must create it the first time you perform such tasks as including add-ons, property panels, or event handlers. Create this file in the `META-INF` directory under the project's Web context root or in the `*application_home*/*project*/src/META-INF` directory. When you run the application, the `pe_ext.xml` file is picked up from the JAR file included in the application classpath. Your application can include more than one extension file. However, you must ensure that the JARs containing the extension files are available on the application classpath so that the `pe_ext.xml` files are picked up for processing. Every JAR with a `pe_ext.xml` in its `META-INF` folder is processed, and the Composer extensions are loaded and combined. For information about the different elements you can define in `pe_ext.xml` to extend Composer capabilities, see Section B.2.1, "pe_ext.xml."

- Application's `adf-config.xml` file

  The `adf-config.xml` file specifies application-level settings that are usually determined at deployment and often changed at runtime. When you perform such tasks as registering new add-ons and custom property panels in Composer, or creating customization layers, you must add appropriate entries in the `adf-config.xml` file. The `adf-config.xml` file is created automatically when you create an application, and when you add a `Page Customizable` component to the page, certain configurations are added to this file.

  For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

19.2 Creating Composer Add-Ons

Composer provides the following default add-ons for runtime editing:

- Page Properties

  This dialog opens when users click the Page Properties icon on the Composer toolbar. The Page Properties dialog displays the current page's properties and enables users to modify property values.

- Reset Page

  The Reset Page dialog opens when users click the Reset Page icon on the Composer toolbar. The Reset Page dialog enables users to remove application customizations made to a page and reset it to a previously-saved version or to its original out-of-the-box state. For more information, see Section 16.5.11, "Reset Page."

In addition to these, you can register new add-ons with Composer. For example, you can create an add-on to display page revision history so that it displays a Revisions icon on the Composer toolbar. Clicking this icon would display the page's revision history.

This section contains the following subsections:

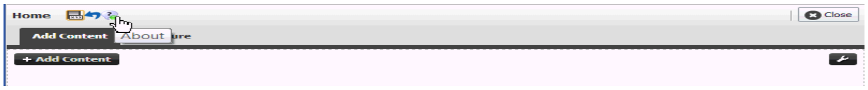
- Section 19.2.1, "How to Create and Register Add-Ons"
- Section 19.2.2, "What Happens at Runtime"
- Section 19.2.3, "How to Exclude Composer Default Add-Ons"
- Section 19.2.4, "How to Display the Customization Manager Add-On"
- Section 19.2.5, "How to Selectively Display Add-Ons"

19.2.1 How to Create and Register Add-Ons

You can create and register custom task flows that can be invoked from icons on the Composer toolbar. All registered add-ons have an associated icon that displays on the toolbar.

This section steps through the procedure of creating an add-on and registering it with Composer. It includes an example that demonstrates how to create an add-on that displays information about the application. The example add-on renders an **About** icon on the Composer toolbar (Figure 19–3) that users can click to invoke a task flow that contains information about the application.

Figure 19–3 About Icon on the Composer Toolbar



This section contains the following subsections:

- Section 19.2.1.1, "Creating an Add-On Task Flow"
- Section 19.2.1.2, "Registering Add-Ons with Composer"
- Section 19.2.1.3, "Registering Add-Ons in adf-config.xml"

19.2.1.1 Creating an Add-On Task Flow

Composer add-ons are task flows you create using JSPX pages or page fragments.

To create an add-on:

1. In your application project, create a JSFF file called `custompanelview.jsff`:
   a. From the **File** menu, select **New**.
   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **JSF Page** or **JSF Fragment**.
   c. Click **OK**.
2. Design the fragment by adding code similar to what is shown in Example 19–1.

Example 19–1 Sample code in the JSFF Fragment

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <af:panelGroupLayout id="pnlgrp1" layout="vertical" halign="center">
    <af:spacer id="sp1" height="20" />
    <af:image id="customimage"
              source="/images/DemoLogo.jpg"
              shortDesc="Demo Logo"/>
    <af:spacer id="sp2" height="20"/>
    <af:outputText id="output1" value="This is a sample shopping cart application
based on Oracle ADF Framework.
It also uses the Oracle WebCenter Portal Framework to enable collaboration,
application customization and user customization features."/>
    <af:spacer id="sp3" height="20"/>
    <af:outputText id="output2" value="Build : 11.1.1"
                   inlineStyle="font-weight:bold;"/>
  </af:panelGroupLayout>
</jsp:root>
```

Note: At runtime, the add-on panel is automatically sized to fit the content in this fragment.

3. Create a task flow definition called `custom-panel-task-flow`:
   a. From the **File** menu, choose **New**.
   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **ADF Task Flow**.
   c. Click **OK**.
4. Drop the `custompanelview.jsff` fragment that you created onto the task flow definition.

   See Also: "Getting Started with ADF Task Flows" in *Fusion Developer's Guide for Oracle Application Development Framework*

5. Save the task flow definition file.

Optionally, if you create the task flow in one application but want to consume it in another application, you must first package the task flow in an ADF library and add the resulting JAR in the consuming application.

To package the task flow in an ADF library:

1. Create a deployment profile for the task flow:
   a. Right-click **Portal** project and choose **New**.
   b. In the New Gallery, expand **General**, select **Deployment Profile**, and then **ADF Library JAR File**, and click **OK**.
   c. In the Create Deployment Profile -- ADF Library JAR File dialog, enter a name for your deployment profile and click **OK**.
   d. In the ADF Library JAR Deployment Profile Properties dialog, click **OK**.
   e. In the Project Properties dialog, click **OK**.
2. In the Application Navigator, right-click the project folder, choose **Deploy**, *deployment profile name*.

3. In the Deploy dialog, choose **Deploy to ADF Library JAR file**.
4. Click **Finish**.

   This creates a **deploy** folder including the JAR file, in the project folder located at *<Application_Root>*\Portal\deploy\.

You can add this JAR file to any application in which you want to consume the add-on.

19.2.1.2 Registering Add-Ons with Composer

After you create the task flows, you must register them with Composer so that they are displayed on the Composer toolbar along with the default options.

To register an add-on with Composer:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *APPLICATION_HOME*`\Portal\src\META-INF` directory):
   1. From the **File** menu, select **New**.
   2. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.
   3. Click **OK**.

   Name the file `pe_ext.xml`.
2. Add an `<addon-config>` element in the file, with a nested `<panels>` element.
3. Add one `<panel>` element for each task flow that you want to register as an add-on.

   Any number of panels can be declared under the `<panels>` element in the extension file.

   Example 19–2 shows the code of the extension file with a `<panel>` entry.

Example 19–2 Composer Extension File

```
<?xml version="1.0" encoding="US-ASCII" ?>
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <panels>
      <panel name="oracle.custom.panel" title="About"

icon="http://myforums.oracle.com/jive3/images/question-pts-available-16x16.gif"

taskflow-id="/WEB-INF/custom-panel-task-flow.xml#custom-panel-task-flow" />
    </panels>
  </addon-config>
</pe-extension>
```

   For more information about the `addon-config` and other nested elements, see Section B.2.1.1, "addon-config."

4. Optionally, register event handlers for the custom panel by adding an `event-handlers` element within the `panel` element as shown in the following example:

   ```
   <event-handlers>
     <event-handler event="close">
       oracle.custom.TaskFlowEventHandler
   ```

```
  </event-handler>
</event-handlers>
```

For more information, see Section 19.6, "Configuring Event Handlers for Composer UI Events."

5. Save the pe_ext.xml file.

19.2.1.3 Registering Add-Ons in adf-config.xml

To register an add-on, you must add a reference to it in the application's adf-config.xml file. Add the addon-panels entry to define new add-ons.

To register add-ons in the adf-config.xml file:

1. Open the application's adf-config.xml file, located in the ADF META-INF folder under Descriptors in the Application Resources panel.
2. Add the following namespace within the adf-config element in the file:

   ```
   xmlns:pe="http://xmlns.oracle.com/adf/pageeditor/config"
   ```

3. Add a <pe:page-editor-config> entry with the namespace and include <pe:addon-panels> inside it.

   When you register a custom add-on, the default add-ons are not displayed in Composer by default. To display all the default add-ons, you must set the show-default-addons attribute on the <pe:addon-panels> tag to true. The default value for this attribute is false.

   Within <pe:addon-panels>, add <pe:addon-panel> entries for the new panels, as shown in Example 19–3.

   The name attribute must contain the name you used to register the panel in the Composer extension file.

Example 19–3 New Add-On Referenced in adf-config.xml

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels show-default-addons="true">

    <pe:addon-panel name="oracle.custom.panel" />

  </pe:addon-panels>
</pe:page-editor-config>
```

> **Note:** If you do not specify any <addon-panel> entries under <addon-panels>, then only the default options are displayed in Composer.

4. Save the adf-config.xml file.

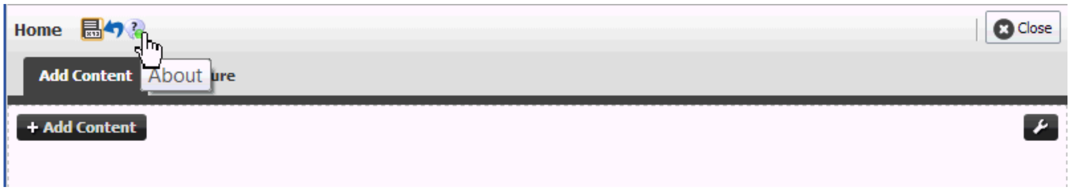
For information about the Composer-specific configurations you can make in adf-config.xml, see Section B.2.2, "adf-config.xml."

19.2.2 What Happens at Runtime

Custom add-ons that you register with Composer are rendered on the Composer toolbar along with the default add-ons.

In the example, an About icon is rendered on the Composer toolbar (Figure 19–4).

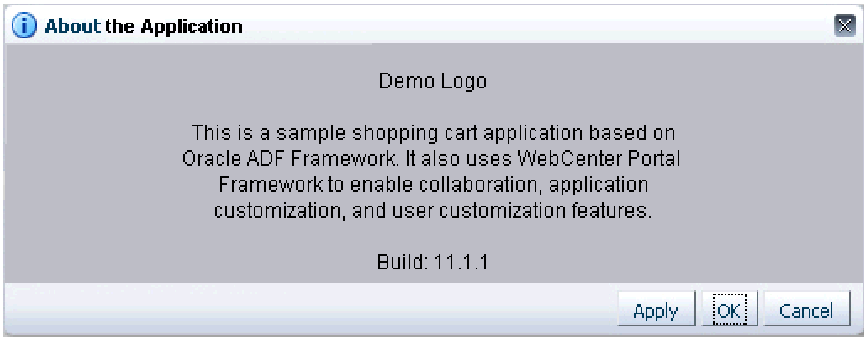
Figure 19–4 About Icon on the Composer Toolbar



Clicking this icon displays the About the Application task flow (Figure 19–5).

Note: The add-on panel is automatically sized to fit the content inside the task flow.

Figure 19–5 About the Application Task Flow



About the Application

Demo Logo

This is a sample shopping cart application based on Oracle ADF Framework. It also uses WebCenter Portal Framework to enable collaboration, application customization, and user customization features.

Build: 11.1.1

19.2.3 How to Exclude Composer Default Add-Ons

You can choose to show or hide the Page Properties, Reset Page, and Customization Manager icons on Composer toolbar. To hide any of these add-ons, you must set the `show-default-addons` attribute on `<pe:addon-panels>` to `true`, add an entry for the default add-on you want to hide, and set the `rendered` attribute on that add-on to `false`.

Example 19–4 shows the code to hide the Page Properties add-on.

Example 19–4 The adf-config.xml File with the Reset Page Option Excluded

```
<pe:addon-panels show-default-addons="true">
  <!-- Hide the Reset Page add-on -->
  <pe:addon-panel name="oracle.adf.pageeditor.addonpanels.page-reset"
rendered="false"/>

  . . .

</pe:addon-panels>
```

The excluded add-on (Reset Page) is not displayed on the Composer toolbar. The other default add-ons are displayed on the toolbar in the default order.

19.2.4 How to Display the Customization Manager Add-On

The Customization Manager is a Composer add-on that enables users to manage application customizations on task flows, pages, and page fragments on a given page. For more information, see Section 16.5.15, "Manage Application Customizations."

The Customization Manager add-on is available in the Composer library, but is not rendered by default. You can enable it by configuring it in your application's `adf-config.xml` file using a `<pe:addon-panel>` element inside `<pe:page-editor-config>`, as shown in the following example:

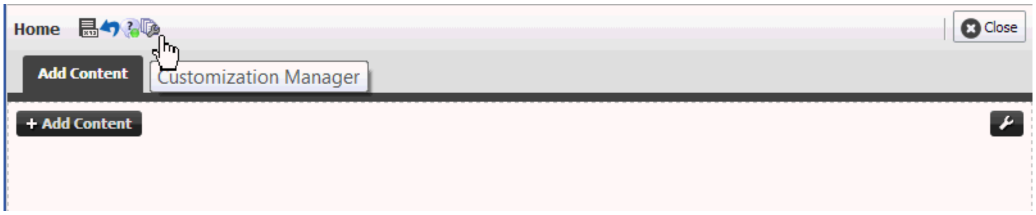
```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels show-default-addons="true">
    <pe:addon-panel
name="oracle.adf.pageeditor.addonpanels.customization-manager"/>

    . . .

  </pe:addon-panels>
  . . .
</pe:page-editor-config>
```

This configuration ensures that the Composer toolbar displays the Customization Manager icon as shown in Figure 19–6.

Figure 19–6 Customization Manager Icon



19.2.5 How to Selectively Display Add-Ons

Depending on your business requirement, you may need to selectively hide the add-ons available to different users in Composer. To selectively hide an add-on, you must set the `show-default-addons` attribute on `<pe:addon-panels>` to `true`, add an entry for the default add-on you want to hide, and set the `rendered` attribute for that add-on to `false` using an EL expression, as shown in Example 19–5.

Example 19–5 rendered Attribute Setting in the adf-config.xml File

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels show-default-addons="true">
    <pe:addon-panel name="oracle.adf.pageeditor.addonpanels.page-reset"
             rendered="#{securityBean.userInPageResetRole}" />
    . . .
  </pe:addon-panels>
  . . .
</pe:page-editor-config>
```

In this example, the `securityBean` backing bean returns either `true` or `false`, depending on the role of the logged-in user. If the returned value is `false`, Composer does not display the Reset Page icon on the Composer toolbar. If the returned value is `true`, Composer displays the Reset Page icon.

Note: If you hide the Reset Page icon on the Composer toolbar, the Reset Task Flow icon displayed while editing task flow content is also hidden.

The default value for `rendered` is `true`. That is, if you do not specify a `rendered` attribute for an add-on, the add-on is always displayed.

19.3 Creating Custom Property Panels

Composer displays the properties of a component in the Component Properties dialog when a user clicks the **Edit** icon on the component. The Component Properties dialog provides a series of tabs. Each tab displays a group of related attributes. The attributes have associated values that control a component's behavior and visual style properties. For example, the Style tab displays the component's style-related properties, such as width, height, and background color.

Similarly, when a user clicks the **Page Properties** icon, a Page Properties dialog opens with its own series of tabs. These tabs contain display-related page properties, page parameters, and security settings.

You can create and register custom property panels to render along with the tabs displayed in the Component Properties or Page Properties dialog. In addition, you can remove the default panels or replace them with custom property panels. For example, you can develop a friendlier property panel for an `Image` component by displaying a picker for its `Source` property. This would make it easier for users to select an image from the available options.

This section describes how to create custom property panels. It also describes how to exclude, override, and selectively render default property panels. It contains the following subsections:

- Section 19.3.1, "How to Create and Register Custom Property Panels"
- Section 19.3.2, "What Happens at Runtime"
- Section 19.3.3, "How to Override Default Property Panels"
- Section 19.3.4, "How to Exclude Default Property Panels"
- Section 19.3.5, "How to Selectively Render Property Panels"
- Section 19.3.6, "How to Display Properties and Parameters in a Custom Property Panel"

19.3.1 How to Create and Register Custom Property Panels

Creating a custom property panel is similar to creating an add-on. That is, you create custom property panels as task flows and register them in the Composer extension file. However, while Composer add-ons are configured using the `addon-panels` element in the `adf-config.xml` file, custom property panels are configured using the `property-panels` element in the extension file itself.

You can configure a custom property panel to display in the Component Properties dialog always. Alternatively, you can configure the panel to display only when a particular component or task flow is selected for editing.

This section describes how to create and register a custom property panel. It contains the following subsections:

- Section 19.3.1.1, "Creating a Custom Property Panel"

- Section 19.3.1.2, "Registering a Custom Property Panel for a Component"
- Section 19.3.1.3, "Registering a Custom Property Panel for a Task Flow"

19.3.1.1 Creating a Custom Property Panel

Property panels provide a means of editing page or component properties. For example, a user can click the **Edit** icon on a selected task flow and modify its parameter values and change its visual attributes in the Component Properties dialog.

Composer enables you to associate property panels with components and task flows. When a user clicks the **Edit** icon on the component or task flow, Composer opens the Component Properties dialog and displays the custom property panels you associated with the object along with the default property panels.

The steps for creating a custom property panel and declaring it in the Composer extension file are similar to those for creating and declaring Composer add-ons. For detailed information, see Section 19.2.1.1, "Creating an Add-On Task Flow" and Section 19.2.1.2, "Registering Add-Ons with Composer."

Example 19–6 shows a sample property panel declaration in the `pe_ext.xml` file.

Example 19–6 Custom Property Panel Declaration in pe_ext.xml

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <panels>
      <panel name="sample-panel" title="Sample Panel"
             taskflow-id="/WEB-INF/sample_task_flow.xml#sample_task_flow"/>
    </panels>
  </addon-config>
</pe-extension>
```

After you create a custom panel and declare it in the `pe_ext.xml` file, you must configure it using the `<property-panels>` element, as shown in Example 19–7. This ensures that the panel displays automatically in the Composer Component Properties and Page Properties dialog.

Example 19–7 Custom Property Panel Configuration in pe_ext.xml

```
<addon-config>
  <panels>
    . . .
  </panels>
  <property-panels>
    <property-panel name="samplepanel">
      <panel name="sample-panel" rendered="true"/>
    </property-panel>
  </property-panels>
</addon-config>
```

Use one `<panel>` element to register each custom panel. A `<panel>` corresponds to a tab in the Component Properties dialog. You can add any number of `<panel>` elements.

19.3.1.2 Registering a Custom Property Panel for a Component

When you register a custom panel in the extension file, you can associate the panel with a component or a task flow. The custom property panel then renders only for that component or task flow. This section describes how to register a property panel for a specific component.

To register a property panel for a component:

1. Create a Composer extension file, `pe_ext.xml`, if it does not already exist.

   For information about creating the extension file, see Section 19.2.1.2, "Registering Add-Ons with Composer."

2. Add a `<property-panels>` element inside the `<addon-config>` section in the `pe_ext.xml` file.

3. Add a `<property-panel>` declaration within the `<property-panels>` element.

   You can have multiple `<property-panel>` entries.

4. Within the `<property-panel>` element, add a `<component>` element to specify the runtime class name of the component (optional) and a `<panel>` element to specify the name you used to declare the panel in the `<addon-config>` section of the file.

   Example 19–8 shows a custom property panel that is associated with a `Command Button` component by specifying the component's fully qualified class name. For information about Oracle ADF components and their runtime classes, see *Fusion Developer's Guide for Oracle Application Development Framework*.

Example 19–8 Code to Register a Property Panel for a Component

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <property-panels>
      <property-panel name="cmdbtn">

<component>oracle.adf.view.rich.component.rich.nav.RichCommandButton</component>
        <panel name="prop.panel.cmdbtn" />
        <panel name="prop.panel.generic" />
      </property-panel>
    </property-panels>
  </addon-config>
  . . .
</pe-extension>
```

> **Note:** When registering a property panel, if you do not associate it with a component or task flow (discussed in the next section), the registered panel is rendered at all times in the Component Properties and Page Properties dialogs.
>
> To configure multiple property panels for a component, you can include multiple `<panel>` elements within a `<property-panel>` element. For more information about the `<property-panels>` element and its nested elements, see Section B.2.1.2, "property-panels."

All the default panels, such as Child Components, Style, and Parameters, are displayed along with the custom panels you define.

19.3.1.3 Registering a Custom Property Panel for a Task Flow

You can define a custom property panel for a task flow by registering it with the Composer extension file. Example 19–9 shows the sample code used to register a custom property panel for a task flow.

A custom property panel registered for a specific task flow appears only when its associated task flow is selected. Otherwise, default property panels appear.

Note: Use task flow-specific custom property panels only to customize task flow parameters or any other aspect related to how the task flow works.

A custom property panel does not function if it is associated with a task flow rendered using the Oracle JSF Portlet Bridge.

To register a property panel for a task flow:

1. Add a `<property-panels>` element within the `<addon-config>` element in the `pe_ext.xml` file.

   For information about creating the extension file, see Section 19.2.1.2, "Registering Add-Ons with Composer."

2. Add a `property-panel` declaration within this.

   You can have multiple `property-panel` entries.

3. Add `taskflow-id` and `panel` elements within the `property-panel` element.

   Add the `taskflow-id` element to specify the task flow name. Add the `panel` element to specify the name you used to declare the property panel in the `addon-config` section of the file.

   Example 19–9 shows a custom property panel associated with a `dashboard` task flow.

Example 19–9 Code to Register a Property Panel for a Task Flow Instance

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <property-panels>
      <property-panel name="dashboard">
        <taskflow-id>/WEB-INF/dashboard-taskflow#prop-panel</taskflow-id>
        <panel name="dashboard.prop-panel" />
      </property-panel>
    </property-panels>
  </addon-config>
  . . .
</pe-extension>
```

Notes:

- If you do not associate a custom property panel with a component or task flow (using the `<component>` or `<taskflow-id>` tag), then the registered panel is rendered for all pages, task flows, and components in the Component Properties and Page Properties dialogs.

  You can register multiple `panel` elements within a `property-panel` element. For more information about the `property-panels` element and its nested elements, see Section B.2.1.2, "property-panels."
- To enable end users to edit the attributes and parameters on a custom property panel, in the panel's task flow fragment you must add a `Show Property` components for each property that you want to expose. The value attribute on a `Show Property` component is tied to a managed bean that contains the logic to read and write values for the properties and parameters. For more information, see Section 19.3.6, "How to Display Properties and Parameters in a Custom Property Panel."

19.3.2 What Happens at Runtime

If you associated the custom property panel with a specific component or task flow, at runtime the panel renders as a tab in the Component Properties dialog invoked from the specified component or task flow. If you did not associate the custom property panel with a specific component or task flow, at runtime the custom property panel renders as a tab in both the Page Properties and Component Properties dialogs for all pages, components, and task flows.

Note: In the Component Properties and Page Properties dialogs, custom panels are sized by the tab component containing the task flows. The size of the tab component itself is determined by a rule in the currently-applied skin. This rule is called `af|panelTabbed.Tab`.

19.3.3 How to Override Default Property Panels

The Component Properties dialog in Composer displays the following panels by default: Display Options, Child Components, Events, Style, Content Style, and Parameters. You can override a particular panel by using the default panel's name when you declare and register the custom panel in the `pe_ext.xml` file. For information about the default panels, see Section B.3, "Composer Default Add-Ons and Property Panels."

Example 19–10 shows the code to override the Display Options panel with a panel defined using a task flow called `custom-panel-task-flow`.

Example 19–10 Sample Code to Override a Default Panel

```
<addon-config>
  <panels>
    <panel name="oracle.adf.pageeditor.pane.generic-property-inspector"
title="Sample Panel"

icon="http://myforums.oracle.com/jive3/images/question-pts-available-16x16.gif"
```

```
taskflow-id="/WEB-INF/custom-panel-task-flow.xml#custom-panel-task-flow" />
  </panels>
  <property-panels>
    <property-panel name="samplepanel">
      <panel name="oracle.adf.pageeditor.pane.generic-property-inspector"
rendered="true"/>
    </property-panel>
  </property-panels>
</addon-config>
```

19.3.4 How to Exclude Default Property Panels

Out-of-the-box, all default property panels are displayed along with custom property panels that you configure. To hide a default property panel in the Page Properties or Component Properties dialog, you can add a line specifically for that panel and set the `rendered` attribute to `false`.

Example 19–11 shows the `rendered` attribute set to `false` for the Content Style property tab of a `Command Button` component. For information about default property panels, see Section B.3, "Composer Default Add-Ons and Property Panels."

Example 19–11 rendered Attribute for a Property Panel

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <property-panels>
      <property-panel name="cmdbtn">
        <component>oracle.rich.CommandButton</component>
        <panel name="prop.panel.cmdbtn" />
        <panel name="oracle.adf.pageeditor.pane.content-style-editor"
rendered="false" />
      </property-panel>
    </property-panels>
  </addon-config>
  . . .
</pe-extension>
```

19.3.5 How to Selectively Render Property Panels

Custom property panels registered in the application are rendered in the Component Properties dialog when users click the **Edit** icon on a specified component. You can configure your application to render a property panel selectively based on different criteria like the role of a logged-in user, the page being viewed, and so on. To display property panels selectively, you can use an EL value in the `property-panel`'s `rendered` attribute as shown in the following example:

```
<property-panel name="global-but-just" rendered="#{bean.showProperty}">
```

19.3.6 How to Display Properties and Parameters in a Custom Property Panel

If you are building a custom property panel for a component, you can use `Show Property` components, available from the Composer tag library, to expose the component's attributes on the custom panel. In the page fragment defining the custom panel task flow, you must add one `Show Property` component for each attribute that you want to expose. `Show Property` is a declarative component that reads a property value on the component or task flow (for which you have created the custom panel), and displays an input field for that property in the custom panel. Users can edit property values in the panel using the input fields.

For more information about custom panels, see Section 19.3.1.1, "Creating a Custom Property Panel."

To add a `Show Property` component:

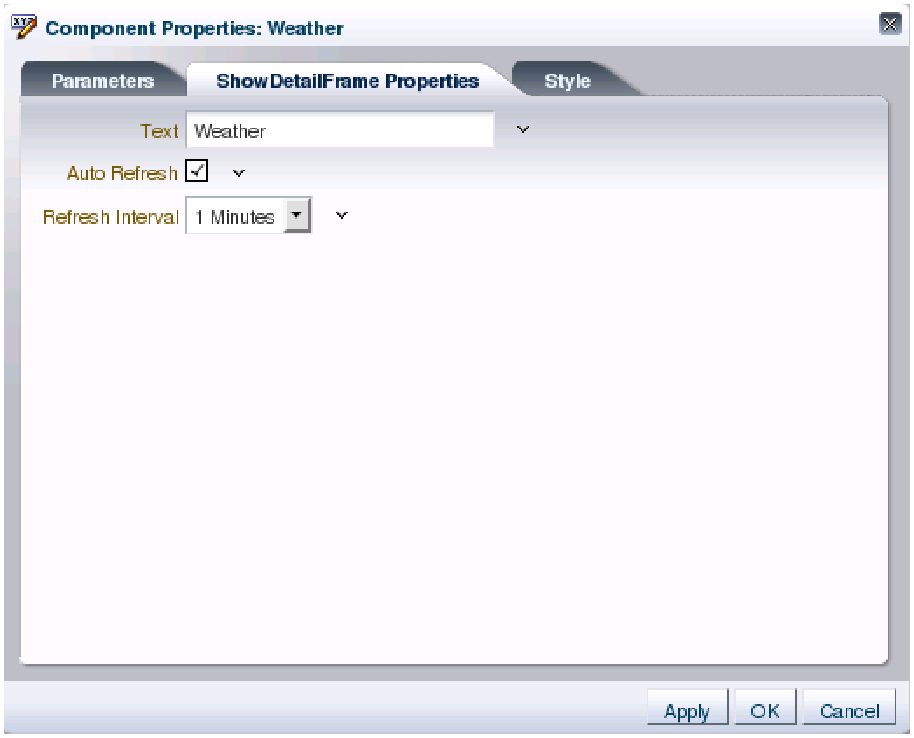
1. Open the page fragment that you created for the custom panel task flow.
2. From the Component Palette, select **Composer**.
3. Drag and drop a `Show Property` component for each component attribute that you want to expose in the custom panel.
4. To ensure that the attribute displays correctly in the custom panel, set the attributes on each `Show Property` component by referring to Section B.1.7, "Show Property."

> **Note:** You can use the `Show Property` component even on pages outside of Composer.

Example

Consider an example of a weather widget that is included inside a `Show Detail Frame` component. A custom property panel is created to enable users to edit the Text, Auto Refresh, and Refresh Interval attributes on the weather widget. It includes three fields for users to provide values for these attributes. To enable users to set the three attributes on the weather widget, one `Show Property` component is added for each attribute that is exposed in the panel. When a user edits the weather widget at runtime, the Component Properties dialog displays the custom panel with the three attributes, as shown in Figure 19–7.

Figure 19–7 Custom Panel to Display Show Detail Frame Component Properties



Component Properties: Weather

Text: Weather

Auto Refresh: ☑

Refresh Interval: 1 Minutes

The weather widget is consumed in a page along with a `Poll` component as shown in the following example:

```
<cust:showDetailFrame text="Weather" id="sdf1" contentStyle="height:220.0px;"
                      partialTriggers="p1">
  <af:region value="#{bindings.weathertaskflowdefinition1.regionModel}"
             id="r1"/>
  <af:poll id="p1" interval="60000"/>
</cust:showDetailFrame>
```

The `Poll` component is used to deliver refreshed content to the weather widget at fixed intervals. The default interval is 60000 milliseconds.

The custom panel contains three `panelLabelandMessage` components to provide input fields for the `Text`, `Auto Refresh`, and `Refresh Interval` attributes. The fields on this panel are implemented as follows:

- A `showProperty` component is added to each `panelLabelandMessage` component as shown in the following example:

  ```
  <!-- Input field for setting the Text attribute, which displays on the
  component header -->
  <af:panelLabelAndMessage label="Text" id="plam2">
    <pedc:showProperty label="Text" id="sp1" simple="true"
                       value="#{sdfCustomPanel.text}"/>
  </af:panelLabelAndMessage>

  <!-- Checkbox to enable auto refresh, which controls whether the widget must be
  refreshed -->
  <af:panelLabelAndMessage label="Auto Refresh" id="plam3">
    <pedc:showProperty label="Auto Refresh" id="sp2" simple="true"
                       type="boolean" autoSubmit="true"
                       value="#{sdfCustomPanel.autoRefresh}"/>
  </af:panelLabelAndMessage>

  <!-- LOV to display values for Refresh Interval when auto refresh is enabled
  -->
  <af:panelLabelAndMessage label="Refresh Interval" id="plam4">
    <pedc:showProperty label="Refresh Interval" id="sp3" simple="true"
                       type="list" disabled="#{!sdfCustomPanel.autoRefresh}"
                       value="#{sdfCustomPanel.refreshInterval}"
                       selectItems="#{sdfCustomPanel.selectItems}"

  binding="#{sdfCustomPanelRequestBean.refreshIntervalShowProp}"/>
  </af:panelLabelAndMessage>
  ```

  where `sdfCustomPanel` references a managed bean, `SDFCustomPanelBean.java`.

- The task flow definition of the custom panel contains a reference to the bean:

  ```
  <managed-bean id="mb1">
    <managed-bean-name id="mb1_name">sdfCustomPanel</managed-bean-name>
    <managed-bean-class id="mb1_
  class">portal.weather.panel.SDFCustomPanelBean</managed-bean-class>
    <managed-bean-scope id="mb1scope">session</managed-bean-scope>
  </managed-bean>
  ```

- The `SDFCustomPanelBean.java` bean provides the logic to handle values for the different attributes exposed in the panel. In the bean, the `SelectionContext` API is used to read and write values for each attribute as follows:

– Get hold of the selected component, that is, the component on which the properties are displayed; in this example, a Show Detail Frame component, as the weather widget is included inside one.

– Read the attribute value on the selected component.

– Get the attribute value that the user specifies and set that value for the component attribute.

For example, the Refresh Interval attribute is enabled only if Auto Refresh in selected, and it displays a drop-down menu with the values defined in the managed bean. The Poll component on the page is wired to the Show Property component so that the widget refresh is driven by the value of the Show Property component. The code to handle the value for the Refresh Interval property is as follows:

```
. . .
/** Set the refresh interval attribute value on the component
public void setRefreshInterval(String _refreshInterval)
{
  this._refreshInterval = _refreshInterval;
}
**/

public String getRefreshInterval()
{
  if (_autoRefresh == true && _refreshInterval != null)
    return _refreshInterval;

  // Get hold of the component whose properties you want to edit
  SelectionContext selCtx =
    Context.getCurrentInstance().getSelectionContext();
  UIComponent selComp = selCtx.getSelectedComponent().getUIComponent();
  if (selComp instanceof ShowDetailFrame)
  {
    // Get the refresh interval value specified for the Poll component
    RichPoll pollComp = (RichPoll) selComp.findComponent("p1");
    if (_autoRefresh == false)
      _refreshInterval = "Refresh interval not applicable";
    else if (pollComp.getInterval() < 0)
      _refreshInterval = "60000";
    else
      _refreshInterval = Integer.toString(pollComp.getInterval());
  }

  return _refreshInterval;
}
. . .
public List<SelectItem> getSelectItems()
{
  return _selectItems;
}
. . .
private static List<SelectItem> _selectItems;
static
{
  _selectItems = new ArrayList<SelectItem>();
  SelectItem si = new SelectItem("60000", "1 Minutes");
  _selectItems.add(si);
  si = new SelectItem("120000", "2 Minutes");
  _selectItems.add(si);
  si = new SelectItem("180000", "3 Minutes");
  _selectItems.add(si);
}
```

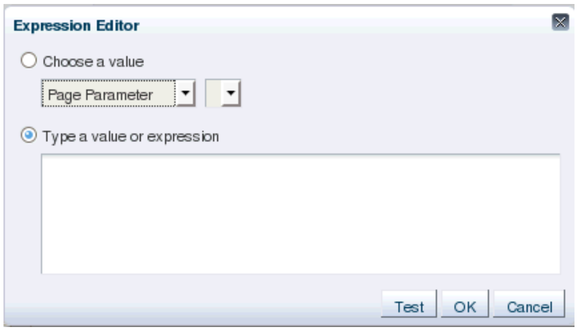
- When a user selects a value for the `Refresh Interval` property and clicks Apply in the Component Properties dialog, the save listener is called and the `save` event handler ensures that the value is saved back to the bean. The relevant code in the save event handler implementation is as follows:

```
public void save()
{
  . . .
  if (_autoRefresh)
  {
    aa = new AttributeComponentChange("interval", Integer.parseInt(_
refreshInterval));
    changeManager.addComponentChange(context, pollComp, aa);
    aa.changeComponent(pollComp);
  }
  else
  {
    aa = new AttributeComponentChange("interval", new Integer(-1));
    changeManager.addComponentChange(context, pollComp, aa);
    aa.changeComponent(pollComp);
  }
}
```

19.4 Extending the Expression Builder

All properties on the Parameters and Display Options tabs in the Component Properties dialog can take Expression Language (EL) expressions. The Expression Builder option available on such parameters opens the Edit dialog, which is a simple expression builder as shown in Figure 19–8. The expression builder is particularly useful when you want a value that is retrievable but otherwise unknown, for example, when you want a value to be the name of the current user or the current application skin.

Figure 19–8 Expression Language Editor



Expression Editor

○ Choose a value

Page Parameter

● Type a value or expression

You can customize the expression builder to provide more options by making the necessary entries in the Composer extension file, `pe_ext.xml`. You can also configure Composer to disable EL or protect existing EL from overwrite.

This section explains how to extend the expression builder to add custom capabilities. It contains the following subsections:

- Section 19.4.1, "How to Extend the Expression Builder"

- Section 19.4.2, "How to Protect Expression Language"
- Section 19.4.3, "What Happens at Runtime"

19.4.1 How to Extend the Expression Builder

You can extend the expression builder by adding custom options to the expression value drop-down list. Custom options must be defined and included in the pe_ext.xml file. For each new option you want to add, you must define and include a <selector> element in the pe_ext.xml file.

To configure custom options in the Composer extension file:

1. Create a Java bean, for example UserInformation.java, with the logic to populate the expression dialog with your custom options. Example 19–12 shows the code of a sample Java bean used to display a new string, User Name, as a custom value in the expression dialog.

Example 19–12 Sample Code to Add a Custom Value in the Expression Dialog

```
package view;

import java.util.ArrayList;
import java.util.List;

import oracle.adf.view.page.editor.elbuilder.ELParameter;
import oracle.adf.view.page.editor.elbuilder.ELParameterValue;

public class UserInformation implements ELParameter {
  public String getName() {
    return mName;
  }

  public List<ELParameterValue> getValues() {
    if (mValues == null)
      {
        mValues = new ArrayList<ELParameterValue>();
        for(String[] args : mValueList)
          {
            mValues.add(new ELParameterValue(args[0], args[1]));
          }
      }
       return mValues;
  }
  private static String[][] mValueList =
    {new String[]{"User Name", "#{securityContext.userName}"}};

  private String mName = "User Name";
  private List<ELParameterValue> mValues;  }
```

2. Add an <elbuilder-config> element in the pe_ext.xml file to register the bean.

   For information about creating the extension file, see Section 19.2.1.2, "Registering Add-Ons with Composer."

3. Add a <selector> element within the <elbuilder-config> section, and provide details about the bean you created, as shown in the following example:

```
<elbuilder-config>
  <!-- define selector -->
  <selector id="UserInformation">
```

```
    view.UserInformation
  </selector>

  <!-- include selector -->
  <selectors>
    <selector id="UserInformation" rendered="true"/>
  </selectors>
</elbuilder-config>
```

You can have multiple `<selector>` entries for different custom options.

Custom options display for all attributes by default. You can use the `rendered` attribute on `<selector>` to display an option conditionally, based on specific criteria.

4. Save the `pe_ext.xml` file.

19.4.2 How to Protect Expression Language

You can configure Composer to disable EL or protect existing EL from overwrite within an application or a specific `.jspx` page. This is especially useful when exposing elements to end users as described in Section 19.11, "Enabling Direct Select in Design or Add Content View."

To define settings for an application, modify the following elements in `adf-config.xml` within the `<pe:page-editor-config>` tag:

- `<pe:allow-el>` defines if an EL can be entered for component properties. The default is `true`. If an EL is already defined for a property, it cannot be changed.
- `<pe:protect-el>` defines whether EL in form elements is read-only. The default is `false`. If an EL is already defined and the component is being edited in a different level, you cannot change the EL.

To define behavior for a specific `.jspx` page, use the following elements within the `<pe:pageCustomizable>` tag:

- `allowEL` (boolean) defines whether or not EL can be run in application pages. The default is `true`. If an EL is already defined for a property, it cannot be changed.
- `protectEL` (boolean) defines whether or not EL in form elements is read-only. The default is `false`. If an EL is already defined and the component is being edited in a different level, you cannot change the EL.

The settings defined in the `.jspx` page override any settings defined in `adf-config.xml`.

19.4.3 What Happens at Runtime

The selector in the runtime expression builder displays the custom value along with the default values.

If EL is disabled, the expression builder will not be accessible, and EL will not be allowed in property fields.

If EL is protected, any EL already present as an attribute value cannot be changed in either the Parameters or Display Options tabs. (EL picked from a LOV is allowed.)

19.5 Configuring Custom LOVs or Pickers for Task Flow Parameters

Typically, while editing a task flow parameter in Composer, the user enters a value in the text box provided in the Component Properties dialog. However, many a time the user is confused about what value to specify in a particular field. Rather than leave them guessing, as a developer who knows the values that each parameter can take, you can make it easier for users by listing all valid options, wherever possible. You can configure Composer to display a list of values (LOV) or a picker against any parameter.

You can display a predefined set of values for a parameter using the following options:

- Static LOV

  To display a list of predefined values.

- Dynamic LOV

  To display a list of values generated by evaluating an EL value that is computed when the page is run.

- Global LOV

  To display a global list of values that can be used in any task flow in the application.

- Picker

  To display all values in a picker format, for example, a document picker.

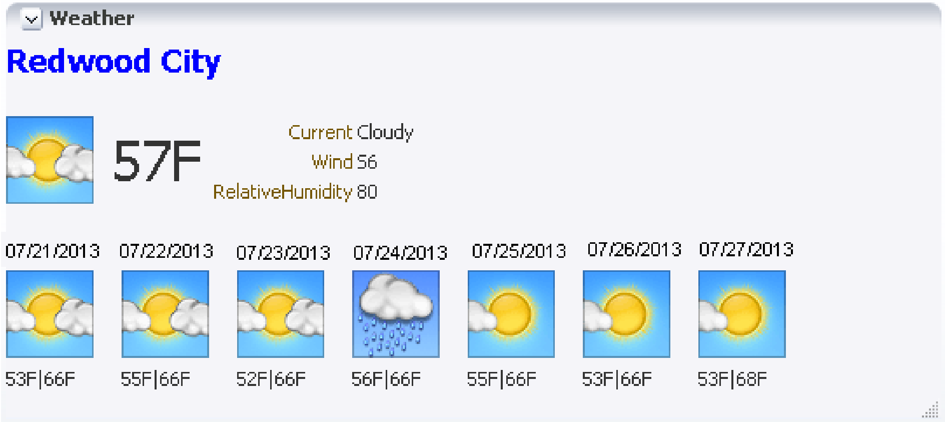
This section describes how to configure different types of LOVs for task flow parameters. It contains the following subsections:

- Section 19.5.1, "How to Configure an LOV"
- Section 19.5.2, "What Happens at Runtime"

Example Used to Describe the Procedures in This Section

Some of the procedures in this section use the example of a simple weather task flow, `weather-task-flow-definition`, which displays weather information for a selected city, as shown in Figure 19–9.

Figure 19–9 Weather Task Flow



Redwood City

57F

Current Cloudy
Wind 56
RelativeHumidity 80

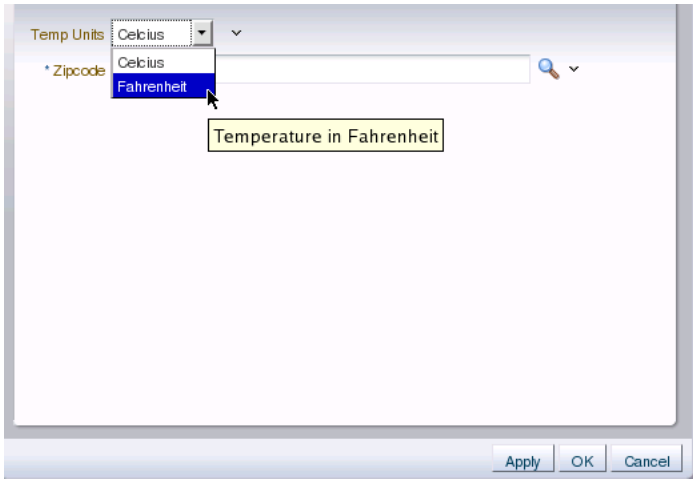
07/21/2013	07/22/2013	07/23/2013	07/24/2013	07/25/2013	07/26/2013	07/27/2013
53F|66F	55F|66F	52F|66F	56F|66F	55F|66F	53F|66F	53F|68F

The task flow provides two parameters, `zipCode` and `tempUnits`, that users can modify to display weather details for a selected city and in a selected temperature unit

(Fahrenheit or Celsius) respectively. This weather task flow example is used to explain how to configure the following types of LOVs:

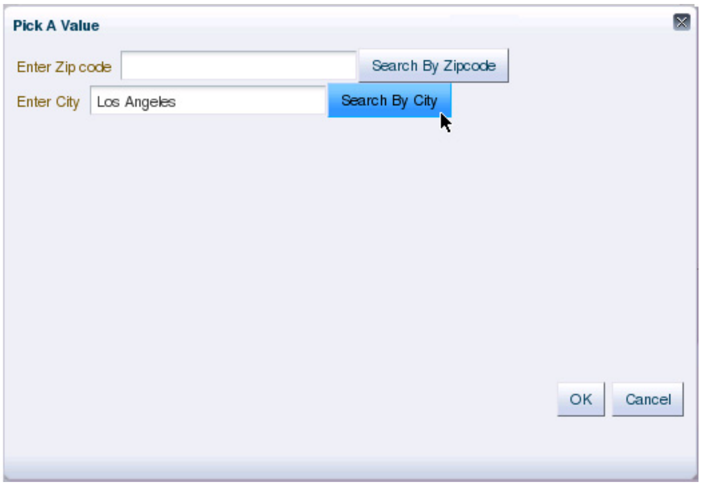
- A static LOV with the values `Celsius` and `Fahrenheit` for the `tempUnits` parameter, as shown in Figure 19–10.

Figure 19–10 Static LOV for the tempUnits Parameter



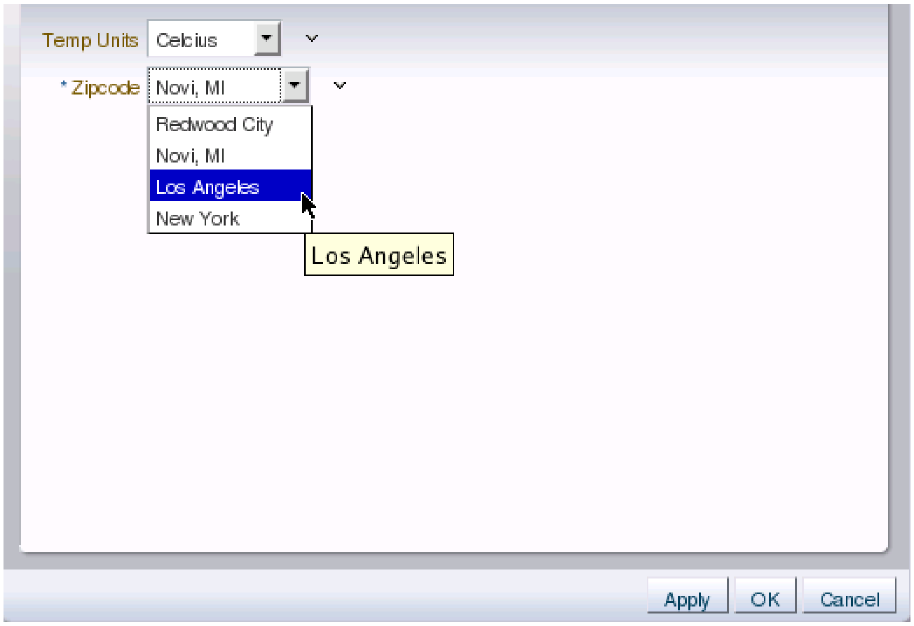
- A picker with two fields that enable users to specify a city name or ZIP code (Figure 19–11) to view corresponding details in the weather task flow.

Figure 19–11 City Picker for the zipCode Parameter



- Alternatively, a dynamic LOV for the `zipCode` parameter to display values (Figure 19–12) based on an EL value that is evaluated at runtime.

Figure 19–12 Dynamic LOV for the zipCode Parameter



The weather task flow includes a task flow definition file, `weather-task-flow-definition.xml`, with the code shown in Example 19–13.

Example 19–13 The weather-task-flow-definition.xml File

```
<?xml version="1.0" encoding="US-ASCII" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2">
  <task-flow-definition id="weather-task-flow-definition">
    <default-activity id="defaultactivity1">weather</default-activity>
    <input-parameter-definition id="inputparam1">
      <name id="inputparam1name">zipcode</name>
      <value>#{pageFlowScope.zipcode}</value>
      <class>java.lang.String</class>
      <required/>
    </input-parameter-definition>
    <input-parameter-definition id="inputparam2">
      <name id="ip2name">tempUnits</name>
      <value>#{pageFlowScope.tempUnits}</value>
      <class>java.lang.String</class>
    </input-parameter-definition>
    <view id="weather">
      <page>/weather.jsff</page>
    </view>
    <use-page-fragments/>
  </task-flow-definition>
</adfc-config>
```

The parameters, shown in **bold** text, are defined in such a way that values provided by users at runtime are stored in a session bean, `pageFlowScope`, from where they can be read by other components.

When you edit the task flow at runtime, the Parameters tab displays two input text fields to provide parameter values. The following sections explain how to enable LOVs for these task flow parameters so that users can choose from a list of predefined options.

19.5.1 How to Configure an LOV

This section describes how to configure different types of LOVs for task flow parameters. It contains the following subsections:

- Section 19.5.1.1, "Configuring a Static LOV"
- Section 19.5.1.2, "Configuring a Dynamic LOV"
- Section 19.5.1.3, "Configuring a Picker"
- Section 19.5.1.4, "Configuring an LOV from a Global List"

19.5.1.1 Configuring a Static LOV

Use a static LOV to display a list of predefined values against a parameter. You can configure a static LOV by defining an `<lov-config>` section with nested `<enumeration>` elements in the Composer extension file, `pe_ext.xml`. This section uses the weather task flow example and describes how to configure a static LOV for the `tempUnits` parameter.

To configure a static LOV:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_HOME`*`\Portal\adfmsrc\META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `pe_ext.xml`.

2. Add an `<lov-config>` section and include the task flow definition with nested `<enumeration>` elements, as shown in the following code example:

```
<lov-config>
  <!-- Entry for the task flow in which you are configuring the LOV -->
  <task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-defini
tion">

    <!-- Specifying the parameter for which you want to define a static LOV -->
    <input-parameter-definition>
      <name>tempUnits</name>
      <!-- List of values to be displayed for the parameter -->
      <enumeration inline="true">
        <item>
          <name>Celcius</name>
          <value>c</value>
          <description>Temperature in Celcius</description>
        </item>
        <item>
          <name>Fahrenheit</name>
          <value>f</value>
          <description>Temperature in Fahrenheit</description>
        </item>
      </enumeration>
    </input-parameter-definition>

  </task-flow-definition>
```

```
</lov-config>
```

You can configure any number of static LOVs within the `<lov-config>` section.

> **Note:** To allow translatable strings to be provided for a parameter name, you can use an EL value for the name, for example, `#{resourceBundle.temp_units}`.

3. Save the file.

19.5.1.2 Configuring a Dynamic LOV

Use a dynamic LOV to display a list that is generated dynamically at runtime by evaluating an EL value. This section uses the weather task flow example and describes how to configure a dynamic LOV for the `zipCode` parameter. To keep the example simple, the managed bean only provides static values that are displayed on the `Zipcode` field at runtime.

To configure a dynamic LOV:

1. Create a bean, for example, `weatherBean`, and define the list of values for the `Zipcode` parameter. The following example shows the relevant code snippet:

```
package portal.weather;

  . . .

  public List<SelectItem> getCitiesList() {
    return citiesList;
  }

  private static final String F = "&deg;F";
  private static final String C = "&deg;C";
  private static final String [][] selectItems = {{"Redwood City", "94065"},
                                                {"Novi, MI", "48375"},
                                                {"Los Angeles", "90001"},
                                                {"New York", "10036"}};

  private static final List<SelectItem> citiesList = new
ArrayList<SelectItem>();
    static {
      for (String[] city : selectItems){
        citiesList.add(new SelectItem(city[1], city[0]));
    }
  }
```

2. Register `weatherBean` in the application's `faces-config.xml` file, as shown in the following example:

```
<managed-bean>
  <managed-bean-name>weatherBean</managed-bean-name>
  <managed-bean-class>portal.weather.WeatherBean</managed-bean-class>
  <managed-bean-scope>request</managed-bean-scope>
</managed-bean>
```

3. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_HOME`*`\Portal\adfmsrc\META-INF` directory):

a. From the **File** menu, select **New**.

b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

c. Click **OK**.

Name the file `pe_ext.xml`.

4. Add an `<lov-config>` section, include the task flow definition with an `<enumeration>` element, and reference the managed bean for the parameter value, as shown in the following example:

```
<lov-config>
  <task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-defini
tion">
    <input-parameter-definition>
      <name>zipcode</name>
      <value>90001</value>
      <enumeration items="#{weatherBean.citiesList}"/>
    <input-parameter-definition>
  </task-flow-definition>
</lov-config>
```

You can configure any number of dynamic LOVs within the `<lov-config>` section.

5. Save the file.

19.5.1.3 Configuring a Picker

Typically, a picker enables users to select a value from a popup dialog that displays all available options, for example, a color picker or date picker. Configuring a picker for a task flow parameter involves the following high level tasks:

- Create the picker task flow with a UI of your choice.
- Define parameters on the picker task flow. These parameters are used to populate the main task flow parameter (the one for which you are configuring the picker).
- Configure the main task flow parameter to display the picker that you created. You must add this configuration in the `pe_ext.xml` file.

This section explains these steps in detail using the weather task flow as an example. It shows how to configure a city picker for the `zipCode` parameter. The picker task flow enables users to specify the city name and get the ZIP code for that place. The ZIP code from the picker is then pushed to the Zipcode field in the weather task flow. This section contains the following subsections:

- Section 19.5.1.3.1, "Creating the Picker Task Flow"
- Section 19.5.1.3.2, "Registering the Picker for a Task Flow Parameter"

19.5.1.3.1 Creating the Picker Task Flow Create a picker task flow with a JSFF fragment. Design the fragment to display fields or options of your choice.

To create the picker task flow:

1. In your application project, create an ADF task flow, for example, `weather-picker-task-flow-definition`:

   a. From the **File** menu, choose **New**.

   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **ADF Task Flow**.

c. Click **OK**.

2. Add a `view` object to the task flow, for example, `weatherPicker`.
3. Double-click the view to create the `weatherPicker.jsff` fragment.

> **See Also:** For information about creating task flows, see the "Getting Started with ADF Task Flows" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*.

4. Design the fragment with components of your choice. Example 19–14 shows a sample task flow containing two `Input Text` components that enable users to search for ZIP codes in an XML file, and two UI controls, `OK` and `Cancel`.

Example 19–14 Sample code in the Picker JSFF Fragment

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:f="http://java.sun.com/jsf/core">
  <af:panelStretchLayout id="psl1">
    <f:facet name="center">
      <af:panelGroupLayout id="pgl1" layout="vertical">

        <af:panelGroupLayout id="pgl2" layout="horizontal">
          <!-- Text field and Search button to search for a city by specifying the
ZIP code -->
          <af:inputText label="Enter Zip Code" id="it1"
                        value="#{pageFlowScope.weatherPicker.searchZipcode}"/>
          <af:commandButton text="Search By Zipcode" id="cb1"

actionListener="#{pageFlowScope.weatherPicker.zipcodeSearch}"/>
        </af:panelGroupLayout>

        <af:panelGroupLayout id="pgl3" layout="horizontal">
          <!-- Text field and Search button to search for a city by specifying the
city name -->
          <af:inputText label="Enter City" id="it2"
                        value="#{pageFlowScope.weatherPicker.searchCity}"/>
          <af:commandButton text="Search By City" id="cb2"

actionListener="#{pageFlowScope.weatherPicker.citySearch}"/>
        </af:panelGroupLayout>

        <!-- Output components to display the result from the search -->
        <af:outputFormatted value="#{pageFlowScope.weatherPicker.city}"
                            id="of2"/>
        <af:outputFormatted value="#{pageFlowScope.weatherPicker.zipcode}"
                            id="of3"/>

      </af:panelGroupLayout>
    </f:facet>
    <f:facet name="bottom">
      <af:panelGroupLayout layout="horizontal" halign="end" id="pkrPgl">

        <!-- OK button -->
        <af:commandButton action="ok"

actionListener="#{pageFlowScope.weatherPicker.populateReturnValue}"
                          text="#{Bundle.OK_BUTTON_TEXT}" id="okBtn"/>
        <af:spacer width="5" id="s1"/>

        <!-- Cancel button -->
        <af:commandButton
actionListener="#{pageFlowScope.weatherPicker.closePickerPopup}"
                          text="#{Bundle.CANCEL_BUTTON_TEXT}"
                          id="cnclBtn"/>
      </af:panelGroupLayout>
    </f:facet>
  </af:panelStretchLayout>
</jsp:root>
```

The action listeners on the OK and Cancel buttons reference a managed bean, weatherPicker. This bean also contains the logic to populate the parameter on the main task flow with the value specified in the picker.

5. Create the bean that you referenced in the picker task flow definition and add the logic to return values to the main task flow.

   The following example shows the relevant code snippet of the weatherPicker bean, which contains the logic to search for a city by name and return the ZIP code:

```
package portal.weather.picker;

. . .

  public void populateReturnValue(ActionEvent ae) {
    Map map =
(Map)RequestContext.getCurrentInstance().getPageFlowScope().get("outParam");
    if (map != null)
      map.put("outParamVal", _zipcode);
  }

  public void closePickerPopup(ActionEvent ae) {
    UIComponent component = ae.getComponent();
      while (!(component instanceof RichPopup))
        component = component.getParent();
        if (component != null)
          ((RichPopup)component).cancel();
  }
  . . .
```

6. Register the weatherPicker bean in the task flow definition file, as shown in the following example:

```
<managed-bean id="pickerbean">
  <managed-bean-name id="pickerbeanname">weatherPicker</managed-bean-name>
  <managed-bean-class
id="pickerbeanclass">portal.weather.picker.WeatherPicker</managed-bean-class>
  <managed-bean-scope id="pickerbeanscope">pageFlow</managed-bean-scope>
</managed-bean>
```

7. Define two input parameters, inParamVal and outParam, on the picker task flow, as shown in the following example:

```
<!-- Parameter used to store the value that must be passed to the main task
flow -->
<input-parameter-definition id="pickerip1">
  <name id="pickerip1name">outParam</name>
  <value>#{pageFlowScope.outParam}</value>
  <class>java.util.Map</class>
</input-parameter-definition>

<!-- Parameter used to store the value specified by the user in the picker -->
<input-parameter-definition id="pickerip2">
  <name id="pickerip2name">inParamVal</name>
  <value>#{pageFlowScope.inParamVal}</value>
  <class>java.lang.String</class>
</input-parameter-definition>
```

These parameters are referenced in `pageFlowScope` and will be used to read and populate the main task flow parameter, `zipCode`. When a user clicks the picker icon next to the Zip Code field, the current value of the field is passed to the session bean using `inParamVal`. When a user specifies a city name in the picker task flow and clicks OK, the bean gets the ZIP code for that city and passes it to the main weather task flow using `outParam`.

8. Define task flow return activities and control flow rules for the `OK` and `Cancel` buttons. These activities and rules ensure that control is returned to the task flow when either of the buttons is clicked. You can define task flow return activities and control flow rules as shown in the following example:

```
<!-- The outcome to be returned to the task flow if a user clicks OK -->
<task-flow-return id="ok">
  <outcome id="ok1">
    <name id="okayed">ok</name>
  </outcome>
</task-flow-return>
<!-- The outcome to be returned to the task flow if a user clicks Cancel -->
<task-flow-return id="cancel">
  <outcome id="cancel1">
    <name id="canceled">cancel</name>
  </outcome>
</task-flow-return>

<!-- Rules to pass control flow to the ok activity if the user clicks OK and to
the cancel activity if the user clicks Cancel -->
<control-flow-rule id="flowrule1">
  <from-activity-id id="fromactivity1">weatherPicker</from-activity-id>
  <control-flow-case id="flowcase1">
    <from-outcome id="fromoutcome1">ok</from-outcome>
    <to-activity-id id="toactivity1">ok</to-activity-id>
  </control-flow-case>
  <control-flow-case id="flowcase2">
    <from-outcome id="fromoutcome2">cancel</from-outcome>
    <to-activity-id id="toactivity2">cancel</to-activity-id>
  </control-flow-case>
</control-flow-rule>
```

The task flow definition will now have code similar to the following example:

```
<?xml version="1.0" encoding="US-ASCII" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2">
  <task-flow-definition id="weather-picker-task-flow-definition">
    <default-activity id="pickeractivity1">weatherPicker</default-activity>
    <input-parameter-definition id="pickerip1">
      <name id="pickerip1name">outParam</name>
      <value>#{pageFlowScope.outParam}</value>
      <class>java.util.Map</class>
    </input-parameter-definition>
    <input-parameter-definition id="pickerip2">
```

```
      <name id="pickerip2name">inParamVal</name>
      <value>#{pageFlowScope.inParamVal}</value>
      <class>java.lang.String</class>
    </input-parameter-definition>
    <managed-bean id="pickerbean">
      <managed-bean-name id="pickerbeanname">weatherPicker</managed-bean-name>
      <managed-bean-class
id="pickerbeanclass">portal.weather.picker.WeatherPicker</managed-bean-class>
      <managed-bean-scope id="pickerbeanscope">pageFlow</managed-bean-scope>
    </managed-bean>
    <view id="weatherPicker">
      <page>/weatherPicker.jsff</page>
    </view>
    <task-flow-return id="ok">
      <outcome id="ok1">
        <name id="okayed">ok</name>
      </outcome>
    </task-flow-return>
    <task-flow-return id="cancel">
      <outcome id="cancel1">
        <name id="canceled">cancel</name>
      </outcome>
    </task-flow-return>
    <control-flow-rule id="flowrule1">
      <from-activity-id id="fromactivity1">weatherPicker</from-activity-id>
      <control-flow-case id="flowcase1">
        <from-outcome id="fromoutcome1">ok</from-outcome>
        <to-activity-id id="toactivity1">ok</to-activity-id>
      </control-flow-case>
      <control-flow-case id="flowcase2">
        <from-outcome id="fromoutcome2">cancel</from-outcome>
        <to-activity-id id="toactivity2">cancel</to-activity-id>
      </control-flow-case>
    </control-flow-rule>
    <use-page-fragments/>
  </task-flow-definition>
</adfc-config>
```

9. Save the task flow definition file.

19.5.1.3.2 Registering the Picker for a Task Flow Parameter To display a custom picker for a task flow parameter, you must configure the picker for that parameter in the Composer extension file, `pe_ext.xml`.

To configure a picker for a task flow parameter:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_HOME`*`\Portal\adfmsrc\META-INF` directory):
   a. From the **File** menu, select **New**.
   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.
   c. Click **OK**.

   Name the file `pe_ext.xml`.

2. Add an `<lov-config>` section and include the task flow definition with an `<enumeration>` element referencing the picker task flow, as shown in the following code example:

```
<?xml version="1.0" encoding="UTF-8"?>
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <lov-config>
    <task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-defini
tion">
      <!-- Parameter for which you defined the picker -->
      <input-parameter-definition>
        <name>zipCode</name>
        <value>null</value>
        <!-- enumeration items coming from the picker task flow -->
        <enumeration
picker="/WEB-INF/weather-picker-task-flow-definition.xml#weather-picker-task-fl
ow-definition"/>
      </input-parameter-definition>
    </task-flow-definition>
  </lov-config>
</pe-extension>
```

You can configure pickers for any number of parameters within the `<lov-config>` section.

3. Save the file.

When you edit the main task flow at runtime, the Component Properties dialog displays a magnifier icon next to that parameter. Clicking the icon invokes the picker task flow, in which users can select a value.

19.5.1.4 Configuring an LOV from a Global List

If you want to reuse an LOV in different task flow parameters within the application, you can define the LOV at a global level and reference it from the task flow parameters.

To configure an LOV from a global list:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_HOME`*`\Portal\adfmsrc\META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `pe_ext.xml`.

2. Add an `<lov-config>` section and list the values within an `<enumeration>` element (outside of the task flow definition), as shown in the following code example:

```
<lov-config>
<!-- Global enumerations ->
  <enumeration id="temperature">
    <item>
      <name>Celcius</name>
      <value>c</value>
      <description>Temperature in Celcius</description>
    </item>
    <item>
      <name>Fahrenheit</name>
      <value>f</value>
      <description>Temperature in Fahrenheit</description>
    </item>
  </enumeration>
  <task-flow-definition . . . >
  . . .
<lov-config>
```

You can configure any number of global LOVs within the `<lov-config>` section.

3. Reference this global LOV from any input parameter definition in the `pe_ext.xml` file, as shown in the following example:

```
<task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-defini
tion">
  <input-parameter-definition>
    <name>tempUnits</name>
    <value>Celsius</value>
    <enumeration ref="temperature"/>
  </input-parameter-definition>
</task-flow-definition>
```

4. Save the file.

19.5.2 What Happens at Runtime

Depending on the type of LOV you configured for the task flow parameter, users will see different options to specify parameter values.

The Temp Units field will list values from the static LOV that you defined in the `pe_ext.xml` file.

If you configured a picker for the Zipcode field, the field shows a magnifier icon to its right. This icon invokes a picker that allows users to select a city by providing a name or ZIP code.

19.6 Configuring Event Handlers for Composer UI Events

Event handlers are Java classes registered with Composer and called when a user performs an action on the page. For example, when a user clicks a **Save** button, Composer calls back into the application code to give the application a chance to respond to the Save *event*. In addition to the event handlers that Composer provides by default, you can configure additional handlers for application-specific events, for example, saving changes in a custom property panel.

This section describes how to create and register event handlers for UI events in Composer. It contains the following subsections:

- Section 19.6.1, "How to Create and Register Handlers for Composer UI Events"
- Section 19.6.2, "What Happens When You Create and Register Event Handlers"
- Section 19.6.3, "Additional Composer Event Handler Configurations"

19.6.1 How to Create and Register Handlers for Composer UI Events

When you register an event handler with Composer, it is called when the corresponding event is fired in the Composer UI.

This section describes how to create an event handler and register it with Composer. It contains the following subsections:

- Section 19.6.1.1, "UI Events that Support Event Handler Registration"
- Section 19.6.1.2, "Creating a Save Event Handler: Example"
- Section 19.6.1.3, "Registering an Event Handler with Composer"

19.6.1.1 UI Events that Support Event Handler Registration

Table 19–1 lists the UI events for which Composer currently supports registering of handlers.

Table 19–1 Events for Which Registering Handlers are Supported

Event	Cause	Event Type	Listener Interface (oracle.adf.view.page.editor.event)	Method	Event Interface
Save	Invoked when a user clicks the **Save** or **Save and Label** button on the Composer toolbar, or the **Apply** (save) or **OK** (save and close) button in the Component Properties dialog or Page Properties dialog.	`save`	`SaveListener`	`processSave`	`SaveEvent`
Close	Invoked when a user clicks the **Close** button on the Composer toolbar.	`close`	`CloseListener`	`processClose`	`CloseEvent`
Deletion	Invoked when a user deletes the component.	`delete`	`DeletionListener`	`processDeletion`	`DeletionEvent` Get the deleted component using `getComponent`.

Table 19–1 (Cont.) Events for Which Registering Handlers are Supported

Event	Cause	Event Type	Listener Interface (oracle.adf.view.page.editor.event)	Method	Event Interface
Addition	Invoked when a user adds a component to the page from the resource catalog by clicking the **Add** button against an item.	`add`	`AdditionListener`	`processAddition`	`AdditionEvent`
Selection	Invoked when a user selects: - The **Edit** icon on a Panel Customizable or Show Detail Frame component in the Design or Add Content view - A component on the page or in the hierarchy in Structure view	`select`	`SelectionListener`	`processSelection`	`SelectionEvent`
Attribute Change	Invoked when a user changes an attribute. If the attribute change is invalid, the listener should raise an `AbortProcessingException` and set the severity for the warning message. If the severity is set to FATAL or ERROR (default), the user will be forced to correct the attribute in the property inspector before clicking **Apply** or **OK**. All other severities will display a notification popup but allow the user to save without further action.	`attribute-change`	`AttributeChangeListener`	`processAttributeChange`	`AttributeChangeEvent` Get and set the warning severity using `getMessageSeverity` and `setMessageSeverity`. Define a message for the warning using `setMessageSummary` and `setMessageDetail`. To display a message even if the listener verifies an attribute change with no errors, use `setMessageSummary("")` `setMessageSeverity(FacesMessage.SEVERITY_INFO);` `setShowMessage(true)`

19.6.1.2 Creating a Save Event Handler: Example

To register an event with Composer, you must first create a Java class and implement the appropriate listener for the event handler. This section describes the steps to create a Save event handler. You can perform similar steps to create event handlers for all the supported events listed in Table 19–1.

A Save event handler is called when a user clicks the **Save** button on the Composer toolbar or the **Apply** or **OK** button in the Component Properties or Page Properties dialog. A Save event handler must implement `oracle.adf.view.page.editor.event.SaveListener`. The `isCommit` method of the Save event can be used to differentiate between changes made to the page and to component properties. A value of `true` implies that the user clicked the Save button on the Composer toolbar to save changes made to the page. A value of `false` implies that the user clicked the Apply or OK button in the Component Properties dialog to save changes made to component properties.

To create a Save event handler:

1. In JDeveloper, select the **Portal** project, and from the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, specify a name for the class, for example, `SaveHandler`.
4. Under the Optional Attributes section, add the `oracle.adf.view.page.editor.event.SaveListener` interface.

> **Note:** If you are not able to see the `oracle.adf.view.page.editor` classpath, make sure that Composer is included in the project's libraries and classpath. To do this, right-click the project in the Application Navigator and select **Project Properties**. In the Project Properties dialog, select **Libraries and Classpath**, and add **Composer** to the list.

5. Click **OK**.

   The Java class source looks like the following:

```
package view;

import javax.faces.event.AbortProcessingException;

import oracle.adf.view.page.editor.event.SaveEvent;
import oracle.adf.view.page.editor.event.SaveListener;

public class SaveHandler implements SaveListener {
  public Class1() {
    super();
  }
  public void processSave(SaveEvent saveEvent) throws AbortProcessingException
{
// Your implementation goes here
  }
}
```

   You must declare the `processSave` method as `throws AbortProcessingException` because the method may throw this exception if the event must be canceled. You can include the reason for canceling this event in the Exception object when you create it.

   On throwing this exception, further processing of this event is canceled and the listeners that are in the queue are skipped.

You can create event handlers for all supported events by performing steps similar to these.

19.6.1.3 Registering an Event Handler with Composer

After creating and implementing an event handler, you must register it with Composer. Registration is necessary for ensuring that the handler is called back by Composer when the corresponding event occurs in the UI.

Register event handlers in the Composer extension file, `/META-INF/pe_ext.xml`. For more information about creating this file, see Section 19.2.1.2, "Registering Add-Ons with Composer."

To register an event handler:

1. In the application's `pe_ext.xml` file, add the following entries:

   ```
   <event-handlers>
     <event-handler event="save">view.SaveHandler</event-handler>
   </event-handlers>
   ```

   The values you provide for the `event` attribute and between the `event-handler` tags are unique to the type of event being entered and the name you specified for the event class.

2. Save the file.

19.6.2 What Happens When You Create and Register Event Handlers

At runtime, registered event handlers are called according to the sequence in the extension file and according to the order in which they were found on the class path. Composer's native event handler is called last.

On invocation of an event handler's `process`*`EventName`* method, if an event handler throws `AbortProcessingException`, then the event is canceled and no further event handlers are called, including Composer's native event handlers.

If, however, an error occurs while instantiating an event handler, then Composer continues with the next event handler. A warning message is logged.

19.6.3 Additional Composer Event Handler Configurations

For every UI event triggered on the page in Composer, the corresponding event handler calls back a method from a listener registered with the application. By performing some additional configurations, you can specify the sequence in which event handlers are executed and configure a listener to terminate a process or notify Composer that the event has been handled.

19.6.3.1 Specifying a Sequence Number for an Event Handler

By specifying the sequence for event handlers, you can decide on the order in which the event handlers, and therefore the listeners, are called. You can assign a sequence number to a listener or modify the default value by defining a `sequence` attribute against the registered event handler in the `pe_ext.xml` file.

To specify a sequence number for a listener:

1. In the application's `pe_ext.xml` file, locate the `event-handler` element for the handler that you want to sequence.

2. Add a `sequence` attribute as follows:

   ```
   <event-handlers>
     <event-handler event="save" sequence="101">view.SaveHandler</event-handler>
   </event-handlers>
   ```

The value for the `sequence` attribute must be a positive integer. If you do not define this attribute, the event handler is internally assigned a default sequence number of `100`.

Composer built-in listeners and listeners with no sequence numbers are assigned a default sequence number of `100`. If you want your event handler to be called before other event handlers, you must specify a value lesser than `100`.

3. Save the file.

19.6.3.2 Terminating Event Processing

You can configure an event handler to terminate processing of the current event and all subsequent events by throwing an exception. For this, you must declare the method used while implementing the listener as `throws AbortProcessingException`. In addition, you can configure the handler to notify Composer that the event has been processed by using the `Event.setEventHandled(true)` method.

For example, you can configure a `delete` event handler to terminate the current event and all pending delete events and throw an exception when a user attempts to delete a component in Composer. To enable this, you must implement the `DeletionListener` interface as shown in Example 19–15.

Example 19–15 DeletionListener Implementation

```
public class DeleteHandler implements DeletionListener
{
  ...
  public void processDeletion(DeletionEvent delEvent) throws
AbortProcessingException
  {
    // Get the component that must be deleted
    UIComponent comp = delEvent.getComponent();

    if (comp != null)
    {
      try
      {
        // Assuming that a custom method, handleDelete(comp), handles deletion of
        // a component and returns true on successful deletion and false in case
        // of failure
        boolean deleteSucceeded = handleDelete(comp);

        // If deletion failed, then notify Composer that the delete event
        // has been handled. No further events are processed.
        if (!deleteSucceeded)
          delEvent.setEventHandled(true);
      }

      catch (Exception e)
      {
       // Catch Exception throw by handleDelete(comp) and handle it by throwing
       // AbortProcessingException to stop processing of delete events.
       throw new AbortProcessingException(e)
      }
    }
  }
  ...
}
```

19.7 Configuring Drop Handlers in the Resource Catalog

Drop handlers are Java classes registered with Composer and called when users click an Add link in the resource catalog. A drop handler declares the data flavors it can handle. Each resource in the catalog has a flavor. When a user clicks an Add link next to a resource, Composer queries all the registered drop handlers to check if they can handle the flavor. If only one drop handler can handle that flavor, then control is passed to that drop handler and the resource is added to the page immediately. If more than one drop handler can handle the flavor, then a context menu displays available drop handlers to users. The resource is dropped on the page when a user selects a Java drop handler from the context menu.

An example for a resource with multiple Java drop handlers is the Personal Documents subfolder available within the Documents folder, if you configured the Documents service in your catalog. This subfolder can be added as a Content Presenter, Document List Viewer, or Document Library.

> **Note:** The `AdditionListener` mechanism used to handle an `Add` operation in release 11.1.1.1 is still available, but now Composer calls drop handlers first to handle an `Add` operation in the catalog. It is recommended that you convert existing `AdditionListeners` to drop handlers.

This section describes the procedure to create and register drop handlers in your application. It contains the following subsections:

- Section 19.7.1, "How to Create and Register Java Drop Handlers"
- Section 19.7.2, "What Happens at Runtime"

19.7.1 How to Create and Register Java Drop Handlers

This section describes how to create a sample drop handler for adding XML content from the resource catalog and register the drop handler with Composer. It contains the following subsections:

- Section 19.7.1.1, "Creating a Drop Handler"
- Section 19.7.1.2, "Registering a Drop Handler with Composer"
- Section 19.7.1.3, "Adding an XML Component to the Resource Catalog"

19.7.1.1 Creating a Drop Handler

To create a drop handler with Composer, you must first extend the abstract base class, `DropHandler`, and implement the `getName()`, `getAcceptableFlavors()`, and `handleDrop()` methods. This section describes an example to add an XML component called `Test` to the resource catalog and create a drop handler named `Custom XML` for adding XML content.

To create a drop handler:

1. In JDeveloper, select the **Portal** project, and from the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, specify a name for the class, for example, `TestDropHandler`.

4. In the Extends field, enter or browse to select the `Drophandler` class, `oracle.adf.view.page.editor.drophandler.DropHandler`.

> **Note:** If you are not able to see the `oracle.adf.view.page.editor` classpath, make sure that Composer is included in the project's libraries and classpath. To do this, right-click the project in the Application Navigator and select **Project Properties**. In the Project Properties dialog, select **Libraries and Classpath**, and add **Composer** to the list.

5. Add the required import statements and click **OK**.

   The Java class source must look like the following:

```
package test;

import java.awt.datatransfer.DataFlavor;
import java.awt.datatransfer.Transferable;

import java.io.ByteArrayInputStream;

import javax.faces.component.UIComponent;
import javax.faces.context.FacesContext;

import javax.xml.parsers.DocumentBuilder;
import javax.xml.parsers.DocumentBuilderFactory;

import oracle.adf.rc.component.XmlComponentFactory;
import oracle.adf.view.page.editor.drophandler.DropEvent;
import oracle.adf.view.page.editor.drophandler.DropHandler;

import org.apache.myfaces.trinidad.change.AddChildDocumentChange;
import org.apache.myfaces.trinidad.change.ChangeManager;
import org.apache.myfaces.trinidad.change.DocumentChange;
import org.apache.myfaces.trinidad.context.RequestContext;

import org.w3c.dom.Document;
import org.w3c.dom.DocumentFragment;

public class TestDropHandler extends DropHandler {
    public TestDropHandler() {
        super();
    }

    public String getName() {
        return null;
    }

    public DataFlavor[] getAcceptableFlavors() {
        return new DataFlavor[0];
    }

    public boolean handleDrop(DropEvent dropEvent) {
        return false;
    }
}
```

6. Implement the `getName()` method as follows to return the name of the drop handler:

```
public class TestDrophandler extends DropHandler {
    public TestDrophandler() {
        super();
    }

    public String getName() {
        return "Custom XML";
    }
. . .
```

This value (`Custom XML`) appears in the context menu on the Add link next to the XML component in the resource catalog.

7. Implement the `getAcceptableFlavors()` method as follows to get a list of supported data flavors for the XML component:

```
public class TestDropHandler extends DropHandler
{
  private static final DataFlavor[] ACCEPTABLE_FLAVORS =
  { XmlComponentFactory.XML_STRING_FLAVOR };

    . . .

    public DataFlavor[] getAcceptableFlavors() {
    return ACCEPTABLE_FLAVORS;
    }
    . . .
```

8. Implement the `handleDrop(DropEvent)` method as shown in the following sample file to handle the drop event and add the XML component to the page.

```
public class TestDropHandler extends DropHandler
{
  . . .

  public boolean handleDrop(DropEvent de) {
    Transferable transferable = de.getTransferable();
    UIComponent container = de.getContainer();
    int index = de.getDropIndex();

    try {
        FacesContext context = FacesContext.getCurrentInstance();
        RequestContext rctx = RequestContext.getCurrentInstance();

        String fragMarkup = null;

        // Get the TransferData from the Transferable (expecting a String)
        Object data = getTransferData(transferable);
        if (data instanceof String) {
          fragMarkup = "<?xml version='1.0' encoding='UTF-8'?>" + (String)data;
        } else {
            return false;
        }

        // Get a DocumentBuilder
        DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
        factory.setNamespaceAware(true);
        factory.setValidating(false);
        DocumentBuilder builder = factory.newDocumentBuilder();

        // Parse the xml string into a Document object using DocumentBuilder
        byte[] markupBytes = fragMarkup.getBytes();
        Document newDoc =
        builder.parse(new ByteArrayInputStream(markupBytes));

        // Transform the Document into a DocumentFragment
        DocumentFragment docFrag = newDoc.createDocumentFragment();
        docFrag.appendChild(newDoc.getDocumentElement());

        // Create an "add child" document change, that is, insert the fragment
        DocumentChange change = null;
        if (index < container.getChildCount()) {
        // Get the ID of the component we'll be adding just before
           String insertBeforeId = container.getChildren().get(index).getId();
           change = new AddChildDocumentChange(insertBeforeId, docFrag);
        } else {
            change = new AddChildDocumentChange(docFrag);
        }

        // Apply the "add child" DocumentChange using ChangeManager
        ChangeManager changeManager = rctx.getChangeManager();
        changeManager.addDocumentChange(context, container, change);

        // Refresh the target container using PPR
        rctx.addPartialTarget(container);

        // Mark the drop as completed.
        return true;
        } catch (Exception e) {
            return false;
        }
    }
```

In this example, a `DropEvent` parameter is passed to the `handleDrop` method. This parameter has three attributes that can be described as follows:

- `transferable`, like `DataFlavor`, is a standard Java class that contains the data being added.
- `container` is the container into which component must be dropped.
- `index` is the position of the component inside the container. For example, first, second, and so on.

9. Save the `TestDropHandler.java` file.

19.7.1.2 Registering a Drop Handler with Composer

After implementing the drop handler, you must register it with Composer. Registration is necessary for ensuring that the handler is called by Composer when a user clicks an Add link in the catalog. Register drop handlers in the Composer extension file, `/META-INF/pe_ext.xml`. For more information about creating this file, see Section 19.2.1.2, "Registering Add-Ons with Composer."

To register a drop handler:

1. In the `pe_ext.xml` file, add the following entries:

```
<drop-handlers>
  <drop-handler>test.TestDropHandler</drop-handler>
</drop-handlers>
```

where `TestDropHandler` is the name of the drop handler implementation.

2. Save the file.

You can register any number of drop handlers in the extension file by adding that many `<drop-handler>` elements.

19.7.1.3 Adding an XML Component to the Resource Catalog

Since you created a drop handler for XML components generated by the `XmlComponentFactory` class, you can test how the drop handler works at runtime by adding an XML component to the resource catalog and then adding that component to your page at runtime.

To add an XML component to the catalog:

1. Open the default catalog definition file, `default-catalog.xml`.

   For information about the location of this file, see Section 14.4, "Selecting the Default Resource Catalog."

2. Add the following code within the `<contents>` section of the file:

```
<component id="pc" factoryClass="oracle.adf.rc.component.XmlComponentFactory">
  <attributes>
    <attribute attributeId="Title" value="Test"/>
    <attribute attributeId="Description" value="XML content you can add to
application pages"/>
    <attribute attributeId="IconURI" value="/adf/pe/images/elementtext_
qualifier.png"/>
    </attributes>
    <parameters>
      <parameter id="xml">
        <af:outputText value="Hello!"
xmlns:af="http://xmlns.oracle.com/adf/faces/rich"/>
      </parameter>
    </parameters>
</component>
```

3. Save the `default-catalog.xml` file.

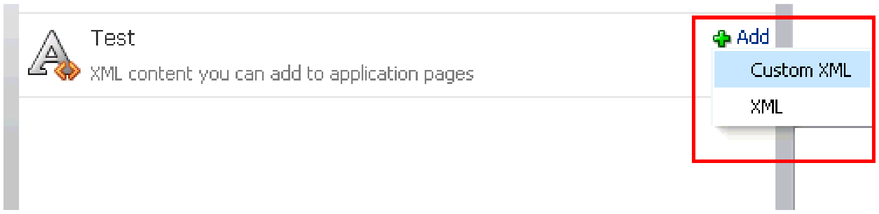
   At runtime, the resource catalog shows the XML component. For more information, see Section 14.3.5, "How to Add a Custom Component to a Resource Catalog."

19.7.2 What Happens at Runtime

When a user clicks the Add link against a component in the catalog, all drop handlers supporting that flavor are displayed as options on the context menu of the Add link. However, if only a single drop handler is available to handle that flavor, then the resource is added to the page immediately.

Figure 19–13 shows the context menu displayed on clicking the Add link of the `Test` XML component with the `Custom XML` option and the default XML option.

Figure 19–13 Drop Handlers on an XML Component in the Catalog



19.8 Defining Property Filters

Some component properties are not displayed in Composer's Component Properties dialog because they are filtered out by default. The default filters are defined in the `<filter-config>` section of the Composer's extension file (/META-INF/pe_ext.xml).

Global filters filter attributes for all components. They are defined using the `<global-attribute-filter>` tag. Tag-level filters filter attributes for a specified component only. They are defined using the `<taglib-filter>` tag.

> **Note:** In an extension file, you can have any number of `<taglib-filter>` tags under `<filter-config>`, but you can have only one `<global-attribute-filter>` tag to define all global attribute filters.

You can define additional filters to hide more properties in the Component Properties dialog. This section describes how. It contains the following subsections:

- Section 19.8.1, "How to Define Property Filters"
- Section 19.8.2, "What Happens at Runtime"
- Section 19.8.3, "How to Remove Property Filters"

19.8.1 How to Define Property Filters

Composer defines a built-in filter configuration. You can use the extension file, `pe_ext.xml`, to define additional property filters and to delete filters. You can define any number of filters, even for a single tag, in different extension files. Composer merges the filtering information from all the extension files.

> **Note:** For information about creating the `pe_ext.xml` file, see Section 19.2.1.2, "Registering Add-Ons with Composer."

To define property filters in an extension file, use the `filter-config` element. The following elements are defined for the contained `attribute` tags.

- The `label` element allows you to override the default label for the element in the UI. You can use EL to retrieve localized strings or display different labels in design and source view.
- The `view` element can be used to filter attributes in specific tags for a specific view (`design` or `source`).
- The `filtered` element can be used to display an attribute even if it is globally filtered. To restore a globally filtered element, use `filtered="false"`.

In the pe_ext.xml file, add the filter-config element as shown in the following example:

```
<filter-config>
   <global-attribute-filter>
    <attribute name="readOnly" filtered="false" label="Read Only"/>
    <attribute name="required" filtered="false" label="Mandatory"/>
    <attribute name="shortDesc" filtered="false" label="#{Bundle.PNL_TB_
SHORTDESC}"/>
  </global-attribute-filter>

  <taglib-filter namespace="http://xmlns.oracle.com/adf/faces/rich">
    <tag name="goLink">
      <attribute name="accessKey" view="design"/>
      <attribute name="targetFrame" filtered="false" view="source"/>
      <attribute name="destination" filtered="false"
label="#{pageEditorPanelBean.layoutView ?  'Where do you want to surf?' :
'Destination'}"/>
    </tag>
    <tag name="inputText">
      <attribute name="all" view="design"/>
      <attribute name="label" label="Field Name" filtered="false" />
      <attribute name="readOnly" filtered="false" />
      <attribute name="required" filtered="false" />
      <attribute name="rendered" filtered="false" />
      <attribute name="wrap" filtered="false" />
    </tag>
  </taglib-filter>
</filter-config>
```

Save the file.

19.8.2 What Happens at Runtime

At runtime, when you edit a component's properties, the properties that were filtered out are not rendered in the Component Properties dialog.

19.8.3 How to Remove Property Filters

You can remove global and tag-level filters so that previously filtered properties are now rendered in the Component Properties dialog. This is useful for displaying properties that are filtered out by Composer's built-in filters or by another extension file defined elsewhere in the application.

> **Note:** After you remove a property filter, it is rendered in the Component Properties dialog even if a filter is defined for that property in another extension file.

To remove a property filter:

1. Edit the Composer extension file, pe_ext.xml, available in the META-INF directory.

   You can remove property filters by editing entries in this file.

2. Search for the attribute from which to remove the filter, and set filtered to false in the <attribute> tag as shown in the following example:

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
. . .
<filter-config>
```

```
  <global-attribute-filter>
    <attribute name="accessKey" filtered="false" />
    <attribute name="attributeChangeListener" />
    . . .
  </global-attribute-filter>
  <taglib-filter namespace="http://xmlns.oracle.com/adf/faces/rich">
    <tag name="activeCommandToolbarButton">
      . . .
      <attribute name="windowWidth" filtered="false"/>
    </tag>
  </taglib-filter>
</filter-config>
</pe-extension>
```

3. Save the file.

19.9 Enabling Parameter Support on the Customization Manager Task Flow

If you enable parameter passing on the task flow, administrators can customize Customization Manager by setting certain parameters. By default, an administrator cannot pass parameters to the Customization Manager task flow in Composer. Table 19–2 describes the parameters supported by the Customization Manager task flow.

Table 19–2 Customization Manager Task Flow Parameters

Parameter Name	Value	Description
defaultPage	Page URI	Used to specify the default page to be managed. If this value is null, the current page will be used.
dynamicNodeMap	`Map<String,List<CustomizationManagerNode>>`	Used to return a list of pages, XML documents, or task flows on a given page or fragment, using the following format: `Page1.jspx -> List of {CustomizationManagerTaskFlowNode or CustomizationManagerPageNode or CustomizationManagerXMLNode }` Use `CustomizationManagerTaskFlowNode` to pass dynamic taskflows in that page. Use `CustomizationManagerPageNode` to pass page template of the page. Use `CustomizationManagerXMLNode` to pass any XML documents owned by this page.
showBase	true/false Default: false	Used to show or hide the column for the base document.
showCurrentLayers	true/false Default: true	Used to show or hide the column showing details about the currently used layer.

Table 19–2 (Cont.) Customization Manager Task Flow Parameters

Parameter Name	Value	Description
showAllLayers	true/false Default: true	Used to show or hide the column showing details about layers other than the current one.
showLayersforCurrent	`Map<String,List<String>>`	Used to specify a list of layers that must be available in the Current Context column. This parameter takes the layer name and list of layer values and patterns that must be shown in the Current Context column. See Example 19–16 for more information.
showLayersforAll	`Map<String,List<String>>`	Used to specify a list of layers that must be available in the All Layers column. This parameter takes the layer name and list of layer values and patterns that must be shown in the All Layers column. See Example 19–16 for more information.
labelPrefixes	`List<String>`	Used to specify a list of space-separated label prefixes that must be displayed in the Promote dialog. Only those labels created with the specified prefixes are displayed in the Promote dialog. By default, all the labels are displayed.
maxDepth	String	Used to restrict the depth of a task flow hierarchy in the Customization Manager. The default value is `10`. Consequently, if you have a task flow with cyclic dependency, this parameter prevents a stack overflow by limiting the depth to ten nested task flows. You can display a maximum nesting of 10 task flows. Customization Manager displays only a depth of 10 even if you specify a value higher than 10.
showDownload	true/false Default: true	Used to show or hide the Download link.
showUpload	true/false Default: true	Used to show or hide the Upload link.
showDelete	true/false Default: true	Used to show or hide the Delete link.
showPromote	true/false Default: true	Used to show or hide the Promote link.

Note: The implementation of `Map` and `List` must be `Serializable` for Customization Manager to work correctly in a cluster-based environment. Typically, `ArrayList` and `HashMap` are `Serializable`.

This section describes the steps to enable parameter editing on the Customization Manager task flow. It contains the following subsections:

- Section 19.9.1, "How to Set the Customization Manager Task Flow Parameters"
- Section 19.9.2, "What Happens When You Enable Parameter Support"

19.9.1 How to Set the Customization Manager Task Flow Parameters

To pass parameters to the Customization Manager task flow, you must define the `parameters` attribute as part of the Customization Manager add-on panel configuration in your application's `adf-config.xml` file.

To enable parameter editing on the task flow:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the following namespace within the `adf-config` element in the file:

   ```
   xmlns:pe="http://xmlns.oracle.com/adf/pageeditor/config"
   ```

3. Add a `<pe:page-editor-config>` entry with the namespace and include an `<pe:addon-panels>` entry.

   Within `<pe:addon-panels>`, add an `<pe:addon-panel>` entry for the default Customization Manager panel and define the `parameters` attribute by setting it to `appUtilBean.customizationManagerParams`, as shown in Example 19–16.

Example 19–16 Customization Manager Add-On Referenced in adf-config.xml

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels>
    <pe:addon-panel name="oracle.adf.pageeditor.addonpanels.customization-manager"
parameters="#{AppUtilBean.customizationManagerParams}"/>
    . . .
  </pe:addon-panels>
</pe:page-editor-config>
```

where `AppUtilBean` is a sample implementation of the `AppUtilBean` class, and is as shown in the following example:

```
public Map<String, Object> getCustomizationManagerParams()
{
  Map<String, Object> paramMap = new HashMap<String, Object>();
  Map<String, List<String>> showLayersForCurrent = new HashMap<String,
List<String>>();
  showLayersForCurrent.put("user", Arrays.asList("admin%", "weblogic"));
  paramMap.put("showLayersForCurrent", showLayersForCurrent);

  Map<String, List<String>> showLayersForAll = new HashMap<String,
List<String>>();
  showLayersForAll.put("enterprise", Arrays.asList("Frys"));
  paramMap.put("showLayersForAll", showLayersForAll);

  return paramMap;
```

```
}
```

4. Save the `adf-config.xml` file.

19.9.2 What Happens When You Enable Parameter Support

Customization Manager displays options to users based on the new parameter settings.

19.10 Customizing the Composer Toolbar

You can customize the default Composer toolbar by adding, removing, or rearranging elements and overriding existing elements. To enable toolbar extensibility, the Composer toolbar elements have been grouped into sections. You can work with these sections to customize your toolbar. Each section has a specific name and contains one or more elements inside it.

> **Notes:** The Save button is displayed on the toolbar only if the application is configured to use a sandbox. For more information, see Section 21.2, "Using Composer Sandbox."
>
> The Help icon is displayed on the toolbar only if you have configured a help provider in your application or hooked up help from Composer panels or dialogs.
>
> The Composer toolbar is created using the ADF Faces `Toolbox` tag. Each row in the toolbar is a `Toolbar` tag. Consequently, UI components such as separator bars are inherited from the `Toolbar` component.

Table 19–3 describes the toolbar areas.

Table 19–3 Toolbar Areas

Section or Area	Description
`message`	Area containing the message with the page name.
`statusindicator`	Area containing the status indicator.
`menu`	Area containing the View menu that allows users to switch between Design view and Structure view.
`addonpanels`	Area containing Composer add-ons. The add-ons are all displayed in a sequence within this area. For more information, see Section 19.2, "Creating Composer Add-Ons."
`help`	Area containing the Help icon.
`button`	Area containing the Save and Close buttons.
`stretch`	Wide space between two sections.
`newline`	A line break between sections. All sections after a line break are pushed to a new line on the toolbar.

Using toolbar sections, you can customize the Composer toolbar in the following ways:

- Rearrange and hide built-in elements

- Add new sections with custom elements
- Modify default sections to display custom elements

This section describes the steps to customize the Composer toolbar. It contains the following sections:

- Section 19.10.1, "How to Rearrange or Hide Toolbar Elements"
- Section 19.10.2, "What Happens at Runtime"
- Section 19.10.3, "How to Add New Sections to the Toolbar"
- Section 19.10.4, "How to Override a Toolbar Section to Display Custom Content"

19.10.1 How to Rearrange or Hide Toolbar Elements

Use the `toolbarLayout` attribute on a `Page Customizable` component to control which toolbar sections are displayed and the order in which they appear.

To customize the toolbar for all editable pages in the application, you can create a template, add a `Page Customizable` component to the template, and specify the `toolbarLayout` attribute against the `Page Customizable` component. You can then base all the pages in the application on that template.

If you do not specify a value for `toolbarLayout`, this attribute is internally set to `message addonpanels stretch button help`, which is the default layout for the Composer toolbar sections.

To customize the toolbar on an application page:

1. Open your customizable JSPX page in JDeveloper and select the `Page Customizable` component in the Structure window.
2. In the Property Inspector, specify space-separated values for the `toolbarLayout` attribute under Appearance.

   The section names in Table 19–3 are valid values for this attribute.

   > **Note:** You can add only one `stretch` value per row on the toolbar. If you add more than one `stretch` value, only the first one is displayed; all others are ignored.

   In Source view, the `toolbarLayout` attribute appears as shown in the following example:

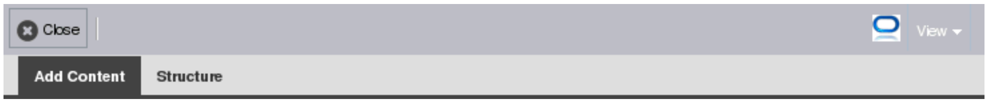
   ```
   <pe:pageCustomizable id="pageCustomizable1"
                        toolbarLayout="button stretch statusindicator menu"
     <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
     <f:facet name="editor">
       <pe:pageEditorPanel id="pep1"/>
     </f:facet>
   </pe:pageCustomizable>
   ```

3. Save the JSPX file.

19.10.2 What Happens at Runtime

At runtime, the toolbar displays the sections you specified in the order you specified them (Figure 19–14).

Figure 19–14 Customized Composer Toolbar



19.10.3 How to Add New Sections to the Toolbar

You can add custom sections by creating facets and specifying the facet names in the `toolbarLayout` attribute. Populate the new facets with elements you want to display on the toolbar. The following example shows you how to create a section; specifically, how to add a **Report a Bug** icon that opens a popup that enables users to report a bug.

To add a custom section:

1. Open the JPSX page for which you want to customize the toolbar.
2. Add a `facet` inside the `Page Customizable` and name it `bugreport`.
3. Add a `Command Toolbar Button` component inside the facet and set the `text` attribute to `Report a Bug`.
4. To add an image to the icon, specify the path to the image using the `icon` attribute.
5. Add the `Show Popup Behavior` component to invoke a popup on clicking the `Command Toolbar Button`.

   In Source view, the `Page Customizable` would appear as follows:

```
<pe:pageCustomizable id="pageCustomizable1"
             toolbarLayout="message stretch bugrep newline menu stretch button"
  <f:facet name="bugrep">
    <af:commandToolbarButton id="cmd1" text="Report a bug"
                             icon="/images/bug.png"
                             clientComponent="true">
      <af:showPopupBehavior popupId="p1" triggerType="action"/>
    </af:commandToolbarButton>
  </f:facet>
. . .
  <af:popup id="p1">
    <af:dialog id="dlg1" title="File a Bug"
               affirmativeTextAndAccessKey="File">
      <af:panelFormLayout labelWidth="30%" id="pfl1">
        <af:inputText id="it0" maximumLength="80"
                      label="Product/Component" required="true"/>
        <af:inputText id="it1" maximumLength="80" label="Subject"
                      required="true"/>
        <af:inputText id="it2" rows="3" label="Problem" required="true"/>
        <af:inputText id="it3" rows="3" label="Steps" required="true"/>
      </af:panelFormLayout>
    </af:dialog>
  </af:popup>
  . . .
</pe:pageCustomizable>
```

6. Save the page.

   At runtime, the Composer toolbar will display a Report a Bug icon. Clicking this icon will display the File a Bug dialog to enable users to report a bug.

19.10.4 How to Override a Toolbar Section to Display Custom Content

You can display custom content in a default toolbar section by adding a facet of the same name as the section and populating it with custom content. The facet content overrides the content of the default section. For example, to display a custom message to users in place of the `Editing Page:` *`Page_Name`* message, you can create a custom facet named `message` and include an `Output Text` component with the text you want to display to users. The `Output Text` component then displays in place of the default message. The following example shows a `Page Customizable` component with a custom toolbar message:

```
<pe:pageCustomizable id="pageCustomizable1"
                     toolbarLayout="message newline button stretch statusindicator
menu"
  <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
  <f:facet name="message">
    <af:outputText value="Welcome!"/>
  </f:facet>
  <f:facet name="editor">
    <pe:pageEditorPanel id="pep1"/>
  </f:facet>
</pe:pageCustomizable>
```

19.11 Enabling Direct Select in Design or Add Content View

Direct select allows you to extend specific customization capabilities from Composer Structure view to Design or Add Content view, allowing users to modify elements from within the page at runtime. This allows you to put more control in the hands of the business user, while creating a safe environment where no damage can be done to the underlying application.

All direct select functionality is available in Structure view, but business users do not have the knowledge or experience to use Structure view safely and effectively. These users could easily break the page and circumvent application logic.

Using direct select, you can enable a small number of chosen components to be selectable and editable. For example, changing the order of fields in a form, changing the labels on form fields, changing column names in a table, or hiding specific fields in a form.

For more information about direct select functionality, see Section 19.11.2, "What Happens at Runtime."

19.11.1 How to Enable and Configure Direct Select

This section explains how to enable and configure direct select in your application.

1. First you must enable the Select view. In `adf-config.xml`, inside the `<pe:page-editor-config>` tag, add the `<pe:enable-design-views>` tag to define the available views. The possible constant values are:
   - `all`: Makes all views available and displays a toolbar with tabs to switch between views.
   - `design`: Makes the Design view the only view available.
   - `add-content`: Makes the legacy Add Content view the only available view.
   - `select`: Makes the Select view the only available view.

- `source`: Makes the Structure view the only available view.
- `preview`: Makes Preview the only available view.

For example, if you want only Select and Add Content views, you can add the following tag:

```
<pe:enable-design-views> select add content</pe:enable-design-views>
```

You can also use EL to determine the appropriate view, as shown in the example below:

```
<pe:enable-design-views>#{testBean.designViews}</pe:enable-design-views>
```

> **Note:** This setting defines the default for the application. You can override this setting in any `pageCustomizable` tag using the `designViews=""` attribute.

2. In pe-ext.xml, add the `<selection-config>` tag to enable or disable direct select for specific components and define associated operations. To make a component selectable, you must define operations within this tag. (If no operations are defined and selection is enabled for a component, selecting the component will display an empty frame.)

Within the `<selection-config>` tag, you can configure direct select globally using `<global-filter>` and by namespace and tag using `<selection-taglib-filter>`. The `<selection>` tag has two required attributes:

- `view`: Defines the view in which the direct select is enabled.
- `enabled`: Sets whether or not direct select is enabled in the specified view.

Available operations are defined within `<operation>` tags under each specific component. The following elements are used to define operations:

- `name`: Defines the operation (standard or custom) to be executed. The operation name is the same as the property panel ID. For a list of standard operations, see Section B.3.2, "Default Property Panels." For custom operations, the name is the same as the custom panel ID. For details on custom operations, see Section 19.3, "Creating Custom Property Panels."
- `label` (optional): Sets the tab label in the popup window. The default label is the operation name.
- `filtered`: Set to `false` to include the operation in the popup window.

> **Note:** It is a recommended practice to provide selection for a small number of components at first, then add more as functionality is tested and learned. This can be done easily by globally disabling selection in the `<global-filter>` tag and enabling selection for individual components using `<selection-taglib-filter>` as shown in the example that follows.

```
<selection-config>
  <global-filter>
    <selection view="design" enabled="false"/>
  </global-filter>

  <selection-taglib-filter
```

```
   namespace="http://xmlns.oracle.com/adf/faces/customizable">
    <tag name="showDetailFrame">
      <selection view="design" enabled="true"/>
      <operation name="oracle.adf.pageeditor.pane.sdfprop"
                 label="SDF Change Property"
                 filtered="false"/>
    </tag>
  </selection-taglib-filter>

  <selection-taglib-filter namespace="http://xmlns.oracle.com/adf/faces/rich">
    <tag name="goLink">
      <selection view="design" enabled="true"/>
      <operation name="oracle.adf.pageeditor.pane.generic-property-inspector"
                 label="Change Property"
                 filtered="false"/>
      <operation name="oracle.adf.pageeditor.pane.inline-style-editor"
                 label="Inline Style"
                 filtered="false"/>
    </tag>
    <tag name="commandButton">
      <selection view="design" enabled="true"/>
      <operation name="oracle.adf.pageeditor.pane.generic-property-inspector"
                 label="Change Property"
                 filtered="false"/>
    </tag>
  </selection-taglib-filter>
</selection-config>
```

To further simplify the user experience, direct select allows you to filter specific attributes for a tag so that a smaller set is displayed. For details, see Section 19.8.1, "How to Define Property Filters."

3. To enable or disable direct select for a specific component within a .jspx page, add the `<f:attribute name="pe-select" value="true|false">` tag within the component tag as shown in the example that follows. The setting in this tag overrides the setting in `<selection-config>` for the component in the pe_ext.xml file. (As noted above, to enable direct select, operations must be defined for the component in the pe_ext.xml file, or selecting it will open an empty dialog.)

```
<af:panelGroupLayout id="pgl2" layout="vertical">
<f:attribute name="pe-select" value="false"/>
  <af:inputText id="it6" label="Unselectable" value="Enter here..."/>
  <af:goLink id="gl1" destination="http://www.oracle.com" text="Oracle"/>
  <af:inputText id="it7" label="Selectable(override)" value="Enter here...">
    <f:attribute name="pe-select" value="true"/>
  </af:inputText>
</af:panelGroupLayout>
```

4. To disallow the use of Expression Language in form fields and protect existing EL from overwrite, see Section 19.4.2, "How to Protect Expression Language."

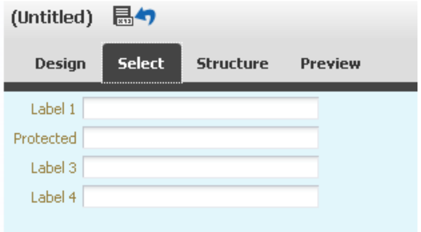
For more information about specific elements, see the following sections in Appendix B, "Composer Component Properties and Files":

- Section B.2.1.8, "selection-config"
- Section B.2.2.5, "enable-design-views"
- Section B.2.2.6, "allow-el and protect-el"

19.11.2 What Happens at Runtime

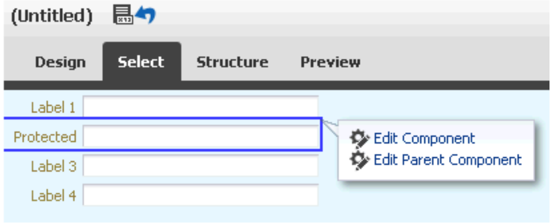
When direct select is enabled, the outward presentation of the page at runtime does not appear any different to the end user (Figure 19–15).

Figure 19–15 Select View



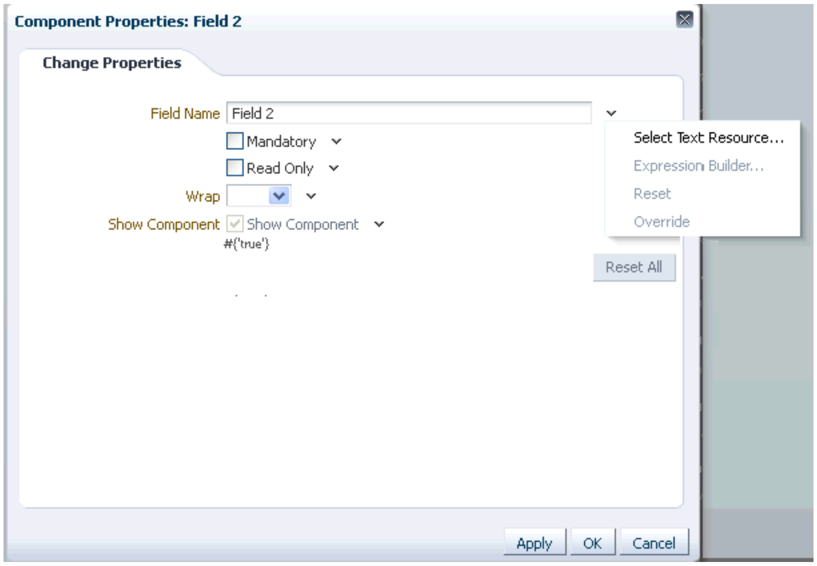
To edit the properties for a component, the user can select an enabled element and click **Edit Component** or **Edit Parent Component**, when applicable (Figure 19–16).

Figure 19–16 Direct Select Enabled for an Element



The **Component Properties** dialog allows the user to edit properties defined for the component and access other operations configured for the component. If the user chose Edit Parent Component, a Manage Children tab is included in the dialog. If EL is not allowed or is protected from overwrite, the Expression Builder and Override options are not available, as shown in Figure 19–17. This image also includes an example of a field that is protected from edit (Show Component).

Figure 19–17 Component Properties Dialog



Component Properties: Field 2

Change Properties

Field Name: Field 2
☐ Mandatory
☐ Read Only
Wrap
Show Component: ☑ Show Component
#{'true'}

Multiple operations are shown in tabs in the dialog. The order of tabs is defined in the panel registration. If an operation references a panel that is not registered for the enclosing component, the tab for that operation will not be displayed. For details on panel registration, see Section 19.3, "Creating Custom Property Panels."

19.12 Troubleshooting Problems with Composer Extensibility Features

This section provides information to assist you in troubleshooting problems you may encounter while using the Composer extensibility features.

For information about configuring logging, see Chapter 18, "Enabling Runtime Editing of Pages Using Composer."

Problem

You created an add-on, but it does not appear on the Composer toolbar.

Solution

Ensure the following:

- The `pe_ext.xml` file is in `/META-INF` folder in a JAR file or the application and is available in the class path.
- The task flow binding ID specified while registering the panel in `pe_ext.xml` is correct.
- An `<pe:addon-panel>` entry exists under the `<pe:page-editor-config>` section in the `adf-config.xml` file.
- If the add-on is in a JAR file, ensure that the JAR file is created as an ADF Library.

For information about add-ons, see Section 19.2, "Creating Composer Add-Ons."

Problem

You have registered a custom property panel. However, it does not appear in the Component Properties dialog when you select a component to display its properties.

Solution

Ensure the following:

- The `pe_ext.xml` file is in `/META-INF` folder in a JAR file or the application and is available in the class path.
- The task flow binding ID specified while registering the panel in `pe_ext.xml` is correct.
- The `property-panel` registration is correct and is specified against the component you want the panel to appear against. Further, the fully qualified class name of the component is correctly specified using the `component` node.
- A duplicate property panel registration is not overriding your panel entry.
- If the panel is configured to use the rendered attribute, ensure that the value or EL evaluates to `true`.
- If the add-on is in a JAR file, ensure that the JAR file is created as an ADF Library.

For information about custom property panels, see Section 19.3, "Creating Custom Property Panels."

Problem

You do not see some properties of a component in the Component Properties dialog.

Solution

Ensure that the component properties are not filtered or restricted. For more information, see Section 19.8.1, "How to Define Property Filters" and Section 22.4, "Applying Attribute-Level Security."

20 Performing Advanced Composer Configurations

This chapter describes how to perform certain advanced Composer configurations to enhance the end user experience.

This chapter contains the following topics:

20.1 Enabling Custom Actions on a Show Detail Frame Component by Using Facets

You can use the `Show Detail Frame` component's facets to define and display custom actions on `Show Detail Frame` components. For example, if your `Show Detail Frame` contains a list of services provided in your application, you can add a custom action, `Show Detailed Information`, which opens up a task flow containing details about the various services.

For information about the facets supported by `Show Detail Frame` components, see Section B.1.5, "Show Detail Frame Component."

Oracle JDeveloper displays all facets available to the `Show Detail Frame` component in the Structure window, however, only those that contain UI components appear activated.

To add a Show Detail Frame facet, perform the following steps:

1. Right-click a `Show Detail Frame` component in the Structure window, and select **Facets - Show Detail Frame**, and click the arrow displayed to the right of this option.
2. From the list of supported facets, select the facet you want to add.

   > **Note:** A check mark next to a facet name means the facet is already inserted in the `Show Detail Frame` component. Selecting that facet name again would result in the facet getting deleted from the page.

   The `f:facet` element for that facet is inserted in the page.
3. Add components in the facet according to your design requirements.

   For an end-to-end example of creating and using `Show Detail Frame` facets, see Section 20.2, "Enabling Custom Actions on a Show Detail Frame Component by Using Facets: Example."

20.2 Enabling Custom Actions on a Show Detail Frame Component by Using Facets: Example

Assume a JSPX page, `Page1`, with a `Panel Customizable` component. Inside the `Panel Customizable` is a `Show Detail Frame` component (`showDetailFrame1`). Inside the `Show Detail Frame` is an ADF task flow. The `Panel Customizable` has two other `Show Detail Frame` components, one above and the other below `showDetailFrame1`. The task flow displays two `Output Text` components on the page.

You can configure an `Additional Actions` facet on the `Show Detail Frame` component to display a **Customize** action on the Actions menu along with the **Move Up** and **Move Down** actions. At runtime, the **Customize** action enables users to customize the text in the `Output Text` components. This section describes the steps you take to achieve this effect. It contains the following subsections:

- Section 20.2.1, "How to Create an ADF Task Flow"
- Section 20.2.2, "How to Include an Additional Actions Facet"
- Section 20.2.3, "How to Create a Redirection Page"
- Section 20.2.4, "How to Create Navigation Rules Between Pages"
- Section 20.2.5, "What Happens at Runtime"

20.2.1 How to Create an ADF Task Flow

To create an ADF task flow:

1. From the **File** menu, select **New**.
2. In the **New** dialog, select **JSF** under Web Tier node, and select **ADF Task Flow** under Items.
3. Click **OK**.

4. In the Create Task Flow dialog, click **OK** to create a task flow definition file by accepting the default values.

5. From the **ADF Task Flow** tag library in the Component Palette, drop two view elements, **view1** and **view2**, onto the task flow definition file.

6. Drop a **Control Flow Case** from view1 to view2.

7. Click the first view element and then click the second view element to draw the control flow line.

   Name this control flow case next.

8. Similarly, drop a **Control Flow Case** from view2 back to view1 and name it prev.

9. Create a backing bean called BackingBean.java to contain values for two variables view1 and view2.

   view1 and view2 are initialized with initialValue1 and initialValue2 respectively. Ensure that the code of the bean is as shown in the following example:

```
package view;

public class BackingBean {
    public BackingBean() {
    }

    private String view2 ="initial Value1";
    private String view1 = "initial Value2";

    public void setView2(String view2) {
        this.view2 = view2;
    }

    public String getView2() {
        return view2;
    }

    public void setView1(String view1) {
        this.view1 = view1;
    }

    public String getView1() {
        return view1;
    }
}
```

10. In the task flow definition file, double-click **view1** to create the page fragment (view1.jsff) for that element.

11. Add a **Panel Group Layout** and two **Output Text** components to view1.jsff.

12. Specify the Value for the first Output Text component to be #{backingBean.view1}, and specify the Value for the second Output Text component to be #{backingBean.view2}.

13. Save view1.jsff, and close it.

14. In the task flow definition file, double-click **view2** to create the page fragment (view2.jsff) for that element.

15. Add just one **Output Text** component to view2.jsff, and specify Value to be #{backingBean.view2}.

16. Save `view2.jsff`, and close it.

20.2.2 How to Include an Additional Actions Facet

To include an Additional Actions facet:

1. Create a JSPX page, `Page1.jspx`, with a `Panel Customizable` component and a nested `Show Detail Frame` component.

2. Add two more `Show Detail Frame` components, above and below the existing `Show Detail Frame` component.

   The purpose of adding three `Show Detail Frame` components is to enable the display of `Move Up` and `Move Down` actions along with the additional action on the first `Show Detail Frame` component, `showDetailFrame1`.

3. Add the task flow definition file that you created in the previous step inside `showDetailFrame1`.

4. Right-click the first `Show Detail Frame` in the Structure window, and select **Facets - Show Detail Frame**.

5. Click the arrow to the right of this option, and from the list of supported facets, select **Additional Actions**.

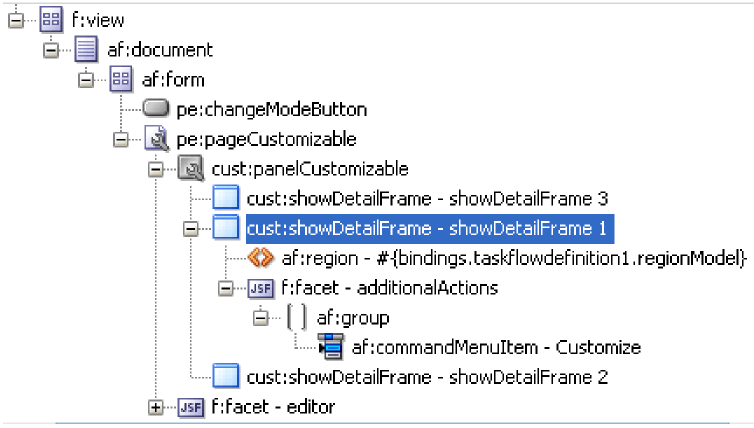
   The `f:facet-additionalActions` element for that facet is inserted in the page.

6. Add a **Panel Group Layout** inside the `Additional Actions` facet, and add a **Button** component inside the `Panel Group Layout` component.

7. Set the `Text` attribute for the `Button` to `Customize`, and specify `customize` as the `Action` value.

   The page in the structure navigator should appear as shown in Figure 20–1.

Figure 20–1 Page1.jspx in Structure Navigator



f:view
af:document
af:form
pe:changeModeButton
pe:pageCustomizable
cust:panelCustomizable
cust:showDetailFrame - showDetailFrame 3
cust:showDetailFrame - showDetailFrame 1
af:region - #{bindings.taskflowdefinition1.regionModel}
f:facet - additionalActions
af:group
af:commandMenuItem - Customize
cust:showDetailFrame - showDetailFrame 2
f:facet - editor

8. Save the page.

20.2.3 How to Create a Redirection Page

To create the redirection page:

1. Create a JSPX page called `Page2.jspx`, and add two **Input Text** components and a **Button** component.

2. Specify the `Value` for the first `Input Text` component to `#{backingBean.view2}`, and set the `Value` attribute for the second `Input Text` component to `#{backingBean.view1}`.

   The purpose of adding `Input Text` components with references to the backing bean is to enable the passing of a user's input to the bean so that it can be reflected in the `Output Text` components on `Page1.jspx`.

3. On the `Button` component, set the `Text` attribute to `OK` and specify `back` as the `Action` value.

4. Save the page.

   You can now enable switching between the two pages by defining navigation rules.

20.2.4 How to Create Navigation Rules Between Pages

To define navigation rules between the pages:

1. In the Application Navigator, under the project's WEB-INF folder, double-click the **faces-config.xml** file to open it.
2. Click the **Overview** tab to view the file in Overview mode.
3. Click the **Add** icon in the Managed Beans section.
4. In the Create Managed Bean dialog, specify `backingBean` as the name.
5. For the Class Name field, click the **Browse** button adjacent to it and browse to the `BackingBean` Java class that you created earlier. Click **OK**.
6. Click **OK**.
7. From the Scope list, select **session** and click **OK**.
8. Select the **Navigation Rules** tab on the page.
9. In the From Views table, select **Page1.jspx**.
10. Under Navigation Cases, select **Page2.jspx** in the To View ID column, **customize** in the From Outcome column, and **true** in the Redirect column.
11. In the From Views table, select **Page2.jspx**.
12. Under Navigation Cases, select **Page1.jspx** in the To View ID column, **back** in the From Outcome column, and **true** in the Redirect column.

    In Source view, these entries appear as follows:

```
<managed-bean>
    <managed-bean-name>backingBean</managed-bean-name>
    <managed-bean-class>view.BackingBean</managed-bean-class>
    <managed-bean-scope>session</managed-bean-scope>
  </managed-bean>
  <navigation-rule>
  <from-view-id>/Page1.jspx</from-view-id>
  <navigation-case>
    <from-outcome>customize</from-outcome>
    <to-view-id>/Page2.jspx</to-view-id>
      <redirect/>
    </navigation-case>
  </navigation-rule>
  <navigation-rule>
    <from-view-id>/Page2.jspx</from-view-id>
  <navigation-case>
```

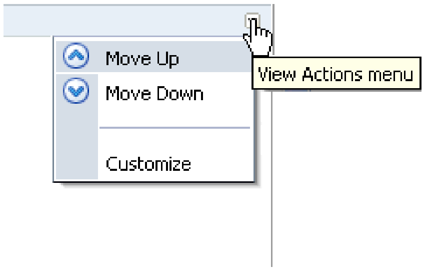
```
            <from-outcome>back</from-outcome>
            <to-view-id>/Page1.jspx</to-view-id>
              <redirect/>
            </navigation-case>
        </navigation-rule>
```

13. Save the file.

20.2.5 What Happens at Runtime

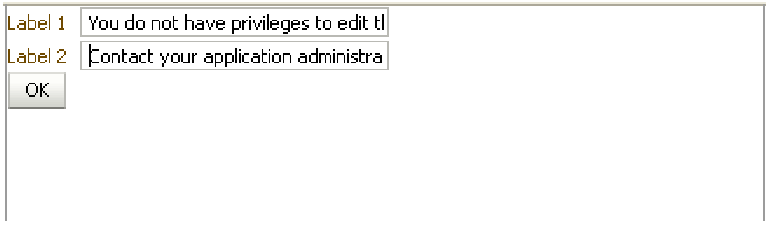
In JDeveloper, run Page1.jspx. The Actions menu on the showDetailFrame1 component displays the Customize action, as shown in Figure 20–2.

Figure 20–2 Customize Action on the Actions Menu



Clicking Customize takes you to Page2.jspx (Figure 20–3), where you can update the values for Label1 and Label2.

Figure 20–3 Page with Option to Edit Text



Label 1
You do not have privileges to edit tl
Label 2
Contact your application administra
OK

Clicking **OK** takes you back to Page1.jspx, which reflects the recent text changes.

20.3 Enabling Custom Actions on a Task Flow

You can customize a task flow by including it in a Show Detail Frame component. The Show Detail Frame component provides certain default actions to rearrange, show, and hide components. Further, you can define custom actions to trigger the desired navigational flow within the task flow at runtime. There are two ways in which you can enable custom actions on a task flow:

- Enable custom actions directly on the task flow so that they are displayed on the Show Detail Frame component's Actions menu.
- Enable custom actions on the Show Detail Frame component enclosing the task flow so that they are displayed on the Show Detail Frame component's Actions menu.

This section describes both approaches. It contains the following subsections:

- Section 20.3.1, "How to Enable Custom Actions Directly on a Task Flow"

- Section 20.3.2, "How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow"
- Section 20.3.3, "What Happens at Runtime"
- Section 20.3.4, "How to Enable Custom Actions On a Show Detail Frame Enclosing a Task Flow: Example"

20.3.1 How to Enable Custom Actions Directly on a Task Flow

Perform the steps in this section if you want the task flow to be self-contained, without the need to inherit global custom actions defined at the application level. You can define custom actions on a task flow by configuring a `<customComps-config>` section with a nested `<customActions>` element in the `adf-settings.xml` file. The additional custom actions specified in the `adf-settings.xml` file are displayed on the `Show Detail Frame` component that surrounds this task flow.

Typically, task flows are packaged and deployed as ADF libraries. When you create an `adf-settings.xml` file containing custom actions for a task flow, this file is also packaged in the ADF library.

To enable custom actions on a task flow:

1. If it does not already exist, create the `adf-settings.xml` file in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_ROOT`*`/Portal/src/META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `adf-settings.xml`.

2. Add a `<custComps-config>` section in the file, with a nested `<customActions>` element.

3. Add one `<customAction>` element for each internal task flow action that you want to display as a custom action on the `Show Detail Frame` Actions menu.

   You can add any number of custom actions under the `<customActions>` element.

   Example 20–1 shows the code of the `adf-settings.xml` file with a `<customAction>` entry.

Example 20–1 The custComps-config Section in an adf-settings.xml File

```
<cust:custComps-config
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <customActions>
   <customAction action="next" location="chrome"
                 rendered="true"
                 icon="/adf/webcenter/editheader_ena.png"
                 text="Next"

taskFlowId="/WEB-INF/task-flow-definition.xml#task-flow-definition"
                 shortDesc="next"/>
    <customAction action="prev" location="chrome"
                 rendered="true"
                 icon="/adf/webcenter/editheader_ena.png"
                 text="Previous"
```

```
taskFlowId="/WEB-INF/task-flow-definition.xml#task-flow-definition"
                shortDesc="prev"/>
 </customActions>
</cust:custComps-config>
```

Custom action definitions are similar at the task flow-level and application-level, except for the taskFlowId attribute that is used in the task flow-level setting. This attribute is used to identify the task flow on which the custom action must be defined. As an ADF library may have multiple task flows, this attribute helps identify the task flow that must render the custom action.

Notes:

- If you are defining an icon for the custom action, you must ensure that the image you specify is available in the project root folder.
- You can define custom actions for the internal actions defined in all task flows on your page; however, at runtime, the Show Detail Frame displays only those custom actions that correspond to the ADFc outcomes of the current view of the task flow.

4. Save the adf-settings.xml file.

20.3.2 How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow

You can define custom actions for a task flow on the enclosing Show Detail Frame component. When these actions are invoked at runtime, they trigger the desired navigational flow in the task flow. For example, you can define a custom action on a Show Detail Frame that specifies that the target task flow fragment opens in a separate browser window rather than inside the Show Detail Frame.

You can specify custom actions on Show Detail Frame components by adding Custom Action components as children of a Show Detail Frame component on the page. Custom actions defined in this way would be available only on the Show Detail Frame instance, which has the custom action as its child. Alternatively, you can specify custom actions in the application's adf-config.xml file. Custom actions defined in this way are available on all Show Detail Frame instances in the application.

This section provides information about defining custom actions on a Show Detail Frame. It contains the following subsections:

- Section 20.3.2.1, "Defining Custom Actions at the Instance Level"
- Section 20.3.2.2, "Defining Custom Actions at the Global Level"
- Section 20.3.2.3, "Configuring Custom Actions that Display Task Flow Views in a Separate Browser Window"

20.3.2.1 Defining Custom Actions at the Instance Level

Define custom actions on a particular Show Detail Frame component instance using the Custom Action component. You can find the Custom Action component in the Composer tag library. Custom actions are stored in the JSPX page definition file of the page that contains the Show Detail Frame.

To define custom actions at the instance level:

1. From the Component Palette, select **Composer**.

2. Drag a **Custom Action** and drop it on the page inside the `Show Detail Frame` component, below the `af:region` element.

   Add one `Custom Action` component for each internal task flow action you want to display as a custom action on the `Show Detail Frame` Actions menu.

   > **Note:** Add `Custom Action` components below the `af:region` element. You may face problems if the region is not the first child component of the `Show Detail Frame`.

3. Define attributes for the `Custom Action` by referring to Table B–9 in Section B.1, "Composer Component Properties."

   Ensure that you populate the `Action` attribute of each `Custom Action` with the correct ADFc outcomes of the associated task flow. The code should be similar to the one shown in Example 20–2.

Example 20–2 Custom Action Code

```
<cust:showDetailFrame text="showDetailFrame 1" id="sdf1">
  <af:region value="#{bindings.taskflowdefinition1.regionModel}"
             id="r1"/>
  <cust:customAction action="navigatefromview1" id="ca1"
                     location="both" icon="/Logo1.JPG"
                     text="View1 Action"
                     shortDesc="Custom View1 Action"/>
  <cust:customAction action="navigatefromview2"
                     location="both" id="ca2"
                     icon="/Logo2.JPG" text="View2 Action"
                     shortDesc="Custom View2 Action"/>
</cust:showDetailFrame>
```

> **Notes:** You can add custom actions for all of the task flow's ADFc outcomes, but depending on the task flow view that is displayed, several or none of the custom actions are available at runtime.
>
> If you define a custom action without a corresponding task flow action, then the custom action is not rendered on the `Show Detail Frame` header at runtime.

> **See Also:** "Creating a Task Flow" in *Fusion Developer's Guide for Oracle Application Development Framework*

4. Save and run the page.

At runtime, when you select an action from the `Show Detail Frame`'s Actions menu, the associated control flow rule is triggered and the target task flow fragment is rendered.

20.3.2.2 Defining Custom Actions at the Global Level

Defining custom actions at the global level means making those custom actions available for all `Show Detail Frame` instances in an application. Though global-level custom actions are available on all `Show Detail Frame` components in an application, at runtime the header of any `Show Detail Frame` displays only those custom actions that correspond to the ADFc outcomes of the current view of the task flow.

Define global-level custom actions in your application's `adf-config.xml` file.

To define custom actions at the global level:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under Descriptors in the Application Resources panel.
2. Define custom actions using the `<customActions>` element with nested `<customAction>` tags for each action, as shown in Example 20–3.

   > **Tip:** To render a custom action only in page Edit mode, you can set the `rendered` attribute on the `<customAction>` tag to `#{composerContext.inEditMode}`. This returns a value of `true` if the page is in Edit mode.

Example 20–3 Custom Actions Definitions in the adf-config.xml File

```
<cust:adf-config-child
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <enableSecurity value="true" />
  <customActions>
    <cust:customAction action="forward" displayName="Move Forward"
                       location="menu" rendered="true"
                       icon="/move_forward.png"/>
    <cust:customAction action="backward" tooltip="Move Backward"
                       location="chrome" rendered="true"
                       icon="/move_backward.png"/>
  </customActions>
</cust:adf-config-child>
```

> **Notes:**
>
> - If you implemented restrictions on the `Show Detail Frame` component's actions by performing the steps in Section 22.5, "Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions," you already have a `cust:customizableComponentsSecurity` section in the `adf-config.xml` file. You can define custom actions in that section itself instead of the `cust:adf-config-child` section shown in Example 20–3.
> - If you are defining an icon for the custom action, you must ensure that the image you specify is available in the project root folder.
> - You can define custom actions for the internal actions defined in all task flows on your page; however, at runtime, the header of any `Show Detail Frame` displays only those custom actions that correspond to the ADFc outcomes of the current view of the task flow.

3. Save the `adf-config.xml` file.

For additional information about defining custom actions, see Section 20.3.4, "How to Enable Custom Actions On a Show Detail Frame Enclosing a Task Flow: Example."

Resolving Conflicts Between Global-Level and Instance-Level Custom Actions

Each custom action is uniquely identified by the value of its action attribute. If you have defined custom actions with the same action attribute value at the global and instance levels, then there may be conflicts in how these custom actions are invoked at runtime, depending on other attribute values. At such times, the inheritGlobalActions attribute of the Show Detail Frame defines the behavior of other custom action attributes (other than the action attribute) as follows:

> **Note:** Regardless of the inheritGlobalActions setting (true or false) on the Show Detail Frame component:
>
> - The rendered attribute is not inherited even if it is not specified at the instance level.
> - The location attribute at the global or instance level should be set to the same value at both the global and instance levels.

- If inheritGlobalActions=true, or you have not specified a value for inheritGlobalActions (defaults to false), the behavior of custom action attributes is as follows:
  - If you defined a custom action attribute at the global and instance levels, then the attribute value specified at the instance level is used.
  - If you defined a custom action attribute only at the instance level, then that attribute value is used.
  - If you defined a custom action attribute only at the global level, then that value is ignored and the default value is used.
- If inheritGlobalActions=true, the behavior of custom action attributes is as follows:
  - If you defined a custom action attribute at the instance level, then its value is used regardless of whether the same attribute is specified at the global level.
  - If you defined a custom action attribute only at the global level, then that value is used.
  - If you have not defined a custom action attribute at the global or instance levels, then the attribute's default value is used.

After you have designed your application pages, you must deploy the application to the production environment. For more information, see Chapter 7, "Deploying and Testing Your Portal Framework Application."

> **Note:** Runtime customizations that you perform on the page in the development environment are not carried over when you deploy the application to a target server.

20.3.2.3 Configuring Custom Actions that Display Task Flow Views in a Separate Browser Window

Custom actions typically display the target task flow views in place, inside the Show Detail Frame component. However, you can define a custom action to display a task flow view in a separate browser window.

To display a task flow view in a separate browser window, the control flow rule to that view must be prefixed with dialog: in the task flow definition file and in the action attribute of the custom action corresponding to that view. The following example shows an `action` attribute definition:

```
<cust:customAction action="dialog:Next" id="ca1"
                   location="both" icon="/move_forward.png"
                   text="Next Action"
                   shortDesc="Next Action"/>
```

Setting Properties on the Popup Window

For a command component inside a task flow region, you can specify the default behavior using the `useWindow`, `windowEmbedStyle`, `windowHeight`, `windowWidth`, and `returnListener` attributes. The command component may have other such attributes that you can use. If you specify a return listener, on closing the dialog a particular action event is called to decide on the next navigation outcome. By default, without this setting, a dummy `Rich Command Link` component is created to trigger the task flow action.

When you define a listener on a command component, you must also configure the custom action to call the action event on this component. The `actionComponent` attribute on a custom action definition (global- and instance-level) enables you to specify the ID of the command component that must be queued for the action event. When the `actionComponent` attribute is specified, the `Show Detail Frame` component queues the action event on this component. Since this command component is inside your task flow, you change its attribute values at any time.

Example

Consider an example where you have included a task flow inside a `Show Detail Frame` component and defined a `Simple Edit` custom action corresponding to the task flow's navigation outcomes. A `Command Button` component inside the task flow is configured to launch a modal inline popup of size `300x200` on clicking the `Simple Edit` custom action. A return listener is configured on the command component so that it is called whenever the popup is closed.

The source code of the Command Button component inside the region is as follows:

```
<af:commandButton text="dialog:simpleEditPoup"
                  id="SDFCustomActionCmd_simpleEditPoup"
                  action="dialog:simpleEditPoup" useWindow="true"
                  windowEmbedStyle="inlineDocument" windowWidth="300"
                  windowHeight="200"
                  windowModalityType="applicationModal"

returnListener="#{pageFlowScope.recentPagesBean.refreshMainView}"
                  visible="false"/>
```

Example 20–4 shows how you can specify a global custom action corresponding to the task flow outcome by defining the custom action in the `adf-config.xml` file. The ID of the `Command Button` component is specified against the `actionComponent` attribute on the custom action.

Example 20–4   Global Custom Action Defined in the adf-config.xml File

```
<customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <enableSecurity value="true"/>
    <customActions>
     <customAction action="dialog:simpleEditPoup"
                   text="Simple Edit"
                   shortDesc="Simple Edit"
```

```
                    location="menu"
                    rendered="#{!changeModeBean.inEditMode}"
                    icon="/adf/pe/images/editproperties_ena.png"
                    actionComponent="SDFCustomActionCmd_simpleEditPoup"/>
    </customActions>
</customizableComponentsSecurity>
```

Example 20–5 shows how you can specify an instance-level custom action corresponding to the task flow outcome by adding a `Custom Action` component from the Composer tag library to the JSPX page. The ID of the `Command Button` component is specified against the `actionComponent` attribute on the custom action.

Example 20–5 Instance-Level Custom Action Defined in the JSPX Page

```
<cust:showDetailFrame id="sdf_for_RecentPagesTF1"
                      text="Recent Pages" stretchContent="false"
                      showResizer="never">
  <af:region id="RecentPagesTF1"
             value="#{bindings.regionBinding1.regionModel}"/>
  <cust:customAction action="dialog:simpleEditPoup"
                     text="My Simple Edit"
                     shortDesc="Simple Edit"
                     location="menu"
                     rendered="#{!changeModeBean.inEditMode}"
                     icon="/adf/pe/images/editproperties_ena.png"
                     actionComponent="SDFCustomActionCmd_simpleEditPoup"/>
</cust:showDetailFrame>
```

> **Note:** A custom action that is launched in a popup dialog is sent as a new request to the server. If you are using a Composer sandbox and are in Edit mode of a page, ensure that this request is launched in View mode by adding code in your servlet filter so that a new sandbox is not created for this page.

20.3.3 What Happens at Runtime

Custom actions configured in the `adf-settings.xml` file are merged with the custom actions configured in the `adf-config.xml` file and all actions relevant to the current view of the selected task flow are displayed on the parent `Show Detail Frame` component's Actions menu.

If you enabled custom actions at a global level, then the header of any `Show Detail Frame` displays these custom actions if they correspond to the navigation outcomes of the current view of the child task flow.

If you prefixed the `action` attribute value with `dialog:`, then the target view of the task flow opens in a separate browser window.

20.3.4 How to Enable Custom Actions On a Show Detail Frame Enclosing a Task Flow: Example

In this example, assume that your application contains a task flow, `customactions`, residing inside a `Show Detail Frame`. The task flow includes three view elements, `view_gadget`, `edit_settings`, and `about_gadget`, and three associated control flow rules, `ViewGadget`, `EditSettings`, and `AboutGadget`. Your object is to define custom actions so that the control flow rules are available as actions on the Actions menu of the `Show Detail Frame` component.

In this example, the control flow rules are added in such a way that users can navigate back and forth between the three views. Each view element has an associated page fragment of the same name:

- The `view_gadget.jsff` fragment has a `Panel Stretch Layout` component. The center facet of this component is populated with an `Active Output Text` component whose `Value` attribute is set to `View Gadget`.
- The `edit_settings.jsff` fragment has a `Panel Stretch Layout` component. The center facet of this component is populated with an `Active Output Text` component whose `Value` attribute is set to `Edit Gadget Settings`.
- The `about_gadget.jsff` fragment has a `Panel Stretch Layout` component. The center facet of this component is populated with an `Active Output Text` component whose `Value` attribute is set to `About This Gadget`.

To enable custom actions on the task flow:

1. Place the `customactions` task flow inside a `Show Detail Frame` component on a customizable page, `MyPage.jspx`.

   For information about creating a customizable page, see Section 18.1.1, "How to Create a Customizable Page."

2. Add a `Custom Action` component from the Composer tag library as a child of the `Show Detail Frame` component, and set the `Action` and `Text` attributes to `ViewGadget` and `View Gadget` respectively.

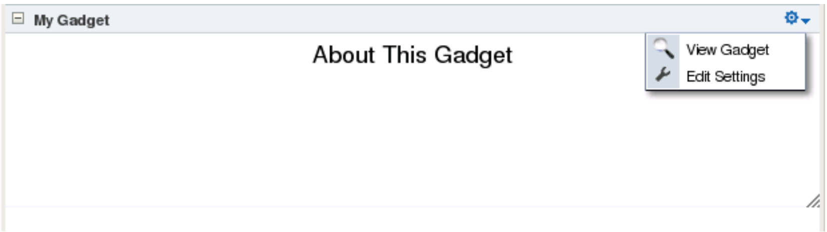
3. Add two more `Custom Action` components to the `Show Detail Frame`:

   - Set the `Action` and `Text` attributes for the first component to `EditSettings` and `Edit Settings` respectively.
   - Set the `Action` and `Text` attributes for the second component to `AboutGadget` and `About Gadget` respectively.

4. Save and run `MyPage.jspx`.

   The `view_gadget` page fragment is rendered in the `Show Detail Frame` component (named **My Gadget**) on the page. The Actions menu displays the **About Gadget** and **Edit Settings** options. Click **About Gadget** to navigate to the `about_gadget` fragment. Note that the Actions menu now displays the navigation rules for the other two fragments (Figure 20–4).

Figure 20–4 Custom Actions on a Show Detail Frame Enclosing a Task Flow

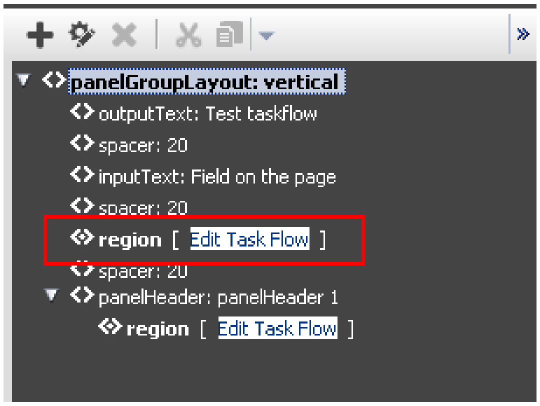


To see this in action, look at the Composer Custom Actions sample application, `ComposerCustomActions.jws`, on the Oracle WebCenter Suite 11*g* Demonstrations and Samples page on Oracle Technology Network (OTN).

20.4 Enabling Custom Actions that Display on Task Flows in the Component Navigator

The component navigator in Composer Structure view provides an option to zoom into a task flow and display the components on its page or fragment, as shown in Figure 20–5.

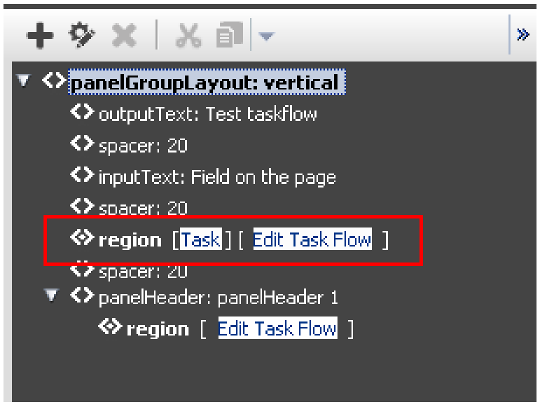
Figure 20–5 Edit Action on a Task Flow Instance



panelGroupLayout: vertical
outputText: Test taskflow
spacer: 20
inputText: Field on the page
spacer: 20
region [Edit Task Flow]
spacer: 20
panelHeader: panelHeader 1
region [Edit Task Flow]

Users can zoom in, edit the page or fragment, and zoom out of the task flow to navigate back to the page containing the task flow. In addition to the Edit Task Flow and Close links displayed next to a task flow name, you can configure your application to also display custom actions next to a task flow name, as shown in Figure 20–6.

Figure 20–6 Custom Action on a Task Flow Instance



panelGroupLayout: vertical
outputText: Test taskflow
spacer: 20
inputText: Field on the page
spacer: 20
region [Task] [Edit Task Flow]
spacer: 20
panelHeader: panelHeader 1
region [Edit Task Flow]

This section describes the procedure to enable custom actions on task flows in the component navigator. It contains the following sections:

- Section 20.4.1, "How to Configure Custom Actions in the Component Navigator"
- Section 20.4.2, "What Happens at Runtime"

20.4.1 How to Configure Custom Actions in the Component Navigator

To display custom actions against a task flow in the component navigator, you must create a Java bean that defines the custom action behavior and call this bean from the application page containing the task flow. This section describes the steps to do so in detail. It contains the following subsections:

- Section 20.4.1.1, "Defining the Logic for the Custom Action"
- Section 20.4.1.2, "Creating a JSPX Page Containing the Custom Action"
- Section 20.4.1.3, "Calling the JSPX Page from the Application Page Containing the Task Flow"

20.4.1.1 Defining the Logic for the Custom Action

To begin with, you must decide on the custom action you want to provide to users and create a Java bean with the logic to be implemented when a user selects the custom action. This section describes the steps to implement simple logic to display a message to users on clicking the custom action. The sample bean also contains the code to display the Close/Edit Task Flow links along with the custom link.

To create a Java bean:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, enter `BackingBean` in the **Name** field and click **OK**.

   The `BackingBean.java` file displays in Source view.
4. Import the required libraries as follows:

```
import javax.faces.application.FacesMessage;
import javax.faces.context.FacesContext;
import javax.faces.event.ActionEvent;
import oracle.adf.view.page.editor.sourceview.ComponentInfo;
```

5. Add the following code:

```
public class BackingBean {
  public BackingBean() {
  }

  public void action(ActionEvent actionEvent) {
      FacesContext context = FacesContext.getCurrentInstance();
      context.addMessage(null,
                         new FacesMessage(FacesMessage.SEVERITY_INFO, "Sample
message to test whether the custom action works.",
                                          null));
  }

  public boolean isRendered() {
      return ComponentInfo.isRegion();
  }

  public String getZoomText() {
      return ComponentInfo.isRootNode() ? "Close" : "Edit Task Flow";
  }
}
```

   With this logic, the sample message you defined is displayed when a user clicks the custom action link against a task flow region.

   Use the `isRegion()` API to ensure that the custom action link is displayed only against task flow regions on the page. Use the `isRootNode()` API to ensure that the

Edit Task Flow or Close link is displayed against the root component of the task flow.

6. Save the bean.

20.4.1.2 Creating a JSPX Page Containing the Custom Action

This section describes the procedure to create a JSPX page containing the custom action that you want to display to users in Composer.

To create the JSPX page:

1. In your application project, create a JSPX file called `customList.jspx`:

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **JSF Page**.

   c. Enter a name for the page and click **OK**.

2. Design the custom action UI using components like `Output Text` and `Command Link`, as shown in the following sample page:

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <af:componentDef var="attrs" componentVar="component">
    <af:panelGroupLayout id="dc_pgl1" rendered="#{backingBean.rendered}">
      <af:outputText value="[" id="dc_ot1"/>
      <af:commandLink text="Test" id="dc_cl1"
                      actionListener="#{backingBean.action}"
                      binding="#{backingBean.customLink}"/>
      <af:outputText value="]" id="dc_ot2"/>
      </af:panelGroupLayout>
    </af:componentDef>
</jsp:root>
```

   This sample creates a custom action called `Test`. The `actionListener` and `binding` attributes on this action are bound to `BackingBean`, which you created earlier.

3. To ensure that the default Edit Task Flow/Close options are also displayed next to the task flow, you must define a facet called `zoom`, as shown in the following example:

```
<af:xmlContent>
  <component xmlns="http://xmlns.oracle.com/adf/faces/rich/component">
    <facet>
      <facet-name>zoom</facet-name>
    </facet>
  </component>
</af:xmlContent>
```

4. Include the `zoom` facet in the page content as shown in the following example:

```
<af:outputText value="[" id="dc_ot3"/>
<af:facetRef facetName="zoom"/>
<af:outputText value="]" id="dc_ot4"/>
```

   The source of the `customLink.jspx` page is as follows:

```
<?xml version='1.0' encoding='UTF-8'?>
```

```
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <af:componentDef var="attrs" componentVar="component">
    <af:panelGroupLayout id="dc_pgl1" rendered="#{backingBean.rendered}">
      <af:outputText value="[" id="dc_ot1"/>
      <af:commandLink text="Test" id="dc_cl1"
                      actionListener="#{backingBean.action}"
                      binding="#{backingBean.customLink}"/>
      <af:outputText value="]" id="dc_ot2"/>
      <af:outputText value="[" id="dc_ot3"/>
      <af:facetRef facetName="zoom"/>
      <af:outputText value="]" id="dc_ot4"/>
      </af:panelGroupLayout>
      <af:xmlContent>
        <component xmlns="http://xmlns.oracle.com/adf/faces/rich/component">
          <facet>
            <facet-name>zoom</facet-name>
          </facet>
        </component>
      </af:xmlContent>
    </af:componentDef>
</jsp:root>
```

5. Save the JSPX page.

20.4.1.3 Calling the JSPX Page from the Application Page Containing the Task Flow

Let us assume that you have a simple JSPX page, `MyPage.jspx`, containing a task flow. The source of the page is as shown in the following example:

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"
          xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <f:view>
    <af:document id="d1">
      <af:form id="f1">
        <af:panelStretchLayout topHeight="50px" id="psl1">
          <f:facet name="top">
            <pe:changeModeLink id="cml1"/>
          </f:facet>
          <f:facet name="center">
            <!-- id="af_one_column_header_stretched"  -->
            <pe:pageCustomizable id="pageCustomizable1">
              <cust:panelCustomizable id="panelCustomizable1" layout="scroll">
                <af:region value="#{bindings.taskflowdefinition1.regionModel}"
                           id="r1"/>
              </cust:panelCustomizable>
              <f:facet name="editor">
                <pe:pageEditorPanel id="pep1"/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:panelStretchLayout>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

The task flow, `taskflowdefinition1`, contains the following `view.jsff` fragment:

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <af:panelGroupLayout layout="scroll" id="pgl1">
    <af:commandButton text="commandButton 1" id="cb1"/>
    <af:commandButton text="commandButton 2" id="cb2"/>
  </af:panelGroupLayout>
</jsp:root>
```

To display the custom action that you created, you must ensure that the `customLink.jspx` page is called from within Composer. Use the `sourceViewNodeAction` attribute on the `Page Customizable` component to reference the JSPX page containing the custom action.

The `Page Customizable` tag appears as follows in the page source:

```
<pe:pageCustomizable id="pageCustomizable1"
                     sourceViewNodeAction="/customLink.jspx">
```

The `sourceViewNodeAction` attribute can take the name of a JSPX file or an EL value that evaluates to a JSPX file name.

20.4.2 What Happens at Runtime

When you run `MyPage.jspx` to the browser and open the page in Composer Structure view, the component navigator displays a Test link and an Edit Task Flow link next to each task flow instance on the page.

20.5 Configuring a Keyboard Shortcut to Access Composer

Typically, users enter page Edit mode by clicking the Edit link or button on the page. You can now configure your application to enable users to enter page Edit mode using keyboard shortcuts. Further, you can configure your application to run some other event on using the shortcut keys. This section explains how to enable a keyboard shortcut to Composer and configure an event handler for the shortcut keys. It contains the following subsections:

- Section 20.5.1, "How to Enable Linkless Entry Into Edit Mode"
- Section 20.5.2, "How to Configure an Event Handler for the Shortcut Key"
- Section 20.5.3, "What Happens at Runtime"

20.5.1 How to Enable Linkless Entry Into Edit Mode

You can configure linkless entry into page Edit mode by adding a `<pe:mode-switch-key>` element to the application's `adf-config.xml` file. The default keyboard shortcut configured when you set the `<pe:mode-switch-key>` element is `ctrl+shift+E`. Users can use this key sequence to toggle between page View and Edit modes. However, you can configure a key of your choice by adding a `<pe:key-sequence>` property.

To add the `<pe:mode-switch-key>` property:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the `<pe:mode-switch-key>` property and set its value to `true`, as shown in Example 20–6. The example shows the `<pe:key-sequence>` property with the shortcut value `ctrl+E`.

Example 20–6 Enabling Linkless Edit Mode Entry

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:mode-switch-key>
    <pe:enabled>true</pe:enabled>
    <pe:key-sequence>ctrl E</pe:key-sequence>
  </pe:mode-switch-key>
. . .
</pe:page-editor-config>
```

3. Save the file.

20.5.2 How to Configure an Event Handler for the Shortcut Key

Use the `<pe:mode-switch-handler>` element to specify the event that must be triggered on using the shortcut keys, as shown in the following example:

```
<pe:mode-switch-key>
  <pe:enabled>true</pe:enabled>

<pe:mode-switch-handler>#{PageEditorBean.handleModeSwitch}</pe:mode-switch-handler
>
</pe:mode-switch-key>
```

where `handleModeSwitch` uses the `ModeChangeEvent` method to provide the logic to toggle between two modes, as shown in the following sample:

```
public void handleModeSwitch(ModeChangeEvent editMode)
  {
    // Your implementation to handle mode change goes here
  }
```

20.5.3 What Happens at Runtime

Users can access the application page and enter Edit mode by using the configured shortcut.

20.6 Creating Event-Enabled Task Flows

Composer provides a means of contextually wiring task flow events. You can wire a contextual event to an action handler to enable the passing of values from a producer component to a consumer component when the event is triggered on the producer.

For events to be available at runtime, event capability must be included in the task flow at design time. When you add event-enabled task flows to your customizable page, each task flow's Component Properties dialog includes an Events tab, where much of the wiring activity takes place. For information about including event capabilities, see the "Creating Contextual Events" section in *Fusion Developer's Guide for Oracle Application Development Framework*.

20.7 Configuring an Application Page to Display in Structure View by Default

When a user invokes Composer by clicking the Edit button or link on a page, the page opens in Add Content or Design view by default. If your business so requires, you can configure your application pages to display in Composer Structure view by default.

20.7.1 How to Configure an Application Page to Display in Structure View by Default

The `Edit Mode view` attribute on the `Page Customizable` component enables you to specify the default page view in Edit mode.

To open a page in Structure view by default:

1. Open your JSPX page in JDeveloper.
2. Select the **Page Customizable** component in the Structure Navigator.
3. In the Property Inspector, click the **Edit Mode View** attribute drop-down list and select **source**.

> **Note:** To open the page in Structure view for selected users only, you can specify an EL value for the `Edit Mode View` attribute.

4. Save the page.

Setting the Structure View Position and Size

By default, the component navigator in Structure view is displayed on the right side of the page, and its default width is 200 pixels. You can specify a different position or size for the component navigator using the `sourceViewPosition` and `sourceViewSize` attributes respectively on the `Page Customizable` component. For more information about these attributes, see Section B.1.1, "Page Customizable Component."

20.7.2 What Happens at Runtime

When a user clicks the Edit link or button on the page, Composer opens the page in Structure view.

20.8 Disabling Structure View for the Application

By default, Structure view is enabled in Composer-enabled pages. You can disable Structure view if you want to prevent users from being able to edit any page components other than task flows, portlets, and layout components. This section describes how. It contains the following subsections:

- Section 20.8.1, "How to Disable Structure View"
- Section 20.8.2, "What Happens at Runtime"

> **Note:** For information about the editing capabilities in Structure view, see Section 16.6, "Editing Capabilities in Structure View in Page Edit Mode."

20.8.1 How to Disable Structure View

You can disable Structure view by setting the `<pe:enable-source-view>` entry to `false` in the application's `adf-config.xml` file.

> **Note:** For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

To disable Structure view:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the `enable-source-view` property and set its value to `false`, as shown in Example 20–7.

Example 20–7 Disabling Structure View in adf-config.xml

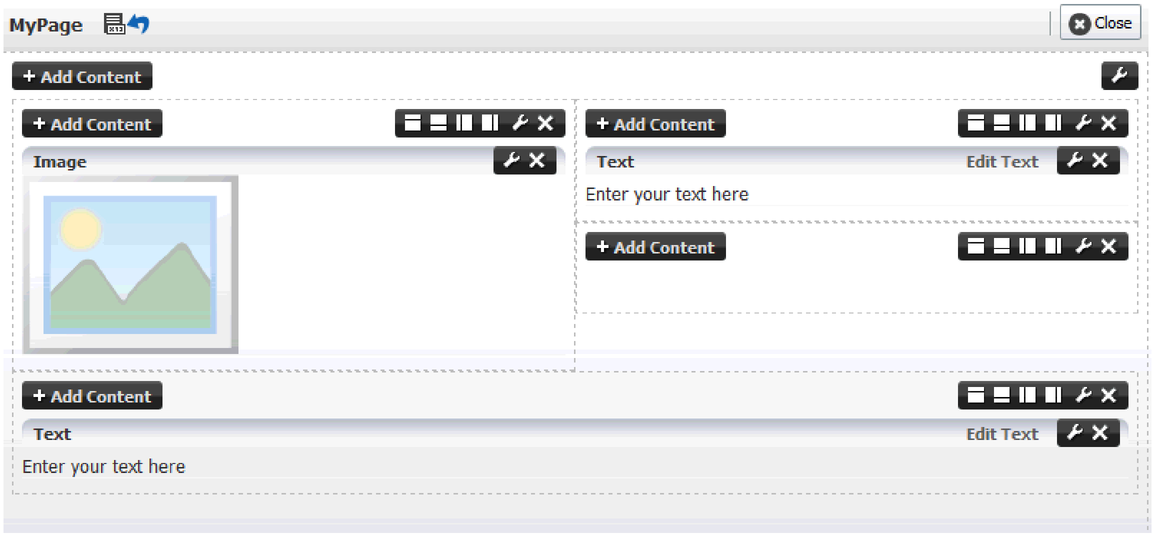
```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:enable-source-view>false</pe:enable-source-view>
</pe:page-editor-config>
```

3. Save the file.

20.8.2 What Happens at Runtime

When a user switches to page Edit mode, the page is rendered in Add Content or Design view and Structure view is not displayed to the user, as shown in Figure 20–7.

Figure 20–7 Add Content View of a Page without the Structure Tab



20.9 Disabling Task Flow Zoom Capability

You can disable the capability to zoom into task flows in the application by setting the `<pe:enable-zoom>` property to `false` in the application's `adf-config.xml` file.

> **Note:** For information about the Composer-specific configurations you can make in adf-config.xml, see Section B.2.2, "adf-config.xml."

To disable task flow zoom capability:

1. Open the adf-config.xml file, located in the ADF META-INF folder under Descriptors in the Application Resources panel.
2. Add the <pe:enable-zoom> property and set its value to false, as shown in Example 20–8.

Example 20–8 Disabling Task Flow Zoom Capability in adf-config.xml

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:source-view>
    <pe:enable-zoom>false</pe:enable-zoom>
  </pe:source-view>
</pe:page-editor-config>
```

3. Save the file.

The ability to zoom into task flows is disabled in the entire application.

20.10 Applying Styles to Components

You can change the look and feel of Composer components by applying different styles to the component header and content using one of the following methods:

- Build a skin using style selectors, and apply the skin to a Portal Framework application. For more information about style selectors and skins, see the "Customizing the Appearance Using Styles and Skins" chapter in *Web User Interface Developer's Guide for Oracle Application Development Framework*.
- Use JDeveloper style properties to specify style information through the Property Inspector. For more information, see Understanding contentStyle and inlineStyle Properties.

> **Notes:** Using JDeveloper style properties overrides the style information from the skin CSS. However, when you define a style property using JDeveloper, this style overrides styles for the selected component only—child components continue to use the styles specified in the skin.

You can adjust the look and feel of Page Customizable, Panel Customizable, Layout Customizable, and Show Detail Frame components at design time by changing the style-related properties inlineStyle and styleClass.

Show Detail Frame components have another associated style property, contentStyle, which defines the style for the content inside the component. The styleClass property enables you to select an extra style from the skin, whereas the inlineStyle and contentStyle properties override the comparable styles specified in the application skin for that particular instance of the component.

The inlineStyle property overrides styleClass. Additionally, properties set on a component instance affect only that instance of the component. Other component instances in the application are not affected.

Note: The `background` property is also useful in adjusting the look and feel of `Show Detail Frame` components. It is used to provide a dark, medium, or light color scheme for the component instance. Unlike `inlineStyle`, `contentStyle`, and `styleClass` properties, the `background` property works with skins. Depending on which value is specified for a component instance's `background` property, the skin applies the relevant style.

Understanding contentStyle and inlineStyle Properties

The style properties `inlineStyle` and `contentStyle` are alike in the types of attributes they support. They differ in their range of influence. While `inlineStyle` provides style information for the *entire component*, `contentStyle` provides style information only for *component content*. The `contentStyle` property is available to `Show Detail Frame` components but not to `Panel Customizable` components.

The `inlineStyle` property applies CSS to the root of the component, that is, the topmost DOM element. It does not override styles on child elements that are picking up color, font, and so on from a skin. For example, if a component header is skinned, then setting `inlineStyle` does not affect the component header. The `contentStyle` applies CSS to the DOM element that surrounds the *content* part of the component. In a `Show Detail Frame`, content refers to the area below the header.

On component content, the value specified for `contentStyle` takes precedence over the value specified for `inlineStyle`. Additionally, `contentStyle` on a component instance takes precedence over both `inlineStyle` and the `contentStyle` values of a parent component (such as a portlet nested in a `Panel Customizable` component).

20.11 Configuring the Persistence Change Manager

To persist user and application customizations across sessions, your application must be configured to use the change persistence framework. When you add Composer components to a customizable page, Composer configures the application to use

ComposerChangeManager so that changes made to a page at runtime are persisted appropriately. This section describes the default change manager configuration in new Portal Framework applications containing Composer-enabled pages.

The first time you add a Composer component to your application page, Composer does the following to enable change persistence:

- Adds the CHANGE_PERSISTENCE context parameter to the web.xml file, and sets the value to ComposerChangeManager. This context parameter registers the ChangeManager class to be used to handle persistence, as shown in the following example:

```
<context-param>
  <param-name>org.apache.myfaces.trinidad.CHANGE_PERSISTENCE</param-name>

<param-value>oracle.adf.view.page.editor.change.ComposerChangeManager</param-va
lue>
</context-param>
```

- Sets the persistent-change-manager element in the adf-config.xml file to the MDSDocumentChangeManager. Composer configures MDSDocumentChangeManager within the adf-faces-config section as follows:

```
<adf-faces-config xmlns="http://xmlns.oracle.com/adf/faces/config">
  <persistent-change-manager>
    <persistent-change-manager-class>
      oracle.adf.view.rich.change.MDSDocumentChangeManager
    </persistent-change-manager-class>
  </persistent-change-manager>
  . . .
</adf-faces-config>
```

  The taglib-config section in the file lists component tags and attributes that are persisted by default, as shown in the following example:

```
<adf-faces-config xmlns="http://xmlns.oracle.com/adf/faces/config">
    ...
    <taglib-config>
      <taglib uri="http://xmlns.oracle.com/adf/faces/customizable">
        <tag name="showDetailFrame">
          <persist-operations>all</persist-operations>
          <attribute name="expansionMode">
            <persist-changes>true</persist-changes>
          </attribute>
          <attribute name="contentStyle">
            <persist-changes>true</persist-changes>
          </attribute>
        </tag>
        <tag name="panelCustomizable">
          <persist-operations>all</persist-operations>
        </tag>
      </taglib>
      <taglib uri="http://xmlns.oracle.com/adf/pageeditor">
        <tag name="layoutCustomizable">
          <persist-operations>all</persist-operations>
          <attribute name="type">
            <persist-changes>true</persist-changes>
          </attribute>
        </tag>
      </taglib>
    </taglib-config>
```

```
</adf-faces-config>
```

You can further enable change persistence for other tags and attributes by defining them in this section and setting the `persist-changes` attribute to `true`. For more information, see Section 22.4.1, "How to Define Change Persistence at the Component Level."

If you want to persist changes to operations as well as attributes, include the `persist-operations` attribute and set the value to `all`. When the `persist-operations` attribute is included in a tag, the tag persists changes such as adding, moving, reordering, and removing children, and adding and removing facets.

For a list of ADF Faces components and attributes that are implicitly persisted, see the "Allowing User Customizations at Runtime" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*.

ComposerChangeManager

A `ChangeManager` class is required for persisting application customizations performed by end users. `ComposerChangeManager` handles change persistence both within a session and across sessions (to MDS). It delegates a user's changes to the appropriate change manager as follows:

- View mode changes are routed to `FilteredPersistenceChangeManager` to ensure that implicit customizations, such as column resizing and header collapse, work according to the filter rules configured in the application's `adf-config.xml` file.
- Edit mode changes are routed to `MDSDocumentChangeManager` to ensure that both implicit and explicit customizations are always persisted and available across sessions.

Notes: When you add Composer components to your application page, the option to enable customizations for the duration of the session (in the Project Properties dialog) is disabled. This is because changes in Composer-enabled application pages must be persisted across sessions, to MDS.

20.12 Configuring Runtime Resource String Editing

Component properties edited in Composer are available only in the current language. For example, if you add a task flow to your page, the task flow title you enter in Composer is available only in the current language. As a result, users in different locales do not see the translated values for such properties. To provide language support for component properties edited at runtime, Composer now provides users the option to edit resource strings for component display options that can take String values. This is similar to the resource string editor feature provided by ADF Faces in JDeveloper. Changes made to resource strings in Composer are saved into an override bundle, which gets translated along with other resource bundles in the application. The translated versions are then imported back into the application. This way, users are able to see the property values in their language.

Note: Composer supports creation of around 500 resource strings at runtime. Beyond this number, application performance slows down.

This section describes the steps to enable resource string editing. It contains the following sections:

- Section 20.12.1, "Overview of the Resource String Editor"
- Section 20.12.2, "How to Enable the Resource String Editor in Your Application"
- Section 20.12.3, "How to Configure the Override Bundle"
- Section 20.12.4, "What Happens at Runtime"

20.12.1 Overview of the Resource String Editor

At runtime, for component display options that can take String values, the Edit menu next to the property field provides a Select Text Resource option. Clicking this option opens the resource string editor, which provides options to search existing resources, edit or delete resource keys, and add new resource key/value pairs. For information about editing resource strings at runtime, see Section 16.5.5, "Edit Resource Strings."

Changes made to resource strings in Composer are saved into an application override bundle. This bundle is sent for translation and the translated versions are imported back into the application. This way, users are able to see the property values in their language.

The `ComposerOverrideBundle.xlf` is an empty XLIFF file that is packaged with Composer libraries. This bundle becomes available to the application when you add Composer components to the page at design time. At runtime, Composer uses this bundle internally to read from and write to the application override bundle while editing resource strings.

New and updated property values are saved into the override bundle. A user must specify a key, value, and description for each string being created or modified. All resource string changes made in an application are saved in a single override bundle. To distinguish runtime changes made in different layers, the key value is prefixed with the MDS layer name and value and must be in the format, `RT_<`*`MDS Layer Name`*`><`*`MDS Layer Value`*`>_`*`Key Name`*. For example, `RT_sitewebcenter_WELCOME_MESSAGE`. For a selected property, users can search and use resource strings created in any MDS layer. However, they can edit only those resource strings that were created in the same MDS layer. In addition to searching the override bundle, users can also search for strings created and used in the JSPX page at design time. Internally, Composer searches for all resource bundles defined using `c:set` tags in the JSPX file.

Runtime resource string changes in English are saved to the default application override bundle. Users can change the language and create or edit a resource string in that language. A separate override bundle is created for each language in which a user writes a resource string and the file name is suffixed with the initials for that language. For example, resource strings edited in French in `Application1` are saved in a bundle named `Application1OverrideBundle_fr.xlf`.

Current Limitations of the Resource String Editor

- Composer supports creation of around 500 resource strings at runtime. Beyond this number, application performance slows down
- The search criteria in the resource string editor is case-sensitive.
- To search for the description of a resource string, the user must provide the complete string value in the search criteria.
- The resource string editor does not display string descriptions for entries created in Properties bundle or List Resource bundle formats in JDeveloper.

- The option to edit resource strings is disabled for properties on the Parameters and Events tabs.

  If the EL value for an ADF resource is referenced in a page definition parameter, such as page parameter, task flow parameter, or portlet parameter, then the binding EL returns an empty value. Users must avoid referencing ADF resource EL values in page definition parameters.

20.12.2 How to Enable the Resource String Editor in Your Application

To enable resource string editing in your application, you must add a `<pe:resource-string-editor>` element in the `<pe:page-editor-config>` section of your application's `adf-config.xml` file, as follows:

```
<pe:page-editor-config>
  <pe:resource-string-editor>
    <pe:enabled>true</pe:enabled>
  </pe:resource-string-editor>
</pe:page-editor-config>
```

If you want to enable resource string selectively, based on specific criteria, such as the page being edited or the user or role, you can use an EL value for the `enabled` attribute.

20.12.3 How to Configure the Override Bundle

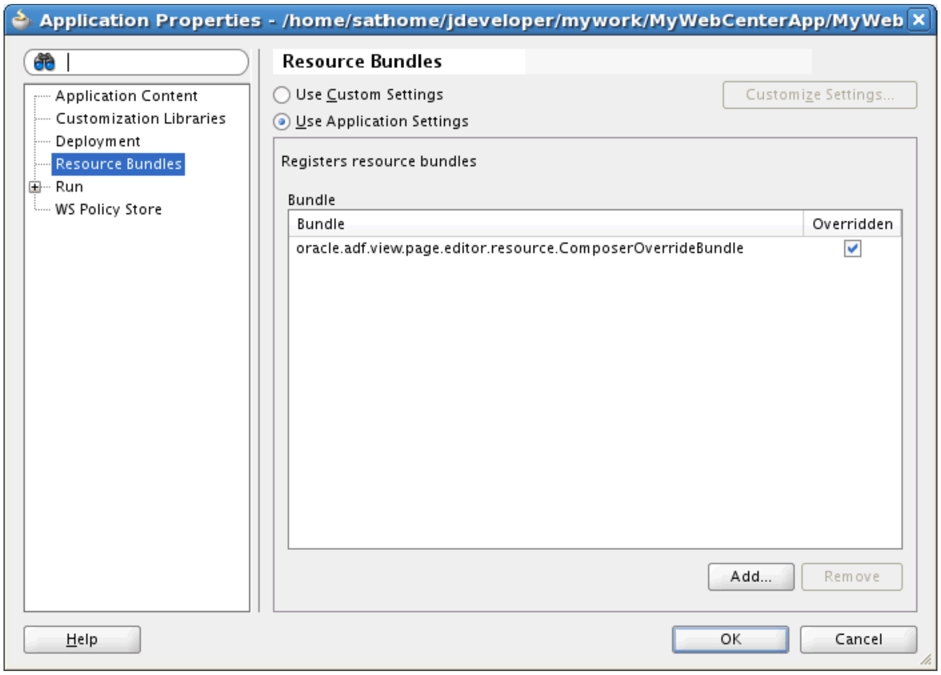
If you enable resource string editing in your application, you must configure your application to use the override bundle, `oracle.adf.view.page.editor.resource.ComposerOverrideBundle.xlf`, if it is not already being used. This override bundle is available in the `pageeditor.jar` file, and is used for reading and writing to the application override bundle when users create or edit resource strings at runtime.

To configure the override bundle:

1. Open your application in JDeveloper.
2. From the **Application** menu, select **Application Properties**.
3. Select Resource Bundles in the left panel of the Application Properties dialog.
4. If the Bundle section does not display `oracle.adf.view.page.editor.resource.ComposerOverrideBundle.xlf`, click the **Add** button to add the bundle.
5. In the File Name field in the Select Resource bundle dialog, enter `oracle.adf.view.page.editor.resource.ComposerOverrideBundle.xlf`, and click **Open**.
6. In the Application Properties dialog, select the **Overridden** check box (Figure 20–9).

   This ensures that the file is available to users at runtime.

Figure 20–9 Application Properties Dialog



○ Use Custom Settings

● Use Application Settings

Registers resource bundles

Bundle

Bundle	Overridden
oracle.adf.view.page.editor.resource.ComposerOverrideBundle	☑

7. Click **OK**.

Repeat the steps in this section to expose any of the resource bundles in your application to users at runtime.

> **Note:** To make a resource bundle accessible for runtime read and write operations, you must ensure that the Override option is selected for that bundle in the Application Properties dialog.
>
> You can make properties bundles, list resource bundles, and XLIFF resource bundles accessible at runtime.

20.12.4 What Happens at Runtime

When a user clicks the **Edit** icon next to a property that takes a String value, the Select Text Resource option is available. Clicking this option opens the resource string editor in which the user can create, modify, or delete resource strings. For more information, see Section 16.5.5, "Edit Resource Strings."

20.13 Troubleshooting Problems with Advanced Composer Configurations

This section provides information to assist you in troubleshooting problems you may encounter on performing advanced Composer configurations.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

You added a global- or instance-level `Custom Action`. However, it neither displays on the chrome nor in the **Action** menu on the `Show Detail Frame`.

Solution

Ensure the following:

- The first child of the `Show Detail Frame` must be `af:region`.
- The view currently displayed on the task flow must have an outcome in its task flow definition file that matches the action of `Custom Action`.
- If the action has the prefix `dialog:`, the outcome in the task flow definition must also have the same prefix.

For information, see Section 20.3.2, "How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow."

Problem

Composer is not working on ADF application pages. Errors are reported in the logs when using Oracle WebCenter Portal's resource catalog or Component Properties dialog. None of the customizations are saved. Objects are not getting added from the catalog.

Solution

Composer is compatible with the `MDSDocumentChangeManager` and `ComposerChangeManager`. You must set the `CHANGE_PERSISTENCE` context parameter in the `web.xml` file to either of these. The following example shows how to set CHANGE_PERSISTENCE to `MDSDocumentChangeManager`:

```
<context-param>
 <param-name>org.apache.myfaces.trinidad.CHANGE_PERSISTENCE</param-name>
 <param-value>oracle.adf.view.rich.change.MDSDocumentChangeManager</param-value>
</context-param>
```

When you configure Composer, the value of `CHANGE_PERSISTENCE` is changed to `oracle.adf.view.page.editor.change.ComposerChangeManager`.

21

Performing Composer-Specific MDS Configurations

This chapter describes how to create customization layers for saving changes made to a page at runtime. It also describes how to enable Composer sandbox creation to provide users the option to preview their changes before saving them to the back end.

This chapter contains the following topics:

- Section 21.1, "Introduction to MDS"
- Section 21.2, "Using Composer Sandbox"
- Section 21.3, "Adding Customization Layers to View and Edit Modes: Example"
- Section 21.4, "Troubleshooting MDS-Related Problems with Composer"

21.1 Introduction to MDS

Most industries customize their enterprise applications to serve different audiences and domains. Problems can arise when an application is modified at the site level. For example, upgrading an application with application-level customizations may lead to data loss or data-merge errors. Consequently, a new version of the application cannot be deployed until all merge conflicts are reconciled.

In the metadata domain, MDS provides the customization feature to address such problems. The customization feature allows for the creation of nonintrusive customization layers that are applied on top of the base application definitions. Customization layers, or layered changes, are described in their own documents and are stored separately from the base application definition. At runtime, applicable customizations are loaded from the metadata store and layered over the base metadata definition to produce the desired effect. Product upgrades and patches affect only the base metadata definition, so customizations continue to function properly.

Customization Layers

MDS enables clients to specify multiple customization types. For example, you can add customizations to runtime modes, application or user roles, application states, or any client specified criteria. Each such customization type is called a *customization layer* and is depicted using a `CustomizationClass`. A `CustomizationClass` is the interface MDS uses to identify the customization layer to be overlaid on the base definition. For example, you can configure your application to save customizations based on the departments to which users belong. You can create a customization layer called `DepartmentCC` in which application customizations made by users in different departments are stored in different folders within the layer. Another example would be to configure MDS to save View mode changes as user customizations in one layer and Edit mode changes as application customizations in another layer or vice versa.

Customization layers are applied in order of precedence, that is, if the same change is made in two different layers that apply to the given user and session, the change defined in the higher precedence layer is applied first.

When you implement a `CustomizationClass`, you must register it with the MDS. The MDS provides a means of associating a list of `CustomizationClass` types with a single `MetadataObject`. This is called the *fine-grained* association. The MDS also provides the means of associating a list of `CustomizationClass` types with a set of `MetadataObjects`. This is called the *coarse-grained* association. For information about the `CustomizationClass` and about creating a customization layer, see Section 21.3, "Adding Customization Layers to View and Edit Modes: Example."

Composer Sandbox

Typically, in a Portal Framework application, runtime customizations are saved immediately in the `*JDEV_HOME*/jdev/*system_directory*/o.mds.dt/adrs/*application_name*/AutoGeneratedMar/mds_adrs_writedir` directory. Changes made in both View and Edit modes are saved in this way. However, in certain circumstances, users might first want to apply customizations in their own view and evaluate whether to keep or cancel the changes before actually saving them to the back end. You can configure Composer to create a *sandbox* if you are using a database repository to store customizations. For information about creating a sandbox, see Section 21.2, "Using Composer Sandbox."

21.2 Using Composer Sandbox

A sandbox is a temporary storage layer for saving runtime page customizations until they are committed to the back end. If you configure a sandbox, a Save button is displayed on the Composer toolbar to enable users to save their changes. In a sandbox-enabled application, if a user clicks Close without first saving changes, a Close Confirm dialog prompts the user to save or cancel changes before closing Composer.

User customizations made in View mode are saved immediately. As such changes are available only to the user modifying the page, there is no particular value in reviewing such changes before saving.

Since Edit mode customizations are available to all users who access the page, you can enable a sandbox so that a user can experiment with page customizations and assess them before committing them. If you enable a sandbox for the application, a Save button is displayed on the Composer toolbar in page Edit mode.

This section discusses the steps you can take to enable sandbox creation and describes runtime behavior of a sandbox-enabled application. It contains the following subsections:

- Section 21.2.1, "How to Enable Composer Sandbox Creation"
- Section 21.2.2, "What Happens at Runtime"
- Section 21.2.3, "How to Disable Sandbox for an Application"
- Section 21.2.4, "How to Destroy Stale Sandboxes"

21.2.1 How to Enable Composer Sandbox Creation

You can enable a sandbox only if your application uses a database store. Therefore, you must ensure that you have configured a database store before performing the steps in this section. For information about setting up a database store, see *Configuring and Managing JDBC Data Sources for Oracle WebLogic Server*.

This section describes how to enable the creation of a Composer sandbox. It contains the following subsections:

- Section 21.2.1.1, "Updating Your Application's adf-config.xml File"
- Section 21.2.1.2, "Updating Your Application's web.xml File"
- Section 21.2.1.3, "Selecting a Database Store for Your Application"
- Section 21.2.1.4, "Enabling a Full Page Refresh at Runtime"

21.2.1.1 Updating Your Application's adf-config.xml File

By default, sandbox creation is enabled for all namespaces that are mapped to the default customization store (defined in the `<mds-config>` section of the `adf-config.xml` file). You can, however, enable sandbox for a selected number of namespaces only. To do this, you must add a `<pe:sandbox-namespaces>` element to the `adf-config.xml` file, and then define the namespaces for which you want to support sandbox creation.

> **Note:** For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

To configure sandbox creation in `adf-config.xml`:

1. Open the `adf-config.xml` file located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.

2. Under the `<metadata-namespaces>` element, ensure that `<namespace>` elements are defined for all metadata for which you want to enable sandbox creation, as shown in Example 21–1.

Example 21–1 Namespace Definitions in the adf-config.xml File

```
<!-- Your jspx customizations alone go here -->
   <namespace path="/pages" metadata-store-usage="WebCenterFileMetadataStore">
     <namespace-restriction type="CUSTOMIZATIONS"/>
   </namespace>
<!-- Your pagedef customizations alone go here -->
   <namespace path="/pageDefs" metadata-store-usage="WebCenterFileMetadataStore">
     <namespace-restriction type="CUSTOMIZATIONS"/>
     </namespace>
```

3. Add the `<pe:sandbox-namespaces>` element within the `<pe:page-editor-config>` section and add individual `<pe:namespace>` tags for all namespaces for which you want to enable sandbox creation, as show in Example 21–2.

Example 21–2 Configuring Namespaces for Sandbox Creation

```
<pe:sandbox-namespaces>
  <pe:namespace path="/pages"/>
  <pe:namespace path="/pageDefs"/>
</pe:sandbox-namespaces>
```

4. Save the adf-config.xml file.

21.2.1.2 Updating Your Application's web.xml File

To ensure that a sandbox is configured when you are in Edit mode of a page, you must create a filter in your application's web.xml file and set the appropriate filter mappings. All requests are then routed through this filter, and a sandbox is created for all Edit mode customizations. If you are using a file system metadata store, then there is no action performed on a filtered request.

> **Note:** For information about the Composer-specific configurations you can make in web.xml, see Section B.2.4, "web.xml."

This section provides the example of defining a Composer-specific filter and its relevant filter mappings in your application's web.xml file. It describes how to add the filter, WebCenterComposerFilter.

To define a Composer-specific filter and the filter mappings:

1. Open the *application_root*/Portal/public_html/WEB-INF/web.xml file.
2. Add WebCenterComposerFilter before the adfBindings filter:

```
<filter>
  <filter-name>composerFilter</filter-name>

<filter-class>oracle.adf.view.page.editor.webapp.WebCenterComposerFilter</filte
r-class>
</filter>
```

3. Add corresponding <filter-mapping> elements before the filter mapping for AdfBindingFilter as shown in Example 21–3.

Example 21–3 Filter Mappings for Composer-Specific Filter

```
<filter-mapping>
  <filter-name>composerFilter</filter-name>
  <servlet-name>Faces Servlet</servlet-name>
  <dispatcher>FORWARD</dispatcher>
  <dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

The <url-pattern> tag is used to specify the pages that must pass through the WebCenterComposerFilter so that sandbox creation can be enabled when a page goes into Edit mode.

> **Note:** The order in which you define filters is important. Requests pass through these filters sequentially and if they are not defined in the correct order, the application will not run as designed. Your web.xml file must have the WebCenterComposerFilter implementation first, followed by the AdfBindingFilter implementation.

4. Save the web.xml file.

21.2.1.3 Selecting a Database Store for Your Application

To enable sandbox creation, your application must be configured to use a database store. Therefore, while deploying your application to a WebLogic Managed Server, ensure that you select a database repository and specify a partition name for the application.

For information about deploying your application from JDeveloper to a WebLogic Managed Server, see Section 7.3.4.1, "Deploying to a Managed Server Using Local Data Sources."

21.2.1.4 Enabling a Full Page Refresh at Runtime

When you enable sandbox creation in your application, you must ensure that a full page refresh is performed on entering and exiting page Edit mode. For the detailed steps to be performed, see Section 21.3.7, "How to Redirect the Servlet to Enable Switch Between MDS Customization Layers."

21.2.2 What Happens at Runtime

When a user switches to page Edit mode, the presence of a **Save** button on the Composer toolbar indicates that sandbox creation is enabled for the application. Changes made to the page or shared components on the page are not saved until the user clicks Save. Once saved, the customizations are available to all application users. If the **Save** button is not rendered, then sandbox is not available and each change is committed immediately.

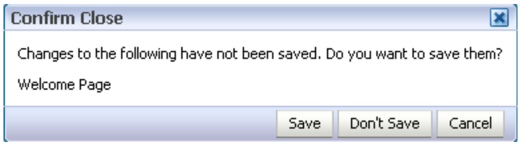
When editing component properties in the Component Properties dialog, clicking **Apply** results in the following:

- If the sandbox is not available, then the page is refreshed to display the changes made to component properties and changes are saved to the back end.
- If the sandbox is available, then the page is refreshed to display the changes made to component properties. To save changes, user must click **Save**.

Clicking **Save** or **Close** on the page results in the following events:

- On clicking **Save**, the sandbox is committed and a new sandbox is created. The page remains in Edit mode.
- On clicking **Close**, either of the following two events can occur:
  - If there are no changes since the last Save operation, then the sandbox is destroyed and Composer is closed, taking the user back to View mode.
  - If there are unsaved changes, then a Close Confirmation dialog lists the page name and unsaved task flow names, as shown in Figure 21–1.

Figure 21–1 Confirm Close Dialog in Composer



Changes to the following have not been saved. Do you want to save them?

Welcome Page

Users can select from the following options:

* Click **Save** to commit the sandbox and close Composer.
* Click **Don't Save** to destroy the sandbox and close Composer.

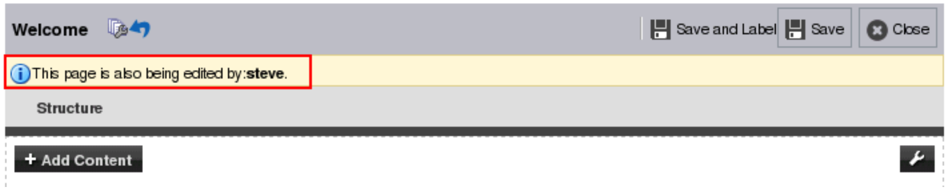
- * Click **Cancel** to close the dialog and return to Composer without saving the changes.

Notes: If a user navigates away from a page while editing it and then returns to the page, any unsaved changes are lost.

What Happens During Concurrent Edits

If two or more users are editing the same page or task flow using the same customization layer, then the page displays a message to each user that another user is editing the page or task flow, as shown in Figure 21–2.

Figure 21–2 Page Concurrency Message



This page is also being edited by:**steve**.

If two or more users have zoomed into a task flow at the same time in the same customization layer and are editing it, then a concurrency message appears, as shown in Figure 21–3.

Figure 21–3 Task Flow Concurrency Message

The shared taskflow **AccountActivities** is also being edited by **steve** via */AccountDashboard/faces/oracle/apps/pages/Welcome.jspx*

Note: If a user zoomed into a task flow, made some customizations, and zoomed out of the task flow, then the task flow concurrency message continues to display to other users until that user saves the customizations.

Changes that are saved last overwrite prior changes. For example, if users A and B are editing a page or task flow simultaneously, then concurrency issues are handled as follows:

- If A saves the page or task flow first, then A's changes are committed to MDS. Later, when B saves the page or task flow, A's changes are overwritten with B's changes.
- If A deletes a component while B is trying to personalize (say move) that same component in View mode, a WebCenter error page is displayed to B. B has to simply navigate back to the original page. The deleted component does not appear, and B can continue working on other components.

21.2.3 How to Disable Sandbox for an Application

To ensure that changes are committed to the back end immediately, you can disable the sandbox.

To disable sandbox:

1. Open the `adf-config.xml` file located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Under the `<pe:page-editor-config>` element, add the `<pe:disable-sandbox>` attribute and set it to `true`.
3. Save `adf-config.xml`.

21.2.4 How to Destroy Stale Sandboxes

When users edit a page at runtime, if the browser closes unexpectedly or the user navigates away from the page, the sandbox used in that session is still available. Any other user accessing the same page continues to see a concurrency message that another user is editing the same page. You can destroy such stale sandboxes to free some space in the database store and enhance performance.

You can ensure that a stale sandbox is destroyed when:

- A session times out.

  The `<session-timeout>` element in the application's `web.xml` file defines the time duration after which the sandbox is destroyed. To ensure this happens, you must configure `WebCenterComposerSessionListener` in your application's `web.xml` file. This listener is called when a session times out. It creates a new sandbox when the same user enters page Edit mode.

- The user logs in to Edit mode of the page again, with the same user name.

  In this case, a new sandbox is created when the same user switches to Edit mode.

To configure `WebCenterComposerSessionListener`:

1. Open the *`application_root`*`/Portal/public_html/WEB-INF/web.xml` file.
2. Define a new listener, `WebCenterComposerSessionListener`, as shown in the following example:

```
<listener>
  <description>Composer Http Session Listener</description>
  <display-name>Composer Http Session Listener</display-name>
  <listener-class>
    oracle.adf.view.page.editor.webapp.WebCenterComposerSessionListener
  </listener-class>
</listener>
```

3. Save the `web.xml` file.

For information about the Composer-specific configurations you can make in `web.xml`, see Section B.2.4, "web.xml."

21.3 Adding Customization Layers to View and Edit Modes: Example

You can apply customizations to a metadata object based on client-defined criteria. For example, you can customize an application and the metadata objects that it uses based on an end user's permissions, an application's deployment location (also called *localization*), or a specific industry domain. Each such category—permissions, localization, and domain—denotes a customization layer, and each is depicted using a `CustomizationClass`. A `CustomizationClass` is the interface MDS uses to identify the customization layer to be overlaid on the base definition. See Section 21.3.3, "How to Create a Custom UserCC Tip Layer" for an example.

When you implement a CustomizationClass, you must also register it with the MDS. The MDS provides the ability to associate a list of CustomizationClass types with a single MetadataObject. This is called *fine-grained* association. The MDS also provides the ability to associate a list of CustomizationClass types with a set of MetadataObjects. This is called the *coarse-grained* association.

A customizable application can have multiple customization layers. You can select the layer to which you want to apply customizations. The layer you choose to customize is called the tip layer. When you drop Composer components onto a JSF page, the ADF configures a default SiteCC (site) tip layer in the application. Consequently, the adf-config.xml file is updated to include the SiteCC customization class. This tip layer stores all customizations made to the page.

This section explains through example how adding customization tip layers to View and Edit runtime modes provides user customization capabilities to all users and application customization capabilities to selected users. To enable application customizations in the Edit mode, the site tip layer is added. To enable user customization in View mode, the user tip layer is added. By default, the user tip layer is applied on top of the site tip layer. The user tip layer stores all user customizations made in View mode in a specific location created for the user who made them. Such changes are visible only to that user. The site tip layer stores all application customizations made in the Edit mode and are visible to all users.

To enable tip layers at runtime, Composer provides the WebCenterComposerFilter filter and supplies a means of defining an abstract factory for creating the MDS SessionOptions object. This object provides applicable customization layers at runtime and enables users to perform user customizations (View mode) or application customizations (Edit mode) based on their role. When creating a new MDS session, the MDSSession.createSession method of this object is used to specify the session options.

This section provides an example exercise for creating, implementing, and registering customization layers, configuring WebCenterComposerFilter, and switching between MDS customization layers. It contains the following subsections:

- Section 21.3.1, "How to Add Composer to a JSF Page"
- Section 21.3.2, "How to Create a Custom SiteCC Tip Layer"
- Section 21.3.3, "How to Create a Custom UserCC Tip Layer"
- Section 21.3.4, "How to Implement the ComposerSessionOptionsFactory Class"
- Section 21.3.5, "How to Register the Implementation with Composer"
- Section 21.3.6, "How to Configure WebCenterComposerFilter"
- Section 21.3.7, "How to Redirect the Servlet to Enable Switch Between MDS Customization Layers"
- Section 21.3.8, "What Happens at Runtime"

21.3.1 How to Add Composer to a JSF Page

This section describes how to add the Page Customizable component to a JSF page. The purpose of this exercise is to provide Composer in the Edit mode at runtime so that the admin user can perform customizations at the site level. This section includes the addition of a Change Mode Link to enable switching from View mode to Edit mode at runtime.

To add Composer to a JSF Page:

1. Open the JSPX page and select **Composer** from the Component Palette.
2. Select **Change Mode Link** and drop it onto the page.
3. Select **Page Customizable** and drop it onto the page.

   The Source view should like this:

   ```
   <af:form id="f1">
     <pe:changeModeLink id="cml1"/>
     <pe:pageCustomizable id="pageCustomizable1">
       <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
         <f:facet name="editor">
           <pe:pageEditor id="pep1"/>
         </f:facet>
     </pe:pageCustomizable>
   </af:form>
   ```

   When you drop these components onto the page, the default `SiteCC` tip layer is extended by the ADF. Consequently, the `adf-config.xml` file is updated with this customization class:

   ```
   <cust-config>
     <match>
       <customization-class name="oracle.adf.share.config.SiteCC" />
     </match>
   </cust-config>
   ```

   > **Note:** If you want your application to use `UserCC` as the default tip layer, you can simply replace `oracle.adf.share.config.SiteCC` with `oracle.adf.share.config.UserCC` in the `cust-config` section of the `adf-config.xml` file. However, to use `UserCC` as the default tip layer, you must have secured your application. You cannot implement a `UserCC` tip layer without provisioning users and roles in your application.

21.3.2 How to Create a Custom SiteCC Tip Layer

This section describes how to create a custom `SiteCC` tip layer, `site`, in which all application-level customizations performed in Edit mode are stored. In this sample application, application-level customizations are stored in the `/mds/mdssys/cust/site/webcenter/`*`pagename`*`.jspx.xml`directory.

To create the `site` tip layer:

1. From the File menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.

3. In the **Name** field, enter `SiteCC`.
4. In the **Extends** field, enter `CustomizationClass`.

   This imports `oracle.mds.cust.CustomizationClass`.

   Ensure the **Implement Abstract Methods** check box is selected.

5. Click **OK.**

   The `SiteCC.java` file is rendered in the Source view.

6. In the Source view, press `Enter` after `public class SiteCC extends CustomizationClass`, and add the following `string`:

   ```
   {
     private static final String DEFAULT_LAYER_NAME = "site";
     private String mLayerName = DEFAULT_LAYER_NAME;
     private String mLayerValue = "webcenter";
   ```

   The following libraries are imported:

   ```
   import oracle.mds.core.MetadataObject;
   import oracle.mds.core.RestrictedSession;
   import oracle.mds.cust.CacheHint;
   ```

7. Update the code as shown in **bold** here:

   ```
   public class SiteCC extends CustomizationClass
   {
     private static final String DEFAULT_LAYER_NAME = "site";
     private String mLayerName = DEFAULT_LAYER_NAME;
     private String mLayerValue = "webcenter";
     //Note: You can provide any site name.

     public CacheHint getCacheHint()
     {
       return CacheHint.ALL_USERS;
     }

     public String getName()
     {
       return mLayerName;
     }

     public String[] getValue(RestrictedSession mdsSession, MetadataObject mo)
     {
       return new String[] { mLayerValue };
     }
   }
   ```

8. Save the `SiteCC.java` file.

21.3.3 How to Create a Custom UserCC Tip Layer

This section describes an example showing how to create a custom `user` tip layer for a user, `scott`. This layer is applied on top of the `site` layer. The user customizations that a user performs in View mode are saved in this `user` tip layer in a folder created specifically for the logged-in user. In this example, the user customizations performed in View mode are saved in the `/mds/mdssys/cust/user/scott/`*`pagename`*`.jspx.xml` directory.

> **Note:** For illustration purpose, this example describes a simple scenario where a `UserCC` tip layer is created for just one user, `scott`. In a real life application, you can configure the `UserCC` layer to return the name of the user who requested the page.

To create the user tip layer:

1. From the **File** menu, choose **New**.

2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.

3. In the **Name** field, enter `UserCC`.
4. In the **Extends** field, enter `CustomizationClass`.

   This imports the `oracle.mds.cust.CustomizationClass`.

   Ensure the **Implement Abstract Methods** check box is selected.

5. Click **OK.**

   The `UserCC.java` file displays in the Source view.

6. In the Source view, press `Enter` after `public class UserCC extends CustomizationClass`, and add the following `string`:

```
{
  private static final String DEFAULT_LAYER_NAME = "user";
  private String mLayerName = DEFAULT_LAYER_NAME;
  private String mLayerValue = "scott"; //The name of the logged-in user
in this example. The logged-in user name can be acquired dynamically.
```

   The following libraries are imported:

```
import oracle.mds.core.MetadataObject;
import oracle.mds.core.RestrictedSession;
import oracle.mds.cust.CacheHint;
```

7. Update the code as shown in **bold** here:

```
public class UserCC extends CustomizationClass
{
  private static final String DEFAULT_LAYER_NAME = "user";
  private String mLayerName = DEFAULT_LAYER_NAME;
  private String mLayerValue = "scott";

  public CacheHint getCacheHint()
  {
    return CacheHint.USER;
  }

  public String getName()
  {
    return mLayerName;
  }

  public String[] getValue(RestrictedSession mdsSession, MetadataObject mo)
  {
    return new String[]{mLayerValue};
  }
}
```

8. Save the `UserCC.java` file.

21.3.4 How to Implement the ComposerSessionOptionsFactory Class

In this section, the `ComposerSessionOptionsFactory` class provided by the ADF is implemented to supply MDS `SessionOptions` for each HTTP request.

To implement the `ComposerSessionOptionsFactory` class:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `AppsSessionOptionsFactoryImpl`.
4. Click **OK.**

   The `AppsSessionOptionsFactoryImpl.java` file is rendered in the Source view.
5. Import the following libraries:

```
import oracle.adf.view.page.editor.mds.ComposerSessionOptionsFactory;
import oracle.adf.view.page.editor.mode.ModeContext;
import oracle.mds.config.CustClassListMapping;
import oracle.mds.config.CustConfig;
import oracle.mds.core.SessionOptions;
import oracle.mds.cust.CustClassList;
import oracle.mds.cust.CustomizationClass;
```

6. Add the following code to implement the `ComposerSessionOptionsFactory` class and provide `SessionOptions`:

```
public class AppsSessionOptionsFactoryImpl
  implements ComposerSessionOptionsFactory
{

  public SessionOptions createSessionOptions(SessionOptions
defaultSessionOptions, String mode)
  {
    CustomizationClass[] custLayer;
    CustConfig custConfig = null;

    if (ModeContext.EDIT_MODE.equals(mode))
    {
      //Mode is Edit, change to SiteCC
      custLayer = EDIT_LAYER;
    }
    else
    {
      //Mode is View, change to UserCC + SiteCC
      custLayer = VIEW_LAYER;
    }

    try
    {
      CustClassList custClassList = new CustClassList(custLayer);
      CustClassListMapping custClassListMapping =
        new CustClassListMapping("/", null, null, custClassList);
      custConfig = new CustConfig(new CustClassListMapping[]
        { custClassListMapping });
    }
    catch (Exception e)
    {
      e.printStackTrace();

    }
if(defaultSessionOptions.getServletContextAsObject() != null)
{
    return new SessionOptions(defaultSessionOptions.getIsolationLevel(),
                              defaultSessionOptions.getLocale(), custConfig,
                              defaultSessionOptions.getVersionContext(),
                              defaultSessionOptions.getVersionCreatorName(),
                              defaultSessionOptions.getCustomizationPolicy(),

defaultSessionOptions.getServletContextAsObject());
  }
    else
    {
      return new SessionOptions(defaultSessionOptions.getIsolationLevel(),
                              defaultSessionOptions.getLocale(), custConfig,
                              defaultSessionOptions.getVersionContext(),
                              defaultSessionOptions.getVersionCreatorName(),
                              defaultSessionOptions.getCustomizationPolicy());
    }
  }

  //Edit mode SiteCC
  private static final CustomizationClass[] EDIT_LAYER =
    new CustomizationClass[]
    { new SiteCC() };

  //View mode SiteCC + USerCC
  private static final CustomizationClass[] VIEW_LAYER =
    new CustomizationClass[]
    { new SiteCC(), new UserCC() };

}
```

7. Save the `AppsSessionOptionsFactoryImpl.java` file.

21.3.5 How to Register the Implementation with Composer

For the `site` and `user` customization layers to function, you must register the `ComposerSessionOptionsFactory` class with Composer. For example, if the concrete class is `view.AppsSessionOptionsFactoryImpl`, the following snippet must be added to the `adf-config.xml` file located in the `/.adf/META-INF` folder in your application directory:

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">

<pe:session-options-factory>view.AppsSessionOptionsFactoryImpl</pe:session-options
-factory>
</pe:page-editor-config>
```

21.3.6 How to Configure WebCenterComposerFilter

You must configure the `WebCenterComposerFilter` filter in the `web.xml` file located in the `Portal/public_html/WEB-INF` folder in your application directory. This filter registers Composer's concrete `SessionOptionsFactory` with the ADF for every HTTP request. When the filter receives a call from the ADF, it forwards the request to the application and gets the `SessionOptions` with the new customized layer. If you have not set the `Sandbox` or `VersionContext` in the `SessionOptions`, then Composer sets its own Sandbox and returns it to the ADF. For more information on Sandbox, see Section 21.2.1, "How to Enable Composer Sandbox Creation."

The `composerFilter` and its filter mapping must be configured before `ADFBindingFilter`. For example, see the following `web.xml` file:

```
....

  <!-- WebCenterComposerFilter goes here -->
  <filter>
    <filter-name>composerFilter</filter-name>

<filter-class>oracle.adf.view.page.editor.webapp.WebCenterComposerFilter</filter-c
lass>
  </filter>
  <filter>
    <filter-name>adfBindings</filter-name>
    <filter-class>oracle.adf.model.servlet.ADFBindingFilter</filter-class>
  </filter>
.....
  <!-- WebCenterComposerFilter mapping goes here -->
  <filter-mapping>
    <filter-name>composerFilter</filter-name>
    <servlet-name>Faces Servlet</servlet-name>
    <dispatcher>FORWARD</dispatcher>
    <dispatcher>REQUEST</dispatcher>
  </filter-mapping>
  <filter-mapping>
    <filter-name>adfBindings</filter-name>
    <servlet-name>Faces Servlet</servlet-name>
    <dispatcher>FORWARD</dispatcher>
    <dispatcher>REQUEST</dispatcher>
  </filter-mapping>
....
```

Note: The order in which you define filters is important. Requests pass through these filters sequentially and if they are not defined in the correct order, the application will not run as designed. Your `web.xml` file must have the `WebCenterComposerFilter` implementation first, followed by the `AdfBindingFilter` implementation.

For information about the Composer-specific configurations you can make in `web.xml`, see Section B.2.4, "web.xml."

21.3.7 How to Redirect the Servlet to Enable Switch Between MDS Customization Layers

To redirect the servlet, that is, to refresh the full page at runtime, you must create:

- The `AppNavigationUtils` class, which calls the `AppNavigationUtils.redirectToSamePage()` method
- The `AppCloseHandler` CloseListener, which uses the `AppNavigationUtils` class
- The `AppModeBean`, which displays Edit mode

This section describes how to create these objects. It contains the following subsections:

- Section 21.3.7.1, "How to Create the AppNavigationUtils Class (start here)"
- Section 21.3.7.2, "How to Create AppCloseHandler"
- Section 21.3.7.3, "How to Register the AppCloseHandler"

- Section 21.3.7.4, "How to Create AppModeBean"

21.3.7.1 How to Create the AppNavigationUtils Class (start here)

To create the `AppNavigationUtils` class:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `AppNavigationUtils` and click **OK**.

   The `AppNavigationUtils.java` file is rendered in the Source view.
4. Import the following libraries:

```
import javax.faces.context.FacesContext;
import javax.servlet.http.HttpServletRequest;
```

5. Add the following code:

```
public class AppNavigationUtils
{

  public static void redirectToSamePage()
  {
    HttpServletRequest request =
(HttpServletRequest)FacesContext.getCurrentInstance().getExternalContext().getR
equest();
    String url = request.getRequestURL().toString();
    String _adfCtrlState = request.getParameter("_adf.ctrl-state");
    url = url + "?_adf.ctrl-state="+ _adfCtrlState;
    System.out.println(url);
    try
    {
      FacesContext.getCurrentInstance().getExternalContext().redirect(url);
      FacesContext.getCurrentInstance().responseComplete();
    }
    catch(Exception e)
    {
      e.printStackTrace();
    }
  }
}
```

6. Save the `AppNavigationUtils.java` file.

21.3.7.2 How to Create AppCloseHandler

To create `AppCloseHandler`:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `AppCloseHandler` and click **OK**.

   The `AppCloseHandler.java` file displays in the Source view.

4. Import the following libraries:

```
import oracle.adf.view.page.editor.event.CloseEvent;
import oracle.adf.view.page.editor.event.CloseListener;
```

5. Add the following code:

```
public class AppCloseHandler
  implements CloseListener
{

  public void processClose(CloseEvent closeEvent)
  {
    AppNavigationUtils.redirectToSamePage();
  }
}
```

6. Save the `AppCloseHandler.java` file.

21.3.7.3 How to Register the AppCloseHandler

After creating `AppCloseHandler`, you must register it in the Composer extension file, `pe_ext.xml`.

To register the event handler:

1. In the `pe_ext.xml` file, add the following entries:

```
<event-handlers>
  <event-handler event="close">view.AppCloseHandler</event-handler>
</event-handlers>
```

2. Save the file.

For more information about event handlers, see Section 19.6, "Configuring Event Handlers for Composer UI Events."

21.3.7.4 How to Create AppModeBean

To create `AppModeBean`:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `AppModeBean` and click **OK**.

   The `AppModeBean.java` file displays in the Source view.
4. Import the following libraries:

```
import javax.faces.event.ActionEvent;
import oracle.adf.view.page.editor.mode.ModeContext;
```

5. Add the following code:

```
public class AppModeBean
{

  public void edit(ActionEvent actionEvent)
  {
    ModeContext.getCurrent().setEditMode();
```

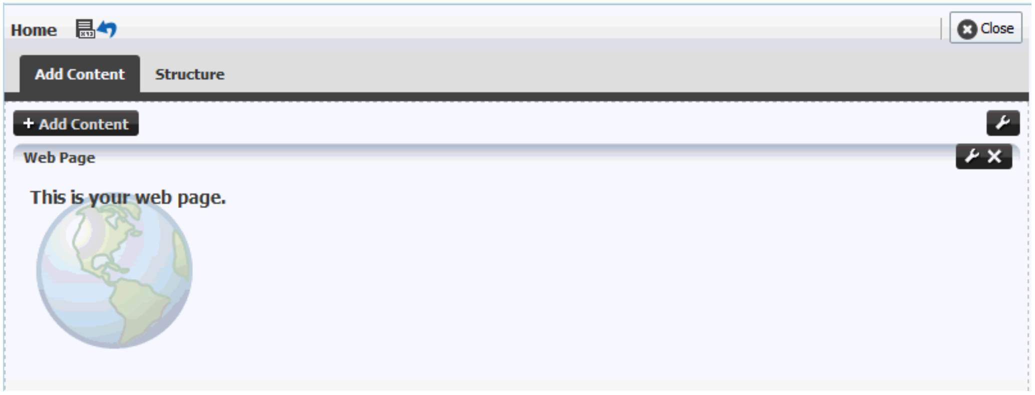
```
            AppNavigationUtils.redirectToSamePage();
          }
        }
```

6. Save the file.

21.3.8 What Happens at Runtime

To see how the `site` customization layer functions, first run the JSF page in a browser. Then log in to the page as `admin`, and click the **Edit** link to switch to Edit mode. At runtime, customize the page. For example, drop a Web page, movable box, or an image onto the page. The page should look like Figure 21–4.

Figure 21–4 Customized Page



Go to `/mds/mdssys/cust/site/webcenter` in your application directory, and open the *`pagename`*`.jspx.xml` file. This is where the application-level customizations that you made to the page are stored.

To use the `user` customization layer, log in to the page as `scott` and personalize the page in View mode. Then go to `/mds/mdssys/cust/user/scott` in your application directory, and open the *`pagename`*`.jspx.xml` file. This is where the user-level customizations that you made to the page are stored.

21.4 Troubleshooting MDS-Related Problems with Composer

This section provides information to assist you in troubleshooting MDS-related problems you may encounter while using Composer.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

Your application is configured to use MDS sandbox. When you run the application, the sandbox either does not work or generates exceptions.

Solution

Ensure the following:

- A database repository is used. Sandbox works only with a database-based repository, and not with a file-based repository.

- Ensure that the order of filters in `web.xml` is correct. The `<filter>` entries must be in the correct order for sandbox to work correctly.

For information, see Section 21.2, "Using Composer Sandbox."

22

Modifying Default Security Behavior of Composer Components

This chapter describes how to override the default security behavior of Composer components.

This chapter contains the following topics:

22.1 Applying Component-Level Restrictions by Defining Customization Policies

By default, the MDS restricts application customization of page components, that is, users cannot customize components or their attributes at runtime. To enable application customization, you must lift the default restrictions on components and their attributes. When you add a `Page Customizable` component to the page and populate it with content, the default customization restrictions on the `Page Customizable` and all its child components are lifted. However, in some instances, such as when the `Page Customizable` component is part of the template used for the page, you may need to explicitly allow application customization of components and their attributes. This section describes how to apply MDS type-level restrictions or instance-level restrictions on components and their attributes.

This section contains the following subsections:

Note: For information about creating customizable pages using page templates, see Section 18.1.7, "How to Create a Page Template for Creating Customizable Pages."

22.1.1 How to Define Type-Level Customization Policies

When you apply type-level restrictions on a component, all instances of the component are restricted. This is useful if you want to allow only a specific set of users to edit a particular component or its attributes while restricting all other users from editing it. For example, if you want to allow only a page creator or application administrator to change the page layout at runtime, you can define type-level restrictions on the `Layout Customizable` component and enable only users with `admin` role to edit this component.

You can enable type-level restrictions on components and their attributes in a standalone XML file and then register this file in the `mds-config` section of the `adf-config.xml` file or in an `mds-config.xml` file. The standalone XML file contains annotations that match the types for which customization restrictions must be specified.

You can create an `mds-config.xml` file in your application's `META-INF` directory and register the standalone file in the `mds-config.xml` file.

To enable application customization of selected components or attributes at the type level:

1. Create an XML document, for example `standalone.xml`, add the following code, and replace the text in bold with appropriate values:

   ```
   <?xml version="1.0" encoding="UTF-8" ?>
   <grammarMetadata xmlns="http://xmlns.oracle.com/bali/xml/metadata"
                    xmlns:mds="http://xmlns.oracle.com/mds"
                    namespace="tag_namespace">
     <elementMetadata elementName="component_name">
       <mds:customizationAllowed>true</mds:customizationAllowed>
         <attributeMetadata attributeName="attribute_name">
           <mds:customizationAllowedBy>security_roles</mds:customizationAllowedBy>
         </attributeMetadata>
     </elementMetadata>
   </grammarMetadata>
   ```

   The `<customizationAllowedBy>` tag can appear only once. Multiple values can be specified as a space-separated list of allowed policies as part of the declaration. To enable or disable application customization for specific users or roles, the users or roles must be included in the customization policy of the MDS session. For more information, see Section 22.2.3, "How to Customize the SessionOptions Object to Include Customization Policy."

   The `<customizationAllowed>` tag takes a Boolean as its value. A value of `true` for this tag means that anyone can customize the specified component, so long as other inherited customization polices allow it.

   The `<customizationAllowedBy>` tags do not serve any purpose if the same object has been tagged with `<customizationAllowed>false</ customizationAllowed>`. Additionally, the customization must be allowed at the top level of the object tree. Otherwise the default behavior dictates that no customization can be permitted at a lower level.

2. Register this XML file in either of the following ways:

To register the XML file in the adf-config.xml file, add the type-config element inside the mds-config section using the following format:

```
<mds-config xmlns="http://xmlns.oracle.com/mds/config">
  <type-config>
    <standalone-definitions>
      <classpath>File_Path/standalone.xml</classpath>
    </standalone-definitions>
  </type-config>
</mds-config>
```

Create an mds-config.xml file in your application's META-INF folder and add a type-config element inside the mds-component-config section of the file in the following format:

```
<?xml version="1.0" encoding="UTF-8" ?>
<mds-component-config version="11.1.1.000"
xmlns="http://xmlns.oracle.com/mds/config">
  <type-config>
    <standalone-definitions>
      <classpath>File_Path/standalone.xml</classpath>
    </standalone-definitions>
  </type-config>
</mds-component-config>
```

3. Make the standalone files and associated XSDs available in a shared library JAR file; otherwise MDS cannot load them.

   At runtime, MDS searches all mds-config instances in the META-INF directories and loads all the customization restrictions specified in standalone files.

22.1.2 How to Define Instance-Level Customization Policies

Instance-level restrictions are useful if you want to allow or restrict customization of a particular instance of a component. The code for instance-level customization policies is similar to that used in the type-level policy definitions. However, instance-level policies override type-level policies. That is, instance-level restrictions hold true irrespective of the restrictions from the type. For example, if you have used a form with some UI elements in your login page and in other pages such as a user preferences page, you may want to allow users to customize all instances of the form except on the login page. For this, you can allow customization of the form at the type level and restrict customization only on the instance in the login page.

You can enable customization on a component or any of its attributes at the instance level. To apply customization restriction at the component level, you can set the customizationAllowed and customizationAllowedBy attributes on the component in JDeveloper (see Section 22.1.1, "How to Define Type-Level Customization Policies"). To apply restrictions on a component's attributes, perform the steps described in this section.

Instance-level policies for component attributes are defined in an RDF file. The RDF file is picked up by MDS, and the policies are implemented.

To define instance-level customization policies:

1. Create an RDF file with the same name as the JSPX file, but using the RDF extension, for example main.jspx.rdf.

   Create this file in the *application_home*/*project*/public_html/mdssys/mdx folder. Creating the RDF file in this folder structure ensures that the file is picked up by MDS and the policies defined here are implemented.

2. Include tags in the following format to apply restrictions on a component's attribute:

   ```
   tag_id(xmlns(tag_prefix=tag_namespace))/@tag_prefix:attribute_name
   ```

   The following example shows how to apply a restriction on a `Go Image Link` component and the `text` attribute of a `Command Button` component:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
   xmlns:dc="http://purl.org/dc/elements/1.1/">
   <rdf:Description rdf:about="/"/>
   <!-- Opens the customization on a tag with ID 'gil1'.  -->
   <rdf:Description rdf:about="gil1">
     <customizationAllowed
   xmlns="http://xmlns.oracle.com/mds">false</customizationAllowed>
   </rdf:Description>

   <!-- Restricts customizations on a commandButton component's 'text' attribute.
   -->
   <rdf:Description rdf:about="cb1/@text">
     <customizationAllowed
   xmlns="http://xmlns.oracle.com/mds">false</customizationAllowed>
   </rdf:Description>
   ```

At runtime, these policies are read and the artifacts are enabled for customization accordingly.

22.2 Applying a Component Instance-Level Customization Restriction By Using Security Roles: Example

This section explains how you can use component-level restrictions to limit access to certain component functions, based on different user roles and responsibilities. Specifically, it describes how to apply an instance-level customization restriction to a `Panel Customizable` component to provide customization access to only users with `admin` role. That is, when a user with `admin` role logs into the system at runtime, the user can customize the `Panel Customizable` on which the instance-level customization is applied.

In Composer's Property Inspector, the properties of the `Panel Customizable` are not displayed to users who do not have `admin` privileges. The Edit icon or menu item is disabled on restricted components. These users cannot drop any `Movable Box` into the `Panel Customizable` because of the applied restriction. Moreover, they cannot rearrange the `Show Detail Frames` inside this `Panel Customizable`.

To restrict a functionality based on user roles is one way to apply customization restrictions. You can also use expression language expressions (ELs), which provide roles-based results, to enable or restrict access to a component function.

> **Note:** MDS customization restrictions are natively honored only by `Panel Customizable`, `Show Detail Frame`, and `Layout Customizable` components, and not ADF Faces components, such as `Splitter` and `showDetailItem`.

This section contains the following subsections:

- Section 22.2.1, "How to Configure ADF Security"

- Section 22.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File"
- Section 22.2.3, "How to Customize the SessionOptions Object to Include Customization Policy"
- Section 22.2.4, "How to Register the Implementation with Composer"
- Section 22.2.5, "How to Configure WebCenterComposerFilter"
- Section 22.2.6, "How to Apply an Instance-Level Customization Restriction"
- Section 22.2.7, "What Happens at Runtime"

22.2.1 How to Configure ADF Security

Before applying an instance-level customization restriction, you must secure your application using ADF security. For information, see Section 74.3, "Configuring ADF Security."

22.2.2 How to Define Roles and Grant Privileges in the jazn-data.xml File

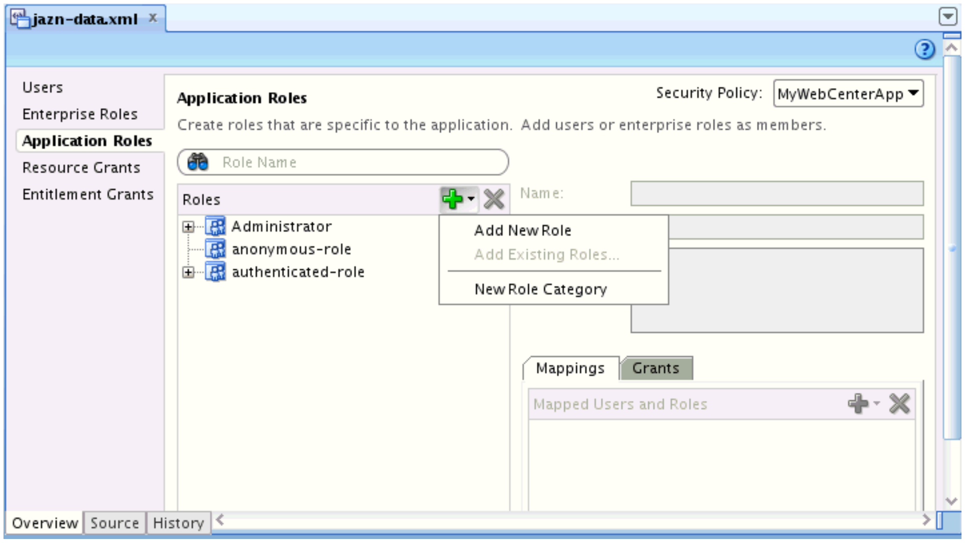
In a previous section, a customization restriction is applied to a `Panel Customizable` component so that, at runtime, only the user with `admin` role can access all the features of `Panel Customizable`, and therefore, can customize its attributes.

In this section, two roles, `admin` and `customer`, are created and page permissions are granted to both users. Users with `admin` role can customize the `Panel Customizable` (`panelCustomizable1`) component. However, because of the customization restriction you applied in an earlier section, users with `customer` role do not have the rights to customize `panelCustomizable1`, and these users cannot use all the features of `panelCustomizable1`.

To create roles in the `jazn-data.xml` file:

1. In the Application Resources panel, right-click the **jazn-data.xml** file and select **Open**.
2. Click the **Application Roles** tab.
3. In the Application Roles page, click the **Add** icon in the Roles section, and select **Add New Role**, shown in Figure 22–1.

Figure 22–1 Application Roles in the jazn-data.xml File



Security Policy: MyWebCenterApp

4. In the **Name** field, specify the role name, `admin`.

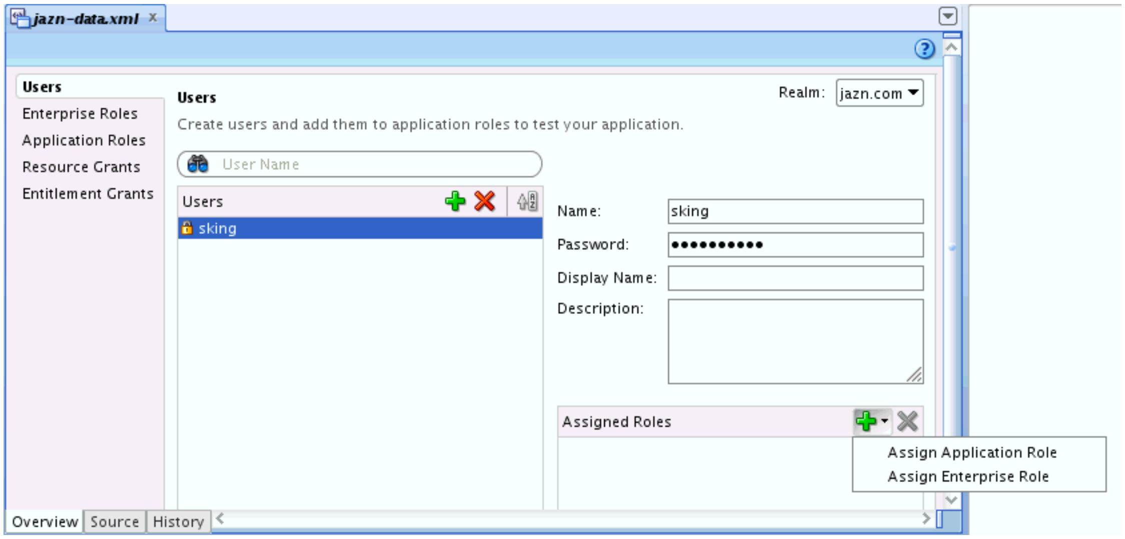
5. Optionally, in the Display Name and Description fields, specify a display name and description for the new role.

6. Repeat steps 3 through 6 to add another role, `customer`.

7. Click the **Users** tab.

8. In the Users page, create new users by clicking the **New User** icon and specifying credentials. Assign roles to these users by clicking the **Assign Roles** icon in the Assigned Roles section and selecting **Assign Application Role**, as shown in Figure 22–2.

Figure 22–2 Users Section in the jazn-data.xml File



Realm: jazn.com

Name: sking

Password: ••••••••••

Display Name:

Description:

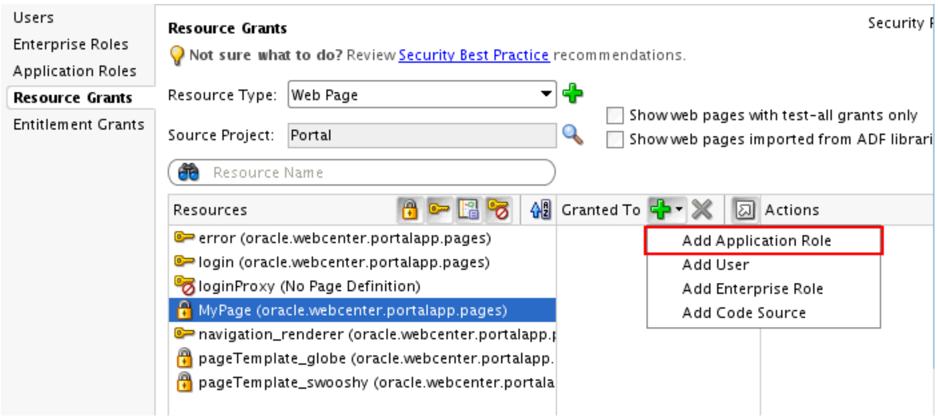
9. Click the **Resource Grants** tab on the left on the page.

10. From Resource Type, select **Web Page**.

11. From the list of page definitions, select the page on which you want to grant privileges.

12. In the Granted To column, click the **Add Grantee** icon, and select **Add Application Role** from the list, as shown in Figure 22–3.

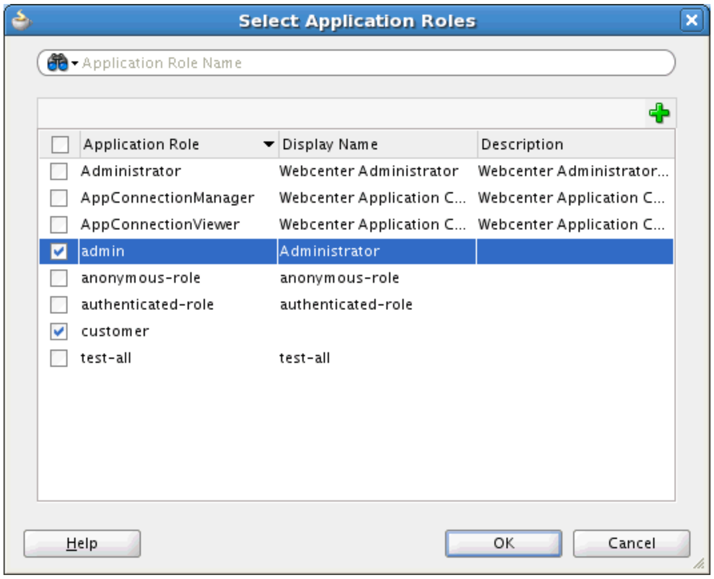
Figure 22–3 Resources in the jazn-data.xml File



error (oracle.webcenter.portalapp.pages)
login (oracle.webcenter.portalapp.pages)
loginProxy (No Page Definition)
MyPage (oracle.webcenter.portalapp.pages)
navigation_renderer (oracle.webcenter.portalapp.p
pageTemplate_globe (oracle.webcenter.portalapp.
pageTemplate_swooshy (oracle.webcenter.portala

13. In the Select Roles dialog (Figure 22–4), select the `admin` and `customer` roles and click **OK**.

Figure 22–4 Select Roles Dialog



☐	Application Role	Display Name	Description
☐	Administrator	Webcenter Administrator	Webcenter Administrator...
☐	AppConnectionManager	Webcenter Application C...	Webcenter Application C...
☐	AppConnectionViewer	Webcenter Application C...	Webcenter Application C...
☑	admin	Administrator	
☐	anonymous-role	anonymous-role	
☐	authenticated-role	authenticated-role	
☑	customer		
☐	test-all	test-all	

14. Select each role and grant all the permissions (customize, grant, personalize, and view), as shown in Figure 22–5.

Figure 22–5 Permissions List in the jazn-data.xml File

☑ personalize
☑ view

For more information about creating users and roles, see the "Enabling ADF Security in a Fusion Web Application" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*.

22.2.3 How to Customize the SessionOptions Object to Include Customization Policy

To enable the expected runtime behavior of the `Panel Customizable` component, where only the user with `admin` role has access to all capabilities of the `Panel Customizable`, including the ability to customize it, the MDS session for this request must include the user roles in its customization policy. To achieve this, the following customization policy is included in the `SessionOptions` object:

```
SecurityContext stx = ADFContext.getCurrent().getSecurityContext();
  cPol = new CustomizationPolicy(stx.getUserRoles());
```

Then the MDS session is created with this customization policy.

To implement the `ComposerSessionOptionsFactory` class:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.
3. In the **Name** field in the Create Java Class dialog, enter `AppsSessionOptionsFactoryImpl`.
4. Click **OK.**

   The `AppsSessionOptionsFactoryImpl.java` file is rendered in the Source view.
5. Import the following libraries:

```
import oracle.adf.share.ADFContext;
import oracle.adf.share.security.SecurityContext;
import oracle.adf.view.page.editor.mds.ComposerSessionOptionsFactory;
import oracle.adf.view.page.editor.mode.ModeContext;
import oracle.mds.config.CustClassListMapping;
import oracle.mds.config.CustConfig;
import oracle.mds.core.SessionOptions;
import oracle.mds.cust.CustClassList;
import oracle.mds.cust.CustomizationClass;
import oracle.mds.cust.CustomizationPolicy;
```

6. Add the following code to implement the `ComposerSessionOptionsFactory` class and provide `SessionOptions`:

```
public class AppsSessionOptionsFactoryImpl
implements ComposerSessionOptionsFactory
{
  public AppsSessionOptionsFactoryImpl()
  {
  }
  public SessionOptions createSessionOptions(SessionOptions sessionOptions,
                                             String mode)
  {
    CustomizationClass[] custLayer;
    CustConfig custConfig = null;
    CustomizationPolicy cPol = null;

    if (ModeContext.EDIT_MODE.equals(mode))
    {
      //Mode is Edit, change to SiteCC
      custLayer = EDIT_LAYER;
    }
    else
    {
      //Mode is View, change to UserCC + SiteCC
      custLayer = VIEW_LAYER;
    }
    try
    {
      CustClassList custClassList = new CustClassList(custLayer);
      CustClassListMapping custClassListMapping =
        new CustClassListMapping("/", null, null, custClassList);
      custConfig = new CustConfig(new CustClassListMapping[]
            { custClassListMapping });
      SecurityContext stx = ADFContext.getCurrent().getSecurityContext();
      cPol = new CustomizationPolicy(stx.getUserRoles());
    }
    catch (Exception e)
    {
      e.printStackTrace();
    }
    if(sessionOptions.getServletContextAsObject() != null)
    {
      return new SessionOptions(sessionOptions.getIsolationLevel(),
                              sessionOptions.getLocale(), custConfig,
                              sessionOptions.getVersionContext(),
                              sessionOptions.getVersionCreatorName(),
                              cPol == null ?
sessionOptions.getCustomizationPolicy() : cPol,
                              sessionOptions.getServletContextAsObject());
    }
    else
    {
      return new SessionOptions(sessionOptions.getIsolationLevel(),
                              sessionOptions.getLocale(), custConfig,
                              sessionOptions.getVersionContext(),
                              sessionOptions.getVersionCreatorName(),
                              cPol == null ?
sessionOptions.getCustomizationPolicy() : cPol);
    }
  }
  //Edit mode SiteCC
  private static final CustomizationClass[] EDIT_LAYER =
    new CustomizationClass[]
    { new SiteCC() };
  //View mode SiteCC + USerCC
  private static final CustomizationClass[] VIEW_LAYER =
    new CustomizationClass[]
    { new SiteCC(), new UserCC() };
```

```
        }
```

22.2.4 How to Register the Implementation with Composer

Perform the steps described in Section 21.3.5, "How to Register the Implementation with Composer" to register the ComposerSessionOptionsFactory class implementation, where user roles were included in the MDS session's customization policy.

22.2.5 How to Configure WebCenterComposerFilter

To configure WebCenterComposerFilter, perform the steps described in Section 21.3.6, "How to Configure WebCenterComposerFilter."

22.2.6 How to Apply an Instance-Level Customization Restriction

In this section, you enable application customization for particular role on a Panel Customizable component. At runtime, only the specified role, for example admin, can access all the features of the Panel Customizable, including customizing its attributes. Users with any other roles can use only a limited set of component features.

To apply an instance-level customization restriction:

1. In the JSPX page, add a **Change Mode Link** component from the Composer tag library.
2. Add a **Page Customizable** component below the Change Mode Link component.
3. Apply an instance-level customization restriction on the component Panel Customizable in the Page Customizable.

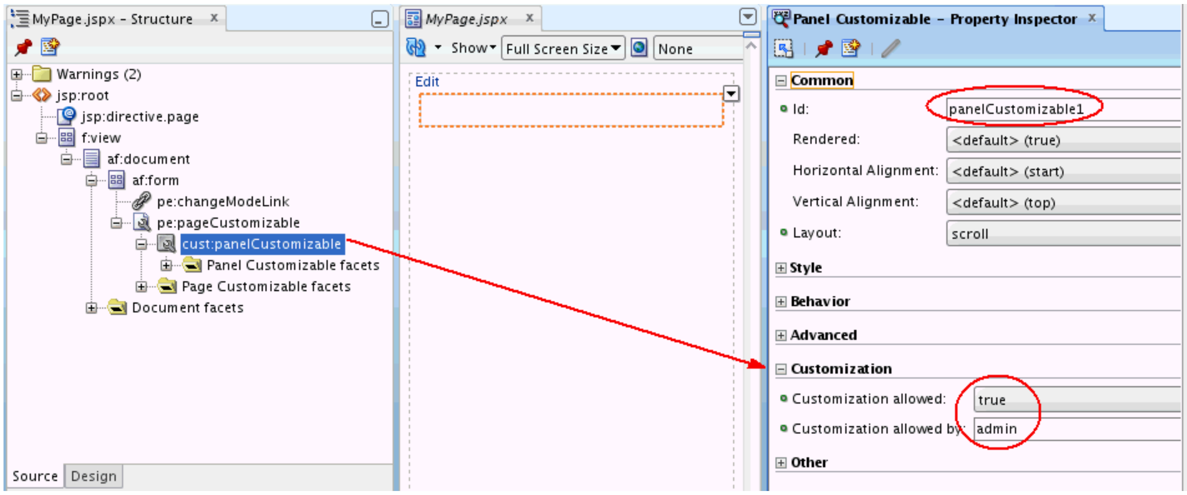
   This restriction is stored in the following directory: public_html/mdssys/mdx/<pagename>.jspx.rdf.

   The Source view should look like this:

   ```
   <pe:changeModeLink id="cml1"/>
   <pe:pageCustomizable id="pageCustomizable1">
     <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
       <f:facet name="editor">
         <pe:pageEditorPanel id="pep1"/>
       </f:facet>
   </pe:pageCustomizable>
   ```

   The design view should look like Figure 22–6.

Figure 22–6 Design View: Customization Allowed



Id: panelCustomizable1
Rendered: <default> (true)
Horizontal Alignment: <default> (start)
Vertical Alignment: <default> (top)
Layout: scroll
Customization allowed: true
Customization allowed by: admin

4. Add a `Show Detail Frame` component within the `Panel Customizable` and include another `Panel Customizable` component as a child of the `Show Detail Frame` component.

> **Note:** This step is for illustration purpose only as it is easier to explain runtime behavior by showing multiple components. For detailed information on how to add Composer components, see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."

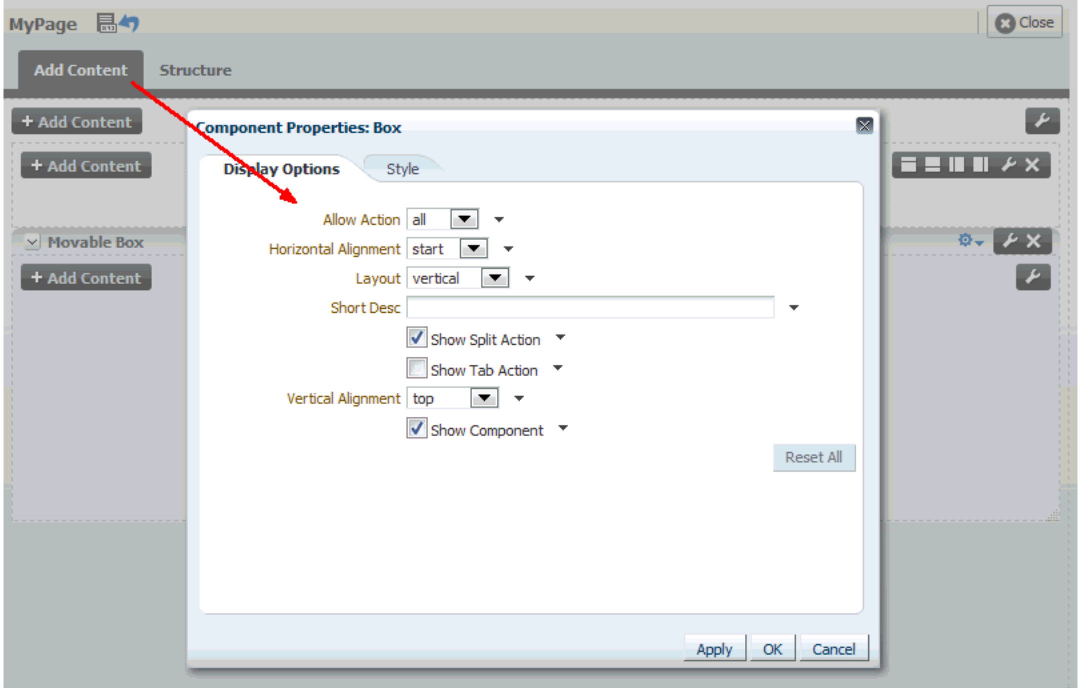
22.2.7 What Happens at Runtime

What happens at runtime is influenced by which user is logged on. To see the difference, log in as one user and then the other. For example:

In the Application Navigator, right-click the JSPX page and select **Run**.

Log in to the page as a user with `admin` role, and switch to Edit mode. The **Add Content** button and the **Edit** icon are displayed on the outer and inner `Panel Customizable` components. As a user with `admin` role, you can access the properties of the outer `Panel Customizable`, as shown in Figure 22–7. That is, users with `admin` role can edit this component.

Figure 22–7 Edit Mode for admin



Component Properties: Box

Allow Action: all

Horizontal Alignment: start

Layout: vertical

Short Desc:

☑ Show Split Action

☐ Show Tab Action

Vertical Alignment: top

☑ Show Component

Log in to the page as a user with `customer` role, and switch to Edit mode. The **Add Content** button and the **Edit** icon are not available on the outer `Panel Customizable`. That is, this component is not editable for users with `customer` role. In Structure view, the Add Content and Edit icons are grayed out for the component.

22.3 Applying Tag-Level Security Using the customizationAllowed Attribute

By default, a `Page Customizable` component enables application customization on all components under it. You may want to change this to restrict customization on some components. The `Page Customizable` component does not enable customization on components that are on a nested page or fragment. You must enable customization on such components manually. To address such requirements, MDS provides the `customizationAllowed` and `customizationAllowedBy` attributes. These attributes can be used to enable or restrict customization on specific component instances on a page.

The `customizationAllowed` attribute controls whether the component can be customized at runtime. If you set this attribute to `false`, then the component cannot be customized at runtime. That is, in the Component Properties dialog the properties are grayed out and do not allow editing.

The `customizationAllowedBy` attribute specifies the roles for which customization is enabled.

This section provides examples of enabling and restricting customization on a component. It contains the following subsections:

- Section 22.3.1, "How to Enable Application Customization on an Image Component"
- Section 22.3.2, "How to Restrict Customization on an Image Component"

For more information, see the "Extended Metadata Properties" section in *Fusion Developer's Guide for Oracle Application Development Framework*.

22.3.1 How to Enable Application Customization on an Image Component

To enable application customization on an Image component:

1. In the `MyPage.jspx` page that you created in Section 18.2, "Designing Editable Pages Using Composer Components: Example," add an ADF Faces Image component, for example, `brandingImage.gif`, inside the `Panel Customizable` called `panelCustomizable1`.

   Application customization is enabled automatically on the `Image` component since it is nested inside a `Page Customizable` component.

2. Run `MyPage.jspx`.
3. Switch to Edit mode of the page.
4. Select **Structure** to switch to Structure view of the page.
5. Select the image in the component hierarchy in the Structure View panel and click the **Show the properties of** icon.

   The Component Properties dialog displays the image properties. You can edit any available property in this dialog. Edit a property and click **OK**. The property's editable value demonstrates that application customization is enabled on the component.

22.3.2 How to Restrict Customization on an Image Component

You can restrict customization of an image on the page by setting the `customizationAllowed` attribute to `false` on the image component.

To restrict customization on the Image component:

1. In Oracle JDeveloper, select the `Image` component that you added in the previous section, and in the Property Inspector set the value for **customizationAllowed** to `false`.
2. Run `MyPage.jspx`.
3. Switch to page Edit mode.
4. Select **Structure** to switch to Structure view of the page.
5. Select the image in the component hierarchy in the Structure view panel, and click the **Show the properties of** icon.

   In the Component Properties dialog, the properties are grayed out and cannot be edited.

22.4 Applying Attribute-Level Security

You can choose whether specific component attributes can be customized at runtime. Additionally, you can specify whether the changes made to an attribute must be persisted to a persistence store, such as MDS. You can apply attribute-level security in the following ways:

- By defining property filters
- By persisting changes at the component level

For information about applying property filters, see Section 19.8.1, "How to Define Property Filters."

This section describes how to persist changes at the component level. It contains the following subsections:

- Section 22.4.1, "How to Define Change Persistence at the Component Level"
- Section 22.4.2, "What Happens at Runtime"

22.4.1 How to Define Change Persistence at the Component Level

If your application is configured to use `FilteredPersistenceChangeManager` to persist changes, you can use the `persist-changes` attribute in the `adf-config.xml` file to specify whether changes to a specific attribute must be persisted.

> **Note:** For information about change persistence, see Section 20.11, "Configuring the Persistence Change Manager."
>
> For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

Example 22–1 shows a sample `adf-config.xml` file with `persist-changes` attributes defined for some attributes.

Example 22–1 Using the persist-changes Attribute in the adf-config.xml File

```
<adf-config xmlns="http://xmlns.oracle.com/adf/config">
  <adf-faces-config xmlns="http://xmlns.oracle.com/adf/faces/config">
    <persistent-change-manager>
      <persistent-change-manager-class>
       oracle.adf.view.rich.change.MDSDocumentChangeManager
      </persistent-change-manager-class>
    </persistent-change-manager>
    <taglib-config>
      <taglib uri="http://xmlns.oracle.com/adf/pageeditor">
        <tag name="imageLink">
          <attribute name="destination">
            <persist-changes>true</persist-changes>
          </attribute>
        </tag>
        <tag name="customAction">
          <attribute name="text">
            <persist-changes>true</persist-changes>
          </attribute>
          <attribute name="icon">
            <persist-changes>true</persist-changes>
          </attribute>
        </tag>
      </taglib>
    </taglib-config>
  </adf-faces-config>
</adf-config>
```

22.4.2 What Happens at Runtime

If you include the `persist-changes` attribute and set the value to `true`, then a change made to the component attribute is persisted in any instance of that component.

Note: The persist-changes attribute applies only to implicit customization made in View mode.

22.5 Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions

The ability of a user to perform actions on Panel Customizable and Show Detail Frame components is inherited from page security. Inheritance is based on the value of the application-wide switch, enableSecurity, in the adf-config.xml file. If you select the WebCenter Portal Framework Application template when you create your application, then the adf-config.xml file is located in the ADF META-INF folder under Descriptors in the Application Resources panel.

This section describes how to apply action-level restrictions on Panel Customizable and Show Detail Frame component actions. It contains the following subsections:

- Section 22.5.1, "How to Add an enableSecurity Section to adf-config.xml"
- Section 22.5.2, "Defining Security at the Actions Category Level"
- Section 22.5.3, "Defining Security at the Actions Level"

22.5.1 How to Add an enableSecurity Section to adf-config.xml

The enableSecurity element is not available by default in adf-config.xml. To override or extend the page-level security inheritance for Panel Customizable and Show Detail Frame components, you must add the customizableComponentsSecurity section in the adf-config.xml file, as shown in Example 22–2, and set the enableSecurity element in that section to true.

Example 22–2 enableSecurity Element in the Customizable Components Security Section in adf-config.xml

```
<cust:customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <cust:enableSecurity value="true"/>
    <cust:actionsCategory>
       .........................................
</cust:customizableComponentsSecurity>
```

Restrictions on actions can be implemented at the following levels:

- **Page level**: You can define security for Oracle WebCenter Portal Customizable Components so that page-level privileges are inherited by these components. This is the default behavior.

  By default, customizable components inherit allowable actions from the defined page-level permissions, such as edit, personalize, or customize. That is, a user who has edit, personalize, or customize privileges on a page can perform View mode user customizations on that page. The enableSecurity element enables you to override the security inheritance behavior. It can take either of the following values:

  – true: If set to true (the default when not specified), then the ability of a user to modify a component is first determined from the page permissions and then adjusted according to the current set of actions defined for that type of permission. For example, if a user has customize permission, then the actions that constitute the customize category (move, customize, and so on) are available to the user, but they are overridden by the actions that are defined in the adf-config.xml file.

- false: If set to false, then all actions are available to users. A user's page permissions and actions configured in adf-config.xml are ignored.

- **Actions category level**: You can define security on all actions for Panel Customizable and Show Detail Frame components.

  You can add an actionsCategory element in the adf-config.xml file to define security on multiple actions simultaneously. Depending on the actionCategory attributes that you enable, appropriate privileges are provided on the components.

- **Actions level**: You can define security on individual actions for Panel Customizable and Show Detail Frame components.

  You can use the actions element in the adf-config.xml file to enable or disable individual actions. Depending on the actions attributes that you enable, appropriate privileges are provided on the components.

Notes:

- If you set enableSecurity to true in the adf-config.xml file and define restrictions on actions or action categories, then for these restrictions to take effect you must grant Personalize or Customize privilege on the page, in addition to View privilege.

  If you are not using the enableSecurity element or it is set to false, then page-level permissions are honored. In such a case, having View privilege on the page is sufficient as all customizable components actions are rendered by default on the page.

- Privileges can be inherited from the parent only. Inheritance from a component in any other position in the hierarchy is not supported.

- Restrictions defined at the actions category level or actions level are applicable to all instances of the Panel Customizable or Show Detail Frame component across the application. You cannot apply restrictions on a single instance of the component.

You can define security for component actions at the application level if enableSecurity is set to true in the adf-config.xml file. A value of true implies that permission checks are made in addition to the actionsCategory and actions values specified in the adf-config.xml.

22.5.2 Defining Security at the Actions Category Level

You can add an actionsCategory element in the customizable components actions security section in the adf-config.xml file to define security on multiple Panel Customizable and Show Detail Frame components actions. Depending on the actionsCategory attributes that you enable, appropriate privileges are provided on the components.

The actions and actionsCategory elements in the adf-config.xml file have certain default mappings. Table 22–1 describes the different actionsCategory attributes and the actions they support by default.

For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

Table 22–1 Actions Categories and Actions Mapping

actionsCategory	Actions Supported
`personalizeActionsCategory`	showMoveAction showRemoveAction showMinimizeAction showResizer allowAction
`customizeActionsCategory`	showEditAction showAddContentAction showSplitAction

The behavior of components based on a combination of `personalizeActionsCategory` and `customizeActionsCategory` settings is as follows:

- If both `personalizeActionsCategory` and `customizeActionsCategory` are set to `false`, then users cannot move, expand, collapse, delete, resize, or edit `Show Detail Frame` components and they also cannot edit or delete `Panel Customizable` components or add content inside them.
- If `personalizeActionsCategory` is set to `true` and `customizeActionsCategory` is set to `false`, then users can move, expand, collapse, delete, or resize `Show Detail Frame` components but not edit them. Additionally, they can delete `Panel Customizable` components and rearrange components inside them but not edit them or add components to the page.

> **Note:** The `allowAction` setting, along with other actions settings, controls the ability to add content to the page and move or rearrange content on the page. For more information, see Section 22.5.3, "Defining Security at the Actions Level."

- If both `personalizeActionsCategory` and `customizeActionsCategory` are set to `true`, then users can move, expand, collapse, delete, resize, and edit `Show Detail Frame` components and they can also edit and delete `Panel Customizable` components and add content inside them. Users can add content from the resource catalog using the **Add Content** button, add Box components using the Add Box icons, and move components from other `Panel Customizable` components by dragging and dropping them.

> **Note:** It is not recommended that you set `personalizeActionsCategory` to `false` and `customizeActionsCategory` to `true` as privileges cascade from Grant to Customize to Personalize to View. That is, when you enable Customization, the user must already have Personalize privilege on the page.

Example 22–3 shows the `actionsCategory` entry that you can add to the customizable components actions security section in the `adf-config.xml` file.

Example 22–3   actionsCategory Element in the Customizable Components Security Section

```
<cust:customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <cust:enableSecurity value="true"/>

  <cust:actionsCategory>
    <cust:actionCategory name="personalizeActionsCategory" value="true"/>
    <cust:actionCategory name="customizeActionsCategory" value="false"/>
  </cust:actionsCategory>

  <cust:actions>
  ..........................................
  </cust:actions>

</cust:customizableComponentsSecurity>
```

You can also use EL for these element values, as shown in Example 22–4.

Example 22–4   EL Used in Customizable Components an actionCategory Entry

```
<cust:actionsCategory>
  <cust:actionCategory name="personalizeActionsCategory"
value="#{appBusinessRules.InsideCorpNetwork}"/>
</cust:actionsCategory>
```

For reference, the managed bean, `appBusinessRules`, is defined as shown in Example 74–7 in Section 74.15, "Overriding Inherited Security on Portlets and Customizable Components."

22.5.3 Defining Security at the Actions Level

You can use the `actions` element in the customizable components actions security section of the `adf-config.xml` file to show or hide individual `Show Detail Frame` actions. Depending on the `actions` attributes that you enable, appropriate privileges are provided on the `Show Detail Frame` components.

For information about Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

The `allowAction` setting, along with other actions settings, controls the ability to add content to the page and move or rearrange page content.

In Composer, users can add and arrange content in the following ways:

- Add `Box` components using the **Add Box** icons.
- Add content inside a `Box` component, from the resource catalog, using the **Add Content** button.
- Move `Show Detail Frame` components within a `Panel Customizable` component by using the Move Up and Move Down actions on the `Show Detail Frame` component's Actions menu.
- Drag and drop `Show Detail Frame` components across `Panel Customizable` components.

Table 22–2 explains the ability to add content depending on the `allowAction` and `showAddContentAction` settings.

Table 22–2 Actions Settings for Adding Content to a Page

allowAction Setting	showAddContentAction Setting	Add Content Button Displayed?
`true`	`true`	Yes
`true`	`false`	No
`false`	true	No
`false`	`false`	No

Table 22–3 explains the ability to add content using the Add Box icons depending on the `allowAction` and `showSplitAction` settings.

Table 22–3 Actions Settings for Rearranging Content on a Page

allowAction Setting	showSplitAction Setting	Add Box Icons Displayed?
`true`	`true`	Yes
`true`	`false`	No
`false`	`true`	No
`false`	`false`	No

Table 22–4 explains the ability to move content on the page depending on the `allowAction` and `showMoveAction` settings.

Table 22–4 Actions Settings for Moving Content on a Page

allowAction Setting	showMoveAction Setting	Move Content on the Page?
`true`	`true`	Yes
`true`	`false`	No
`false`	`true`	No
`false`	`false`	No

Note:

- If you define security both at the actions category level and actions level and the values for some actions contradict, then a value of `false` takes precedence over `true`. For example, if you set `personalizeActionsCategory` to `true` and `allowAction` to `false`, then users cannot add content to their application pages at runtime. Similarly, if you set `personalizeActionsCategory` to `false` but set `allowAction` to `true`, then too users cannot add content to their application pages at runtime.
- Restrictions using actions settings are applicable only in Add Content or Design view of a page. That is, if you set an action, such as `showEditAction` or `showRemoveAction`, on `Show Detail Frame` components to `false`, then users cannot edit or delete such components in Add Content or Design view of the page. However, users can still select such components in Structure view and edit or delete them.

Example 22–5 shows the `actions` entry that you can add to the customizable components actions section of the `adf-config.xml` file. You can use EL for element values.

Example 22–5 action Elements in the Customizable Components Security Section

```
<cust:customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <cust:enableSecurity value="true"/>

  <cust:actionsCategory>
    .........................................
  </cust:actionsCategory>

  <cust:actions>
    <cust:action name="showMinimizeAction" value="true"/>
    <cust:action name="showMoveAction" value="false"/>
  </cust:actions>

</cust:customizableComponentsSecurity>
```

22.6 Implementing Task Flow Security

Since editing task flow permissions has a far reaching impact on the task flow editing experience, the Edit permission on task flows is disabled by default. In fact, no permissions are provisioned on task flows by default. To ensure that only users with appropriate permissions can edit a task flow, you can implement task flow security by performing the following two tasks in the Composer context:

- Explicitly grant Edit, Customize, or Grant permission on the task flow.
- Enable Composer to check for a task flow's permissions and allow only users with appropriate permissions to edit or customize the task flow.

This section explains how to apply restrictions and enable permission checks on task flows. It contains the following subsections:

- Section 22.6.1, "Granting Permissions on Task Flows"
- Section 22.6.2, "Enabling Task Flow Permission Check"

22.6.1 Granting Permissions on Task Flows

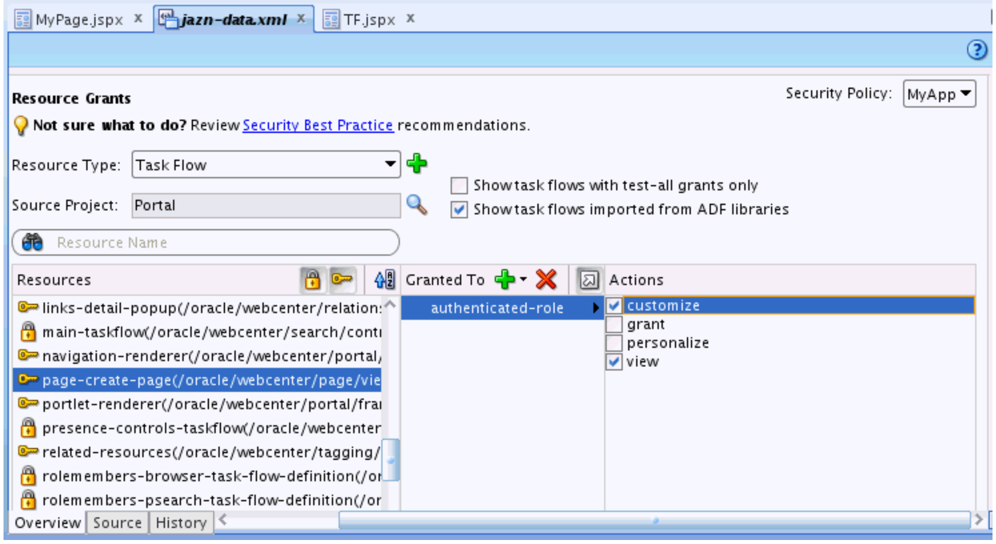
You can define the access policy for a task flow by creating permission grants in the Resource Grants page of the `jazn-data.xml` file overview editor. The grants you create will appear as metadata in the policy store section of the file. These grants, or permissions, control the ability to zoom into and edit the task flow in Composer.

To grant or revoke permissions on a task flow in the `jazn-data.xml` file:

1. From the Application menu, select **Secure**, and then **Resource Grants**.
2. In the `jazn-data.xml` file, from **Resource Type**, select **Task Flow**.
3. From Resources list, select the task flow and click the **Add Grantee** icon in the Granted To column, then select the required role category, such as **Add Application Role**.
4. Select the roles to which you want to grant permissions or create a new role by clicking the **Add** icon.
5. Click **OK**.

6. Select one or more permissions in the Actions column (Figure 22–8).

Figure 22–8 Task Flow Security Region in the jazn-data.xml File



Resource Grants

Not sure what to do? Review Security Best Practice recommendations.

Security Policy: MyApp

Resource Type: Task Flow

Source Project: Portal

☐ Show task flows with test-all grants only

☑ Show task flows imported from ADF libraries

- authenticated-role

Actions

☑ customize
☐ grant
☐ personalize
☑ view

7. Save the jazn-data.xml file.

Note: The permission grant would appear as follows in the source view of the file if `customize` and `view` permissions are granted:

```
<permissions>
  <permission>

<class>oracle.adf.controller.security.TaskFlowPermission</class>

<name>/WEB-INF/task-flow-definition.xml#task-flow-definition</name>
    <actions>customize,view</actions>
  </permission>
</permissions>
```

The `TaskFlowPermission` class defines task flow-specific actions that it maps to the task flow's operations.

For more information about Composer's behavior based on task flow permissions, see Section 16.8.1, "Page and Task Flow Security."

For more information about defining permission grants on task flows, see the "How to Define Security Policies for ADF Bounded Task Flows" section in *Fusion Developer's Guide for Oracle Application Development Framework*.

22.6.2 Enabling Task Flow Permission Check

When a user tries to edit a task flow, Composer does not check the task flow's permissions by default. To enhance task flow security, you must configure Composer to check for a task flow's permissions and allow only users with the required privileges to edit it. You can do so by setting the `check-permission` property on the `<pe:task-flow-security>` element in the application's `adf-config.xml` file, as shown in the following example:

```
<pe:page-editor-config>
  <pe:security-config>
    <pe:task-flow-security check-permission="true" />
  </pe:security-config>
</pe:page-editor-config>
```

For more information about `adf-config.xml` settings, see Section B.2.2, "adf-config.xml."

Note: In earlier releases, you could enable permission checks on task flows by running the server with the following JVM parameter:

`-Doracle.composer.enableTaskflowPermissionCheck=true`

However, this method is now deprecated. For backward compatibility, Composer checks for the `enableTaskflowPermissionCheck` flag first, and then the setting in the `adf-config.xml` file.

22.7 Overriding Composer's Default Security Policies

Composer performs the following security checks to enable customization:

- Regions on the page have been granted edit or customize privilege.
- Task flows have been granted edit or customize privilege.

Note: This is an optional security setting, which is not enabled by default.

- A component is not nested in an iterator.
- MDS customization restrictions have been applied on components and attributes.

Users can customize pages and task flows only if all the above criteria are met. By default, Composer uses `pagePolicy` to perform page-level security checks.

There may be situations where you want to perform different security checks; probably add a few application-level checks to what Composer already provides. You can do so by overriding Composer's default security policy with a custom policy. This section explains how to do this. It contains the following sections:

- Section 22.7.1, "How to Create a Custom Security Policy"
- Section 22.7.2, "How to Register a Custom Policy with Composer"
- Section 22.7.3, "What Happens at Runtime"

22.7.1 How to Create a Custom Security Policy

You can create custom policies by extending Composer's base security classes. Depending on whether you want to check pages or task flows, you can extend the following base security classes:

- Page Policy: `oracle.adf.view.page.editor.security.BasePageSecurityPolicy`
- Task Flow Policy: `oracle.adf.view.page.editor.security.TaskflowPermissionPolicy`

To take you one step further, you can configure your policy in such a way that Composer's default checks are performed in case the custom checks are not applicable or do not provide the desired results. For this, you must extend the `DefaultPageSecurityPolicy` class and call the `super.isCustomizable()` method, as shown in Example 22–6.

Example 22–6 Custom Policy Extending DefaultPageSecurityPolicy

```
public class CustomPageSecurityPolicy extends DefaultPageSecurityPolicy
{
  . . .

  public boolean isCustomizable()
  {
    // Security checks that this custom page policy must perform should go here
    . . .
    // If we cannot determine the security policy, chain it to Composer's default 
implementation
    return super.isCustomizable();
  }
}
```

22.7.2 How to Register a Custom Policy with Composer

To configure a custom policy to override the Composer security policy, you must include the `<pe:security-config>` section in the application's `adf-config.xml` file and register the custom security policy.

To register a custom security policy:

1. Open the application's `adf-config.xml` file from the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add a `<pe:page-editor-config>` section if it does not already exist, and add the following code inside it:

```
<pe:security-config>
  <pe:security-policies>
    <pe:security-policy name="optional_unique_name" override="composer_
security_policy_name">
      <pe:policy-class>fully_qualified_custom_policy_class_
name</pe:policy-class>
    </pe:security-policy>
  </pe:security-policies>
</pe:security-config>
```

   where,

   `override` specifies the default policy to be overridden. Options are `pagePolicy` and `taskflowPolicy`.

   For information about task flow policies, see Section 22.6, "Implementing Task Flow Security."

   > **Note:** Out-of-the-box policies that are not mentioned here will continue to be checked by default.

   `<pe:policy-class>` specifies the name of the custom policy class.

3. Save the `adf-config.xml` file.

22.7.3 What Happens at Runtime

Composer performs the security checks defined in your custom policy and enables customization on components accordingly.

22.8 Troubleshooting Problems with Composer Components Security

This section provides information to assist you in troubleshooting security-related problems you may encounter while using Composer components.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

The `Show Detail Frame` and `Panel Customizable` do not show the **Edit** icon, or the `Panel Customizable` does not show the **Add Content** button. Also, you are not able to move the `Show Detail Frame` out of a `Panel Customizable` component or drop it into another `Panel Customizable` component.

Solution

Ensure that the `Panel Customizable` is not restricted by using MDS and the component actions are not secured by using entries in `adf-config.xml`.

Problem

You are not able to grant permissions on task flows in the `jazn-data.xml` file.

Solution

Ensure that you run the server with the Java startup parameter, as mentioned in Section 22.6, "Implementing Task Flow Security."

23

Customizing WebCenter Portal Tools and Services Task Flows

This chapter describes how to extend or alter the look and feel or functionality of Oracle WebCenter Portal tools and services task flows using the Oracle JDeveloper Customization Developer role.

This chapter includes the following topics:

23.1 Introduction to Task Flow Customization

When you apply task flow customizations to WebCenter Portal or a deployed Portal Framework application, the customizations apply to all instances of that task flow in the application. You do not need to deploy customizations for individual task flow instances.

In JDeveloper, task flow customizations are deployed at application-level, so any customizations that you make will apply to all portals. To customize a task flow for a specific portal only, you must use WebCenter Portal's administration tools for task flow customization as explained in the "Customizing Task Flows for a Portal" chapter in *Using Oracle WebCenter Portal*. If your customization involves minor modifications like adding text, hiding existing content or rearranging existing content, you can also use runtime administration tools. If your customization requires complex layout changes to be applied to all instances of a portal, use the development-based customization approach explained in this chapter.

Note: While you can perform view-level customizations to Portal Framework applications, such as task flow customization, ADF model and Controller customizations are not supported in this release. To learn more about the different customization types, see the *Java EE Developer's Guide for Oracle Application Development Framework*.

23.2 Preparing for Task Flow Customization

This section includes the following topics:

- Section 23.2.1, "WebCenter Portal: Install the WebCenter Portal Customization JDeveloper Extension"
- Section 23.2.2, "WebCenter Portal: Create a Task Flow Customization Application"
- Section 23.2.3, "WebCenter Portal Framework Applications: Enable Customization"

23.2.1 WebCenter Portal: Install the WebCenter Portal Customization JDeveloper Extension

To customize task flows for WebCenter Portal, you must first install the WebCenter Portal Customization JDeveloper extension.

The WebCenter Portal Customization JDeveloper extension includes the WebCenter Portal Task Flow Customization Application template and some Portal Server specific task flows that are not included in the Oracle WebCenter Portal Framework and Services Design Time JDeveloper extension bundle.

Note: If you have not already installed the latest version of the Oracle WebCenter Portal Framework and Services Design Time extension, you must install it before the customization extension.

To install the WebCenter Portal Customization JDeveloper extension:

1. In JDeveloper, choose **Help** then **Check for Updates**.
2. In the Check for Updates wizard, if the Welcome page displays, click **Next**.
3. On the Source page, from the **Search Update Centers** list, select **Oracle Fusion Middleware Products**, and click **Next**.
4. On the Updates page, select the **Oracle WebCenter Portal Customization Framework Design Time** extension and click **Finish**.
5. Exit and restart JDeveloper.

23.2.2 WebCenter Portal: Create a Task Flow Customization Application

If you are customizing task flows for WebCenter Portal, you must also create a WebCenter Portal Task Flow Customization application.

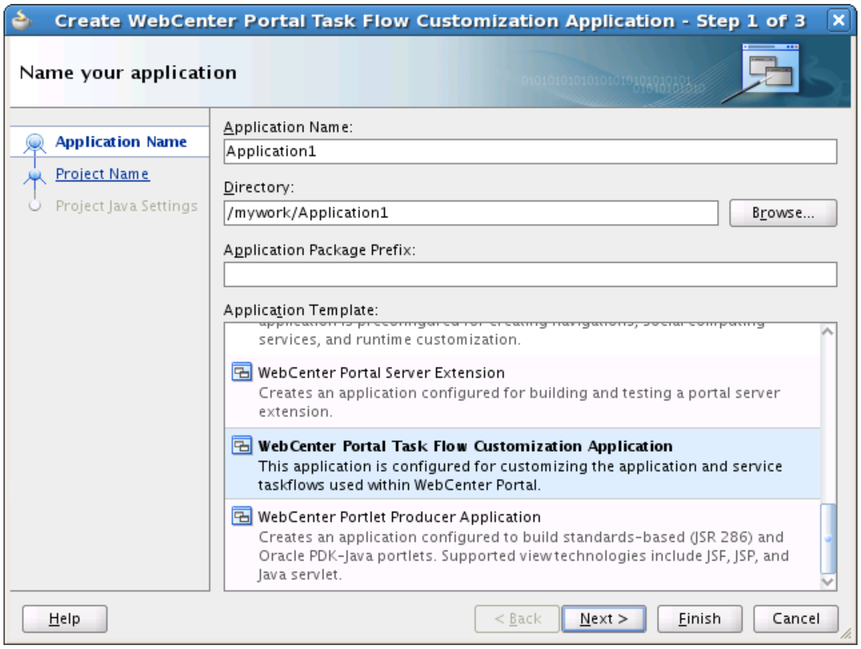
To create a task flow customization application:

1. Access the Create WebCenter Portal Task Flow Customization Application wizard in any of the following ways:

- From the **File** menu, choose **New**. In the New Gallery dialog, expand **General**, select **Applications** then **WebCenter Portal Task Flow Customization Application**, and then click **OK**.
- From the **Application** menu, choose **New**. In the Create Generic Application wizard, in the **Application Template** list select **WebCenter Portal Task Flow Customization Application**.
- If you have an existing application open, in the Application Navigator, click the application name and choose **New Application**. In the Create Generic Application wizard, in the **Application Template** list select **WebCenter Portal Task Flow Customization Application**.
- If you have an existing application open, then in the Application Navigator, right-click the application name and choose **New**. In the New Gallery dialog, expand **General**, select **Applications** then **WebCenter Portal Task Flow Customization Application**, and then click **OK**.

2. In the Name your application page of the application creation wizard (Figure 23–1), in the **Application Name** field, enter a name for the application.

Figure 23–1 The Create WebCenter Portal Task Flow Customization Application Wizard



Create WebCenter Portal Task Flow Customization Application - Step 1 of 3

Name your application

Application Name: Application1

Directory: /mywork/Application1

Application Package Prefix:

Application Template:

services, and runtime customization.

WebCenter Portal Server Extension
Creates an application configured for building and testing a portal server extension.

WebCenter Portal Task Flow Customization Application
This application is configured for customizing the application and service taskflows used within WebCenter Portal.

WebCenter Portlet Producer Application
Creates an application configured to build standards-based (JSR 286) and Oracle PDK-Java portlets. Supported view technologies include JSF, JSP, and Java servlet.

3. In the **Directory** field, accept the default path or enter a path to the directory where the application should be stored.

   For example:

   ```
   C:\JDeveloper\mywork\myCustomizationApplication
   ```

   Optionally, click the **Browse** button to navigate to the desired directory.

4. If required, in the **Application Package Prefix** field, enter a prefix to use for packages to be created within the application.
5. Click **Finish** to create the task flow customization application with default project configurations.

23.2.3 WebCenter Portal Framework Applications: Enable Customization

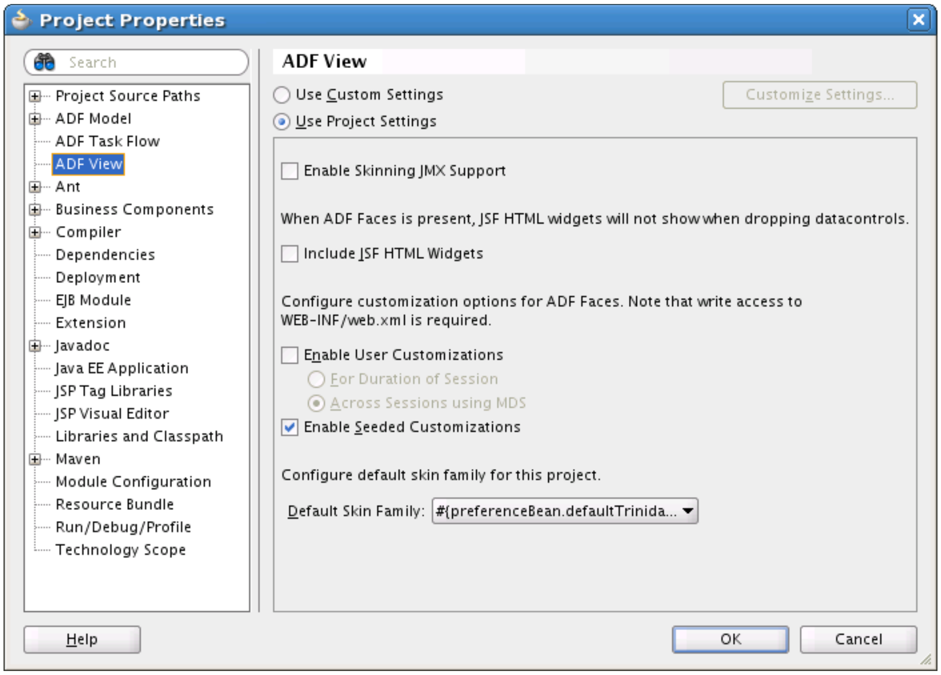
To enable task flow customization in a Portal Framework application, first ensure that you have created your application using the WebCenter Portal Framework Application template (see Section 6.1, "Creating a New WebCenter Portal Framework Application"). Then follow the steps below.

To enable customization in a Portal Framework application:

1. In the Application Navigator, right-click the **Portal** project, and choose **Project Properties**.

2. In the Project Properties dialog, select **ADF View**, then select the **Enable Seeded Customizations** check box (Figure 23–2).

Figure 23–2 Enable Seeded Customizations Option



ADF View

○ Use Custom Settings

● Use Project Settings

□ Enable Skinning JMX Support

When ADF Faces is present, JSF HTML widgets will not show when dropping datacontrols.

□ Include JSF HTML Widgets

Configure customization options for ADF Faces. Note that write access to WEB-INF/web.xml is required.

□ Enable User Customizations

○ For Duration of Session

● Across Sessions using MDS

☑ Enable Seeded Customizations

Configure default skin family for this project.

Default Skin Family: #{preferenceBean.defaultTrinida...

3. Click **OK** and save your files.

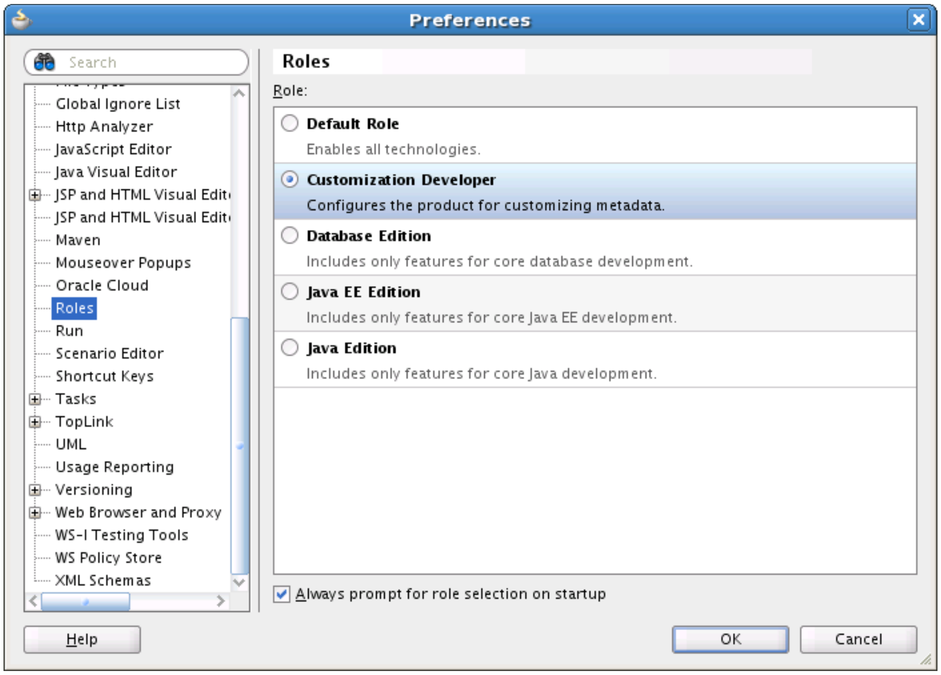
23.3 Configuring the JDeveloper Customization Developer Role

After you have created your customization application, or enabled customization for your application as described in Section 23.2, "Preparing for Task Flow Customization," you must configure the customization layer values to use the JDeveloper Customization Developer role.

1. In JDeveloper, choose **Tools** and then **Preferences**.

2. In the Preferences dialog, select **Roles** and then select the **Customization Developer** option (Figure 23–3).

Figure 23–3 Customization Developer Option



Preferences

Search

- Global Ignore List
- Http Analyzer
- JavaScript Editor
- Java Visual Editor
- JSP and HTML Visual Edit
- JSP and HTML Visual Edit
- Maven
- Mouseover Popups
- Oracle Cloud
- Roles
- Run
- Scenario Editor
- Shortcut Keys
- Tasks
- TopLink
- UML
- Usage Reporting
- Versioning
- Web Browser and Proxy
- WS-I Testing Tools
- WS Policy Store
- XML Schemas

Roles

Role:

○ **Default Role**
Enables all technologies.

● **Customization Developer**
Configures the product for customizing metadata.

○ **Database Edition**
Includes only features for core database development.

○ **Java EE Edition**
Includes only features for core Java EE development.

○ **Java Edition**
Includes only features for core Java development.

☑ Always prompt for role selection on startup

3. Click **OK**.

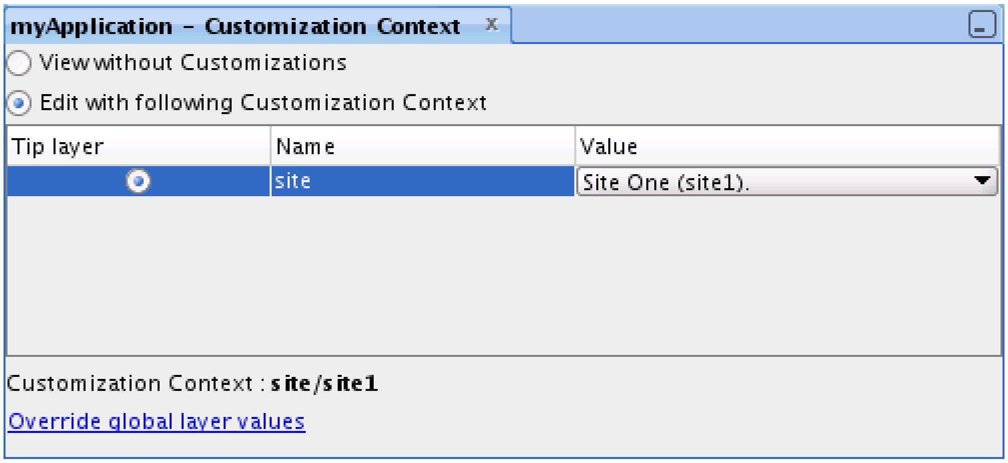
   JDeveloper prompts you to exit. Click **Yes** and then when you restart JDeveloper it will be using the Customization Developer role.

   When started using the Customization Developer role, JDeveloper displays an icon that includes a small figure next to your application name in the Application Navigator (Figure 23–4).

Figure 23–4 Icon Indicating Customization Developer Role

You will also see a Customization Context window (Figure 23–5).

Figure 23–5 Customization Context Window



myApplication – Customization Context

○ View without Customizations

● Edit with following Customization Context

Tip layer	Name	Value
●	site	Site One (site1).

Customization Context : **site/site1**

4. For Portal Framework applications, in the Customization Context window, click **Override global layer values**.

5. In the Confirm Override dialog, click **Yes**.

6. In the `CustomizationLayerValues.xml` file, enter the configuration for your application's customization class. For applications using the default ADF site customization class, use the following code:

```
<cust-layers xmlns="http://xmlns.oracle.com/mds/dt">
  <cust-layer name="site" id-prefix="s">
    <cust-layer-value value="site" display-name="Site" id-prefix="s"/>
  </cust-layer>
</cust-layers>
```

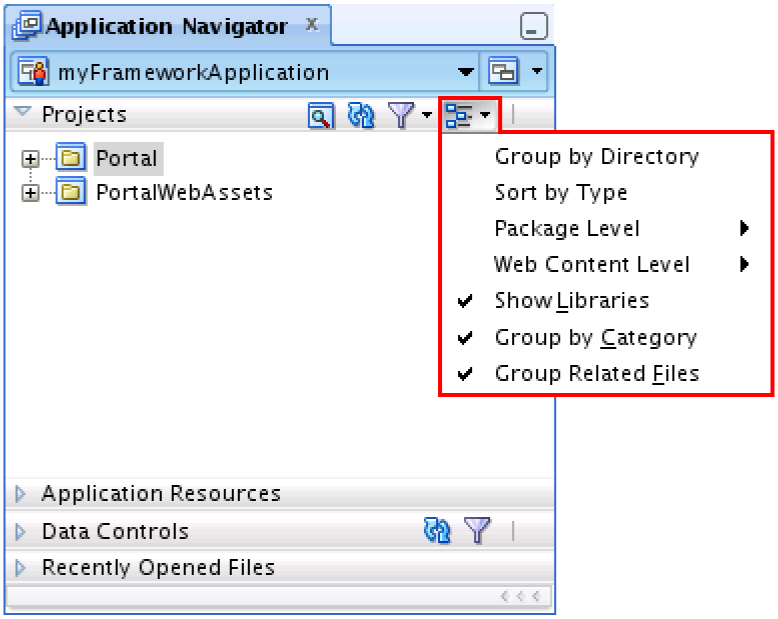
7. Save your files.

   The layer value in the Customization Context window is now set to the value that you defined in `CustomizationLayerValues.xml`. This indicates that you have successfully configured your application to enable customization of Oracle WebCenter Portal tools and services task flows

8. In the Application Navigator, ensure that **Show Libraries** is enabled in the Navigator Display Options drop-down menu (Figure 23–6).

   Tip: The **Navigator Display Options** icon is on the far right of the Projects toolbar.

Figure 23–6 Navigator Display Options - Show Libraries



23.4 Customizing Oracle WebCenter Portal Tools and Services Task Flows

JDeveloper's Customization Developer role is a powerful mechanism that allows you to customize the ADF Library without changing the code in the base library JAR. Since both Oracle WebCenter Portal and Oracle ADF leverage MDS, you can use the Customization Developer role to extend WebCenter Portal tools and services task flows. All WebCenter Portal tools and services task flows are packaged in the ADF

Library so task flow customization is possible in JDeveloper design time. For instructions on configuring the Customization Developer role, see Section 23.3, "Configuring the JDeveloper Customization Developer Role"

The use cases that can be achieved by task flow customization include:

- Change labels including column names for task flows.
- Change icons used in task flows, for example replacing the Edit and Refresh icons with new icons on the Discussions Forums task flow.
- Change the order of table columns in a task flow.
- Remove an entire region or component, such as the Search box from primary tab.
- Show additional attributes using Expression Language, for example customizing the People Picker task flow to show an additional user profile attribute.

After you have prepared your application for customization as described in the previous sections, open the application and make any necessary customizations.

- For examples of task flow customization, see Section 23.4.1, "Examples: Customizing Task Flows for WebCenter Portal" and Section 23.4.2, "Examples: Customizing Task Flows for WebCenter Portal Framework Applications."
- For a list of customizable task flows, see Section 23.7, "Catalog of Customizable Oracle WebCenter Portal Tools and Services Task Flows."
- After you have completed your customizations, deploy them as described in Section 23.5, "Applying Task Flow Customizations to WebCenter Portal or Deployed WebCenter Portal Applications."

23.4.1 Examples: Customizing Task Flows for WebCenter Portal

To customize task flows for WebCenter Portal, open the customization application you created in Section 23.2.2, "WebCenter Portal: Create a Task Flow Customization Application" and make your customizations.

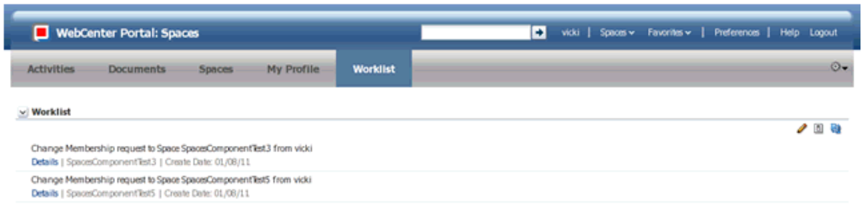
This section provides examples that explain two common customizations. It includes the following topics:

- Section 23.4.1.1, "Example: Customizing the Worklist Task Flow"
- Section 23.4.1.2, "Example: Customizing the Discussion Forums Task Flow"
- Section 23.4.1.3, "Example: Customizing the Document Explorer Task Flow"

23.4.1.1 Example: Customizing the Worklist Task Flow

This example shows how to customize the Worklist task flow by replacing the two-row entry for each worklist item with a single row that provides a link to the worklist item details with a popup that displays the details that were previously shown on the second row. Figure 23–7 shows a sample Worklist with the default two-row entry configuration.

Figure 23–7 Worklist - Before Customization



Worklist

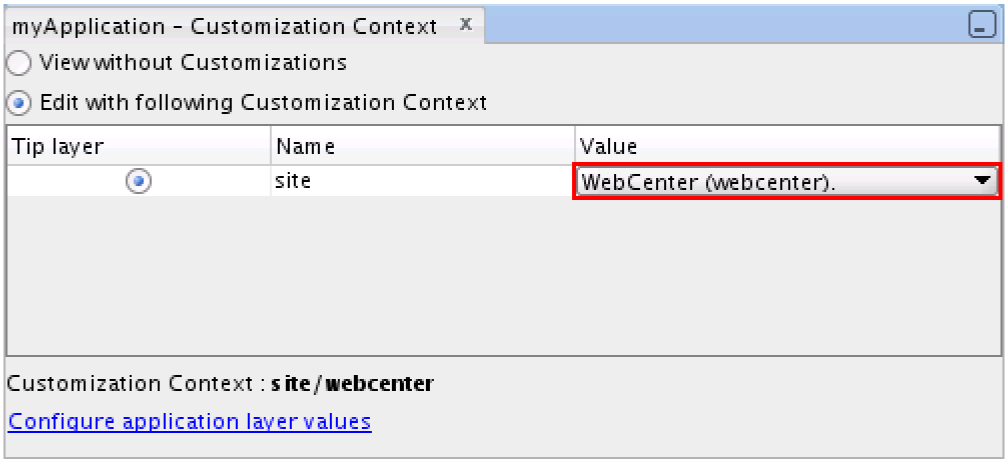
Change Membership request to Space SpacesComponentTest5 from vicki
Details | SpacesComponentTest5 | Create Date: 01/08/11

To customize the Worklist task flow:

1. If you are not already using the Customization Developer role, switch to this role as described at the beginning of Section 23.3, "Configuring the JDeveloper Customization Developer Role."
2. Open your WebCenter Portal Task Flow Customization Application.
3. In the Customization Context window, ensure that **Edit with following Customization Context** is selected and that **WebCenter (webcenter)** is selected as the customization layer (Figure 23–8).

Figure 23–8 Customization Context for WebCenter Portal



○ View without Customizations

● Edit with following Customization Context

Tip layer	Name	Value
●	site	WebCenter (webcenter)

Customization Context : **site/webcenter**

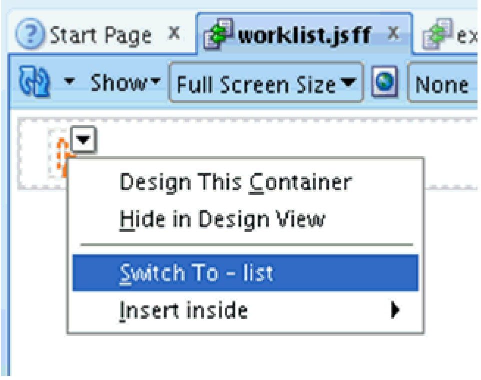
Configure application layer values

4. In the Application Navigator, expand the **ViewController** project to view all the libraries available in the project.

> **Tip:** If you cannot see the libraries, click the **Navigator Display Options** icon in the Projects bar, and choose **Show Libraries**.

5. Expand the **WebCenter Worklist Service View** library and then **worklist-service-ui-component-view.jar**, **oracle.webcenter.worklist**, **view**, **jsf**, and **fragments**.
6. Right-click **worklist.jsff** and choose **Open**.
7. Switch to the list view facet of the view. Click the empty facet on the page and choose **Switch To - list** (Figure 23–9).

Figure 23–9 Switch To List View

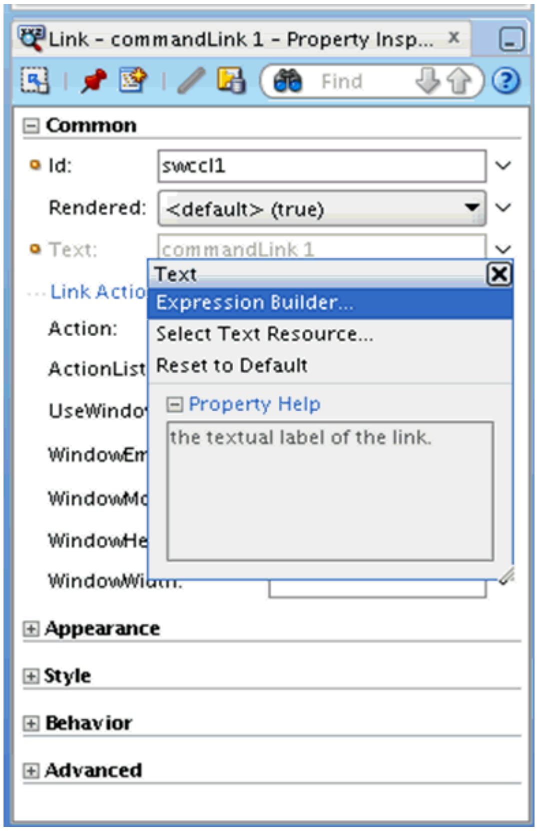


8. In the Structure window, expand the structure tree to locate the `af:outputText - #{row.title}` component. Right-click the component and choose **Insert Before af:outputText - #{row.title}** > **Link**.

9. In the Structure window, click on the newly created `af:commandLink` to open the Property Inspector dialog.

10. In the Property Inspector, click the down arrow next to the **Text** field and choose **Expression Builder** (Figure 23–10). Enter `#{row.title}` as the expression.

Figure 23–10 Property Inspector



Link - commandLink 1 - Property Insp...

Common

Id: swccl1

Rendered: <default> (true)

Text: commandLink 1

11. Expand the Appearance section of the Property Inspector. Click the down arrow next to the **ShortDesc** field and choose **Expression Builder**. Enter `#{row.dateInfoSummary}` as the expression.

12. In the **ActionListener** field, enter `openTaskDetailsApp()`
13. Find the newly added `commandLink` and delete the following components:
    `af:outputText - #{row.title}`
    `af:panelGroupLayout`
14. The `worklist.jsff.xml` file that is generated (under the ADF Library Customizations node in the Application Navigator) should include code similar to that shown in Example 23–1.

Example 23–1 Updated worklist.jsff file

```
<mds:customization version="11.1.1.61.15"
                   xmlns:mds="http://xmlns.oracle.com/mds">
  <mds:insert parent="pg13" position="first
              xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
    <af:commandLink xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
                  text="#{row.title}" id="swccl1"
                  shortDesc="#{row.dateInfoSummary}"
                  actionListener="#{backingBeanScope.wlbbean.openTaskDetailsApp}"/>
  </mds:insert>
  <mds:replace node="ot2"/>
  <mds:replace node="pg14"/>
</mds:customization>
```

15. Deploy the metadata deployment profile to WebCenter Portal as explained in Section 23.5, "Applying Task Flow Customizations to WebCenter Portal or Deployed WebCenter Portal Applications."

Figure 23–11 shows a sample Worklist after customization, with a single row and a popup.

Figure 23–11 Worklist - After Customization

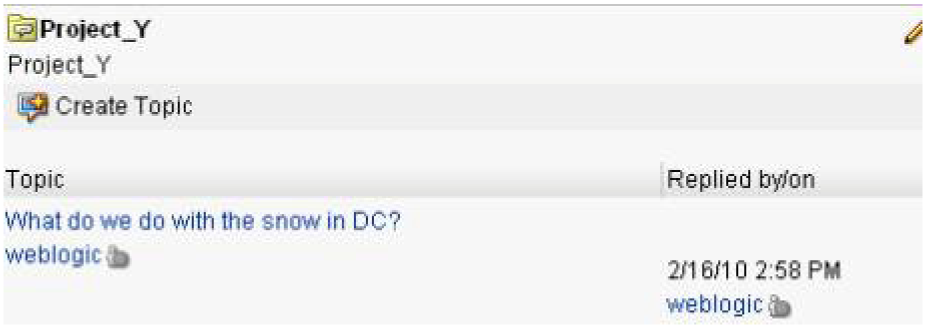
23.4.1.2 Example: Customizing the Discussion Forums Task Flow

This example shows how you can customize the Discussion Forums task flow to display a profile image for the user who initiated the discussion. Figure 23–12 shows a sample Discussion Forum without the profile image.

Figure 23–12 Discussion Forum - Before Customization



Project_Y

Project_Y

Create Topic

Topic	Replied by/on
What do we do with the snow in DC? weblogic	2/16/10 2:58 PM weblogic

To customize the Discussion Forums task flow:

1. If you are not already using the Customization Developer role, switch to this role as described at the beginning of Section 23.3, "Configuring the JDeveloper Customization Developer Role."
2. Open your WebCenter Portal Task Flow Customization Application.
3. In the Application Navigator, expand the **ViewController** project to view all the libraries available in the project.

   > **Tip:** If you cannot see the libraries, click the **Navigator Display Options** icon in the Projects bar, and choose **Show Libraries**.

4. Expand the **WebCenter Discussion Services View** library and then **forum-view.jar**, **oracle.webcenter.collab**, **view**, **forum**, **jsf**, and **fragments**.
5. Right-click **ListTopics.jsff** and choose **Open**.
6. In the Structure window, search for the `<rtc:presence>` tag on the page. This tag renders the user name.
7. Right-click the `rtc.:presence` tag, then choose **Insert After** > **ADF Faces** and select **Panel Group Layout** from the dialog.
8. In the Structure window, right-click the new **Panel Group Layout** and choose **Insert** > **Image Component**.
9. In the Property Inspector for the new Image component, set the Source property to `#{webCenterProfile[row.createdBy].photoURI['SMALL']}`. This EL will return the location of the image that the current user has set as their profile photo.
10. Save your files and rebuild the project.

    The `ListTopics.jsff.xml` file that is generated will contain the following code:

Example 23–2 Updated ListTopics.jsff.xml File

```
<mds:customization version="11.1.1.60.46" xmlns:mds="http://xmlns.oracle.com/mds">
 <mds:insert after="p1" parent="frmltpgl11"
             xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
    <af:panelGroupLayout xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
                    id="swcpgl1">
      <af:image xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
        source="#{webCenterProfile[row.createdBy].photoURI['SMALL']}" id="swci1"/>
    </af:panelGroupLayout>
  </mds:insert>
</mds:customization>
```

11. Deploy the metadata deployment profile to the WebCenter Portal application as explained in Section 23.5, "Applying Task Flow Customizations to WebCenter Portal or Deployed WebCenter Portal Applications."

Figure 23–13 shows a sample Discussion Forum after customization, with a profile image.

Figure 23–13 Discussion Forum - After Customization (With User Profile Image)

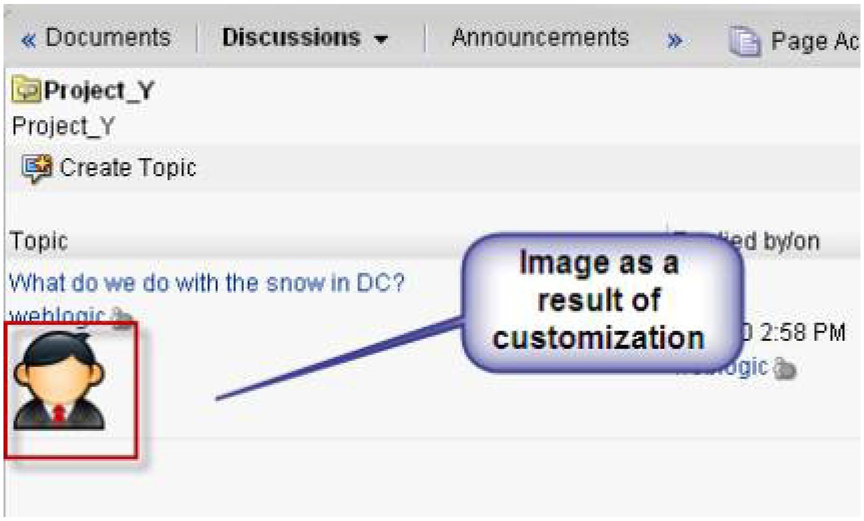


Image as a result of customization

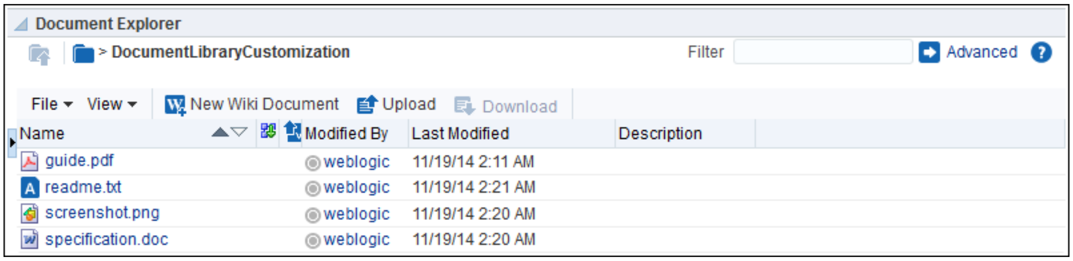
23.4.1.3 Example: Customizing the Document Explorer Task Flow

The example that follows shows how to customize the Document Explorer task flow to display additional metadata for content items. Figure 23–14 shows the Document Explorer task flow, with its default set of fields.

Figure 23–14 Document Explorer Task Flow - Before Customization



Name	Modified By	Last Modified	Description
guide.pdf	weblogic	11/19/14 2:11 AM	
readme.txt	weblogic	11/19/14 2:21 AM	
screenshot.png	weblogic	11/19/14 2:20 AM	
specification.doc	weblogic	11/19/14 2:20 AM	

To customize the Document Explorer task flow:

1. Configure the Documents service to expose additional custom metadata fields:

   a. Log in to the WebLogic Server Administration Console.

   b. Navigate to **Environment > Servers > WC_Spaces**.

   c. Open the **Configuration > Server Start** tab and in the **Arguments** field enter the server startup argument `oracle.webcenter.doclib.attributenames` and specify the metadata field that you want to add to the Document Explorer (this is the name as defined in Oracle WebCenter Content). For example:

   ```
   -Doracle.webcenter.doclib.attributenames=xState
   ```

Tip: If you want to add more than one field, separate the names with commas.

d. Restart the `WC_Spaces` managed server.

2. In JDeveloper, if you are not already using the Customization Developer role, switch to this role as described at the beginning of Section 23.3, "Configuring the JDeveloper Customization Developer Role."

3. Open your WebCenter Portal Task Flow Customization Application.

4. In the Application Navigator, expand the **ViewController** project to view all the libraries available in the project.

   Tip: If you cannot see the libraries, click the **Navigator Display Options** icon in the Projects bar, and choose **Show Libraries**.

5. Expand the **WebCenter Portal Document Library Service View** library and then **oracle.webcenter.doclib**, **view**, **jsf**, **taskflows**, and **folderViewer**.

6. Right-click **folderViewer.jsff** and choose **Open**.

7. In the **Source** view, locate the table that lists the content items and add a column for the new attribute, for example:

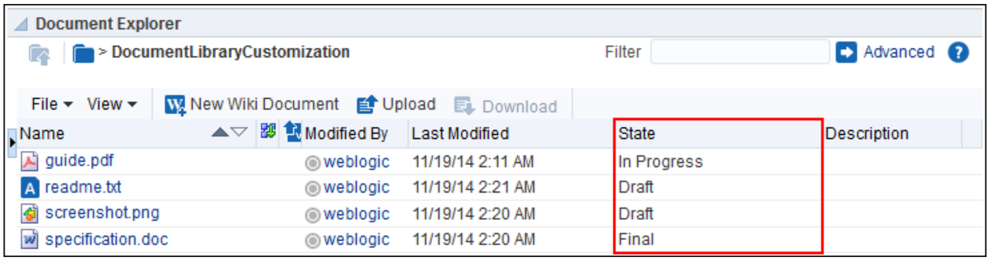
```
<af:column id="stateColumn"
           headerText="State"
           noWrap="false"
           width="250"
           align="start"
           sortable="true"
           sortProperty="attrs.xState">
  <af:outputText id="state" value="#{item.attrs.xState}" />
</af:column>
```

8. Save your files and rebuild the project.

9. Deploy the metadata deployment profile to the WebCenter Portal application as explained in Section 23.5, "Applying Task Flow Customizations to WebCenter Portal or Deployed WebCenter Portal Applications."

   Figure 23–15 shows a sample Document Explorer task flow after customization, with an additional State column.

Figure 23–15 Document Explorer Task Flow - After Customization



Name	Modified By	Last Modified	State	Description
guide.pdf	weblogic	11/19/14 2:11 AM	In Progress	
readme.txt	weblogic	11/19/14 2:21 AM	Draft	
screenshot.png	weblogic	11/19/14 2:20 AM	Draft	
specification.doc	weblogic	11/19/14 2:20 AM	Final	

23.4.2 Examples: Customizing Task Flows for WebCenter Portal Framework Applications

To customize task flows in a Portal Framework application, first follow the instructions in Section 23.2.3, "WebCenter Portal Framework Applications: Enable Customization."

This section provides examples for two possible customizations. It includes the following topics:

- Section 23.4.2.1, "Example: Customizing the Document Library - List View Task Flow"
- Section 23.4.2.2, "Example: Customizing the Content Presenter Task Flow"

23.4.2.1 Example: Customizing the Document Library - List View Task Flow

The example that follows shows how to customize the Document Library – List View task flow to add a new column called HTML Rendition. Before you perform these steps, ensure that you have prepared a customizable Portal Framework application application as described in Section 23.2.3, "WebCenter Portal Framework Applications: Enable Customization."

To customize the Document Library - List View task flow:

1. Open your Portal Framework application in JDeveloper and confirm that you are using the **Customization Developer** role.
2. In the Resource Palette, under My Catalogs, expand the WebCenter Portal Services Catalog and open the Task Flows folder.
3. Right-click **Document Library – List View** and choose **Add to project**. If a confirmation dialog displays, click **Add Library**.
4. In the Application Navigator, expand the **Portal** project to view all the libraries available in the project.

   > **Tip:** If you cannot see the libraries, click the **Navigator Display Options** icon in the Projects bar, and choose **Show Libraries**.

5. Expand the **WebCenter Document Library Service View** library and then **doclib-service-view.jar**, **oracle.webcenter.doclib**, **view**, **jsf**, and **fragments**.
6. Right-click **docListViewerTableTemplate.jsff** and choose **Open**.
7. Add a new column after `ITEM_NAME_COLUMN_HEADER`.
   a. In the Structure window, right-click the column with title `#{dlBndl.ITEM_NAME_COLUMN-HEADER}` and choose Copy and Paste to create a new ADF column component.
   b. In the Property Inspector for the new ADF column component, change the `headerText` property to `HTML Rendition`.
   c. In the Structure window, expand the new column and delete the `af:image` component.
   d. Right click the `af:goLink` component inside `af:switcher -> f:facet - false` and choose **Go to property**.
   e. Change the values of the Text and Destination. For example:

```
Text=" Get Conversion (HTML)"
Destination="http://host:port/idcplg?IdcService=GET_DYNAMIC_CONVERSION
```

```
&amp;dID=#{item.dID}&amp;coreContentOnly=1#{item.portletLinkPostfix}"
```

8. Save your files.

23.4.2.2 Example: Customizing the Content Presenter Task Flow

This example shows how to customize the Content Presenter task flow to control the display of the border and toolbar in Composer Edit mode according to the permission of the current user. Before you perform these steps, ensure that you have prepared a customizable Portal Framework application application as described in Section 23.2.3, "WebCenter Portal Framework Applications: Enable Customization."

To customize the Content Presenter task flow:

1. Open your Portal Framework application in JDeveloper and confirm that you are using the **Customization Developer** role.
2. In the Resource Palette, under **My Catalogs**, expand the **WebCenter Portal Services Catalog** and open the **Task Flows** folder.
3. Right-click **Documents - Content Presenter** and choose **Add to project**. If a confirmation dialog displays, click **Add Library**.
4. In the Application Navigator, expand the **Portal** project to view all the libraries available in the project.

   Tip: If you cannot see the libraries, click the **Navigator Display Options** icon in the Projects bar, and choose **Show Libraries**.

5. Expand the **WebCenter Document Library Service View** library and then **doclib-service-view.jar**, **oracle.webcenter.doclib**, **view**, **jsf**, **taskflows**, and **presenter**.
6. Right-click **presenterSingleView.jsff** and choose **Open**.
7. In Source view, edit the code for the main `af:panelGroupLayout` component as follows:

```
<af:panelGroupLayout id="psvPgl1"
  partialTriggers="psvCtb3 psvPopup2 psvPopup3 psvPopup4 psvCbNp1 psvCbNp0"
  layout="vertical"
  inlineStyle="#{composerContext.subView == 'contentContribution'
    and pageServiceBean.canEdit ? 'border:2px dashed blue' : ''}">
```

   Tip: You can also change the border for `2px dashed blue` to a different style.

8. Edit the code for the `af:panelBox` component as follows:

```
<af:panelBox id="psvPbNp0" showHeader="never" background="light"
  ramp="highlight" inlineStyle="width:350px"
  rendered="#{composerContext.subView == 'layout'
    and backingBeanScope.presenterBacking.nodePending
    and pageServiceBean.canEdit}">
```

9. Edit the code for the `af:toolbar - 1` component under the `contentContribution` facet as follows:

```
<af:toolbar id="psvTb1" flex="1"
  stretchId="psvSp1" rendered="#{pageServiceBean.canEdit}">
```

10. Save your files.

23.5 Applying Task Flow Customizations to WebCenter Portal or Deployed WebCenter Portal Applications

The previous sections explained how to customize WebCenter Portal tools and services task flows for different scenarios. The output of these exercises is the generated MDS customization. The customizations show up as `.xml.xml` or `.jsff.xml` files in the Portal or ViewController project of the application under the `libraryCustomization` package. These customization documents are essentially instructions for MDS to apply changes on top of the base document that is shipped to show the customized behavior at runtime.

Once you complete a task flow customization, you must apply it to the deployed application. To see customizations performed on task flows in JDeveloper at runtime, you must import these customizations to the MDS repository of the deployed application.

> **Note:** This process updates the runtime WebCenter Portal application metadata repository; back up the MDS schema before performing these steps. Also, it is best practice to test your customizations in a development or stage environment first.

This section includes the following topics:

- Section 23.5.1, "WebCenter Portal Framework Applications: Creating a Metadata Deployment Profile"
- Section 23.5.2, "Deploying Task Flow Customizations Directly from JDeveloper"
- Section 23.5.3, "Deploying Task Flow Customizations Using WLST"

23.5.1 WebCenter Portal Framework Applications: Creating a Metadata Deployment Profile

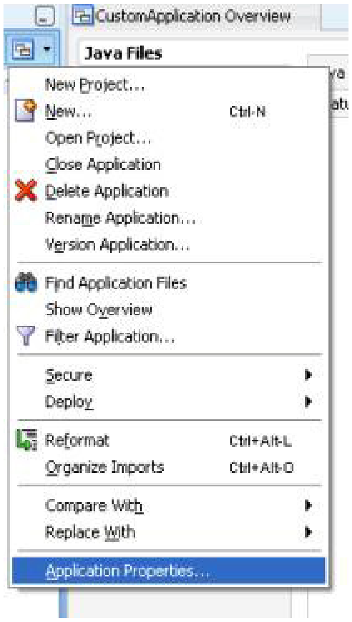
For Portal Framework applications, you must first create a metadata deployment profile.

> **Note:** These steps are not necessary if you are using the WebCenter Portal Task Flow Customization Application to customize task flow for WebCenter Portal.

To create a metadata deployment profile:

1. In the Application Navigator, right-click the application name and choose **Application Properties** (Figure 23–16).

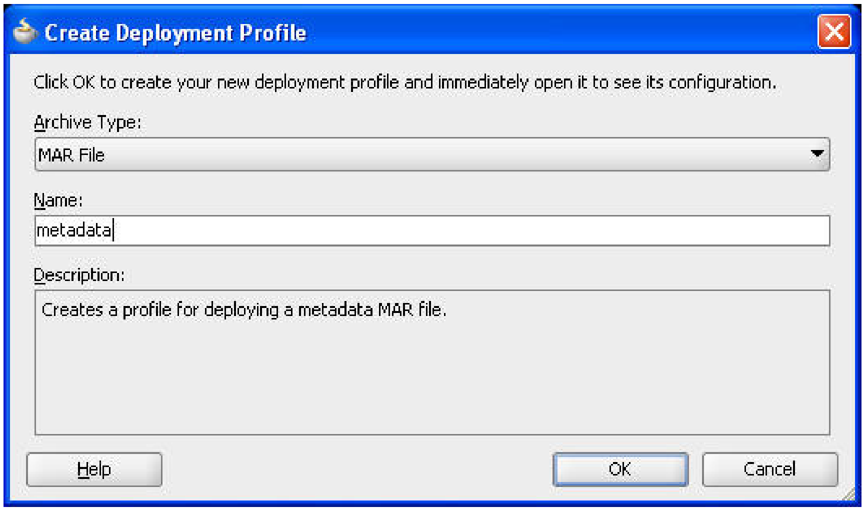
Figure 23–16 Application Properties



2. Click **Deployment** and then click **New** to create a new metadata deployment profile.

3. In the Create Deployment Profile dialog (Figure 23–17), from the **Archive Type** drop-down list, select **MAR File**.

Figure 23–17 Creating a Deployment Profile



Create Deployment Profile

Click OK to create your new deployment profile and immediately open it to see its configuration.

Archive Type: MAR File

Name: metadata

Description: Creates a profile for deploying a metadata MAR file.

4. Click **OK** to close the Create Deployment Profile dialog.

5. Click **OK**, then click **OK** again to finish creating the deployment profile.

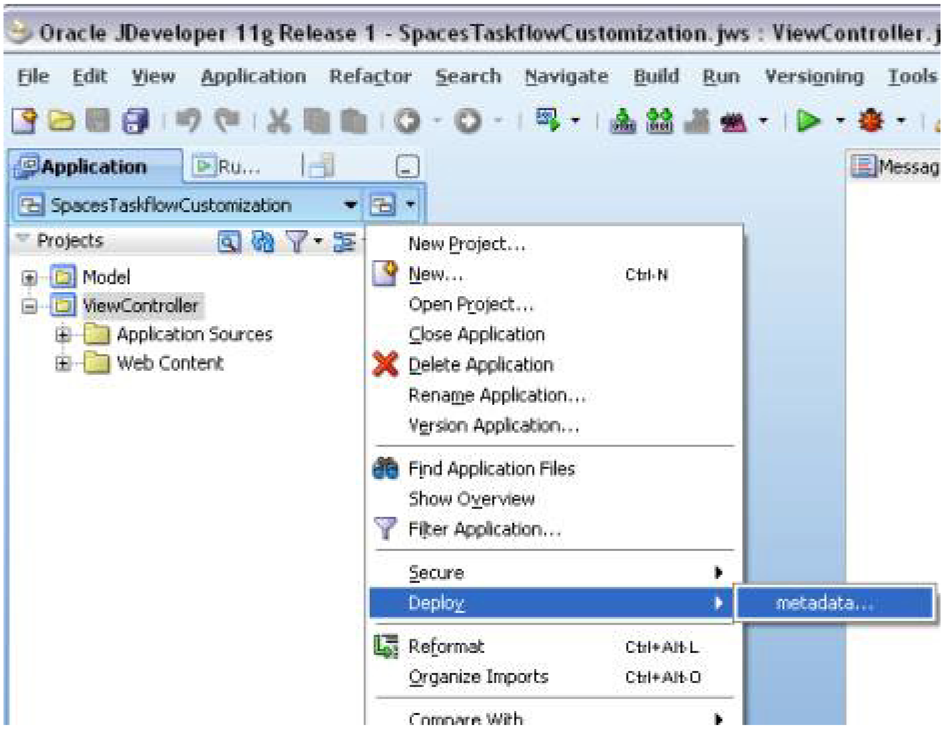
23.5.2 Deploying Task Flow Customizations Directly from JDeveloper

You can deploy your task flow customizations directly from JDeveloper.

To deploy task flow customizations directly from JDeveloper:

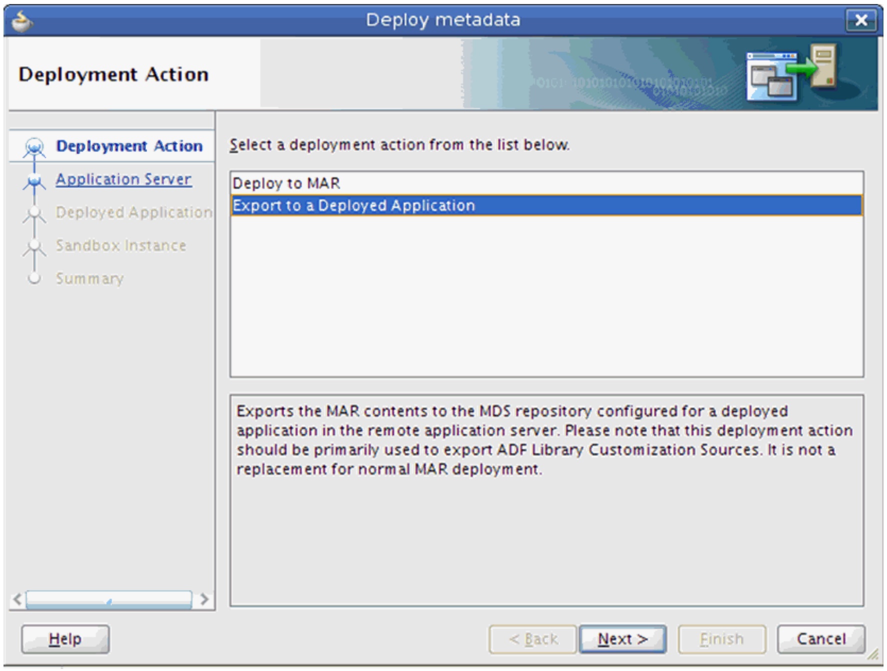
1. In the Application Navigator, right-click the application name and choose **Deploy** and then the metadata deployment profile (Figure 23–18).

Figure 23–18 Deploying the Metadata Deployment Profile



2. In the **Deploy metadata** dialog (Figure 23–19), select **Export to a Deployed Application** and click **Next**.

Figure 23–19 Deploy Metadata Dialog



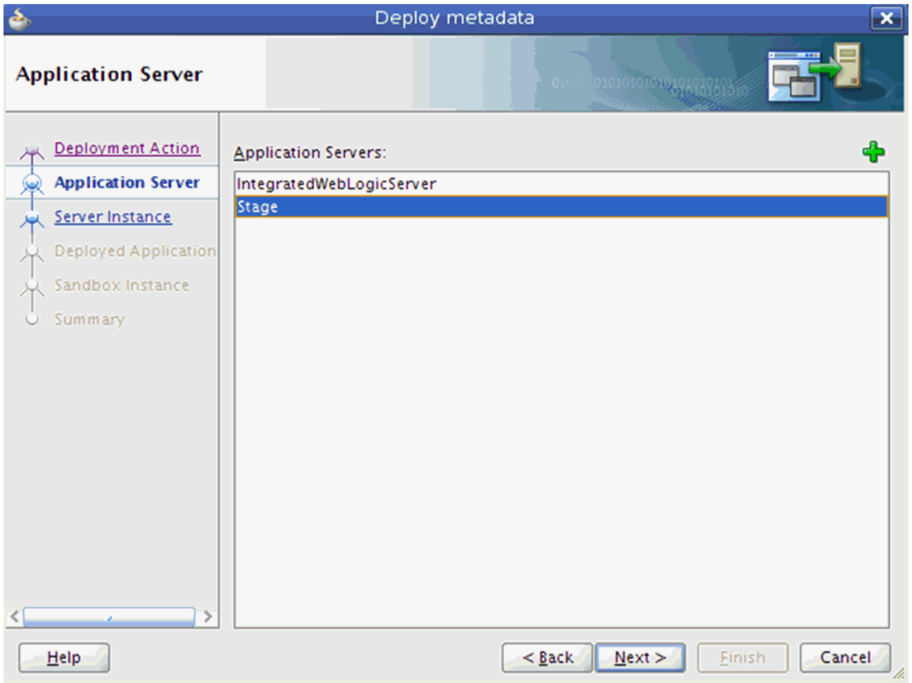
Select a deployment action from the list below.

Deploy to MAR
Export to a Deployed Application

Exports the MAR contents to the MDS repository configured for a deployed application in the remote application server. Please note that this deployment action should be primarily used to export ADF Library Customization Sources. It is not a replacement for normal MAR deployment.

3. On the **Application Server** page (Figure 23–20), select the application server connection for the instance to which you are deploying or create a new connection by clicking the "+" icon. Click **Next**.

Figure 23–20 Deploy Metadata: Application Server



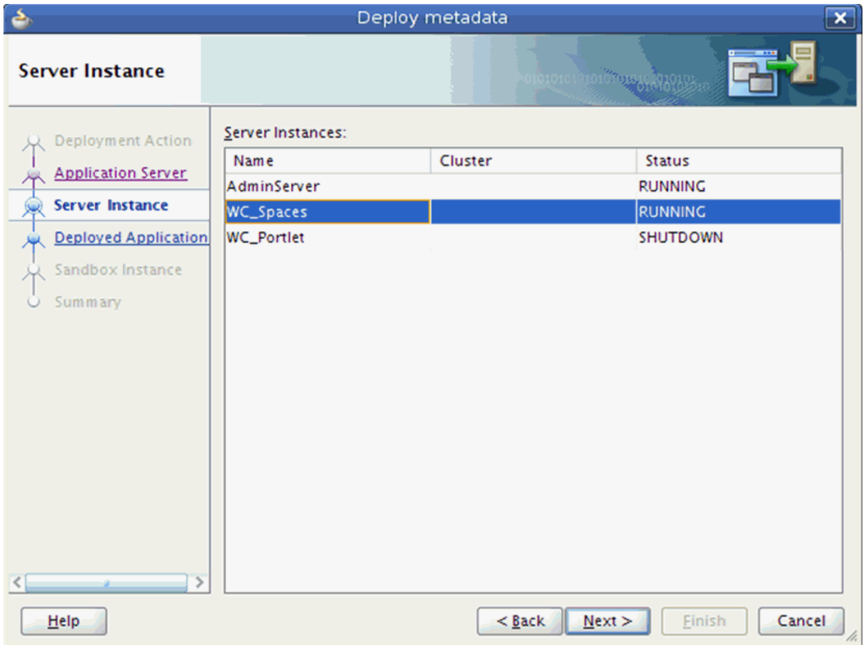
Application Servers:

IntegratedWebLogicServer

Stage

4. On the **Server Instance** page (Figure 23–21), select the server on which the application you are customizing is deployed. For a high availability installation with multiple servers hosting a single application, the customizations only need to be deployed to one server. Click **Next**.

Figure 23–21 Deploy Metadata Dialog: Server Instance

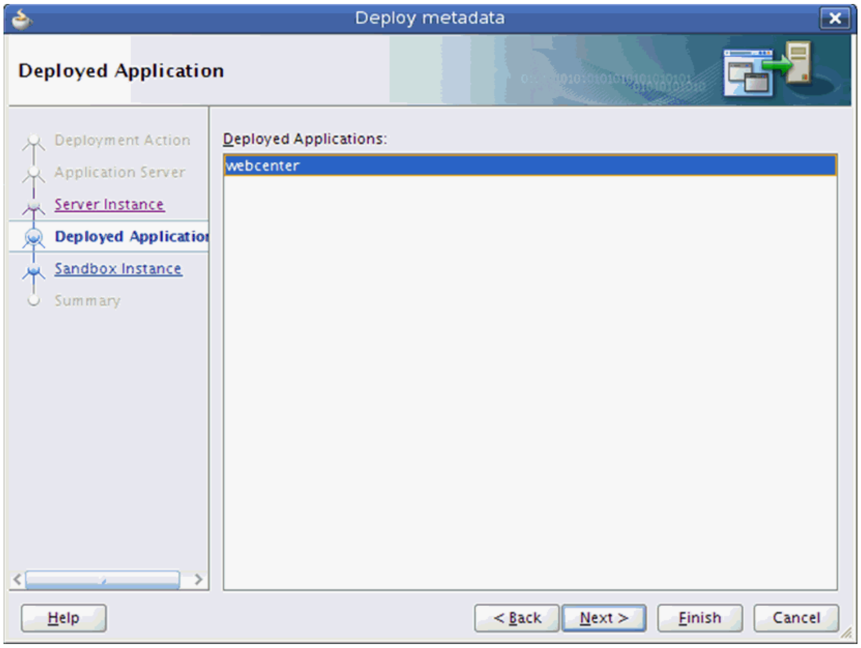


Server Instances:

Name	Cluster	Status
AdminServer		RUNNING
WC_Spaces		RUNNING
WC_Portlet		SHUTDOWN

5. On the **Deployed Application** page (Figure 23–22), select the application to which the customizations should be deployed then click **Next**.

Figure 23–22 Deploy Metadata: Deployed Applications



6. Click **Finish** to deploy the customization.

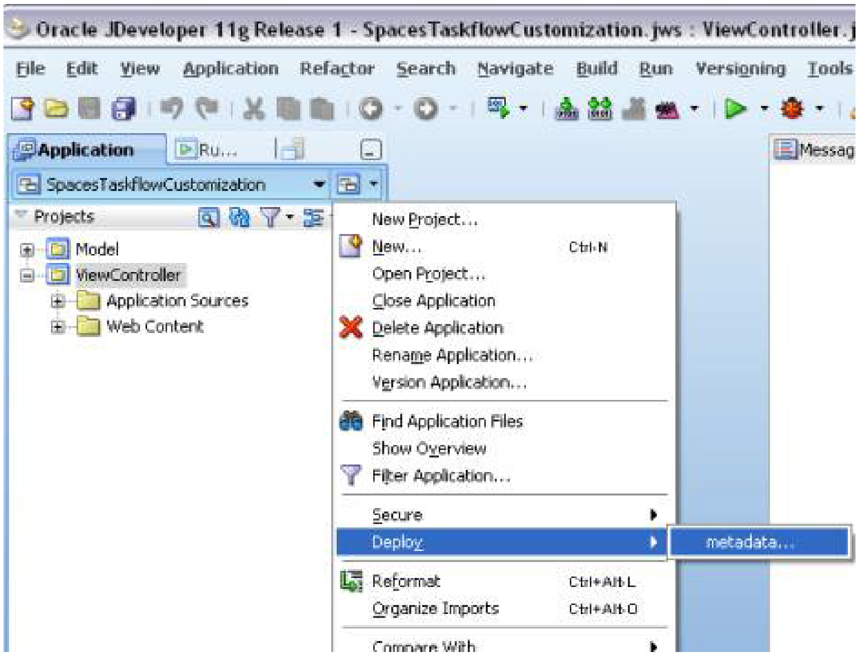
23.5.3 Deploying Task Flow Customizations Using WLST

You can also use the WLST command `importMetadata` to deploy task flow customizations.

To deploy task flow customizations using WLST:

1. In the Application Navigator, right-click the application name and choose **Deploy** and then the name of the metadata deployment profile (Figure 23–23).

Figure 23–23 Deploying the Metadata Deployment Profile



2. In the Deploy metadata dialog, choose Deploy to MAR file, then click **Finish**.

   > **Tip:** Alternatively, you can export the metadata to a deployed application by selecting the **Export to Deployed Application** option, configuring the connection details of the server on which the application is deployed, and selecting the appropriate application.

3. JDeveloper creates the MAR file in the application directory of your *JDEV_USER* home directory. Copy this MAR file, which contains the customizations, to the directory where the target application is deployed. Maintain a backup of this file so that you always have a version of the customizations for this application.

4. Use the MDS WLST command `importMetadata` command to import the task flow customizations to the application's MDS repository.

   Example 23–3 shows an example of how to run the `importMetadata` WLST command. For command syntax and detailed examples, see the "importMetadata" section in the *WebLogic Scripting Tool Command Reference*.

Example 23–3 Command Line for Importing Customizations

```
wls:/weblogic/serverConfig>importMetadata(application='webcenter',
          server='WC_Spaces', fromLocation='/path/metadata.mar',
          docs='/**')
```

For information on how to run WLST commands, see the "Running Oracle WebLogic Scripting Tool (WLST) Commands" section in *Administering Oracle WebCenter Portal*.

23.6 Removing Customizations from Deployed WebCenter Portal Applications

You can revert task flow behavior or look and feel to the original deployment by removing task flow customizations.

Use the MDS WLST command `deleteMetadata` to remove the applied customizations.

> **Note:** Use the `deleteMetadata` command with caution as incorrect use of this command may cause the unintended loss of metadata documents. The sample command below removes the customization created in Section 23.4.1.2, "Example: Customizing the Discussion Forums Task Flow."

Example 23–4 shows an example of how to run the deleteMetadata WLST command. For command syntax and detailed examples, see the "deleteMetadata" section in the *WebLogic Scripting Tool Command Reference*.

Example 23–4 Command to Delete the Customization Metadata from a Deployed WebCenter Portal Application

```
deleteMetadata(application='webcenter',server='WC_Spaces',
       docs='/oracle/webcenter/webcenterapp/view/taskflows/discussionServices/**',
       excludeBaseDocs='true')
```

For information on how to run WLST commands, see the "Running Oracle WebLogic Scripting Tool (WLST) Commands" section in *Administering Oracle WebCenter Portal*.

23.7 Catalog of Customizable Oracle WebCenter Portal Tools and Services Task Flows

The following Oracle WebCenter Portal tools and services task flows have been validated for view-level customizations. You can find these task flows in the libraries or JAR files and definition paths specified in Table 23–1.

> **Note:** To customize analytics task flows, you must add the following JARs to the project:
>
> *JDEV_HOME*/webcenter/modules/oracle.webcenter.framework_11.1.1/analytics-reporting-service-view.jar
>
> *JDEV_HOME*/webcenter/modules/oracle.webcenter.framework_11.1.1/analytics-reporting-service-model.jar

Table 23–1 Oracle WebCenter Portal Tools and Services Customizable Task Flows

Description	Library/JAR Files	Definition Path	Notes
Activity Stream - Mini View	WebCenter Portal Activity Streaming Service View	`oracle/webcenter/activitystreaming/controller/taskflows/activity-streaming-miniview.xml`	Activity stream table is a custom tag and cannot be customized.

Part IV

Integrating and Publishing Content

Part IV contains the following chapters:

- Chapter 24, "Introduction to Integrating and Publishing Content"
- Chapter 25, "Configuring Content Repository Connections"
- Chapter 26, "Working with Content Data Controls"
- Chapter 27, "Creating Content Presenter Display Templates"
- Chapter 28, "Integrating Documents"
- Chapter 29, "Adding Content Task Flows and Document Components to a Portal Page"
- Chapter 30, "Integrating Wikis and Blogs"
- Chapter 31, "Content Management REST API"

24

Introduction to Integrating and Publishing Content

This chapter describes the various ways to integrate content into a WebCenter Portal Framework application: content data controls, Content Management Interoperability Services (CMIS) REST APIs, Content Presenter, and the Documents tool. The method you choose is dependent on the requirements of the application and how you want to expose content to end users.

You can integrate content into a Portal Framework application using any of the following methods (for more information, see the references at the end of this chapter):

- **Documents** task flows and components offer a variety of formats to display folders and files, including wikis and blogs, on a page in a Portal Framework application. You can choose the task flows appropriate for your application to provide features for accessing, adding, and managing folders and files; configuring and viewing file and folder properties; and searching file and folder content in WebCenter Content, Oracle Portal, or SharePoint content repositories.

  > **Note:** The availability of SharePoint as a content repository requires the installation of the SharePoint adapter, as described in Section 25.2.3.1, "Installing the Oracle WebCenter Adapter for SharePoint." Administration for SharePoint is performed using WLST commands, not Oracle Enterprise Manager Fusion Middleware Control Console.

  Using documents task flows and document components (such as links, previews, and images), you can add content to the application, and also provide end users with content and documents task flows built into the application to manage, display, and search documents at runtime.

- **Content Presenter** enables you to precisely customize the selection and presentation of content in a Portal Framework application. The Content Presenter task flow is available only when the connected content repository is WebCenter Content and your WebCenter Portal administrator has completed the prerequisite configuration. With Content Presenter, you can select a single item of content, contents under a folder, a list of items, query for content, or select content based on the results of a Personalization Conductor scenario, and then select a template to render the content on a page in a Portal Framework application. Content Presenter has no dependency on the Documents tool for adding or managing the content it displays.

- **CMIS REST APIs** surface and manage content in WebCenter Content.

- **Content data controls** use JCR adapters to enable read-only access to content in a WebCenter Content, Oracle Portal, or SharePoint content repository, and maintain tight control over the way the content displays in a Portal Framework application.

  This functionality is available primarily for backward compatibility with prior releases, and for requirements outside the capability of Content Presenter or the Documents tool and its task flows.

Table 24–1 provides a comparative overview of these methods to help you select the most appropriate method for your needs.

Table 24–1 Methods of Integrating Content into a Framework Application

	Content Data Controls	Content Management REST APIs	Content Presenter	Documents Tool
Repository	■ WebCenter Content ■ Oracle Portal ■ SharePoint	■ WebCenter Content	■ WebCenter Content	■ WebCenter Content ■ Oracle Portal ■ SharePoint
Content Types	■ Folders and content files	■ Folders and content files with support for metadata properties	■ Folders and content files with support for metadata properties ■ Supports Oracle Site Studio region definitions-based content	■ Folders and content files ■ WebCenter Content only: supports folder and content file metadata properties
Content Display	■ Surface content using ADF render components: ADF Go Link, ADF Go Button, ADF Image, and ADF inline frame functions.	■ Surface content using REST APIs and custom client or server side application code. ■ Surface content through single item selection, by folder, and by query results.	■ Task flow-based component intended primarily for rendering content. ■ Surface content through single item selection, by folder, and by query results. ■ Surface content in display templates: either built-in templates or custom display templates developed in JDeveloper. ■ Reuse Oracle Site Studio display templates for Site Studio content. ■ Supports WebCenter Personalization Services Conductor scenario (query results).	■ Task flow-based components intended primarily for collaborating and managing content WebCenter Content only: ■ Document preview ■ View links ■ View images ■ View file information (properties, version history) ■ View metadata

Table 24–1 (Cont.) Methods of Integrating Content into a Framework Application

	Content Data Controls	Content Management REST APIs	Content Presenter	Documents Tool
Content Management	None	Manage content using REST APIs and custom client or server side application code Create, update, delete folders and content files and associated metadata fields	In-context contribution editing for HTML and Site Studio content	Manage content through graphical user interface Create, update, delete folders and content files WebCenter Content only: ■ Manage associated metadata properties ■ Item-level security ■ Oracle Workflow (WebCenter Portal only) ■ View metadata
Benefits	Standard JCR API integrates with many different content repositories.	Flexible REST-based APIs useful for client-side style development	Flexible display using display templates Oracle Site Studio support	Choice of task flows to provide easy UI access to managing content
Limitations	Read-only content No Oracle Site Studio support	Content must reside in Oracle Content Server repository No Oracle Site Studio support	Content must reside in WebCenter Content repository	No Oracle Site Studio support

The following chapters provide information that you will need for *any* method you use:

- "Managing Content Repositories" in *Administering Oracle WebCenter Portal* to configure and manage content repositories used by WebCenter Portal applications.
- Chapter 25, "Configuring Content Repository Connections" to configure and edit content repository connections that provide access to decentralized content.

The following chapter provides information about using *content data controls*:

- Chapter 26, "Working with Content Data Controls" to use Java Content Repository (JCR) data controls to enable read-only access to any content repository.

The following manual provides information about using *CMIS (Content Management Interoperability Services) REST APIs*:

- *Oracle Fusion Middleware Content Management REST Service Developer's Guide*

The following chapters provide information about using *Content Presenter*:

- Chapter 27, "Creating Content Presenter Display Templates"
- Chapter 29, "Adding Content Task Flows and Document Components to a Portal Page"
- "Publishing Content Using Content Presenter" in *Building Portals with Oracle WebCenter Portal* to work with content at runtime in WebCenter Portal applications.

The following chapters provide information about using the *Documents tool*, which includes the documents task flows, document components (links, inline frames, and images), wikis, and blogs:

- Chapter 28, "Integrating Documents"
- Chapter 29, "Adding Content Task Flows and Document Components to a Portal Page"
- Chapter 30, "Integrating Wikis and Blogs"
- "Working with Content in a Portal" in *Building Portals with Oracle WebCenter Portal* to work with content at runtime in WebCenter Portal applications.

25

Configuring Content Repository Connections

This chapter describes how to configure connections to content repositories to provide access to the content, and how to add content to pages in a Portal Framework application.

For information about other ways in which to integrate content into a Portal Framework application, see Chapter 24, "Introduction to Integrating and Publishing Content."

This chapter includes the following sections:

- Section 25.1, "Overview of Content Adapters"
- Section 25.2, "Configuring Content Repository Connections"
- Section 25.3, "Editing Content Repository Connections"
- Section 25.4, "Using an Existing Repository Connection for a New Portal Framework Application"

25.1 Overview of Content Adapters

In your Portal Framework application, you can use the following adapters:

- Oracle WebCenter Content: Content Server: The Content Server adapter is used to integrate content from an automated information system managed by Content Server. This system enables sharing, managing, and distributing of business information through a Web site as a common access point.

  This adapter is bundled with Oracle WebCenter Portal extension bundle, so it is integrated by default.

- Oracle Portal: The Oracle Portal adapter is used to integrate content from a content repository located in the Oracle Portal schema.

  This adapter is bundled with Oracle WebCenter Portal extension bundle, so it is integrated by default.

- Oracle WebCenter Adapter for SharePoint: This adapter is used to integrate content from the Microsoft SharePoint 2007 repository.

  You must install this adapter, as described in Section 25.2.3.1, "Installing the Oracle WebCenter Adapter for SharePoint."

- File System: The File System adapter is used to add content located on your operating system's file system to JSF pages.

  This adapter is bundled with Oracle WebCenter Portal extension bundle, so it is integrated by default.

Note: The File System adapter is intended to be used in development environments only.

25.2 Configuring Content Repository Connections

Content repository connections are required to access the repository content to be published on JSF pages. These connections are also required to access the repository content through the WebCenter Portal REST API.

This section describes how to configure content repository connections based on Oracle WebCenter Content: Content Server, Oracle Portal, Oracle WebCenter Adapter for SharePoint, and file system adapters. Content Presenter can connect to and retrieve content available in Content Server content repositories. With JCR data controls, you can connect to Content Server, Oracle Portal, Oracle WebCenter Adapter for SharePoint, and file systems.

Connections can be created under Application Resources in the Application Navigator and under IDE Connections in the Resource Palette.

This section includes the following subsections:

- Section 25.2.1, "Creating a Content Repository Connection Based on the Oracle Content Server Adapter"
- Section 25.2.2, "Creating a Content Repository Connection Based on the Oracle Portal Adapter"
- Section 25.2.3, "Creating a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint"
- Section 25.2.4, "Creating a Content Repository Connection Based on the File System Adapter"
- Section 25.2.5, "What Happens When You Create a Repository Connection"
- Section 25.2.6, "About Creating a Repository Connection"

25.2.1 Creating a Content Repository Connection Based on the Oracle Content Server Adapter

This section describes how to configure a Content Server-based content repository connection. To successfully perform the subsequent steps, you must use Content Server release 11.1.1.8.0 or later. For information about how to configure Content Server for Oracle WebCenter Portal, see the "Configuring an Oracle WebCenter Content Server Repository" section in *Administering Oracle WebCenter Portal*.

For an overview of the prerequisites and tasks required to get Content Server working in a portal or Framework application, see the "Configuration Roadmap for Content Server" section in *Administering Oracle WebCenter Portal*.

To create a Content Server-based repository connection:

1. In Oracle JDeveloper, open your Portal Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection**, then **Content Repository**.
3. In the Create Content Repository Connection dialog, specify a connection name for the connection; for example, `MyOCSConnection`.

Note: If you plan to deploy your portal to a managed WebLogic Server instance for which a connection is already established (for example, by an administrator using WLST), then you must use the same **Connection Name** here as was used for the managed server connection. Consult with your portal system administrator if you are unsure about the correct connection name.

Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **Oracle Content Server** from the **Repository Type** box.

5. Select **Set as primary connection for Documents**, to make this connection the primary (default) connection for all content management operations through the documents tool or Content Presenter. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection. If `connectionName` parameter is specified for a documents task flow, that value overrides this setting.

   Note: To be able to set a connection as the primary (default) connection for documents, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

6. Under **Configuration Parameters**, enter values for the parameters, as shown in Table 25–1 and Figure 25–1.

Table 25–1 Configuration Parameters for Content Server

Configuration Parameters	Values
RIDC Socket Type	Determines whether the client library connects on the Content Server listener port or the Web server filter. It accepts `socket`, `socketssl`, `web`, or `jaxws`. `socket`: Uses an `intradoc` socket connection to connect to the Content Server. The client IP address must be added to the list of authorized addresses in the Content Server. This corresponds to the `SocketHostAddressSecurityFilter` setting in the Content Server configuration file. `socketssl`: Uses an `intradoc` socket connection to connect to the Content Server that is secured using the SSL protocol. The client's certificates must be imported in the server's trust store for the connection to be allowed. `web`: Uses an HTTP(S) connection to connect to the Content Server. jaxws: Uses an HTTP(S) connection to connect to Content Server. Table 25–2 includes more information on the configuration parameters required for each RIDC socket type.
Server Host Name	Host name of the system where the Content Server is running. For example: `mycontentserver.mycompany.com`.

Table 25–1 (Cont.) Configuration Parameters for Content Server

Configuration Parameters	Values
Content Server Listener Port	Port of the server specified in the **Server Host Name** field. This corresponds to the `IntradocServerPort` setting in the Content Server configuration file, which defaults to port `4444`. **Note:** Although the intradocport value for a particular Content Server defaults to 4444, that value may change depending on the Content Server configuration.
URL of the Web Server Plugin	If the RIDC socket type is `web`, then the URL must be: For Content Server release 11.1.1.8.0: `http://`*`host_name:port_number/_dav/web_root/plugin_root`*. For example: `http://mycontentserver:4444/_dav/cms/idcplg`
Web Server Context Root	The Web server context root for Content Server to integrate advanced metadata and Site Studio capabilities in the Portal Framework application. The format of the Web server context root is `/`*`context_root`*. For example, `/cs`.
Admin Username	The user name with administrative rights for the Content Server instance. It defaults to `sysadmin`.
Admin Password	The password for the Content Server admin user. For example: `password`. This is needed for `web` connections only.
KeyStore File Location	Location of key store that contains the private key used to sign the security assertions. The key store location must be an absolute path. For example: `c:\keys\keystore.xyz`.
KeyStore Password	The password required to access the keystore.
Private Key Alias	The client private key alias in the keystore. The key is used to sign messages to the server. The public key corresponding to this private key must be imported in the server keystore.
Private Key Password	The client private key password required to retrieve the key from the keystore.
JAX-WS Client Security Policy	Enter the client security policy to be used when the **RIDC Socket Type** is **JAX-WS**. The JAX-WS client security policy can be any valid OWSM policy, but must match the security policy configured for the Content Server's Native Web Services IdcWebLogin service. For more information about the IdcWebLogin service, see the "Getting Started with Integrating WebCenter Content into Your Environment" section in *Developing with Oracle WebCenter Content*. For information about predefined security policies, see the "Security Policies" section in *Security and Administrator's Guide for Web Services*.
Cache Invalidation Interval	The interval (in minutes) used by WebCenter caches to automatically detect external Content Server content changes. This allows WebCenter to automatically clear cached items when changes to those items are made directly in the Content Server UI. The interval is in minutes. A value of `0` disables cache invalidation. The minimum valid value to enable cache invalidation is `2`.
Binary Cache Maximum Entry Size	The maximum size (in bytes) for WebCenter caching of Content Server binary documents. Documents larger than this size are not cached by WebCenter. The unit is bytes and defaults to `102400` (`100 Kb`).

Table 25–2 Content Server Connection Parameters for Each RIDC Socket Type

Connection Parameters	RIDC Socket Type: web	RIDC Socket Type: socket	RIDC Socket Type: socketssl	RIDC Socket Type: jaxws
Server Host Name	Not Applicable	Mandatory for Content Presenter Defaults to local host.	Mandatory for Content Presenter Defaults to local host.	Not Applicable
Content Server Listener Port	Not Applicable	Port specified for the incoming provider in the server. Defaults to `4444`. **Note:** Although the intradocport value for a particular Content Server defaults to 4444, that value may change depending on the Content Server configuration.	Port specified for the `sslincoming` provider in the server. Defaults to `4444`.	Not Applicable
URL of the Web Server Plugin	Mandatory	Not Applicable	Not Applicable	Mandatory Use format: `http://`*`hostname:port`*`/web_root` For example: http(s)://*`myhost.com:9044`*`/idcnativews`
Web Server Context Root	Optional	Optional	Optional	Optional

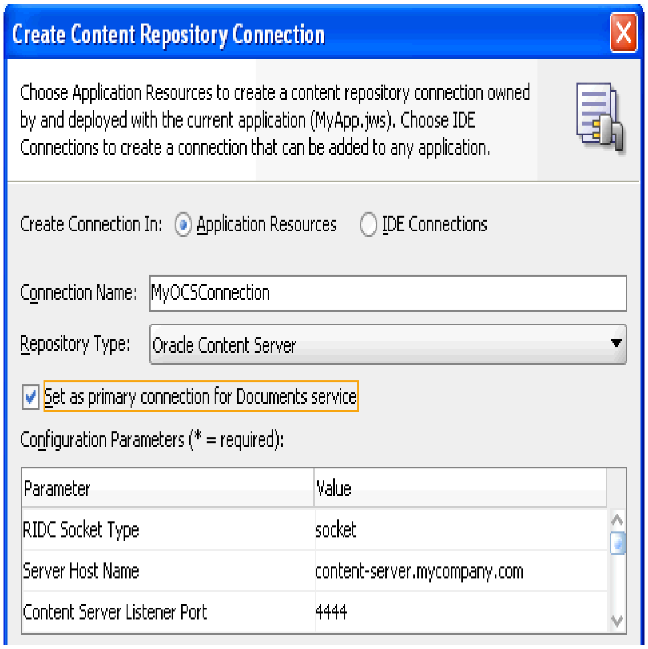
Table 25–2 (Cont.) Content Server Connection Parameters for Each RIDC Socket Type

Connection Parameters	RIDC Socket Type: web	RIDC Socket Type: socket	RIDC Socket Type: socketssl	RIDC Socket Type: jaxws
JAX-WS Client Security Policy	Not Applicable	Not Applicable	Not Applicable	Mandatory, unless Global Policy Attachment is used, in which case it should be left empty. This is the name of an OWSM client security policy. This policy must match the corresponding server side policy applied on the Content Server. For information about security policies, see the "Security Policies" section in the *Security and Administrator's Guide for Web Services*.
Admin Username	Mandatory	Optional Defaults to `sysadmin`	Optional Defaults to `sysadmin`	Optional Defaults to `weblogic`
Admin Password	Mandatory	Not Applicable	Not Applicable	Whether the password is used or not depends on the selected JAX-WS security policy.
Key Store and Private Key	Not Applicable	Not Applicable	Mandatory	Not Applicable
Identity Propagation	Not supported at runtime	Supported For testing purpose, connects as guest if no/invalid user name is specified.	Supported For testing purpose, connects as guest if no/invalid user name is specified.	Supported, provided that the JAX-WS security policy supports identity propagation.
External Application	Mandatory	Supported Password is not used.	Supported Password is not used.	Supported Whether the password is used or not depends on the selected JAX-WS security policy.

Table 25–2 (Cont.) Content Server Connection Parameters for Each RIDC Socket Type

Connection Parameters	RIDC Socket Type: web	RIDC Socket Type: socket	RIDC Socket Type: socketssl	RIDC Socket Type: jaxws
User Name and Password	Supported	Supported The password is not verified during the test connection operation.	Supported The password is not verified during the test connection operation.	Supported Whether the password is used or not depends on the selected JAX-WS security policy.

Figure 25–1 Content Repository Connection - Content Server



Create Content Repository Connection

Choose Application Resources to create a content repository connection owned by and deployed with the current application (MyApp.jws). Choose IDE Connections to create a connection that can be added to any application.

Create Connection In: ● Application Resources ○ IDE Connections

Connection Name: MyOCSConnection

Repository Type: Oracle Content Server

☑ Set as primary connection for Documents service

Configuration Parameters (* = required):

Parameter	Value
RIDC Socket Type	socket
Server Host Name	content-server.mycompany.com
Content Server Listener Port	4444

7. In the **Login Timeout (ms)** field, specify the time in milliseconds. This timeout determines how long the application must wait when trying to establish a session with the content repository. If the network connection or the content repository server to which you are trying to connect is slow, then consider overriding the default value specified in this field.

8. Select the applicable authentication method. See Section 25.2.6.1, "About Using Identity Propagation and External Application Authentication Methods" for information. If you select the Identity Propagation authentication method, then you must configure secure socket layer (SSL) in Content Server. For information, see the "Prerequisites to Configuring Content Server " section in *Administering Oracle WebCenter Portal*.

9. **User Name** and **Password** fields under the **Specify login credentials for the current JDeveloper session** checkbox are optional for the Identity Propagation authentication method. In a secured application when Identity Propagation is the chosen authentication method, selecting the Specify login credentials for the current JDeveloper session checkbox lets you navigate to the authenticated content repository connection at design time. When this checkbox is selected, you can also validate if user name and password you specified can be authenticated.

Note: If the **Specify login credentials for the current JDeveloper session** checkbox is selected, then the credentials you entered are used. If the checkbox is not selected, then the connection is tested using External Application credentials (if they exist), otherwise null credentials are used.

If you have selected **External Application** for authentication and also specified either public or shared credentials, then you can leave these fields blank, as the public or shared credentials can be used to login at design time. However, if you have selected **External Application** but have not specified public or shared credentials, then you must specify user name and password here.

10. Click **Test Connection** to check whether you have entered the connection details correctly. You should see a `Success!` status.

    During testing, the user name and password are used (if specified). If they are not specified, but an external application is defined with either shared or public credentials, then this is used. Otherwise, the guest user is used.

11. Click **OK**.

12. In the Application Resources panel, expand the repository connection you just created. The Connection Credentials dialog displays.

Note: The Connection Credentials dialog displays if you do not save the credentials, that is, you do not select the **Specify login credentials for the current JDeveloper session** checkbox, or if you do not specify an external application that uses public or shared credentials.

13. Enter the **User Name** and **Password** for the Content Server connection and click **OK**. The connection displays under the Application Resources panel.

25.2.2 Creating a Content Repository Connection Based on the Oracle Portal Adapter

This section describes how to create a content repository connection based on the Oracle Portal adapter. Before creating a repository connection, see Section 25.2.6, "About Creating a Repository Connection." You can use this connection to configure a content data control that will enable you to add content from the Oracle Portal repository to JSF pages.

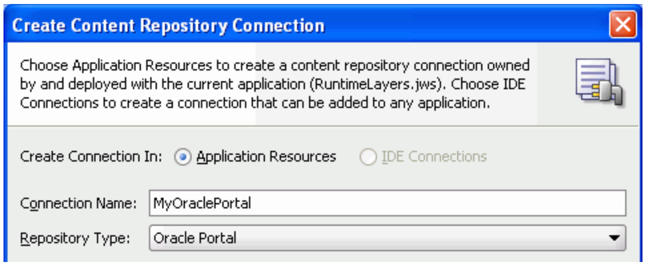
To create an Oracle Portal repository connection:

1. In Oracle JDeveloper, open your Portal Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection** and then **Content Repository**.
3. In the Create Content Repository Connection dialog, specify a name for the connection; for example, `MyOraclePortal`.

Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **Oracle Portal** from the **Repository Type** box, as shown in Figure 25–2.

Figure 25–2 Content Repository Connection - Oracle Portal



Create Content Repository Connection

Choose Application Resources to create a content repository connection owned by and deployed with the current application (RuntimeLayers.jws). Choose IDE Connections to create a connection that can be added to any application.

Create Connection In: ● Application Resources ○ IDE Connections

Connection Name: MyOraclePortal

Repository Type: Oracle Portal

5. Select **Set as primary connection for Documents** to make this connection the primary (default) connection for all content management operations through the documents tool or Content Presenter. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection. If `connectionName` parameter is specified for a documents task flow, that value overrides this setting.

   Note: To be able to set a connection as primary (default) connection for documents, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

6. Select a connection from the **Database Connection** list, or create a new connection to the Oracle Portal schema:

   a. In the Create Database Connection wizard, specify the connection name and type.

   b. Enter the database user name and password of the Oracle Portal schema. By default, the user is PORTAL.

   c. Under **Oracle (JDBC) Settings**, if you intend to specify a custom JDBC URL, then select the **Enter Custom JDBC URL** checkbox, and specify the database URL of the Portal schema in the `jdbc` format:

      ```
      jdbc:oracle:thin:@dbhost:dbport:dbsid
      ```

   d. If you did not perform the above step, then select a driver, enter the host name, JDBC port, SID, and service name, as shown Table 25–3 and Figure 25–3.

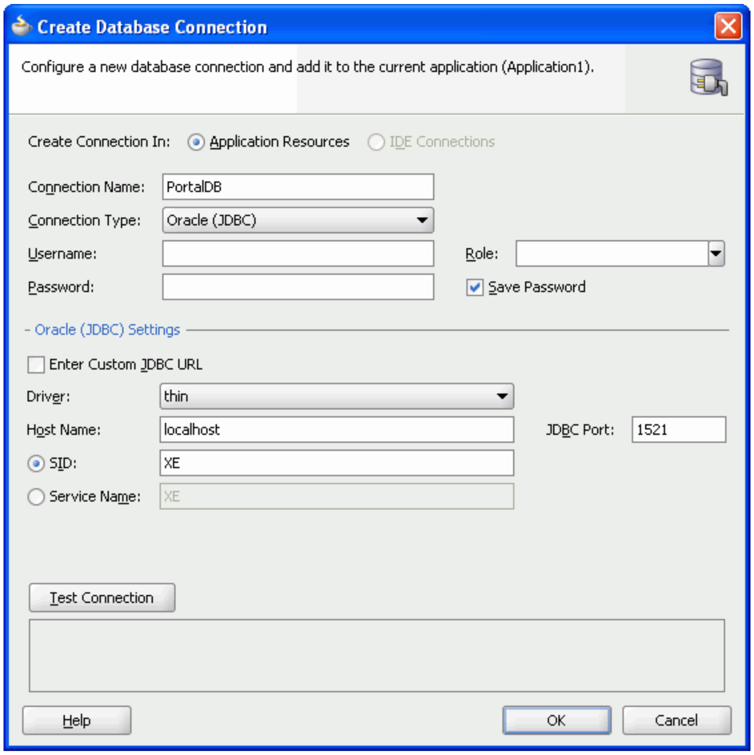
Table 25–3 Parameters for Creating Oracle Portal-based Content Data Control

Parameters	Description
Driver	There are two types of drivers: thin and oci8. The thin driver can be used to connect to Oracle Database release 8*i* or later databases with TCP/IP network protocols. This driver is included in the default Oracle JDBC library for all projects. The oci8 driver is used when creating a Java application that runs against an Oracle Application Server. This is a thick driver optimized for the Oracle Database. It is a mix of Java and native code. This driver handles any database protocol (TCP, IPX, BEQ, and so on). It is recommended for applications that are run from the computer on which they are stored.

Table 25–3 (Cont.) Parameters for Creating Oracle Portal-based Content Data Control

Parameters	Description
Host Name	Name of the Oracle Database. Use an IP address or a host name that can be resolved by TCP/IP; for example, `myserver`. The default value is `localhost`.
JDBC Port	Value to identify the TCP/IP port.
SID	Unique system identifier of an Oracle database instance.
Service Name	The service name for an Oracle database instance.

Figure 25–3 Create Database Connection



Create Database Connection

Configure a new database connection and add it to the current application (Application1).

Create Connection In: ● Application Resources ○ IDE Connections

Connection Name: PortalDB

Connection Type: Oracle (JDBC)

Username:

Role:

Password:

☑ Save Password

- Oracle (JDBC) Settings

□ Enter Custom JDBC URL

Driver: thin

Host Name: localhost

JDBC Port: 1521

● SID: XE

○ Service Name: XE

e. Click **Test Connection** to check whether you have entered the connection details correctly. You should see a `Success!` status.

f. Click **OK**.

7. In the Create Content Repository Connection dialog, in the **Login Timeout (ms)** field, specify the time in milliseconds. This timeout determines how long the application must wait when trying to establish a session with the content repository. If the network connection or the content repository server to which you are trying to connect is slow, then consider overriding the default value specified in this field.

8. Select the applicable authentication method. See Section 25.2.6.1, "About Using Identity Propagation and External Application Authentication Methods" for information.

9. Select the **Specify login credentials for current JDeveloper session** checkbox and enter the Oracle Portal single sign-on user name and password for logging in to your portal instance. The Oracle Portal single sign-on user name and password

entered here are used to test the connection and are functional only at design time. Then click **OK**.

> **Note:** If the **Specify login credentials for current JDeveloper session** checkbox is selected, then the credentials you entered are used. If the checkbox is not selected, then the connection is tested using External Application credentials (if they exist), otherwise null credentials are used.
>
> If you have selected **External Application** for authentication and also specified either public or shared credentials, then you can leave these fields blank, as the public or shared credentials can be used to login at design time. If you specified both public and shared credentials for the external application, then the public credentials have higher precedence. However, if you have selected **External Application** but have not specified public or shared credentials, then you must specify user name and password here.

10. In the Application Resources panel, expand the repository connection you just created. The Connection Credentials dialog displays.

> **Note:** The Connection Credentials dialog displays if you do not save the credentials, that is, you do not select the **Specify login credentials for the current JDeveloper session** checkbox, or if you do not specify an external application that uses public or shared credentials.

11. Enter the user name and password for Oracle Portal connection and click **OK**. The connection displays under the Application Resources panel.

> **See Also:** To create a data control using this connection, perform the procedure described in Section 26.2, "Configuring Content Data Controls for JCR Adapters".

25.2.3 Creating a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint

The Oracle WebCenter Adapter for SharePoint extracts and searches content within a Microsoft SharePoint 2007 repository. The adapter accesses the repository using the Microsoft SharePoint SOAP interfaces. Oracle recommends that you study Section 25.2.6.3, "About Oracle WebCenter Adapter for SharePoint" before configuring and using Oracle WebCenter Adapter for SharePoint.

This section includes the following subsections:

- Section 25.2.3.1, "Installing the Oracle WebCenter Adapter for SharePoint"
- Section 25.2.3.2, "Creating a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint"
- Section 25.2.3.3, "Mapping Microsoft SharePoint Content and Services"

25.2.3.1 Installing the Oracle WebCenter Adapter for SharePoint

Before you configure the Oracle WebCenter Portal adapter for SharePoint, you must install it in JDeveloper.

The adapter files are located in the **Oracle WebCenter Portal Companion DVD** in the `ofm_wc_generic_jcr_sharepoint_adapter_11.1.1.4.0.zip` file. When you extract this ZIP file to a temporary location, you will find the adapter files in the `*TEMP_LOCATION*/WebCenter/services/content/adapters` directory.

To install the adapter:

1. Start Oracle JDeveloper, if it is not already running.
2. From the **Help** menu, select **Check for Updates**.
3. Click **Next** in the Welcome page of the Check for Updates wizard.
4. On the Source page, select **Install From Local File**, then select `oracle.webcenter.content.jcr.sharepoint.ear` from the `*TEMP_LOCATION*/WebCenter/services/content/adapters` directory. This is the temporary directory in which you extracted the contents of the `ofm_wc_generic_jcr_sharepoint_adapter_11.1.1.4.0.zip` file from the Oracle WebCenter Portal Companion DVD.
5. Click **Finish**. When prompted, restart JDeveloper.

25.2.3.2 Creating a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint

To create a repository connection based on Oracle WebCenter Adapter for SharePoint:

1. In Oracle JDeveloper, open your Portal Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection**, then **Content Repository**.
3. In the Create Content Repository Connection dialog, specify a connection name for the connection; for example, `MySPConnection`.

   Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **JCR SharePoint Adapter** from the **Repository Type** box.

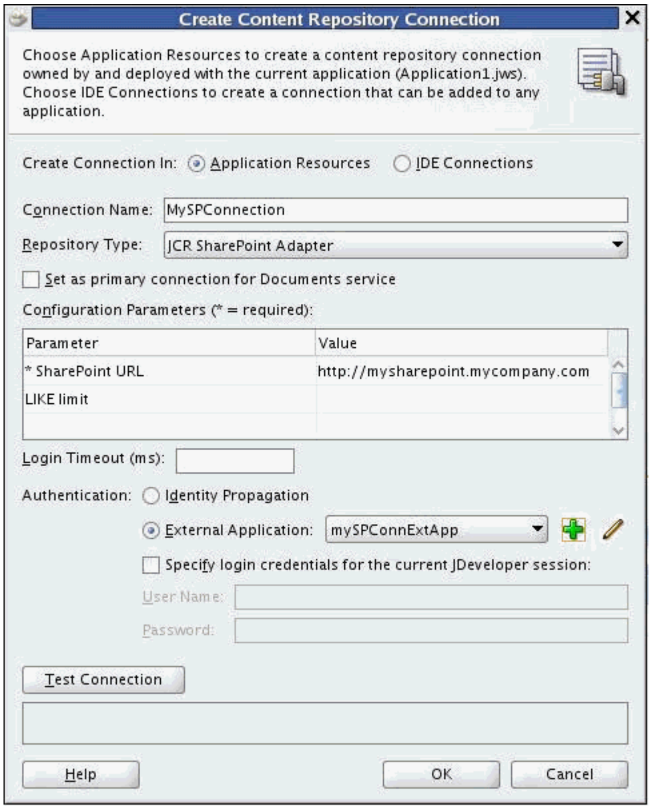
   Note: This option displays only if the extension for Oracle WebCenter Adapter for SharePoint is installed.

5. Select **Set as primary connection for Documents**, if you intend to make it the default connection for documents. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection for documents. If a Document Library task flow is used without any `connectionName` input parameter, then this connection is used. For information about documents, see Chapter 28, "Integrating Documents."

   Note: To be able to set a connection as primary connection for documents, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

6. Under **Configuration Parameters**, enter the **SharePoint URL** which is the Web address of the SharePoint site to which you want to connect. For example, `http://mysharepoint.mycompany.com`, as shown in Figure 25–4.

Figure 25–4 Content Repository Connection - Oracle WebCenter Adapter for SharePoint



Create Content Repository Connection

Choose Application Resources to create a content repository connection owned by and deployed with the current application (Application1.jws). Choose IDE Connections to create a connection that can be added to any application.

Create Connection In: ● Application Resources ○ IDE Connections

Connection Name: MySPConnection

Repository Type: JCR SharePoint Adapter

□ Set as primary connection for Documents service

Configuration Parameters (* = required):

Parameter	Value
* SharePoint URL	http://mysharepoint.mycompany.com
LIKE limit	

Login Timeout (ms):

Authentication: ○ Identity Propagation

● External Application: mySPConnExtApp

□ Specify login credentials for the current JDeveloper session:

User Name:

Password:

7. Enter an integer value representing the number of characters for the LIKE limit. If no value is set, the LIKE limit defaults to `64` characters as the limit for search pattern strings that are passed to the Microsoft SharePoint Server. If the value is set to zero, then the full string is passed to the server. That is, the LIKE limit is disabled. This parameter is optional. Oracle recommends that it be left to its default state. For related information, see Section 25.2.6.3, "About Oracle WebCenter Adapter for SharePoint."

8. In the **Login Timeout (ms)** field, specify the time in milliseconds. This timeout determines how long the application must wait when trying to establish a session with the content repository. Oracle recommends that there is a fast network connection between the deployed application and the Microsoft SharePoint repository. If the network connection or the content repository server to which you are trying to connect is slow, then consider overriding the default value specified in this field.

9. Select the **External Application** authentication method. For information about this authentication method, see Section 25.2.6.1, "About Using Identity Propagation and External Application Authentication Methods."

Note: Oracle WebCenter adapter for Microsoft SharePoint does not support the **Identity Propagation** authentication method. Therefore, the **External Application** authentication method lets you use a single shared set of credentials for all users when accessing the repository. You can also configure this option to enable each user to enter their own login credentials when accessing the repository the first time by omitting both the Shared and Public credentials in the External Application configuration. The system then reuses each unique credential on subsequent access requests.

---

10. Select the **Specify login credentials for the current JDeveloper session** checkbox and specify **User Name** and **Password**. This step is optional, and only required if you want to override the **External Application** authentication credentials created in the previous step. Moreover, this override only applies to the JDeveloper design time.
11. Click **OK**.
12. Optionally, to test the connection, expand the repository connection you just created, in the Application Resources panel. The Connection Credentials dialog displays.

Note: The Connection Credentials dialog displays if you do not save the credentials, that is, you do not select the **Specify login credentials for the current JDeveloper session** checkbox, or if you do not specify an external application that uses public or shared credentials.

---

13. Enter the **User Name** and **Password** for this connection and click **OK**. The connection displays under the Application Resources panel.

    This step is optional.

25.2.3.3 Mapping Microsoft SharePoint Content and Services

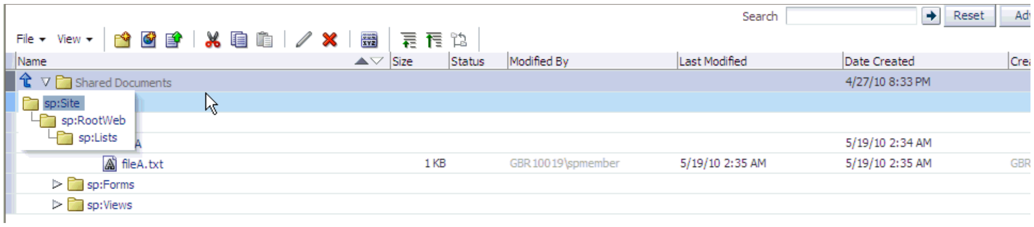
The Oracle WebCenter Adapter for SharePoint is designed to map the content managed in SharePoint servers, such as sites, lists, list items, metadata, documents, as well as content services delivered by Microsoft SharePoint, such as search and security.

The adapter maps content and content services that are relevant to the JCR standard. In other words, the adapter does not map the Microsoft SharePoint graphical user interface (GUI) and the application-level functions that are not part of the JCR standard. For example, the adapter does not map the GUI application logic of the Microsoft SharePoint server (not covered by JCR), but it provides GUI-relevant metadata so that JCR or Java applications can restore some of the GUI logic such as SharePoint lists, if that is the goal of the application.

Default JCR Location of the Microsoft SharePoint Documents Libraries

For a SharePoint Services v3 Team Site, the Shared Documents Library appears at path:`/sp:Site/sp:RootWeb/sp:Lists/Shared Documents/sp:Files`, as shown in Figure 25–5.

Figure 25–5 The Shared Documents Library Path for a SharePoint Services v3 Team Site



Name	Size	Status	Modified By	Last Modified	Date Created	Cre

fileA.txt	1 KB		GBR10019\spmember	5/19/10 2:35 AM	5/19/10 2:35 AM	GBR
sp:Forms						
sp:Views						

For the Microsoft Office SharePoint Server (MOSS) 2007 site created during installation, the Documents Center Document Library appears at path: `/sp:Site/sp:RootWeb/sp:Webs/Docs/sp:Lists/Documents/sp:Files`, as shown in Figure 25–6. This path reflects the structure where the Documents Center is a sub-site in the SharePoint main site.

Files are JCR nodes of primary type `nt:file`, and of mix-in type `sp:File`. Folders are JCR nodes of primary type `nt:folder` and of mix-in type `sp:Folder`. The `sp:` mix-ins are similar to `nt:unstructured` in their definitions.

25.2.4 Creating a Content Repository Connection Based on the File System Adapter

This section describes the procedure to create a content repository connection based on the file system adapter. The File System adapter is intended to be used in development environments only.

To create a File System repository connection:

1. In Oracle JDeveloper, open your Portal Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection** and then **Content Repository**.
3. In the Create Content Repository Connection dialog, enter a name for the connection; for example, `MyConnection`.

Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **File System** from the **Repository Type** box.
5. Select **Set as primary connection for Documents** to make this connection the primary (default) connection for all content management operations through the documents tool or Content Presenter. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection. If `connectionName` parameter is specified for a documents task flow, that value overrides this setting.

Note: To be able to set a connection as primary (default) connection for documents, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

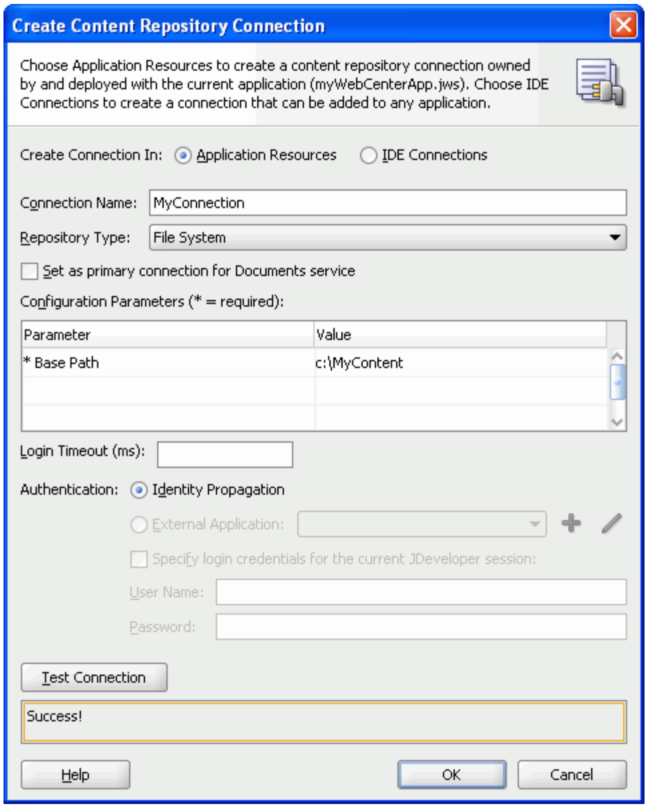
6. Under **Configuration Parameters**, select the **Base Path** row, and enter the path to the folder in which your content is placed, for example, `C:\MyContent`.

Note: The following must be considered while creating a file system connection:

- The base path value is used as the root (`"/"`) for the file system-based data control in Section 26.5, "Integrating Content Using Content Data Controls."
- When you work on a Unix system, the File System adapter inherits the case-sensitive file name characteristic of Unix systems. So, on Unix systems, you must ensure that references to files follow the same case as that used in the original file names. For example, suppose the `Test.html` file was created on a Microsoft Windows system. When you reference this file on a Linux system, you must ensure that you use `Test.html`, and not, for example, `test.html` or `TEST.html`.

7. Leave the **Login Timeout (ms)** field blank.
8. Click **Test Connection** to check whether you have entered the connection details correctly. You should see a `Success!` status, as shown in Figure 25–7.

Figure 25–7 File System Connection



Create Content Repository Connection

Choose Application Resources to create a content repository connection owned by and deployed with the current application (myWebCenterApp.jws). Choose IDE Connections to create a connection that can be added to any application.

Create Connection In: ● Application Resources ○ IDE Connections

Connection Name: MyConnection

Repository Type: File System

□ Set as primary connection for Documents service

Configuration Parameters (* = required):

Parameter	Value
* Base Path	c:\MyContent

Login Timeout (ms):

Authentication: ● Identity Propagation

○ External Application:

□ Specify login credentials for the current JDeveloper session:

User Name:

Password:

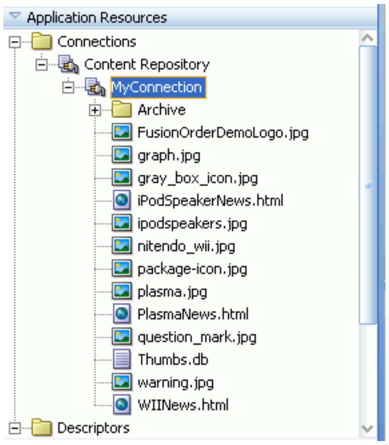
Success!

9. Click **OK**.
10. In the Application Resources panel, expand the repository connection you just created.

25.2.5 What Happens When You Create a Repository Connection

When you create a connection to a repository, the contents in the main directory of the repository display under the Content Repository connection in the Application Resources panel, as shown in Figure 25–8. You can double-click folders and files to view them.

Figure 25–8 Application Resources



```

```

You can use repository connections to create JCR data controls that enable integration of the repository content with JSF pages. See Section 26.2, "Configuring Content Data Controls for JCR Adapters" and Section 26.5, "Integrating Content Using Content Data Controls" for information. These connections can also be consumed through the documents tool and Content Presenter task flows. See Chapter 28, "Integrating Documents" for information.

25.2.6 About Creating a Repository Connection

This section includes:

- Section 25.2.6.1, "About Using Identity Propagation and External Application Authentication Methods"
- Section 25.2.6.2, "About Oracle Portal"
- Section 25.2.6.3, "About Oracle WebCenter Adapter for SharePoint"

25.2.6.1 About Using Identity Propagation and External Application Authentication Methods

The Create Content Repository Connection dialog provides the following options for authentication methods:

- **Identity Propagation**: If you select this option, no credentials are passed to the repository. The repository connector instead uses the current user's identity as determined from the Java security context. This must only be used when the application and the repository use the same identity store to authenticate users.

  To apply this authentication method, it is best to configure security for your application using the Configure ADF Security wizard since repositories may support only authenticated users or provide only limited access to the public or guest user. See Section 26.4, "Securing a Content Repository Data Control".

- **External Application**: The External Application method can be used in all other cases where the current user identity should not be propagated directly to the repository. For more information, see Section 74.13, "Working with External Applications" and Section 28.3, "Setting Security for the Documents Tool."

  External applications allow different types of credentials to be associated with a connection:

  – Public credentials are used whenever an application is not secured, or the user has not yet logged in.

  – Shared credentials are used for any authenticated user.

  – If shared credentials are not specified, then mapped credentials can be used to obtain a result similar to identity propagation when the application and content repository do not use the same user store. In that case the external application service provides runtime screens through which users can provide their credentials for accessing the content repository. Those credentials are securely stored and used for any future connection that this user tries to establish.

  If you intend to configure external applications, then click **New** to launch the Register External Application wizard and do the following:

  a. Specify name of the external application.

  b. In the **Login URL** field, enter the URL of the external application; for example, `http://content-server.mycompany.com/idc/`

Note: This URL is optional and is required only to provide *click through login* to the content repository's own user interface. See the external application documentation for more information on how to configure click through login.

c. Then, under **Authentication Details**, select **Basic** from the list. Leave the fields under **Login Details** blank.

   This option is selected when *click through login* is not required. If *click through login* is enabled, then you must select another option based on the authentication method used in the repository.

d. Accept the default values and click **Next**.

e. Enter shared credentials that can be used at design time and runtime. Do not specify shared credentials, if users must specify their own credentials.

f. Enter public credentials that can be used at design time and runtime. Specify public credentials only if you intend public users to view documents or contents.

g. Click **Finish**.

25.2.6.2 About Oracle Portal

The following should be considered while using the Oracle Portal adapter:

- To use Oracle Portal-based content data control capabilities, you can install Oracle Portal release 10.1.4.1, 10.1.4.2, or 11.1.1.0.0 provided that the appropriate patches have been applied. Consult Oracle Application Server Release Notes for Microsoft Windows (for the required platform) for release 11.1.1.0.0 for the exact patches to be applied.
- Only `file`, `image`, `imagemap`, and `text` item types and custom types based on these item types are supported.
- The `portal:container` page type and its extensions are supported.
- Content is always exposed in the default language of the page group. For example, if there are three page groups with different default languages, then the content displays only for those default languages and not for any translations that exist.

25.2.6.3 About Oracle WebCenter Adapter for SharePoint

Consider the following while configuring and using Oracle WebCenter Adapter for SharePoint:

- The adapter does not support connecting to a Microsoft SharePoint repository configured to allow `anonymous` access.
- There should be a fast network connection between the application server instance on which the adapter is running and the Microsoft SharePoint repository.
- **Microsoft SharePoint versions**: Oracle WebCenter Portal supports the following Microsoft SharePoint versions:
  – Microsoft Office SharePoint Server (MOSS) 2007 SP2
  – Microsoft Windows SharePoint Services (WSS) version 3 SP2
- **Versioning Settings**: Oracle WebCenter Portal supports the following Microsoft SharePoint 2007 Document Library versioning settings:

  - Require Check Out : No
  - Content Approval : No
  - Document Version History : No versioning

  The adapter does not function correctly if any other Versioning Settings are configured. For example, upload operations fails if `Require CheckOut` is set to `yes`. If document version history or content approval are enabled, new versions or documents have restricted visibility.

- **Session-Based Memory Cache**: For performance reasons, Oracle WebCenter Adapter for SharePoint maintains a session-based memory cache. A Portal Framework application, which uses this adapter, must configure an `Http Session time-out` in the application's `web.xml` file to ensure that any unused sessions are closed, and the adapter memory cache is released.
- **Mapping**: The mapping takes into account only those content artifacts and services, which are relevant and defined in the JCR API. Additionally, the adapter maps the content and services to the extent supported by native SharePoint Web services, as the adapter does not rely on custom additional server-side components. Consequently:
  - Full text search only returns items that are indexed by the SharePoint server.
  - Set of searchable columns is limited.
  - A fixed set of node types is supported in searches.
  - Some searches require additional network round trip as the adapter does not receive the full information necessary to map results to JCR from the Web services.

  The adapter exposes content from a Microsoft SharePoint server in a hierarchical way, which is similar to the way in which the content is exposed by the native Web interface. The items of the hierarchy have a primary type of either `nt:folder`, `nt:file`, or a combination of these. Additional SharePoint-specific characteristics are in some instances added as mix-ins (that is, `sp:Folder`, `sp:File`, and so on). The SharePoint-specific namespace, which is identified by the `sp` prefix in these examples, is used for items controlled by the SharePoint server. Items controlled by the user (Webs, documents, list items, and the like) are in the default namespace. The adapter allows write access to SharePoint document libraries. That is, it allows folders and files to be created within document libraries in correspondence with creating folders or uploading files to the native SharePoint Web interface. Examples that demonstrate this hierarchical mapping are described in the following list item.
- **Site Structure**: The structure mapping of a SharePoint site is as follows:
  - `/sp:Site`: The root element of the site.
  - `/sp:Site/sp:RootWeb`: The root Web element.
  - `/sp:Site/sp:RootWeb/sp:Lists`: The path to the root of all lists in the site.
  - `/sp:Site/sp:RootWeb/sp:Lists/Shared Documents/sp:Files`: The path to the start of the file and folder hierarchy within a document library. In this example, the Shared Documents library is shown. All site document libraries are mapped under `/sp:Site/sp:RootWeb/sp:Lists`, each mapped by their own document library name.
  - `/sp:Site/sp:RootWeb/sp:Lists/Shared Documents/sp:Files/myFiles`: An example of a folder within the sites Shared Documents document library.

  - /sp:Site/sp:RootWeb/sp:Webs/mySubSite: A site's subsites are all mapped under /sp:Site/sp:RootWeb/sp:Webs. This example shows the path to a subsite named mySubSite. The sub-site may itself contain Document Libraries.
  - The adapter does not support the write access to a SharePoint Document Library with settings that require one or more mandatory SharePoint columns.

- **Search and indexing**:
  - **JCR and native Microsoft SharePoint search**: The Oracle WebCenter Adapter for SharePoint uses the native SharePoint search Web service to evaluate JCR queries. Features present in JCR 1.0 but not available in the SharePoint search service are usually ignored.
  - **Indexed items**: The native search finds only those items that are indexed by the Microsoft SharePoint server. Other items that may match the query criteria are ignored. By default, SharePoint Services 2007 is configured for search and full-text indexing of a limited set of document types. For more information, and information on how to enable search and indexing in more complex deployments, see Microsoft documentation.
  - **LIKE limit**: The SharePoint native query language uses a LIKE keyword that the adapter uses to constrain queries by URLs (document paths) that match a pattern. The native LIKE operator supports a pattern match on strings up to 64 characters. Therefore, the Oracle WebCenter Adapter for SharePoint applies a client-side filtering on result sets to ensure that the correct constraint on URL is applied. The adapter's LIKE limit parameter controls this feature, and if this limit is not set, it defaults to applying a 64 character limit. The parameter can be set to 0 to disable client-side filtering. The parameter can also be set to some other positive value to apply a different character limit. However, this limit can only be increased if the SharePoint instance supports LIKE tests on URLs greater than 64 characters.
  - **Creation and Modification timestamps**: When displaying the contents of a SharePoint Document Library, the adapter reports the Creation and Modification timestamps as the times that the document was created on or last updated in the library. In the case of some document types, for example Microsoft Office documents, the native SharePoint search evaluates against the document metadata stored within each document. This can be different from the times when the document was uploaded or updated in the Document Library, and therefore, it appears to give misleading search results.
  - **Combining search keywords**: The adapter does not support combining search keywords in an OR expression.
  - **Search by Last Modifier**: The adapter does not support search by Last Modifier.
  - **Search by Creator:** The value provided for the task flow should have values in the form GBR10021\\spmember rather than GBR10021\spmember, as the latter will result in an IllegalState exception and the page will not load.
  - **Supported JCR search operators and properties**: The adapter supports the following:
    - Relational operators for comparison: =, >=, >, <=, <, LIKE, <>, IS NULL, IS NOT NULL. Predicates, descendants, and self operators (//) are supported on the last location step.

- * Properties for comparison: `Size`, `Author`, `Modified`, `URL`, `Title`, `IsDocument`, `ContentClass`, `SiteName`, Description, `FileName`, `jcr:data`, `jcr:mimeType`, `jcr:created`, `jcr:lastModified`.

25.3 Editing Content Repository Connections

This section describes how you can edit a common or an application-specific content repository connection. This section includes the following subsections:

- Section 25.3.1, "How to Edit a Common Repository Connection"
- Section 25.3.2, "Editing a Framework Application-Specific Content Repository Connection"

25.3.1 How to Edit a Common Repository Connection

Common repository connections (IDE connections) are created and edited under the Resource Palette.

To edit a common repository connection:

1. Under the Resource Palette, right-click the repository connection you intend to edit and choose **Properties**, as shown in Figure 25–9. The Edit Repository Connection dialog displays, as shown in Figure 25–10.

Figure 25–9 Resource Palette - Properties

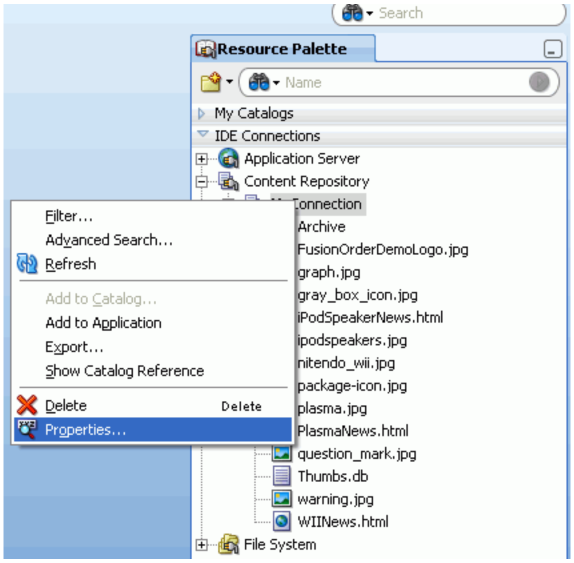

Figure 25–10 Edit Content Repository Connection

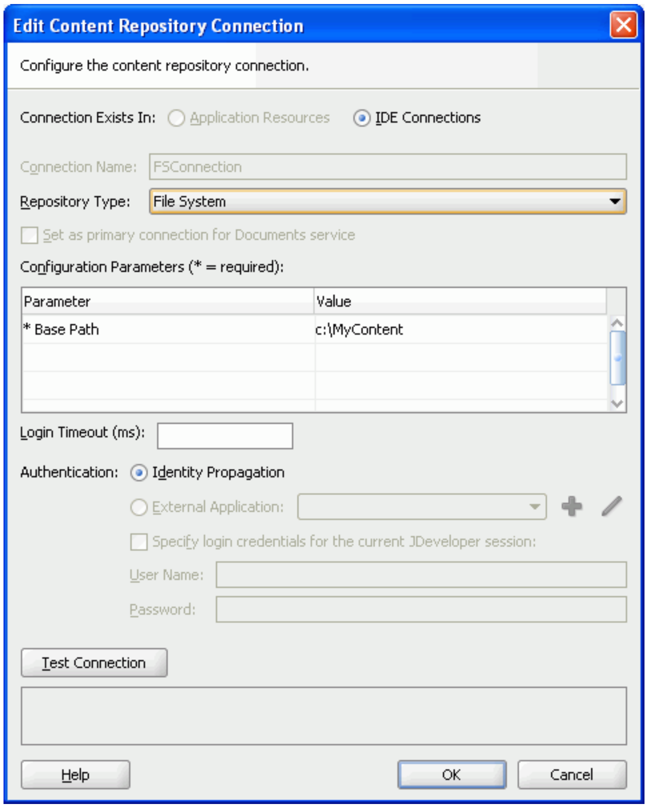

Edit Content Repository Connection

Configure the content repository connection.

Connection Exists In: ○ Application Resources ● IDE Connections

Connection Name: FSConnection

Repository Type: File System

□ Set as primary connection for Documents service

Configuration Parameters (* = required):

Parameter	Value
* Base Path	c:\MyContent

Login Timeout (ms):

Authentication: ● Identity Propagation

○ External Application:

□ Specify login credentials for the current JDeveloper session:

User Name:

Password:

2. Change the appropriate parameters.
3. Test the connection and click **OK**.

25.3.2 Editing a Framework Application-Specific Content Repository Connection

Application-specific content repository connections exist under the Application Resources panel.

To edit a Portal Framework application-specific content repository connection:

1. In the Application Resources panel, right-click the connection you intend to edit, and choose **Properties**, as shown in Figure 25–11. The Edit Content Repository Connection dialog displays, as shown in Figure 25–12.

Figure 25–11 Application Resources - Properties

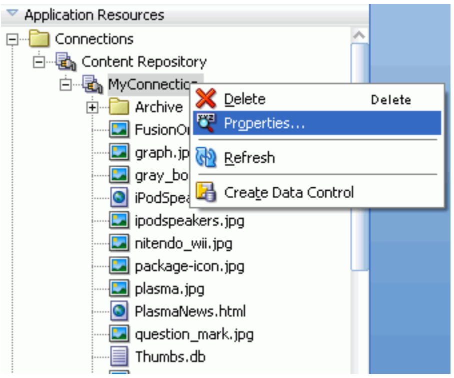

Figure 25–12 Edit Content Repository Connection

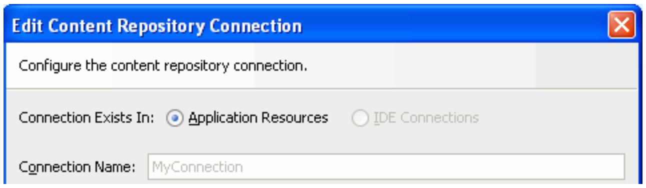


Edit Content Repository Connection

Configure the content repository connection.

Connection Exists In: ● Application Resources ○ IDE Connections

Connection Name: MyConnection

2. Change the appropriate parameters. Depending on the repository type, see the earlier sections that describe how to create repository connections. For example, for Content Server, see Section 25.2.1, "Creating a Content Repository Connection Based on the Oracle Content Server Adapter."

3. Test the connection and click **OK**.

25.4 Using an Existing Repository Connection for a New Portal Framework Application

You can use an existing repository connection for any Portal Framework application if you created it as a common repository under the Resource Palette.

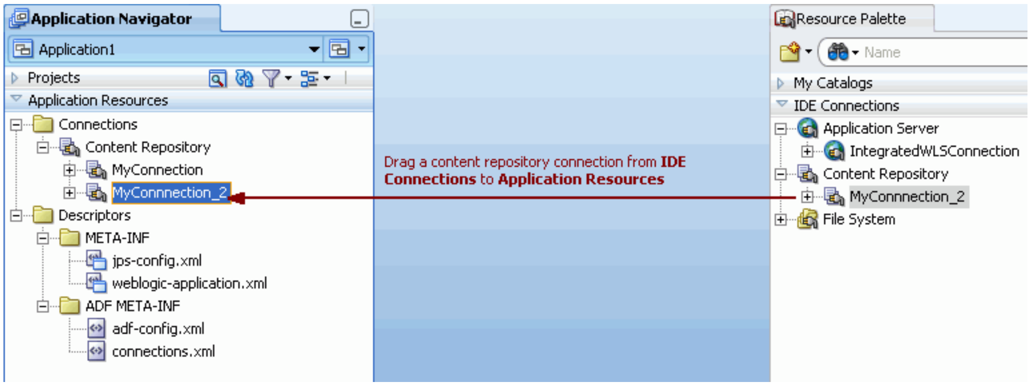
To use an existing repository connection:

1. In Oracle JDeveloper, open the Portal Framework application for which you intend to use an existing repository connection.

2. Go to the Resource Palette and select the repository connection that you intend to use for a new application, for example `MyConnection_2`, and drop it under the Application Resources panel of the new application, as shown in Figure 25–13.

> **Tip:** Alternatively, right-click the connection and choose **Add to Application**. The connection is displayed under the Application Resources panel.

Figure 25–13 Dragging an Existing Common Repository Connection (IDE Connection) to an Application



You can now configure a data control for your new application from this repository connection, as described in Section 26.2, "Configuring Content Data Controls for JCR Adapters".

26 Working with Content Data Controls

This chapter describes how to use JCR data controls to access content such as documents and relational content.

The JCR API enables independent access to content, regardless of the underlying repository or the type of the content. The JCR 1.0 API, as defined in JSR 170, provides a set of basic capabilities for reading, writing, browsing, and searching content. The JCR data controls also enable you to connect to and read from other JCR 1.0 repositories. To add content available in Content Server, Oracle Portal, Oracle WebCenter Adapter for SharePoint, and file systems to JSF pages, you first create connections to the repositories, then use the connections to create data controls based on the repositories. For more information, see Chapter 24, "Introduction to Integrating and Publishing Content."

This chapter includes the following sections:

- Section 26.1, "Overview of Content Data Controls"
- Section 26.2, "Configuring Content Data Controls for JCR Adapters"
- Section 26.3, "Editing Content Repository Data Controls"
- Section 26.4, "Securing a Content Repository Data Control"
- Section 26.5, "Integrating Content Using Content Data Controls"

26.1 Overview of Content Data Controls

A content data control is a container for all the data objects, collections, methods, and operations used to create user interface (UI) components within your Portal Framework application. The data controls provide you with easy-to-use methods that you can drag and drop onto JSF pages to publish content as ADF components, such as URLs, files, and folders. While methods, parameters, and default attributes to publish content are similar across all JCR data controls, the content integration module gives you the flexibility to customize attributes based on your requirements.

Each type of content data control contains methods and parameters to publish content as links, tables, files, and folders, and to add search and advanced search capabilities for your content. Parameters include two types of attributes: default and custom. The default attributes are common across data controls based on File System, Oracle Portal, Oracle WebCenter Content: Content Server, and Oracle WebCenter Adapter for SharePoint. The custom attributes are repository-specific and can be added while creating content data controls.

The following sections describe the methods, parameters, and default attributes that are common across data controls based on File System, Oracle Portal, Content Server, and Oracle WebCenter Adapter for SharePoint:

- Section 26.1.1, "getItems Method"
- Section 26.1.2, "search Method"
- Section 26.1.3, "advancedSearch Method"
- Section 26.1.4, "getURI Method"
- Section 26.1.5, "getAttributes Method"

26.1.1 getItems Method

The getItems method returns the files and folders stored starting at a particular location in the repository. This method enables you to publish content in forms, tables, and hierarchical trees. Using this method, you can also create navigation lists and buttons.

Table 26–1 describes the parameters of the getItems method.

Table 26–1 Parameters of the getItems Method

Parameter	Description
path	Defines the starting point for getItems.
type	Specifies what should be returned: only files, only folders, or any object.

The getItems method returns the attributes described in Table 26–2.

Table 26–2 Return Attributes of the getItems Method

Parameter	Description
icon16	Provides a URI to the icon that documents use for an item.
icon32	Provides a URI to the icon that documents use for an item.
ID	Parameter to document task flows that require an ID.
lastModified	Describes the last modified date of an item.
name	Describes the name of the returned file or folder.
path	Describes the location of the returned file or folder within the content repository.
URI	The direct access URL of a file or folder.
primaryType	Describes whether the returned object is a file or folder or some other type.

26.1.2 search Method

The search method enables you to create a simple search by name pattern or keyword.

Table 26–3 describes the parameters of the search method.

Table 26–3 Parameters of the search Method

Parameter	Description
path	Starting path of the search.

Table 26–3 (Cont.) Parameters of the search Method

Parameter	Description
isRecursive	Specifies whether only the specified folder (=false) or the whole tree starting at the specified path (=true) should be searched. The default value is false, that is, if this field is left blank, then the search is performed in the specified folder. Only if the value is true, the search is performed in the entire hierarchy.
keyword	Search keyword for full text search.
namePattern	Pattern search on name. Use the % wildcard to match any number of characters and the _ wildcard to match one character.

The search method returns the attributes described in Table 26–4.

Table 26–4 Return Attributes of the search Method

Parameter	Description
icon16	Provides a URI to the icon that documents use for an item.
icon32	Provides a URI to the icon that documents use for an item.
ID	Parameter to the document task flows that require an ID.
lastModified	Describes the last modified date of an item.
name	Describes the name of the returned file or folder.
path	Describes the location of the returned file or folder within the content repository.
URI	The direct access URL of a file or folder.
primaryType	Describes whether the returned object is a file or folder or some other type.

26.1.3 advancedSearch Method

The advancedSearch method enables you to perform an advanced search by creating a set of search criteria out of any available attribute.

Table 26–5 describes the parameters of the advancedSearch method.

Table 26–5 Parameters of the advancedSearch Method

Parameter	Description
path	Starting path of the search.
isRecursive	Specifies whether only the specified folder (=false) or the whole tree starting at the specified path (=true) should be searched. The default value is false, that is, if this field is left blank, then the search is performed in the specified folder. Only if the value is true, the search is performed in the entire hierarchy.
keyword	Search keyword for full text search.
namePattern	Pattern search on name. Use the % wildcard to match any number of characters and the _ wildcard to match one character.
matchAny	Specifies whether all predicates (=false) or any predicate (=true) should be matched.
predicates	A collection of SimplePredicate parameters that consist of attributes, comparators, and values.

Table 26–5 (Cont.) Parameters of the advancedSearch Method

Parameter	Description
`type`	Specifies what should be returned: only files, only folders, or any object.

The `advancedSearch` method returns the attributes described in Table 26–6.

Table 26–6 Return Attributes of the advancedSearch Method

Parameter	Description
`icon16`	Provides a URI to the icon that documents use for an item.
`icon32`	Provides a URI to the icon that documents use for an item.
`ID`	Parameter to the document task flows that require an ID.
`lastModified`	Describes the last modified date of an item.
`name`	Describes the name of the returned file or folder.
`path`	Describes the location of the returned file or folder within the content repository.
`URI`	The direct access URL of a file or folder.
`primaryType`	Describes whether the returned object is a file or folder or some other type.

26.1.4 getURI Method

The `getURI` method returns the URI attribute, which is the direct access URL of the file or folder. Its `path` parameter describes the path to the object. You can use this method to create links to content and to inline content in your page. The `getURI` method returns the `URI` attribute.

26.1.5 getAttributes Method

The `getAttributes` method returns the list of attributes and their values for a given file or folder. Its `path` parameter describes the path to the object.

Table 26–7 describes the attributes that the `getAttributes` method returns.

Table 26–7 Return Attributes of the getAttributes Method

Parameter	Description
`name`	Name of the attribute.
`value`	Value of the attribute.

26.2 Configuring Content Data Controls for JCR Adapters

This section describes how to create a content data control based on a content repository connection:

- Section 26.2.1, "Configuring a Content Repository Data Control"
- Section 26.2.2, "What Happens When You Configure a Content Repository Data Control"

26.2.1 Configuring a Content Repository Data Control

The procedure to create content repository data controls is the same regardless of the types of connections used to create data controls. If you have not created a connection to your content repository, then see Section 25.2, "Configuring Content Repository Connections." In this section, a content data control is created using a Content Server-based connection.

To create a content data control using an existing content repository connection:

1. In the Application Navigator, select the **Portal** project, in which the project entries for the new data control should be created.

   You must do this to ensure that the data control definition is separate from the data control usage. When you select the **Portal** project, data control definition files are created in its sub folder, **Application Sources** and not in the **ViewController** project in which the user interface is created.

2. In the Application Resources panel, expand the **Connections** folder in which you created the repository connection.

3. Drag the repository connection that you intend to use for the new data control and drop it into the Data Controls panel.

   Alternatively, from the **File** menu, choose **New**. In the New Gallery, expand **Business Tier**, select **Content Repository** and then **Content Repository Data Control**, and click **OK**.

   The Create Content Repository Data Control dialog displays with the name of the connection selected in the **Connection Name** list.

   > **Note:** If you created your repository connection under the Resource Palette, then right-click the connection under the Resource Palette and choose **Create Data Control**. From the Resource Palette, you can also drag and drop the required connection onto the Data Controls panel.
   >
   > To add a new connection, click the **Create new content repository connection** icon to display the Create Content Repository Connection dialog. For more information, see Section 25.2, "Configuring Content Repository Connections".

4. In the **Data Control Name** field, enter a name for your data control, for example `MyDataControl`.

5. To add custom attributes, click **Add**. Then, enter a name for the attribute as it should appear in the Data Controls panel, select its type, and enter the JCR path.

   In Content Server, a metadata attribute named `dPropertyName` is mapped in the adapter as shown here:

   ```
   jcr:content/idc:metadata/idc:dPropertyName
   ```

   For example, if the property name is `dWorkflowState`, then it is mapped as `jcr:content/idc:metadata/idc:dWorkflowState`.

   In Oracle Portal, a metadata attribute is mapped in the adapter as shown here:

   ```
   portal:name of the attribute in Oracle Portal
   ```

Note: To retrieve the JCR paths of item attributes, run the `getAttributes` method on the required items. Then reenter the wizard to include those paths by right-clicking the respective data control in the Data Controls panel and choosing **Edit Definition**.

---

6. Click **OK**.

Note: The data controls include the predefined node types of JCR. These basic node types represent folders (`nt:folder`) and files (`nt:file`). These are derived from `nt:hierarchyNode`, which is a child of the `nt:base` supertype. Additional node types can be derived from the basic types to customize the experience to a particular repository.

26.2.2 What Happens When You Configure a Content Repository Data Control

Once the data control is successfully configured, it appears as a node in the Data Controls panel. You can expand the node to see the hierarchical list of methods, parameters, and operations for the new data control as shown in Figure 26–1. For more information on using the Data Control panel, see the "Using ADF Model in a Fusion Web Application" section in *Fusion Developer's Guide for Oracle Application Development Framework*.

Table 26–8 describes the icons and object hierarchy of a data control.

Table 26–8 The Data Controls Panel Icons and Object Hierarchy

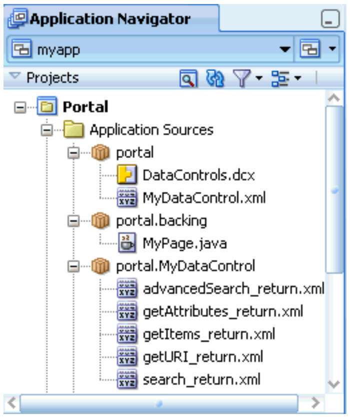
Icon	Name	Description	Usage
	Data Control	Represents a data control. You cannot use the data control itself to create UI components, but you can use any of the child objects listed under it. Depending on how your business services were defined, there may be multiple data controls.	Serves as a container for the other objects, and is not used to create anything
	Method	Represents an operation in the data control or one of its exposed structures that may accept parameters, perform some business logic and optionally return single value, a structure or a collection of those	Command components For methods that accept parameters: command components and parameterized forms
	Method Return	Represents an object that is returned by a custom method. The returned object can be a single value or a collection. A method return appears as a child under the method that returns it. The objects that appear as children under a method return can be attributes of the collection, other methods that perform actions related to the parent collection, and operations that can be performed on the parent collection.	For single values: text fields and selection lists For collections: forms, tables, trees, and range navigation components When a single-value method return is dropped, the method is not invoked automatically by the framework. A user either has to also create an invoke action as an executable, or drop the corresponding method as a button to invoke the method.
XYZ	Attribute	Represents a discrete data element in an object (for example, an attribute in a row). Attributes appear as children under the collections or method returns to which they belong. Only the attributes that were included in the view object are shown under a collection. If a view object joins one or more entity objects, that view object's collection will contain selected attributes from all of the underlying entity objects.	Label, text field, date and selection list components
⚙	Operation	Represents a built-in data control operation that performs actions on the parent object. Data control operations are located in an Operations folder under collections or method returns, and also under the root data control node. The operations that are children of a particular collection or method return operate on those objects only, while operations under the data control node operate on all the objects in the data control. If an operation requires one or more parameters, they are listed in a Parameters folder under the operation.	UI components such as buttons or links
	Parameter	Represents a parameter value that is declared by the method or operation under which it appears. Parameters appear in the Parameters folder under a method or operation.	Label, text, and selection list components

The following files (Figure 26–2) are created under the **Portal** project:

- `DataControls.dcx`: Oracle JDeveloper creates this file the first time a data control is created. This file lists all the Oracle ADF data controls created under the current project. This file is required to initialize the data control.
- *`datacontrolname`*`.xml`: This file includes attributes, accessors, and operations of a data control.

- `advancedSearch_return.xml`: This file includes the return type definition for the `advancedSearch` method.
- `getAttributes_return.xml`: This file includes the return type definition for the `getAttributes` method.
- `getItems_return.xml`: This file includes the return type definition for the `getItems` method.
- `getURI_return.xml`: This file includes the return type definition for the `getURI` method.
- `search_return.xml`: This file includes the return type definition for the `search` method.
- `Return.xml`: This file defines the standard operations on collections.

Figure 26–2 Projects Panel - Portal Project



26.3 Editing Content Repository Data Controls

This section describes a generic procedure to edit content data controls that you configured as described in Section 26.2, "Configuring Content Data Controls for JCR Adapters."

To edit a content data control:

1. In Oracle JDeveloper, go to the application that contains your content data control.
2. Under Data Controls panel, right-click the data control you intend to edit, and choose **Edit Definition**, as shown in Figure 26–3. The Edit Content Repository Data Control dialog displays, as shown in Figure 26–4.

Figure 26–3 Edit Data Controls

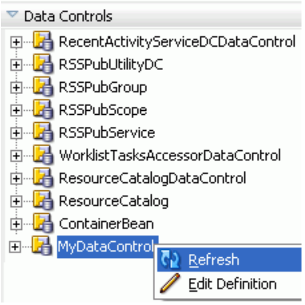


Figure 26–4 Edit Content Repository Data Control Dialog

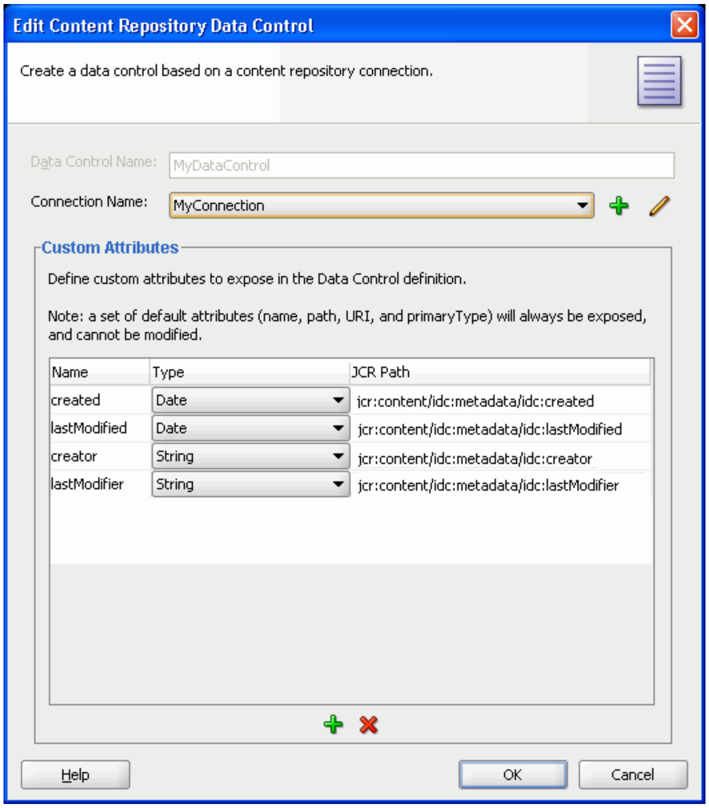


Edit Content Repository Data Control

Create a data control based on a content repository connection.

Data Control Name: MyDataControl

Connection Name: MyConnection

Custom Attributes

Define custom attributes to expose in the Data Control definition.

Note: a set of default attributes (name, path, URI, and primaryType) will always be exposed, and cannot be modified.

Name	Type	JCR Path
created	Date	jcr:content/idc:metadata/idc:created
lastModified	Date	jcr:content/idc:metadata/idc:lastModified
creator	String	jcr:content/idc:metadata/idc:creator
lastModifier	String	jcr:content/idc:metadata/idc:lastModifier

3. To select a different connection, use the **Connection Name** list.

4. To add a connection, click the **Create new content repository connection** icon to display the Create Content Repository Connection dialog. Refer to Section 25.2, "Configuring Content Repository Connections" for information about the configuration parameters specific to the connection type you intend to create.

5. To edit an existing connection, click the **Edit selected content repository connection** icon to display the Edit Content Repository Connection dialog. Depending on the type of connection that you intend to modify, see relevant sections in Section 25.2, "Configuring Content Repository Connections" for information about its configuration parameters.

6. To add or remove custom attributes, use the **Add new attribute** icon and the **Remove selected attribute** icon respectively in the Custom Attributes box.

7. Click **OK** to apply the changes.

26.4 Securing a Content Repository Data Control

You can enable security for your content repository connections. For information, see Chapter 74, "Securing Your WebCenter Portal Framework Application."

26.5 Integrating Content Using Content Data Controls

In this section, you will use `getURI`, `getItems`, `search`, and `advancedSearch` methods of your data control. The basic procedure to use any data control method is to drag and drop it onto a page. When a method is dropped, its ADF Faces tag is added to the source of the page, and the tag is displayed in the Structure window. For example, dropping the URI attribute of getURI as a Go Link adds an af:goLink to the page. The destination of the af:goLink is set to the EL expression #{bindings.URI.inputValue}. This EL expression ties the destination value of the af:goLink to the binding container's URI value.

In the page definition file, methodIterator is added to the executables element, and methodAction is added to the bindings element. The methodIterator and methodAction elements define which data control and method is to be used. The NamedData attribute of the methodAction defines what input parameter values should be provided to this method call. The path and type parameters are common across all data control methods. However, NamedData for search and advancedSearch includes additional parameters that are unique to those methods. For example, in the advancedSearch method, the NamedData can also be used to define the search predicates, whether the search is recursive, and so on.

The page definition includes the AttrNames element, which defines the attributes of the items available in the bindings container to ADF. These items are based on default attributes and custom attributes that were defined when creating the data control.

For detailed information on using the Data Control panel and working with page definition files, see the "Using ADF Model in a Fusion Web Application" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*.

The examples in this section use the following data control methods:

- getURI to add textual and clickable image links to the repository folder.
- getItems to publish the repository content in an ADF table and tree.
- search and advancedSearch to display those items of the repository that match the search criteria.

This section includes the following subsections:

- Section 26.5.1, "Publishing Content As Links"
- Section 26.5.2, "What Happens at Runtime"
- Section 26.5.3, "Publishing Content in a Table"
- Section 26.5.4, "What Happens at Runtime"
- Section 26.5.5, "Publishing Folder Content in a Tree"
- Section 26.5.6, "What Happens at Runtime"
- Section 26.5.7, "Adding Search Capabilities to Content Repositories"
- Section 26.5.8, "What Happens at Runtime"
- Section 26.5.9, "Using Search Capabilities"

26.5.1 Publishing Content As Links

This section describes how to create hyperlinks to files stored in a file system and convert them into textual and image links. You use the **ADF Go Link** and the getURI method to create textual links and the Image of **ADF Faces** to create image links.

This section includes the following procedures:

- Section 26.5.1.1, "Publishing Content As a Textual Link"
- Section 26.5.1.2, "Creating a Clickable Image to Link to a Document"

Before you begin:

1. Configure a repository connection as described in Section 25.2, "Configuring Content Repository Connections."
2. Configure a data control as described in Section 26.2, "Configuring Content Data Controls for JCR Adapters."
3. Create a page as described in Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."

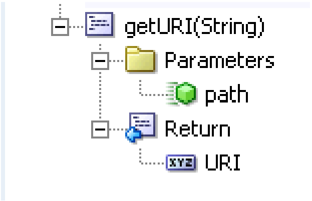
26.5.1.1 Publishing Content As a Textual Link

In this section, you will use the **Oracle ADF Go Link** option of the `getURI` method to publish your content as a textual link. You will also create a link to show a specific item of a repository.

To publish content as a textual link:

1. In the Application Navigator, double-click a page, for example `myPage.jspx`, to open it in the visual editor.
2. In the Data Controls panel, under the repository connection, expand the **getURI (String)** method and expand **Return**. You should see the `URI` attribute, as shown in Figure 26–5.

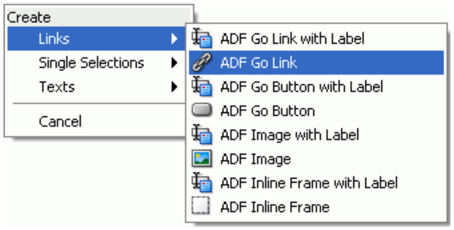
Figure 26–5 The URI Attribute of the getURI Method



3. To create a textual link, select the **URI** attribute and drop it on to the page, or in the Structure window under `af:form`. From the **Create** menu, choose **Links** and then **ADF Go Link**, as shown in Figure 26–6.

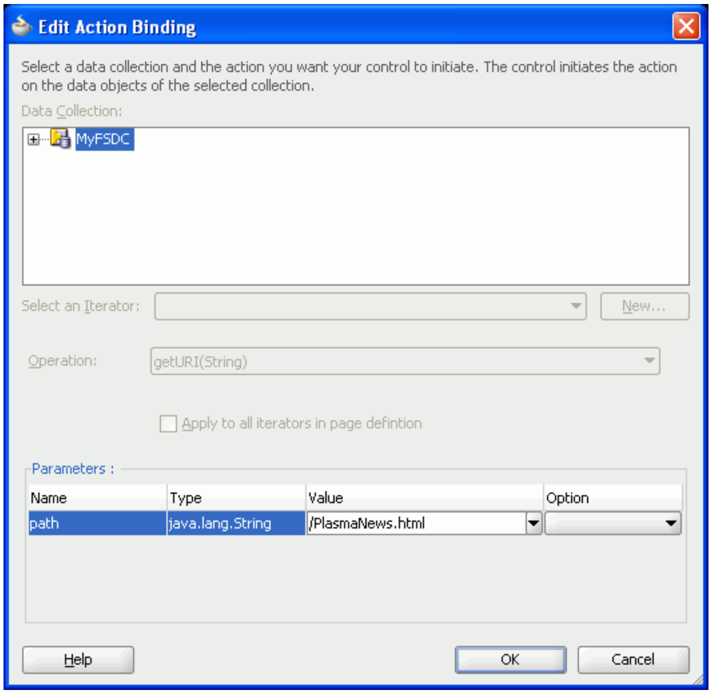
   If this is the first time you have dropped a node onto the page, then the Edit Action Binding dialog displays.

Figure 26–6 Oracle JDeveloper Context Menu for the getURI method



4. In the **Value** field of the **path** parameter, enter the path of the file for which you intend to create the link, as shown in Figure 26–7. You must enter a leading slash (`/`), for example `/PlasmaNews.html`. To modify or delete this path later, click the arrow icon next to the node in design mode and choose **Go to Binding** from the context menu.

Figure 26–7 Edit Action Binding



Edit Action Binding

Select a data collection and the action you want your control to initiate. The control initiates the action on the data objects of the selected collection.

Data Collection:

⊞ MyFSDC

Select an Iterator: | New...

Operation: getURI(String)

□ Apply to all iterators in page defintion

Parameters :

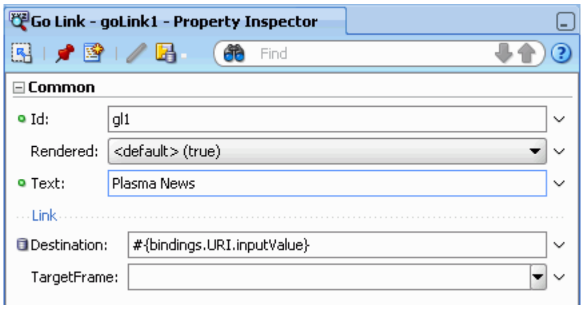
Name	Type	Value	Option
path	java.lang.String	/PlasmaNews.html	

Note: To grant edit, personalize, customize, and view permissions at the attribute level, see Section 26.4, "Securing a Content Repository Data Control".

---

5. Click **OK**.
6. Right-click the page and select **Run**. In your browser, you should see the URL for the file path entered in the Edit Action Binding dialog without any formatting.
7. By default, the link displays the text `goLink1`. In the Structure window, select **af:goLink - goLink1** and view the properties in the Property Inspector.
8. In the **Text** field, enter a name for the link, for example, `Plasma News`, as shown in Figure 26–8.

Figure 26–8 Go Link Properties



Go Link - goLink1 - Property Inspector

⊟ Common

Id: gl1

Rendered: <default> (true)

Text: Plasma News

Link

Destination: #{bindings.URI.inputValue}

TargetFrame:

9. Right-click your page and choose **Run**. The page appears in your browser window with the new link, as shown in Figure 26–9.

Figure 26–9 ADF Go Link in a Browser

FOD News-Plasma TV

LCD, Plasma TVs Found Highly Reliable

LCD and plasma TVs require few repairs during the first three years of use, and buyers would be wasting their money during the holiday shopping season if they bought extended warranties on the highly reliable devices, Consumer Reports found in a study released Friday. The consumer review firm's Annual Product Reliability Survey, featured in the upcoming December issue, found that the flat panel sets overall had a 3% repair rate. Rear-projection TVs, on the other hand, were found to be much more repair prone than its two rivals. Panasonic's 50-inch TH-50PZ700U plasma model was named Consumer Reports' best flat-panel TV ever tested. Overall, Panasonic liquid crystal display and plasma sets had a 2% average repair rate. Among LCDs, Dell (Dell), which recently stopped selling its own brand of TVs, and Hitachi were among the less reliable brands, as were Philips plasma TVs. Aside from Panasonic, other brands with low repair rates included Sony, Samsung, Toshiba and JVC in LCDs; and Pioneer and Samsung in plasmas.

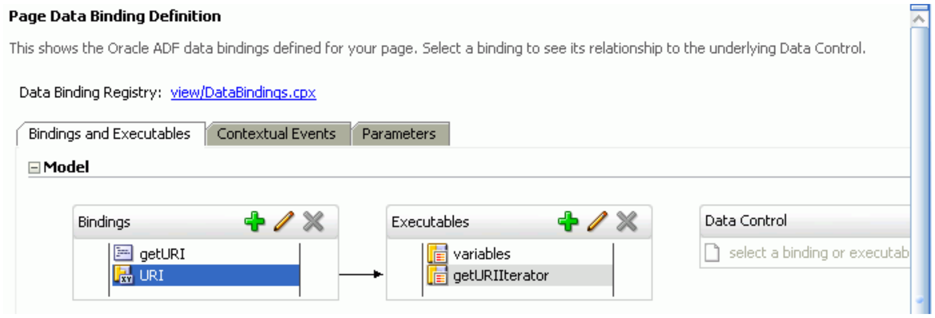
10. Click the link to check that the correct file is displayed.

In Section 26.5.1.2, "Creating a Clickable Image to Link to a Document", you will extend this textual link into an image link.

To add a link to another item, in the same JSF page:

1. In the Application Navigator, right-click the page in which you created the ADF Go Link, and choose **Go to Page Definition**. The Page Data Binding Definition displays in the design view, as shown in Figure 26–10.

Figure 26–10 Page Data Binding Definition



Page Data Binding Definition

This shows the Oracle ADF data bindings defined for your page. Select a binding to see its relationship to the underlying Data Control.

Data Binding Registry: view/DataBindings.cpx

2. Go to the source view of the page definition.

3. In the executables element, add another methodIterator and change the methodIterator id and value of Binds, as shown in **Bold** in the following example:

```
<executables>
  <variableIterator id="variables"/>
  <methodIterator Binds="getURI.result" DataControl="MyDataControl"
     RangeSize="25" BeanClass="portal.MyDataControl.getURI_return"
     id="getURIIterator"/>
  <methodIterator Binds="getURI1.result" DataControl="MyDataControl"
    RangeSize="25" BeanClass="portal.MyDataControl.getURI_return"
    id="getURIIterator1"/>
  </executables>
```

4. In the `Bindings` element, add another `methodAction` and change the `methodAction` `id`, `ReturnName`, and `NDValue`, as shown in **Bold** in the following example:

```
<methodAction id="getURI"
  RequiresUpdateModel=true Action="invokeMethod" MethodName="getURI"
  IsViewObjectMethod="false" DataControl="MyDataControl"
  InstanceName="MyDataControl"
  ReturnName="MyDataControl.methodResults.getURI_MyDataControl_getURI_result">
  <NamedData NDName="path" NDValue="/PlasmaNews.html"
    NDType="java.lang.String"/>
</methodAction>
<methodAction id="getURI1"
  RequiresUpdateModel="true" Action="invokeMethod" MethodName="getURI"
  IsViewObjectMethod="false" DataControl="MyDataControl"
  InstanceName="MyDataControl"
  ReturnName="MyDataControl.methodResults.getURI_MyDataControl_getURI1_result">
  <NamedData NDName="path" NDValue="/FusionOrderDemoLogo.jpg"
    NDType="java.lang.String"/>
</methodAction>
```

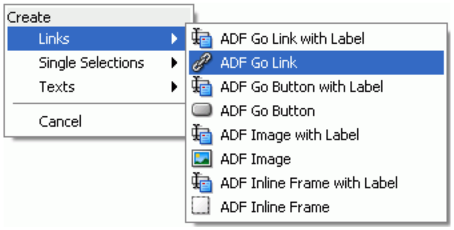
5. In the `Bindings` element, add another `attributeValues` tag to specify the new Id, as shown in **bold** in the following example:

```
<attributeValues
      IterBinding="getURIIterator"
      id="URI">
   <AttrNames>
      <Item Value="URI"/>
   </AttrNames>
</attributeValues>
<attributeValues
        IterBinding="getURIIterator1"
        id="URI1">
  <AttrNames>
        <Item Value="URI"/>
  </AttrNames>
</attributeValues>
```

6. In the Data Controls panel, under the repository connection, expand the **getURI (String)** method and expand **Return**. You should see the `URI` attribute.

7. To create a textual link, select the **URI** attribute and drop it on to the page, or in the Structure window under `af:form`. From the **Create** menu, choose **Links** and then **ADF Go Link**, as shown in Figure 26–11.

Figure 26–11 Oracle JDeveloper Context Menu for the getURI method



8. In the Structure window, double-click the new goLink; for example, **af:goLink2** to display the Go Link Properties window.

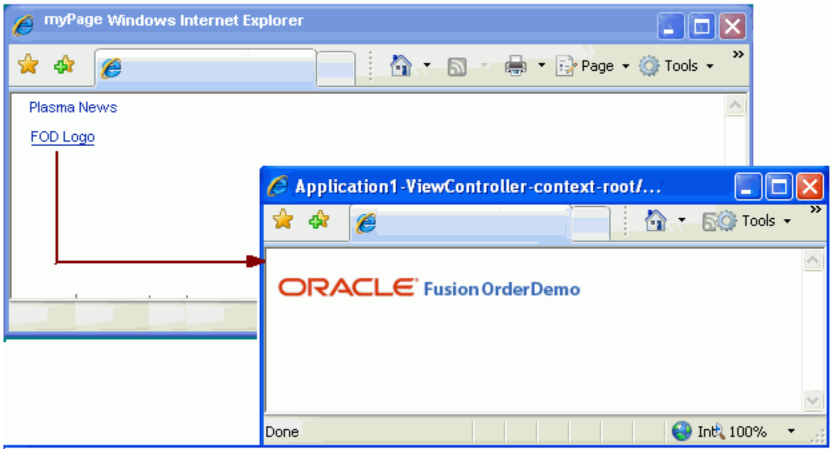
9. In the **Text** field, enter a display name for your new link; for example, `FOD Logo`.

10. In the **Destination** field, click the down arrow to display the Expression Builder dialog. Then, expand **ADF Bindings**, **bindings**, and **URI1**.

11. Double-click **inputValue** variable to create the `#{bindings.URI1.inputValue}` expression, and click **OK**. This expression is based on new elements that you added in `executables` and `bindings`.

12. Run your page. The new link should display content from the new path (`NDValue`) that you specified in step 4. Figure 26–12 shows the new link, `FOD Logo`, in addition to the `Plasma News` link that was added in the first part of Section 26.5.1.1, "Publishing Content As a Textual Link".

Figure 26–12 New Textual Link



myPage Windows Internet Explorer
Page
Tools
Plasma News
FOD Logo
Application1-ViewController-context-root/...
Tools
ORACLE Fusion OrderDemo
Done
Int 100%

You can add as many links as required by following these steps.

26.5.1.2 Creating a Clickable Image to Link to a Document

In this section, you will use the Image option of ADF Faces to publish a document as a clickable image, that is, clicking the image object will display your document.

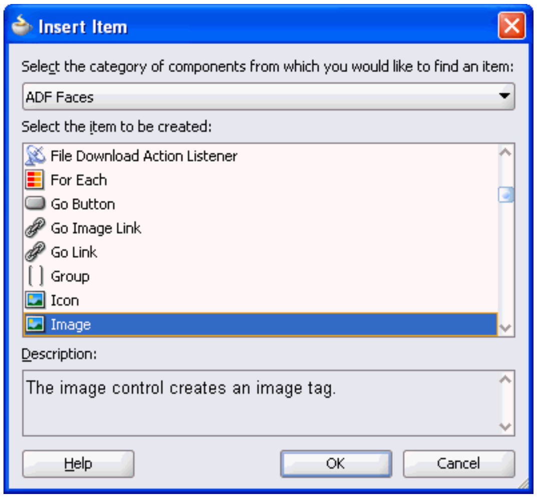
To publish content as a clickable image object:

1. In the Application Navigator, open the page, in which you created the ADF Go Link, by double-clicking it.

2. To convert the textual link that you created in the first part of Section 26.5.1.1, "Publishing Content As a Textual Link", in the Structure window, select **Insert inside af:goLink** and choose **Browse**. The Insert Item dialog displays.

3. From the **Select the item to be created** list, select **Image**, as shown in Figure 26–13.

Figure 26–13 Insert ADF Faces Item



Select the category of components from which you would like to find an item:

ADF Faces

Select the item to be created:

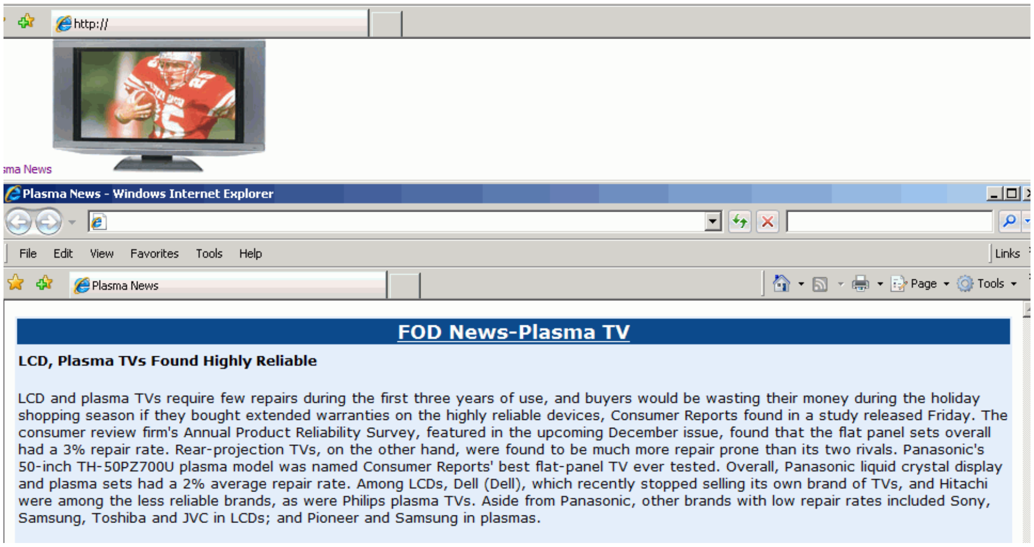
Image

Description:

The image control creates an image tag.

4. Click **OK**. The Insert Image dialog displays.
5. Browse to the image file you intend to display as the image link; for example, `plasma.jpg`.
6. Click **Finish**.
7. Right-click your page and choose **Run**. Figure 26–14 shows a sample output.

Figure 26–14 ADF Object Image Link in a Browser



FOD News-Plasma TV

LCD, Plasma TVs Found Highly Reliable

LCD and plasma TVs require few repairs during the first three years of use, and buyers would be wasting their money during the holiday shopping season if they bought extended warranties on the highly reliable devices, Consumer Reports found in a study released Friday. The consumer review firm's Annual Product Reliability Survey, featured in the upcoming December issue, found that the flat panel sets overall had a 3% repair rate. Rear-projection TVs, on the other hand, were found to be much more repair prone than its two rivals. Panasonic's 50-inch TH-50PZ700U plasma model was named Consumer Reports' best flat-panel TV ever tested. Overall, Panasonic liquid crystal display and plasma sets had a 2% average repair rate. Among LCDs, Dell (Dell), which recently stopped selling its own brand of TVs, and Hitachi were among the less reliable brands, as were Philips plasma TVs. Aside from Panasonic, other brands with low repair rates included Sony, Samsung, Toshiba and JVC in LCDs; and Pioneer and Samsung in plasmas.

26.5.2 What Happens at Runtime

In the preceding examples, you created hyperlinks to files that are stored in a file system using **ADF Go Link** and converted them into textual and image links using the `getURI` method and the **Image** component of **ADF Faces**.

At runtime, the ADF framework uses the information from the page definition file to invoke the data control methods required by the page. For information about the page lifecycle, see the "Understanding the Fusion Page Lifecycle" chapter in *Fusion Developer's Guide for Oracle Application Development Framework*.

At runtime, the getURI data control method is invoked to convert the given path into a valid HTTP URI for the content repository for which the data control is configured. The returned URL is syntactically correct for the target repository, but is not guaranteed to find a resource, that is, the getURI method does not validate that the path corresponds to an existing JCR node. When the page is rendered and the clickable image or link is clicked, the application's get handler converts the HTTP URL into a JCR path and attempts to retrieve the content for the JCR path. The get handler also supplies mimeType information in the response Content-Type header, if such information is available from the repository. This is because in JCR, jcr:mimeType is an optional property of the nt:resource node type.

26.5.3 Publishing Content in a Table

In this section, the getItems data control method is used to publish file and folder information in a table. This section describes the following procedures:

- Section 26.5.3.1, "Displaying Files and Folders in Read-Only Format"
- Section 26.5.3.2, "Displaying the Name Attribute As a Go Link"
- Section 26.5.3.3, "Configuring a Table to Show Only Files"

Before you begin:

1. Configure a repository connection as described in Section 25.2, "Configuring Content Repository Connections."
2. Configure a data control as described in Section 26.2, "Configuring Content Data Controls for JCR Adapters."
3. Create a page as described in Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."

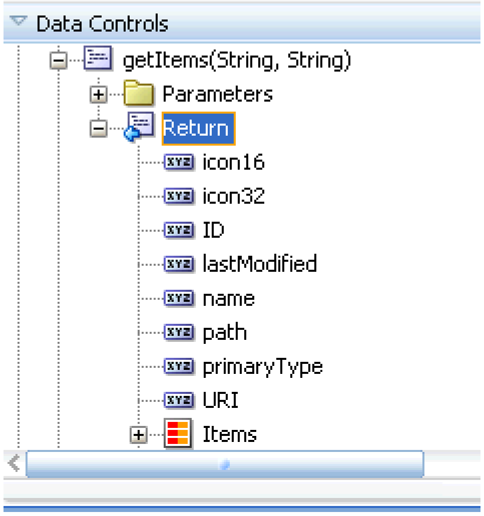
26.5.3.1 Displaying Files and Folders in Read-Only Format

Here you will create a read-only ADF table using the getItems method.

To display folder content in a read-only table:

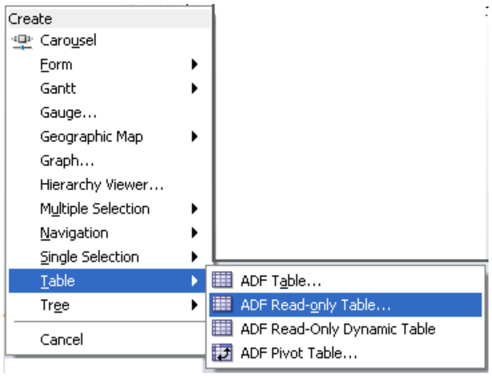
1. To open the page in the visual editor, double-click it in the Application Navigator.
2. In the Data Controls panel, under your data control, expand the **getItems** method and the **Return** node, as shown in Figure 26–15.

Figure 26–15 The Return node of the getItems method



3. To create a table that lists every file and folder available through this data control, drop the **Return** node on to the page or under `af:form` in the Structure window. From the **Create** menu, choose **Table** and then **ADF Read-only Table**, as shown in Figure 26–16.

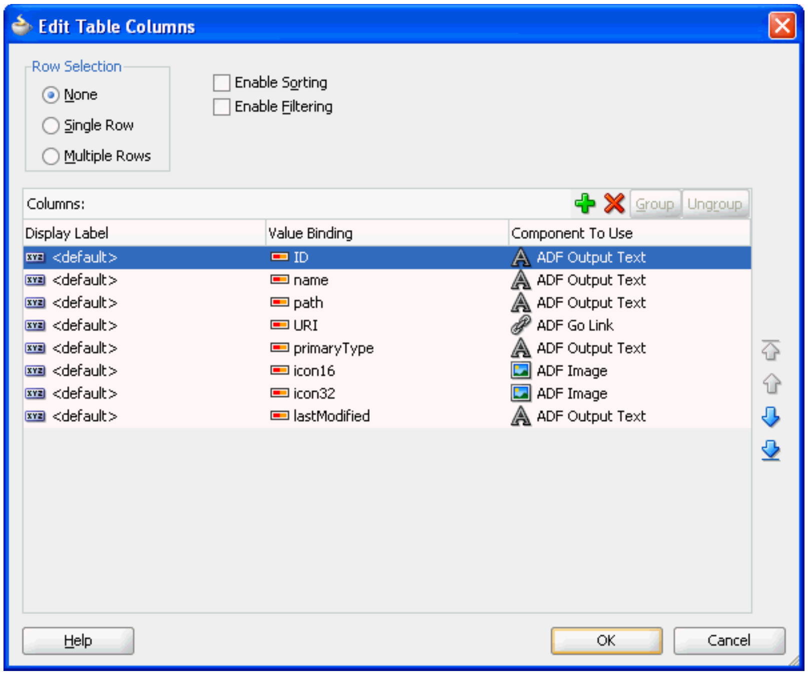
Figure 26–16 The Create Context Menu for getItems Method



4. In the Edit Table Columns dialog, as shown in Figure 26–17, Select the row for the `getItems.name` **Value Binding** and enter an appropriate value for the **Display Label**; for example, `Name`.

   Repeat this step for the **path**, **URI**, **primaryType**, and **lastModified** attributes. Enter new display labels such as `name`, `Location`, `URL`, and so on, then click **OK.**

Figure 26–17 Edit Table Columns



Row Selection

● None

○ Single Row

○ Multiple Rows

□ Enable Sorting

□ Enable Filtering

Columns:

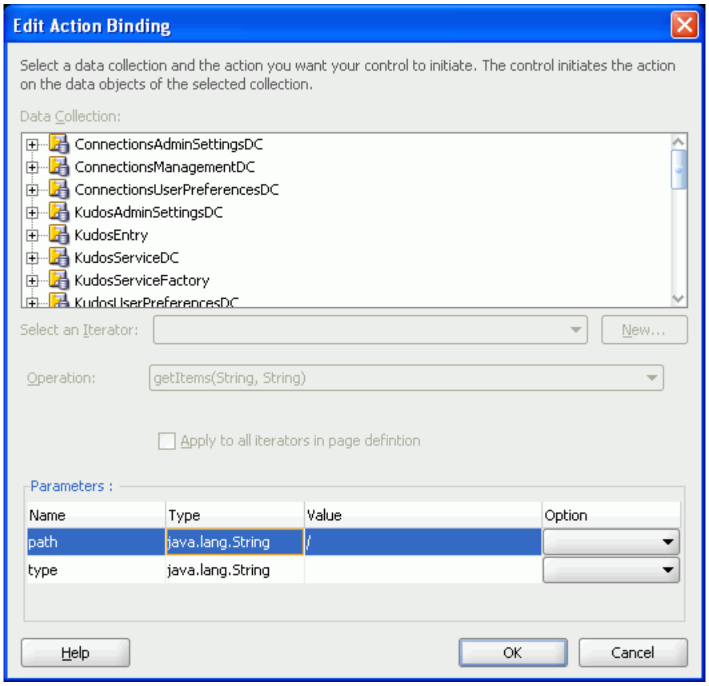
Display Label	Value Binding	Component To Use
<default>	ID	ADF Output Text
<default>	name	ADF Output Text
<default>	path	ADF Output Text
<default>	URI	ADF Go Link
<default>	primaryType	ADF Output Text
<default>	icon16	ADF Image
<default>	icon32	ADF Image
<default>	lastModified	ADF Output Text

5. If this is the first time you have dropped a node onto the page, the Edit Action Binding dialog displays.

In the Edit Action Binding dialog, enter the path of the content directory as the `path` parameter, as shown in Figure 26–18. You must enter a leading slash (`/`). To modify or delete this path later, click the arrow icon next to the node in design mode and choose **Go to Binding** from the context menu.

Leave the `type` parameter blank. This implies that the table displays both files and folders.

Figure 26–18 Edit Action Binding



Edit Action Binding

Select a data collection and the action you want your control to initiate. The control initiates the action on the data objects of the selected collection.

Data Collection:

- ConnectionsAdminSettingsDC
- ConnectionsManagementDC
- ConnectionsUserPreferencesDC
- KudosAdminSettingsDC
- KudosEntry
- KudosServiceDC
- KudosServiceFactory
- KudosUserPreferencesDC

Select an Iterator:

Operation: getItems(String, String)

□ Apply to all iterators in page defintion

Parameters :

Name	Type	Value	Option
path	java.lang.String	/	
type	java.lang.String		

6. Click **OK.** You should now see a table on the page that looks like Figure 26–19.

Figure 26–19 Read-Only Table for Publishing Folder Content

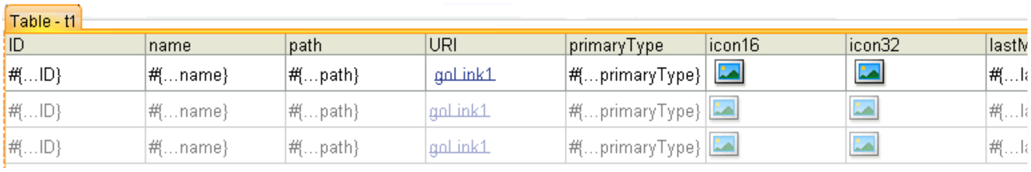


Table - t1

ID	name	path	URI	primaryType	icon16	icon32	lastM
#{...ID}	#{...name}	#{...path}	golLink1	#{...primaryType}	🖼	🖼	#{...la
#{...ID}	#{...name}	#{...path}	golLink1	#{...primaryType}	🖼	🖼	#{...la
#{...ID}	#{...name}	#{...path}	golLink1	#{...primaryType}	🖼	🖼	#{...la

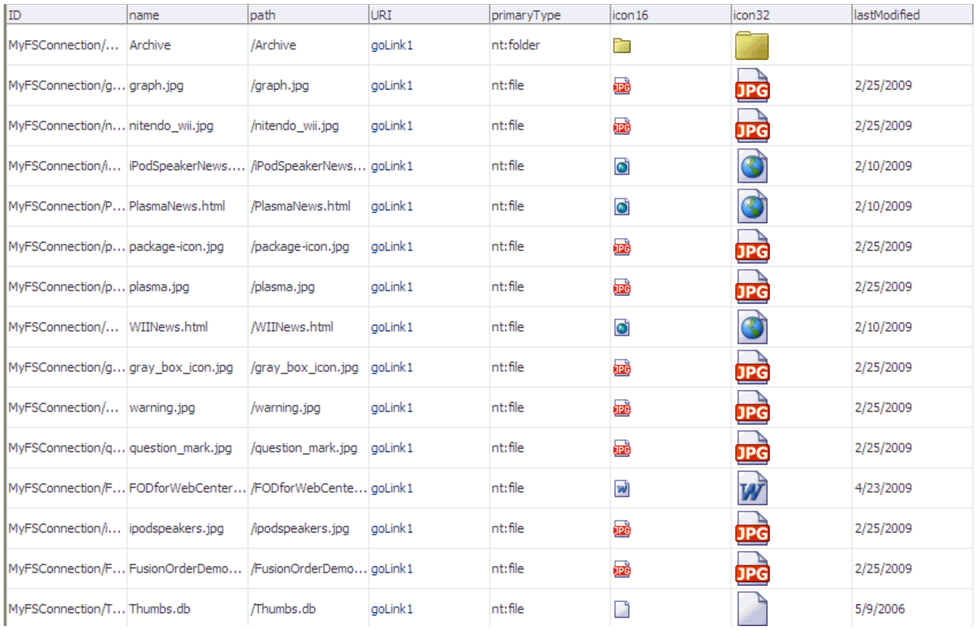
---

Note: You can turn the page caching on or off. To do so, open the page definition and expand **executables**, and select **getItemsIterator** in the Structure window. Then, in the Property Inspector, set **CacheResults** to **true** or **false**, as required.

---

7. Run the page. You should see a list of all files and folders available in your content directory. Figure 26–20 shows a read-only table displaying both files and folders at runtime.

Figure 26–20 Files and Folders Displayed in a Read-Only Table



ID	name	path	URI	primaryType	icon16	icon32	lastModified
MyFSConnection/...	Archive	/Archive	goLink1	nt:folder	📁	📁

MyFSConnection/T...	Thumbs.db	/Thumbs.db	goLink1	nt:file	🗋	🗋	5/9/2006

By default, the table displays file or folder attributes as read-only text (`af:outputText`). The next section describes how to display the `Name` attribute (`name`) as a Go Link (`af:goLink`).

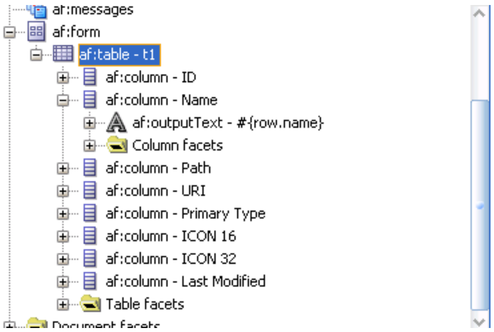
26.5.3.2 Displaying the Name Attribute As a Go Link

In this section, you will convert the `Name` attribute of the table that you created in Section 26.5.3.1, "Displaying Files and Folders in Read-Only Format" into a link using an **ADF Go Link** component. You will also configure the table to show only the **Name** column.

To display the Name attribute as a Go Link:

1. In the Structure window (Figure 26–21), expand the first column of the table (`af:column - Name`) to show the default display format `af:outputText - #{row.name}`.

Figure 26–21 Default Formatting for the Name Column



```
af:messages
af:form
  af:table - t1
    af:column - ID
    af:column - Name
      af:outputText - #{row.name}
      Column facets
    af:column - Path
    af:column - URI
    af:column - Primary Type
    af:column - ICON 16
    af:column - ICON 32
    af:column - Last Modified
    Table facets
Document facets
```

2. In the source view for the page, change the name column to use a go link. The link displays the name but links to the URI of the entry:

   Replace the `af:outputText` in **bold**

   ```
   <af:column sortProperty="#{bindings.Return.hints.name.name}"
   ```

```
        sortable="false" headerText="Name" id="c7">
      <af:outputText value="#{row.name}" id="ot3"/>
</af:column>
```

with an `af:goLink` as shown in **bold**:

```
<af:column sortProperty="#{bindings.Return.hints.name.name}"
         sortable="false" headerText="Name" id="c7">
   <af:goLink text="#{row.name}" id="goLink2"
destination="#{row.bindings.URI.inputValue}"/>
</af:column>
```

3. In the Structure window, right-click `af:column - URI` and select **Delete**.
4. Right-click the page in the Application Navigator and choose **Run**. You should see a list of hyperlinked file and folder names like the one shown in Figure 26–22. This figure shows the `name` attribute as a link. Clicking a link in the **URI** column opens the respective file or folder and shows its contents.

Figure 26–22 Folder Content Displayed as Hyperlinks

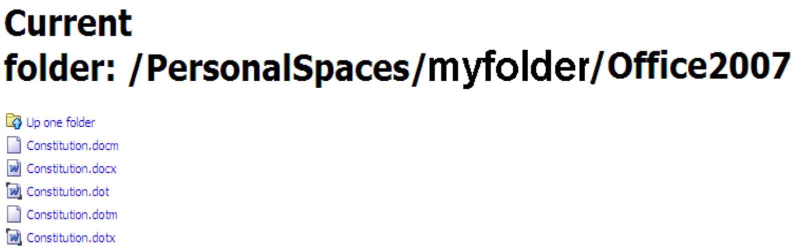
5. Click a file name. The file you pick should appear in a browser window.
6. Click the name of a folder, the contents of the folder display, as shown in Figure 26–23.

Figure 26–23 Folder Contents



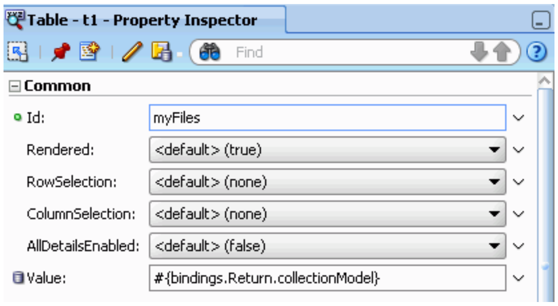
Current folder: /PersonalSpaces/myfolder/Office2007

Up one folder
Constitution.docm
Constitution.docx
Constitution.dot
Constitution.dotm
Constitution.dotx

To configure the table to show only the Name column:

1. In the Structure window, under the **af:table - t1** node, delete all but the **Name** column.
2. Double-click the **af:table - t1** node to display the Property Inspector.
3. Under the **Common** tab, in the **Id** field, enter a name, for example `myFiles`, as shown in Figure 26–24.

Figure 26–24 Table Properties - Common Tab



Id: myFiles

Rendered: <default> (true)

RowSelection: <default> (none)

ColumnSelection: <default> (none)

AllDetailsEnabled: <default> (false)

Value: #{bindings.Return.collectionModel}

4. Run the page to view the output. Figure 26–25 shows only one column of the table since other rows were removed from the Structure window at design time. This table shows both files and folders, because you left the `type` parameter blank when creating the table.

Figure 26–25 Files and Folders Displayed in a Single-Column Table

In the next section, the **Name** column will be configured to show only files.

26.5.3.3 Configuring a Table to Show Only Files

The `type` attribute is used to configure a table to show only files and not folders.

To configure the table to show files:

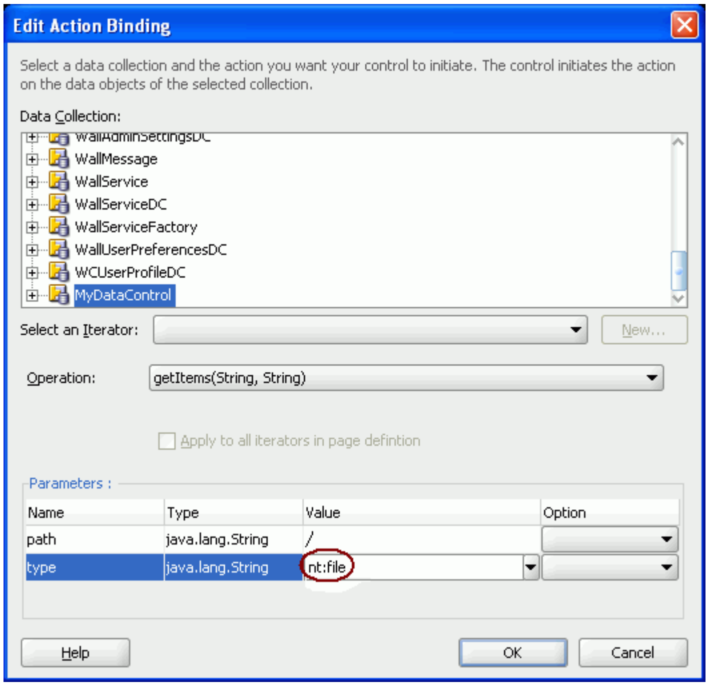
1. Right-click your page and choose **Go to Page Definition**.

   > **Note:** The `RangeSize` binding setting, which is used to control the number of items displayed on a page, is set to `10` by default in the page definition file. You can change it, as required, in the Property Inspector.

2. In the **Overview** tab, double-click **getItems** under **Bindings**. The Edit Action Binding dialog displays.

3. The **type** options are `nt:file` and `nt:folder`. To specify the display of only files, enter `nt:file` under the **Value** column, as shown in Figure 26–26, and click **OK**.

Figure 26–26 Display Files Only



Select a data collection and the action you want your control to initiate. The control initiates the action on the data objects of the selected collection.

Data Collection:

- WallAdminSettingsDC
- WallMessage
- WallService
- WallServiceDC
- WallServiceFactory
- WallUserPreferencesDC
- WCUserProfileDC
- MyDataControl

Select an Iterator:

Operation: getItems(String, String)

☐ Apply to all iterators in page defintion

Parameters :

Name	Type	Value	Option
path	java.lang.String	/	
type	java.lang.String	nt:file	

4. Now run the page. Figure 26–27 shows only files in the single-column table because the column type is `nt:file`.

26.5.4 What Happens at Runtime

The `getItems` method of the JCR data control retrieves the child items of a JCR folder (type `nt:folder`). This method is called with a path to a folder and optionally a type to which the returned child nodes are restricted.

The `path` parameter must be the path of a folder. An exception to this rule is that the root of the repository does not have to be a folder. Hence, the `getItems` method can retrieve the child items for a path that corresponds to a folder, or that is the root of the repository. Otherwise the `getItems` method does not attempt to retrieve the child items and therefore the result set is never populated.

At runtime, the JCR data control calls the `Session.getItem` method. This method returns a JCR node. The data control then calls the `node.getNodes` to retrieve child nodes. The child nodes are filtered according to the specified type; for example, the `nt:file` type. The data control passes on these child nodes to ADF. The data control ensures that the JCR node object is adapted to ADF so that JCR properties are available as data control item attributes that can be consumed through the bindings container.

In the example, each row in the collection returned by the data control is stored as a row in the `af:table` table. However, a column is only displayed for each `af:column` defined in the `af:table`, and not for every possible ADF item attributes returned by the data control. In the first part of the example, the drag and drop action creates an `af:column` for every ADF attribute available for each ADF item returned by the data control.

If the `af:table` is modified to include only the `af:column` for the name, then at runtime it only requests the name of the ADF item. That is, the data control runs a method to fetch the name of the JCR node. At design time, when the name column is converted to an `af:goLink`, the destination of **Go Link** destination is set to the **URI** value of the item, as shown in the following syntax:

```
<af:goLink text="#{row.name}" destination="#{row.URI}"/>
```

At runtime, for each ADF item in the table, the data control runs methods to return both the JCR name of the item and its HTTP URL.

26.5.5 Publishing Folder Content in a Tree

In this section, you will use the `getItems` method to publish content in a hierarchal tree format. This section describes the following procedures:

- Section 26.5.5.1, "Displaying Files and Folders in Read-Only Format"
- Section 26.5.5.2, "Displaying File Names As Hyperlinks"

Before you begin:

1. Configure a repository connection as described in Section 25.2, "Configuring Content Repository Connections."
2. Configure a data control as described in Section 26.2, "Configuring Content Data Controls for JCR Adapters."
3. Create a page as described in Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."

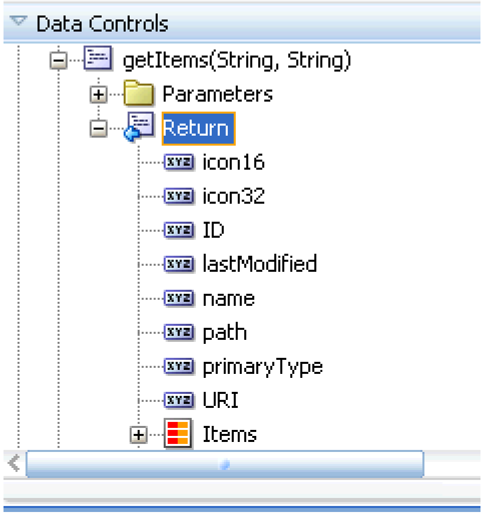
26.5.5.1 Displaying Files and Folders in Read-Only Format

In this section, you will display your content in the tree format.

To display your content in the tree format:

1. In the Application Navigator, double-click your page to open it in the design view.
2. In the Data Controls panel, under your data control, expand the **getItems** method as shown in Figure 26–28.

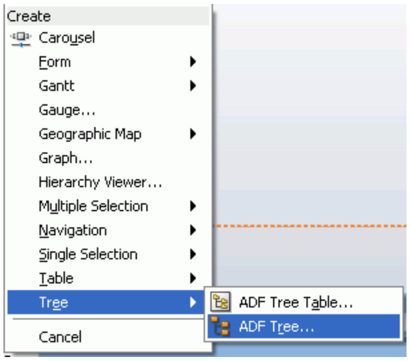
Figure 26–28 Parameters of the getItems Method



3. To display your content as an **ADF Tree**, select the **Return** node and drag it onto the page. From the Create menu, choose **Tree** and then **ADF Tree**, as shown in Figure 26–29.

   If this is the first time you have dropped a node onto the page, the Edit Action Binding dialog displays.

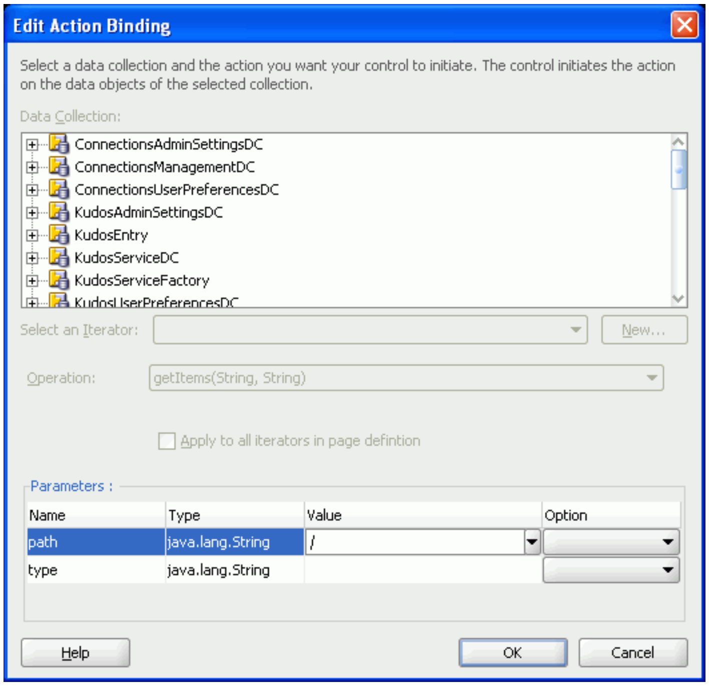
Figure 26–29 Oracle JDeveloper Create Menu for getItems



4. To create a tree that displays everything under the base path, enter the slash (`/`) for the `path` parameter, as shown in Figure 26–30. To modify or delete this path later, click the arrow icon next to the node in the design mode and choose **Go to Binding** from the context menu.

   Leave the `type` parameter blank to show both files and folders.

Figure 26–30 The Edit Action Binding Dialog



Edit Action Binding

Select a data collection and the action you want your control to initiate. The control initiates the action on the data objects of the selected collection.

Data Collection:

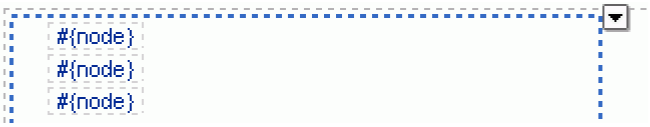
⊞ Target Data Source

8. Click **OK.** A tree displays in the page that looks like Figure 26–32.

Figure 26–32 Tree for Navigating Folder Content



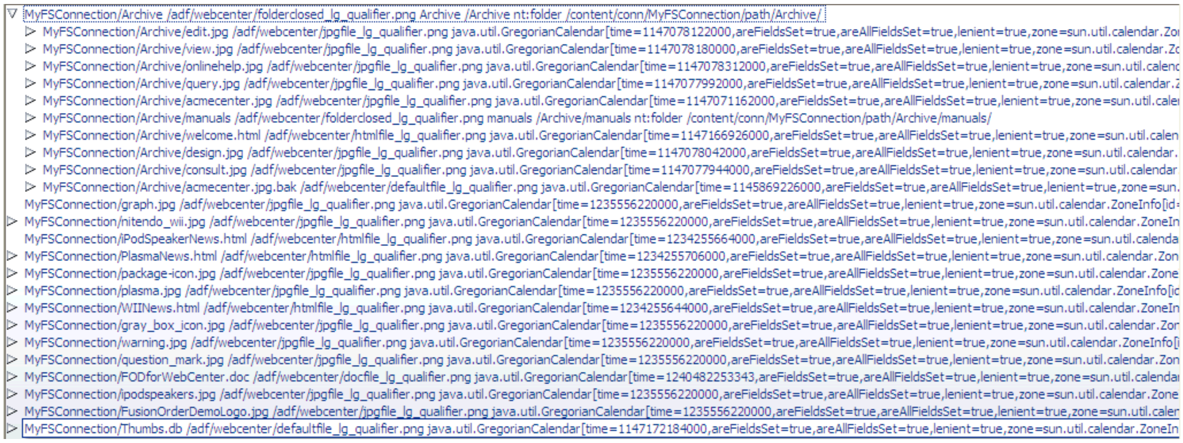
#{node}
#{node}
#{node}

9. Run your page to display the results.

   When the page appears in your browser window, you should see a list of files and folders available through your data control. Figure 26–33 displays a tree of files and folders in the read-only format based on **ADF tree** dropped on the JSF page. Expand a branch to see the content in this subdirectory.

> **Note:** By default, the range size is `10`. To change the number of items displayed in the tree, edit the **RangeSize** property for the data control in the page definition file (*`name`*`PageDef.xml`).

Figure 26–33 Folder Content Displayed in a Tree



```

By default, the tree displays file and folder names as read-only text. The next section describes how to create hyperlinks to file names. In the following section, folder names will remain read-only text because they are required for navigation through the tree.

26.5.5.2 Displaying File Names As Hyperlinks

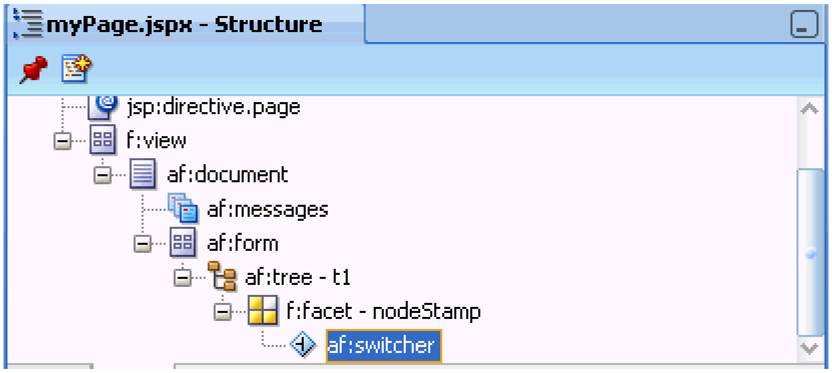
To create hyperlinks to file names and to keep folder names read-only, you need the `af:switcher` component with two facets: one for folders and one for files.

To use the Switcher component for folders and files:

1. In the Structure window, navigate to `f:facet - nodeStamp` and delete `af:outputText-#{node}`.
2. Right-click **nodeStamp** and choose **Insert inside f:facet - nodeStamp** and then **Browse**.
3. In the Insert Item dialog, from the dropdown list for selecting the category, select **ADF Faces**.
4. From the **Select the item to be created** list, select **Switcher**, and click **OK**.

   A Switcher is added under **f:facet - nodeStamp** in the Structure window, as shown in Figure 26–34.

Figure 26–34 Output Text Converted to a Switcher Component



```
jsp:directive.page
f:view
  af:document
    af:messages
    af:form
      af:tree - t1
        f:facet - nodeStamp
          af:switcher
```

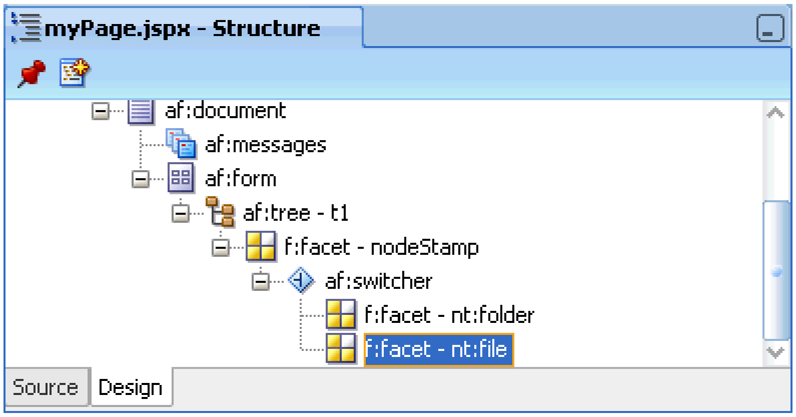
5. Double-click **af:switcher** to display the Property Inspector, if it is not displayed.

6. Under the **Common** tab, in the **FacetName** field, enter the expression `#{node.primaryType}`.

7. In the Structure window, insert two facets for the switcher. Right-click **af:switcher**, choose **Insert Inside af:switcher** and then **Facet**. The Insert Facet dialog displays.

8. Name the first facet `nt:folder` and click **OK**. Folder names require no additional formatting, so you can display the node names as plain text. Name the second facet `nt:file`. The facets look like Figure 26–35.

Figure 26–35 Switcher Component with Two Facets



9. Right-click **f:facet - nt:folder**, choose **Insert Inside f:facet - nt:folder** and then **Browse**.

10. In the Insert Item dialog, choose **ADF Faces** from the dropdown list.

11. From the **Select the item to be created** list select **Output Text** and click **OK**.

12. Double-click **af:outputText - outputText1** to display the Property Inspector, if it is not displayed already. Under the **Common** tab, in the **Value** field, enter the expression `#{node.name}`.

13. Right-click **f:facet - nt:file**, choose **Insert Inside f:facet - nt:folder** and then **Browse**.

14. In the Insert Item dialog, choose **ADF Faces** from the dropdown list.

15. From the **Select the item to be created** list select **Go Link** and click **OK**.

16. In the Structure window, double-click **af:goLink - goLink** to display the Property Inspector, if it is not already displayed.

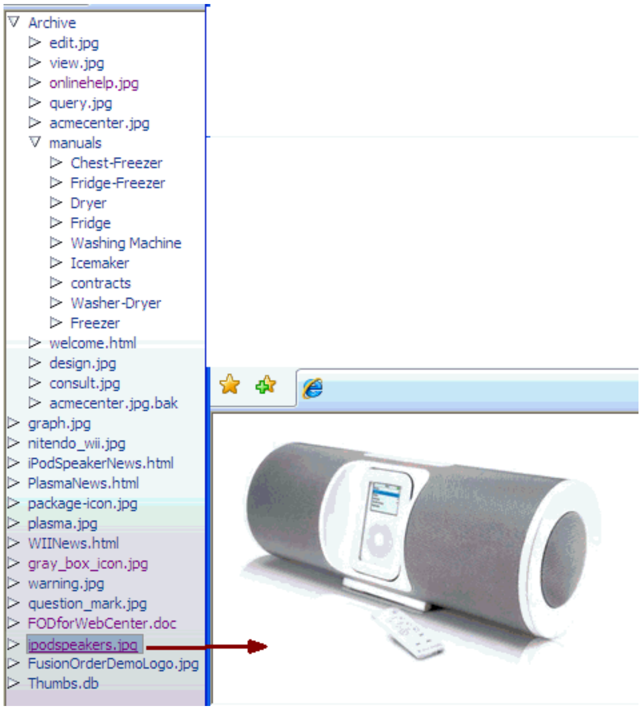
17. Under the **Common** tab, in the **Text** field, enter the `#{node.name}` expression.

18. In the **Destination** field, enter the expression `#{node.URI}`.

19. From the **TargetFrame** list, select **_blank**.

20. Run the page. Figure 26–36 displays files names as hyperlinks, because the `nt:file` facet of the switcher under `af:tree` was converted to a link (`node.URI`). Clicking a link displays the respective item.

Figure 26–36 Tree with File Names as Hyperlinks



26.5.6 What Happens at Runtime

The JCR data control `getItems` method is designed to retrieve the child items of a JCR folder (type `nt:folder`). The method is invoked with a path to a folder and optionally a type to which the returned child nodes are restricted. The `path` parameter must be the path of a folder for the `getItems` method to retrieve the child items. An exception to this rule is that the root of the repository does not have to be a folder. Hence, the `getItems` method can retrieve the child items for a path that corresponds to a folder, or that is the root of the repository. Otherwise the `getItems` method does not attempt to retrieve the child items and therefore the result set is never populated. If the path is valid, then the data control invokes `JCR Session.getItem()` on this path which returns a JCR node, and then it invokes `node.getNodes()` to retrieve all child nodes. The child nodes are filtered according to the type supplied; for example, to return only the `nt:file` type child node. This is the result that is provided by the data control to ADF. The data control ensures that the JCR node object is adapted to ADF such that JCR properties are available as data control item attributes that can be consumed by way of the bindings container.

The `af:tree` renders each node in the collection returned by the data control as a node in its tree. In the first part of the example, it displays the `name`, `type`, and `URI` for each node. Each of these values is retrieved through the data control. When the switcher is added to the `af:tree` the node's `primaryType` value is used to differentiate how a node is rendered. If the node is of primary type `nt:folder`, then only its name is shown in the tree node. However if the node is of type `nt:file`, then the node renders `go:Link`, the destination of which is the node's URI. The data control `getItems` method is invoked again to retrieve the child nodes of any folder node in the tree.

26.5.7 Adding Search Capabilities to Content Repositories

With the help of two examples, this section describes how to add simple and advanced search capabilities for the integrated content. The simple search enables users to search for the content based on name or content fragments in specific locations. The advanced search enables users to search by attribute values of the content.

This section contains the following:

- Section 26.5.7.1, "Adding Simple Search Capabilities"
- Section 26.5.7.2, "Adding Advanced Search Capabilities"

Before you begin:

1. Configure a repository connection as described in Section 25.2, "Configuring Content Repository Connections."
2. Configure a data control as described in Section 26.2, "Configuring Content Data Controls for JCR Adapters."
3. Create a page as described in Section 15.2, "Creating Pages in a WebCenter Portal Framework Application."

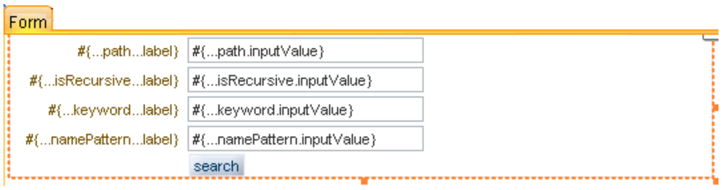
26.5.7.1 Adding Simple Search Capabilities

In this section, you will enable simple search capabilities in your page. This will let you perform wildcard (`%`) search.

To enable the search function:

1. In the Application Navigator, double-click your page to open it.
2. In the Data Controls panel, select the **search** node.
3. To enable users to perform a search by clicking a button, drag and drop the **search** node on your page. From the Create menu, choose **Parameters** and then **ADF Parameter Form**. The Edit Form Fields dialog displays.
4. Click **OK**. The ADF parameter form is added to the page, as shown in Figure 26–37.

Figure 26–37 ADF Parameter Form in the Design View

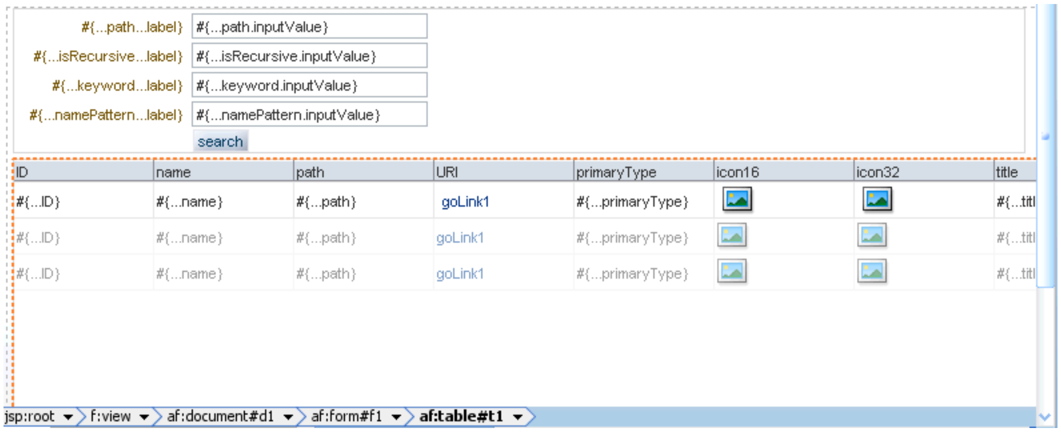


Form

#{...path...label}	#{...path.inputValue}
#{...isRecursive...label}	#{...isRecursive.inputValue}
#{...keyword...label}	#{...keyword.inputValue}
#{...namePattern...label}	#{...namePattern.inputValue}

5. To enable the display of search results in a read-only table, drag and drop the **Return** node onto the page. From the **Create** menu, choose **Table** and then **ADF Read-Only Table**. The Edit Table Columns dialog displays.
6. Click **OK**. A table similar to Figure 26–38 displays.

Figure 26–38 Table with Four Columns - search

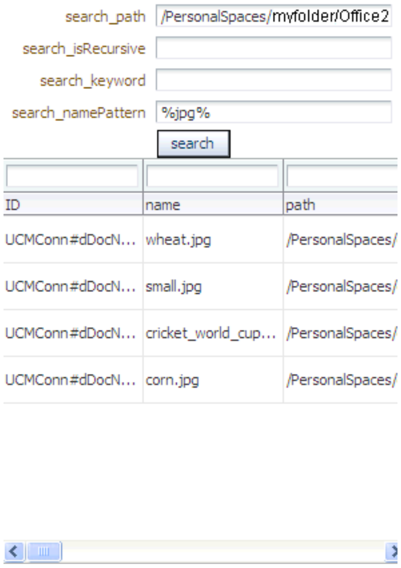


#{...path...label}	#{...path.inputValue}
#{...isRecursive...label}	#{...isRecursive.inputValue}
#{...keyword...label}	#{...keyword.inputValue}
#{...namePattern...label}	#{...namePattern.inputValue}

ID	name	path	URI	primaryType	icon16	icon32	title
#{...ID}	#{...name}	#{...path}	goLink1	#{...primaryType}	🖼	🖼	#{...titl
#{...ID}	#{...name}	#{...path}	goLink1	#{...primaryType}	🖼	🖼	#{...titl
#{...ID}	#{...name}	#{...path}	goLink1	#{...primaryType}	🖼	🖼	#{...titl

7. Run this page and specify / for **search_path** and %jpg% for **namePattern**. All .jpg files stored in the root of your repository display, as shown in Figure 26–39.

Figure 26–39 Search Results for .jpg Files



search_path	/PersonalSpaces/myfolder/Office2
search_isRecursive	
search_keyword	
search_namePattern	%jpg%

ID	name	path
UCMConn#dDocN...	wheat.jpg	/PersonalSpaces/
UCMConn#dDocN...	small.jpg	/PersonalSpaces/
UCMConn#dDocN...	cricket_world_cup...	/PersonalSpaces/
UCMConn#dDocN...	corn.jpg	/PersonalSpaces/

26.5.7.2 Adding Advanced Search Capabilities

In this section, you will add advanced search capabilities to your page that will enable you to perform search based on the last modified dates of items located in your file system repository.

To enable the advanced search function:

1. In the Application Navigator, open your page in which you intend to create the advanced search function. The page must be automatically exposed in new managed bean, where name=advancedSearch, class=AdvancedSearch, package=view. (In the Create JSF Page dialog > Page Implementation > Automatically Expose UI Components in a New Managed Bean)

   In this example the page is called advancedSearch.jspx.

2. Double-click the page to open it.

3. In the Component Palette, select **ADF Faces**.
4. From the list of **ADF Faces** - **Layout** components, drag **Panel Form Layout** onto the page.
5. From the Component Palette, drag **Input Date** into the **Panel Form Layout**.
6. In the Property Inspector, under the **Common** tab, set the **Label** to **Modified after**.
7. In the Application Navigator, under **portal.backing**, double-click **AdvancedSearch.java** to open it.
8. Add the following import declarations. These declarations are required for the `getPredicates` method, which will be added in the next step.

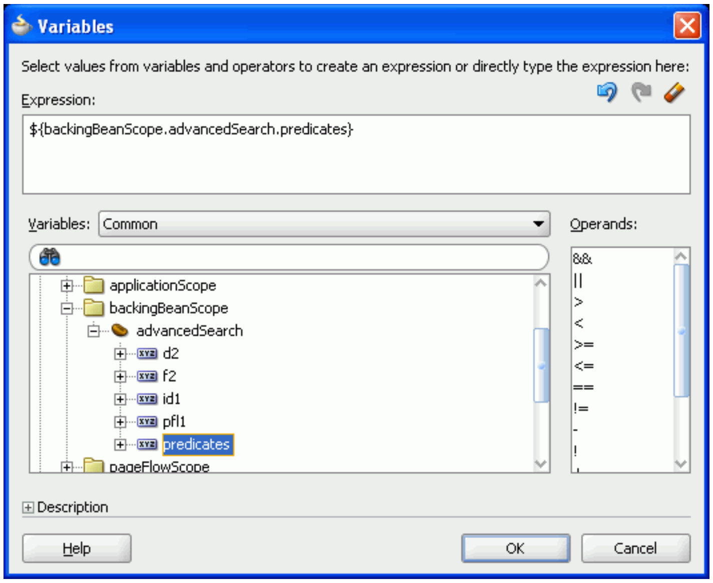
```
import java.util.ArrayList;
import java.util.Calendar;
import java.util.Date;
import java.util.List;
import oracle.vcr.datacontrol.search.Predicate;
import oracle.vcr.datacontrol.search.Operator;
```

9. Add the following method to enable the advanced search based on last modified dates of the items stored in the repository:

```
public List<Predicate> getPredicates() {
        ArrayList<Predicate> predicates = new ArrayList<Predicate>();
        if (id1.getValue() != null && !id1.getValue().equals(""))
{
            Calendar cal = Calendar.getInstance();
            cal.setTime((Date)id1.getValue());
            predicates.add(new Predicate("jcr:content/jcr:lastModified"
                                          , Operator.GREATER_THAN
                                          , cal));
        }
        // ... other predicates
        if (predicates.size()>0)
            return predicates;
        return null;
    }
```

10. From the Data Controls panel, drag the **advancedSearch** node onto the page. From the Create menu, choose **Methods** and then **ADF Button**. The Edit Action Binding dialog displays.
11. For **Path**, specify the path to the directory in which the search will be performed; for example, `/`. For **isRecursive** specify `true`, and **matchAny** specify `false`.
12. For predicates, select the arrow next to the **Value** field and then select **Show El Expression Builder**. The Variables dialog displays.
13. Expand **ADF Managed Beans**, **backingBeanScope**, **advancedSearch** and select **predicates**. This adds the expression `${backingBeanScope.advancedSearch.predicates}`, as shown in Figure 26–40, and click **OK**.

Figure 26–40 Variables Dialog - predicates



Select values from variables and operators to create an expression or directly type the expression here:

Expression:

${backingBeanScope.advancedSearch.predicates}

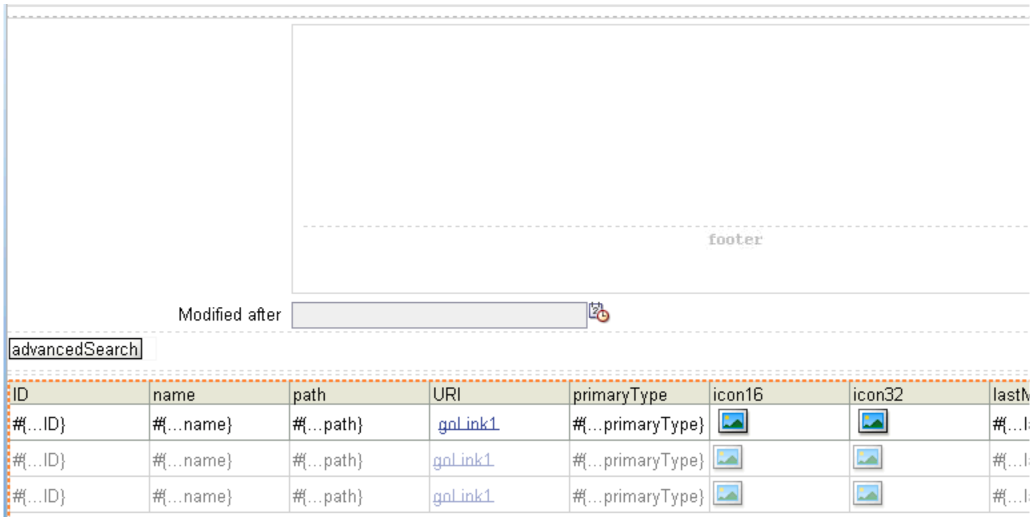
Variables: Common

14. Click **OK** in the Edit Action Binding dialog.

15. In the Data Controls panel, expand the **advancedSearch** node. Then drag **Return** and drop it onto the page, after the advancedSearch ADF button. From the Create menu, choose **Table** and then **ADF Read-only Table**.

16. In the Edit Table Columns dialog, edit labels of the columns, if needed. Then click **OK**. The Design view looks like Figure 26–41.

Figure 26–41 Advanced Search - Design View



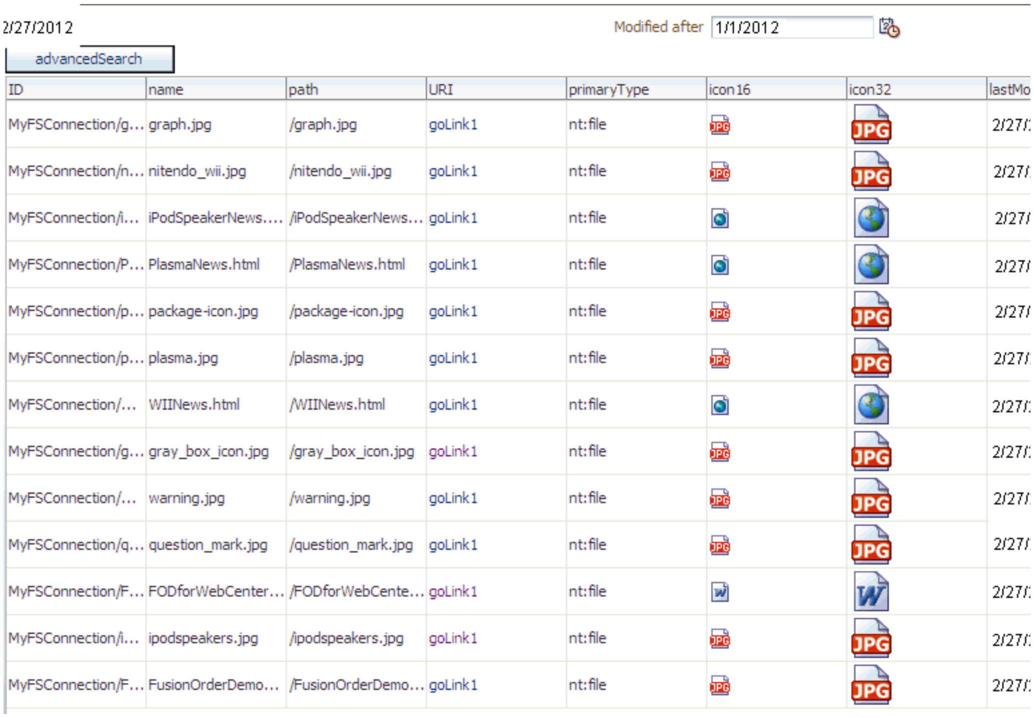
ID	name	path	URI	primaryType	icon16	icon32	lastM
#{...ID}	#{...name}	#{...path}	goLink1	#{...primaryType}	🖼	🖼	#{...l
#{...ID}	#{...name}	#{...path}	goLink1	#{...primaryType}	🖼	🖼	#{...l
#{...ID}	#{...name}	#{...path}	goLink1	#{...primaryType}	🖼	🖼	#{...l

17. In the Property Inspector, under the **Behavior** tab, set the `ContentDelivery` property to `immediate`.

18. To view the page in a browser, under the Application Navigator, right-click the page and choose **Run**. The `advancedSearch` page displays in the browser.

19. Enter a *last modified* date and click the **advancedSearch** button. The files modified after that date are displayed, as shown in Figure 26–42.

Figure 26–42 Advanced Search Results



2/27/2012 Modified after 1/1/2012

26.5.8 What Happens at Runtime

Clicking the **search** button at runtime invokes the `search` method and the values provided through the UI are used as the parameters for the search. At runtime, you can perform the wild (`%`) card search. For example, to search for files that have `.jpg` extension, enter `/` in the **search_path** field, enter `%jpg` in the namePattern field and then click **Search**. All files with the `.jpg` extension will display in the read-only table.

At runtime the JCR data control uses the given parameters to construct an `XPath` query for the given parameters. For the simple search example, the query is:

```
Non-recursive:
XPath query /jcr:root/element(*, nt:file)[jcr:like(ojcr:local-name(), '%jpg%')]

Recursive:
XPath query /jcr:root//element(*, nt:file)[jcr:like(ojcr:local-name(), '%jpg%')]
```

In the advanced search example, first a backing bean is added to the page, because the backing bean is required to construct the `predicate` parameter value of the `advancedSearch` method. Then the **Panel Form Layout UI** component is dropped onto the page. In this component, the `InputDate` component is dropped, which is used at runtime to supply the date-based search criterion. The `advancedSearch` method predicates parameter allows for a combination of predicates to be supplied to the `search` method. Each can specify the value of an item's properties that must apply for the search. In this example, only a modification date is tested in the predicates, but potentially multiple tests could be included, for example a modification date and a `mimeType`.

The backing bean's `getPredicates` method is hardcoded to construct the `predicates` method from the date provided by the page at runtime. At design time, the return value of the `predicates` method is bound into the predicates `advancedSearch` method parameter. At runtime this invokes the getPredicates method before invoking the advancedSearch method to construct the correct predicate value.

At runtime the JCR data control uses the given parameters to construct an XPath query for the given parameters. For this example the query is:

```
/jcr:root//element(*, nt:hierarchyNode)[jcr:content/@jcr:lastModified >
xs:dateTime('2009-02-15T00:00:00.000+05:30')]
```

26.5.9 Using Search Capabilities

Consider the following points while adding search capabilities:

- How certain operations work depends on the implementation of the adapter and the underlying repository. While read and query operations are similar, full text search works differently. Another example is, the file system and Oracle Portal adapters do not support search based on the primaryType attribute. The only supported way to search based on type is through the element (*, type) construct.
- If you use the Oracle Portal adapter, then the behavior of search functionality varies depending on whether Oracle Text is enabled or not. If Oracle Text is disabled, then the search is performed in the Oracle Portal content metadata. With Oracle Text turned on, all indexed content is searched, which includes the contents of files. This also applies to Content Server. That is, Content Server-based adapter performs full text index operation on its documents using Oracle Text.
- The Oracle Portal adapter does not support translations and only returns content in the base language of a page group. Searching across multiple page groups with different base languages is not supported.

27 Creating Content Presenter Display Templates

This chapter describes the out-of-the-box Content Presenter display templates, how to create new display templates, and how to make display templates available to users.

> **Note:** Content Presenter can only be used with Content Server-based content. No other content repository connection types are supported.

This chapter includes the following topics:

27.1 About Content Presenter Display Templates

A *Content Presenter display template* is a JSFF file (JSF page fragment) that defines how Content Presenter renders content items (including images and text) on a portal or Framework application page. WebCenter Portal provides several out-of-the-box display templates to get you started, but you can also create your own templates to solve specific display requirements.

Some typical situations where Content Presenter display templates provide value are:

- Providing different layouts for different parts of a page. For example, you may have articles from different sources on the same page, each requiring its own layout (for more information, see Section 27.3.3, "Defining Multiple-Item Display Templates").
- Presenting content based on the capabilities of the viewing device. You can provide display templates that respond to whether the viewing device is a standard monitor, tablet or smart phone (for more information, see Section 27.3.4, "Using Responsive Templates").

Making content available through Content Presenter display templates lets you solve complex display issues through a standardized template rather than doing each individual layouts by hand. By making display templates available to users you enable them to solve layout requirements based on predefined department or company standards without developer involvement.

> **Tip:** You can find sample display templates in `$ORACLE_HOME/jdeveloper/webcenter/samples/contentpresenter`. These sample files were installed as part of WebCenter Portal's extension for Oracle JDeveloper.

Display templates can use the full set of Rich ADF components, so you can quickly and easily create robust and attractive templates to display your content. Note, however, that you are not required to use these components in your template.

A Content Presenter display template can handle either single-content items, multiple-content items, or combinations of the two. For example, a multiple content item template might render tabs for each item and then call a single item template to render the details of a selected item.

Each content item is associated with a specific *content type* defined in the WebCenter Content repository. A content type defines the properties of the content item. Content types can map to WebCenter Content profile definitions and Site Studio region definitions.

> **Tip:** Oracle recommends that you use Content Presenter ADF templates to integrate Site Studio and WebCenter Portal instead of Site Studio region templates. The recommended flow is:
>
> - Develop region definitions in Site Studio
> - Develop ADF templates referencing region definitions using JDeveloper
> - Publish the templates and import them into Portal Server
> - Use Content Presenter to render the content and to enable users to contribute content

Content types are created on the content repository (WebCenter Portal Content Server). As a Content Presenter display template developer, you need to know the names of the properties defined for the associated content type so that you can define how to display the selected content item(s) on the page.

> **Tip:** One way to determine the properties for the existing content types defined in WebCenter Content is to use the Content Presenter Configuration dialog in a portal. For a detailed description of this technique, see Section 27.3.8, "Discovering Content Type Property Names."

At runtime, an authorized end user can choose a display template in the Content Presenter Configuration dialog. For more information about best practices and determining when and how to use Content Presenter templates, see the blog entry at:

```
http://www.ateam-oracle.com/portal-and-content-content-integration-best-practices
```

27.2 Using the Out-of-the-Box Display Templates

WebCenter Portal provides several out-of-the-box Content Presenter display templates. These pre-built templates provide options for displaying single content items and multiple content items.

For example, the Default Document Details View template displays detailed information about any single content item including creation date, modification date, created by username, modified by username, and path. Figure 27.4 shows a content item displayed at runtime with this template.

Figure 27–1 Default Document Details View Display Template

Several options are provided for displaying multiple content items, such as the Accordion View, which displays multiple content items in an accordion format. In this format, each item can be expanded to display its details, as shown in Figure 27–2. (Note that one item will always be open in an accordion view. That is, you cannot close all of the items, you can only change which single item is open at any time.)

For a complete list of out-of-the-box display templates, see Section 29.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates."

27.3 Creating Content Presenter Display Templates

If the out-of-the-box display templates (see Section 27.2, "Using the Out-of-the-Box Display Templates") do not meet your needs, you can define custom Content Presenter templates.

> **Tip:** As well as creating new Content Presenter display templates, you can also copy one of the out-of-the-box templates and modify it.

This section discusses these topics:

- Section 27.3.1, "About Content Presenter Display Templates"
- Section 27.3.2, "Creating Single-Item Display Templates"
- Section 27.3.3, "Defining Multiple-Item Display Templates"
- Section 27.3.4, "Using Responsive Templates"
- Section 27.3.5, "Extending Responsive Templates"
- Section 27.3.6, "Using Image Renditions in Content Presenter Display Templates"
- Section 27.3.7, "Using EL Expressions to Retrieve Content Item Information"
- Section 27.3.8, "Discovering Content Type Property Names"
- Section 27.3.9, "Referencing External Files in Display Templates"
- Section 27.3.10, "Referencing Site Studio Region Elements in a Custom View"
- Section 27.3.11, "Using a Content Presenter Display Template"

27.3.1 About Content Presenter Display Templates

Depending on your needs, the approach you take to defining Content Presenter display templates will vary. Typically, you define display templates for specific single items of content, then define a multiple content item display template that includes calls to the single item display templates.

Template definitions can include calls to other display templates in any of the following ways:

- A single content item display template can call another single content item display template.
- A multiple content item display template can call a single content item display template (as shown in the examples below).
- A multiple content item display template can call another multiple content item display template.

The basic tasks for creating Content Presenter display templates include:

- Deciding whether to create a single or multiple item display template. See Section 27.3.2, "Creating Single-Item Display Templates" and Section 27.3.3, "Defining Multiple-Item Display Templates."
- Deciding what kind of information you want to display with content items. Consider also, for example, using WebCenter Portal's EL expressions in your template to retrieve and display this information. See Section 27.3.7, "Using EL Expressions to Retrieve Content Item Information," and Appendix G, "Expression Language Expressions" for more information about using EL expressions.

- Designing the look and feel of the template. In addition to standard JSFF constructs, display templates can use ADF components. See *Web User Interface Developer's Guide for Oracle Application Development Framework*.
- Exporting the template as a portal resource. See Section 27.5.1, "Export a Content Presenter Display Template as a Portal Resource."
- Configuring Content Presenter to use Coherence as the caching mechanism for production (optional, but recommended) and HA environments (required) as described in Section 27.7, "Configuring Coherence as the Caching Mechanism."

27.3.2 Creating Single-Item Display Templates

Examples of single content items for which you may want to create Content Presenter display templates are:

- Individual items to display with a specific look and feel on a page.
- Different views of a specific type of item (such as short and detailed views of an article).
- Different versions of a similar item (such as Press Releases that may be formatted differently for different groups and using a different set of properties).

The definition of a single content item display template uses the JSP tags listed in Table 27–1.

Table 27–1 Content Display Template Tags for Single Content Items

JSP Tag	Description	Example

`contentTemplateDef`	Required. Defines a single content item template.
	Attributes:
	`var` - Specifies the content node that will be rendered by this display template. In the template definition code, you can use the EL expressions described in Section 27.3.7.1, "Retrieving Basic Information About a Content Item" to retrieve required information about the node.
		`<dt:contentTemplateDef var="node">`
		`  <af:outputText value="#{node.name}" />`
		`</dt:contentTemplateDef>`

`renderProperty`	Optional. Retrieves and renders the string value(s) of the specified node property inline.
	Attributes:
	`id` - Identifies this component. This value must be unique within the closest parent component that is a naming container.
	`name` - Specifies the name of the property to get. If this is a system property (`cm_createdBy`, `cm_createdDate`, `cm_modifiedDate`, and `cm_path`) then the value on the node will be used. If not specified, then the `primaryProperty` will be used if defined.
	`node` - Specifies the node to use. This value can either be a bound attribute to a managed bean, or a request attribute variable.
	`blockSize` - Specifies the size of the blocks in bytes, to read the bytes of a binary property. Default is 2048 bytes.
	`startIndex` - Specifies the index (from 0) in the document's bytes at which to start printing. Defaults to 0.
	`endIndex` - Specifies the index (from 0) in the document's bytes at which to stop printing. Defaults to value of `blockSize`.
	`rendered` - Specifies whether or not this component should be rendered (during Render Response Phase), or processed on any subsequent form submit. The default value is `true`.
		`<!--`
		`  Handling of text-based primary`
		`  properties (HTML, text, etc.).`
		`-->`
		`<dt:contentTemplateDef var="node">`
		`    <cmf:renderProperty id="rp1"`
		`     name="#{node.primaryProperty.name}"`
		`      node="#{node}"/>`
		`</dt:contentTemplateDef>`

Table 27–1 (Cont.) Content Display Template Tags for Single Content Items

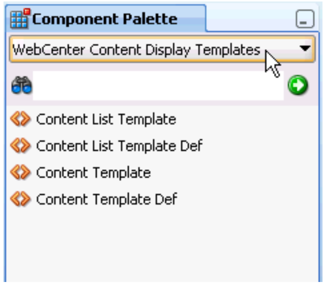
JSP Tag	Description	Example

`contentTemplate`	Optional. Nested under `contentTemplateDef`.
	Calls another single item template.
	Attributes:
	`node` - Required. Specifies the content repository node that should be displayed.
	`nodesHint` - Optional. When the display template is called in an iterating component, allows the pre-inclusion of all possible templates. This attribute is not needed when `contentTemplate` is used inside a `contentTemplateDef` tag.
	`view` - Optional. Specifies the target view name.
	`id` - Optional. Specifies the JSF component ID.
	`rendered` - Optional. Specifies whether the component should be rendered.
		`<dt:contentTemplateDef var="node">`
		`  <af:outputText value="#{node.name}" >`
		`  <dt:`**`contentTemplate`**` node="#{node}"`
		`     view="templates.pressrelease.item"`
		`     />`
		`  </af:outputText>`
		`</dt:contentTemplateDef>`

To create a display template for a single content item:

1. In JDeveloper, create a JSFF file:
   a. From the **File** menu, choose **New**.
   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **JSF Page Fragment**.
   c. Click **OK**.
   d. In the Create New JSF Page Fragment dialog, enter a name for the display template file.
   e. Set the Directory field to point to the `oracle/webcenter/portalapp/pages` folder of your portal Web project. This directory must be set from the correct root path. In JDeveloper, the root path is *PROJECT_NAME* > Web Content. On the file system, the root path is *PROJECT_ROOT*`/public_html`. For example: *PROJECT_ROOT*`/public_html/oracle/webcenter/portalapp/pages`. A good practice is to first create a subfolder in `pages` and store the JSFF in the subfolder.
2. Select **View**, then **Component Palette** to open the Component Palette.
3. From the dropdown list at the top of the Component Palette (Figure 27–3):
   - Select **WebCenter Content Display Templates** for a list of display template tags.
   - Select **WebCenter Content Management Faces** for the `renderProperty` tag.

Figure 27–3 Content Display Template Tags in Component Palette



4. In Source view, drag and drop the required display template tags from the Component Palette onto the page to define your template. Refer to Table 27–1 for information about each tag and required parameter values.

Example 27–1 and Example 27–2 show sample single content item display template definitions. These examples illustrate a use case where a certain kind of document (a press release) is produced by two different departments inside a company, and each department has defined its own content type and properties. These sample Content Presenter display templates allow these two different content types to be displayed in a consistent manner.

The template shown in Example 27–1 handles a press release that uses a property named `xHeading` to describe the heading of the press release document, and `xDestinationUrl` to describe the location of the document. To learn how you can retrieve these property names for a given content type, see Section 27.3.8, "Discovering Content Type Property Names."

Example 27–1 Sample Content Presenter Display Template for a Press Release Document

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"
          version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates">
   <dt:contentTemplateDef var="node">
      <af:goImageLink text="#{node.propertyMap['xHeading'].value}"
                      id="gil1"
                      icon="#{node.icon.smallIcon}"
                      destination="#{node.propertyMap['xDestinationUrl'].value}"
                      targetFrame="_blank">
      </af:goImageLink>
   </dt:contentTemplateDef>
</jsp:root>
```

The template shown in Example 27–2 handles a press release that uses a property named `dDocTitle` to describe the heading of the press release document, and `xLinkUrl` to describe the location of the document.

Example 27–2 Sample Content Presenter Template for Another Press Release Document

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"
          version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates">
   <dt:contentTemplateDef var="node">
```

```
        <af:goImageLink text="#{node.propertyMap['dDocTitle'].value}"
                        id="gil1"
                        icon="#{node.icon.smallIcon}"
                        destination="#{node.propertyMap['xLinkUrl'].value}"
                        targetFrame="_blank">
        </af:goImageLink>
   </dt:contentTemplateDef>
</jsp:root>
```

27.3.3 Defining Multiple-Item Display Templates

Examples of multiple content items for which you may want to create Content Presenter display templates are:

- A group of similar items that you want to display on a page, such as a list of books or an employee directory of pictures.
- Query results, such as all documents modified in the last week.
- A list of all documents in a WebCenter Content folder.

A Content Presenter display template can also combine both single and multiple items. For example, a multiple content item template might render tabs for each item and then call a single item template to render the details of a selected item. For an example of how to do this, see the A-Team blog entry "Enable Content Editing of Iterative Components."

The definition of a multiple content item display template uses the JSP tags listed in Table 27–2.

Table 27–2 Content Display Template Tags for Multiple Content Items

JSP Tag	Description	Example
contentListTemplateDef	Required. Defines the multiple content item template. **Attributes**: var - Specifies the content node that will be rendered by this display template. In the template definition code, you can use the EL expressions described in Section 27.3.7.1, "Retrieving Basic Information About a Content Item" to retrieve required information about the node.	<dt:**contentListTemplateDef** var="nodes"> <af:iterator value="#{nodes}" var="node"> <af:outputText value="#{node.name}" /> </af:iterator> </dt:**contentListTemplateDef**>
contentListTemplate	Optional. Nested under contentListTemplateDef. Calls another multiple item template. **Attributes**: nodes - Required. Provides the list of VCR nodes that should be displayed category - Required. Specifies the target template category. view - Required. Specifies the target view name. id - Optional. Specifies the JSF component ID. rendered - Optional. Specifies whether the component should be rendered.	<dt:contentListTemplateDef var="nodes"> <!-- Reuse the default bulleted list view, but indent it with a <blockquote> --> <f:verbatim> <blockquote> </f:verbatim> <dt:**contentListTemplate** nodes="#{nodes}" category="oracle.webcenter.content. templates.default.category" view="oracle.webcenter.content. templates.default.list.bulleted"/> <f:verbatim> </blockquote> </f:verbatim> </dt:contentListTemplateDef>
contentTemplate	Optional. Nested under contentListTemplateDef. Calls a single item template. **Attributes**: node - Required. Specifies the content repository node that should be displayed. nodesHint - Optional. When the display template is called in an iterating component, allows the pre-inclusion of all possible templates. This attribute is usually required when contentTemplate is used inside a contentListTemplateDef tag. view - Optional. Specifies the target view name. id - Optional. Specifies the JSF component ID. rendered - Optional. Specifies whether the component should be rendered.	<dt:contentListTemplateDef var="nodes"> <af:iterator rows="0" var="node" varStatus="iterator" value="#{nodes}"> <dt:**contentTemplate** node="#{node}" view="templates.pressrelease.listitem" nodesHint="#{nodes}"/> </af:iterator> </dt:contentListTemplateDef>

To define a display template for multiple content items:

1. In JDeveloper, create a JSFF file and open the Component Palette, as described in Step 1 through Step 3 in Section 27.3.2, "Creating Single-Item Display Templates."
2. In Source view, drag and drop the required display template tags from the Component Palette onto the page. Refer to Table 27–2 for information about each tag and required parameter values.

Example 27–3 shows a sample multiple content item display template definition.

Example 27–3 Sample display template definition for the display of multiple press releases (press-release-list-view.jsff)

This template definition iterates over the data items selected for display, and processes them according to the referenced view (`view="mycorp.content.templates.pressrelease.listitem"`).

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates">
   <dt:contentListTemplateDef var="nodes">
      <af:panelGroupLayout layout="scroll" id="nodeListPanel" valign="middle">
        <af:iterator rows="0" var="node" varStatus="iterator" value="#{nodes}">
           <dt:contentTemplate node="#{node}"
               view="mycorp.content.templates.pressrelease.listitem"
               nodesHint="#{nodes}"/>
        </af:iterator>
      </af:panelGroupLayout>
   </dt:contentListTemplateDef>
</jsp:root>
```

27.3.4 Using Responsive Templates

Using CSS3 media queries, you can render content to adapt to conditions such as screen resolution. The out-of-the-box Content Presenter templates "Articles View" and "Full Articles View" are examples of how CSS3 media queries can be used in a Content Presenter template for a responsive layout. For information about how these responsive templates can be extended, see Section 27.3.5, "Extending Responsive Templates." For information about Content Presenter's out-of-the-box display template parameters, see Section 29.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates." For information about optimizing viewport settings for mobile devices such as smart phones and tablets, see the "Optimizing Portals for Mobile Devices" section in *Building Portals with Oracle WebCenter Portal*.

- Section 27.3.4.1, "Prerequisites"
- Section 27.3.4.2, "Displaying Multiple Articles"
- Section 27.3.4.3, "Using CSS3 Media Queries"

27.3.4.1 Prerequisites

The Articles View and Full Article View templates described in Section 27.3.4.2, "Displaying Multiple Articles," rely on the Site Studio `RD_ARTICLE` region definition. Consequently, Site Studio must be enabled in WebCenter Content to allow the Articles View and Full Article View Content Presenter templates to be used.

Follow the steps below to enable Site Studio and seed Content Server with the `RD_ARTICLE` region definition:

1. Enable Site Studio (see the "Understanding Site Studio Integration" section in *Building Portals with Oracle WebCenter Portal*).
2. Start (or restart) WebCenter Portal after Site Studio has been enabled (this will seed the `RD_ARTICLE` region definition).

27.3.4.2 Displaying Multiple Articles

The template definition in Example 27–4 iterates over the data items selected for display, and uses three style classes:

- **`article`** - applied to each content item
- **`article-3`** - applied to each content item that will be in the first column if the page is split into rows of three columns
- **`article-2`** - applied to each content item that will be in the first column if the page is split into rows of two columns

The style classes are defined in the `articles.css` style sheet.

Example 27–4 Sample display template definition for displaying multiple articles (articles.jsff)

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:rah="http://xmlns.oracle.com/webcenter/resourcehandler"
          xmlns:tr="http://myfaces.apache.org/trinidad">
   <dt:contentListTemplateDef var="nodes">
      <af:resource type="css"
source="/oracle/webcenter/content/templates/seeded/articles.css"/>
      <af:iterator rows="0" var="node" varStatus="iterator" value="#{nodes}"
                   id="it0">
         <h:panelGroup styleClass="#{(iterator.index % 3 == 0) ? 'article-3 ' :
''}#{(iterator.index % 2 == 0) ? 'article-2 ' : ''}article"
                       id="pg1">
            <af:commandLink immediate="true" partialSubmit="true" id="cl2">
               <rah:resourceActionBehavior id="rah1"

serviceId="oracle.webcenter.content.presenter"
                                           resourceId="#{node.id}"
                                           resourceTitle="#{node.propertyMap['RD_
ARTICLE:TITLE'].asTextHtml}"
                                           useResourcePopup="never"/>
               <f:attribute name="taskFlowInstId"
                            value="a5fafea8-90e6-4972-997d-314401b6c98b"/>
               <f:attribute name="datasourceType" value="dsTypeSingleNode"/>
               <f:attribute name="datasource"

value="#{node.id.repositoryName}#dDocName:#{node.propertyMap['dDocName'].value}"/>
               <f:attribute name="templateView"

value="oracle.webcenter.content.templates.sitestudio.fullarticle"/>
               <f:attribute name="regionTemplate" value="#{false}"/>
               <af:outputText value="#{node.propertyMap['RD_
ARTICLE:IMAGE'].asTextHtml}"
                              escape="false" id="ot4"/>
               <tr:panelHeader text="#{node.propertyMap['RD_
ARTICLE:TITLE'].asTextHtml}"
                               id="ph1">
                  <af:outputText value="#{node.propertyMap['RD_
ARTICLE:SUMMARY'].asTextHtml}"
                                 escape="false" id="ot3"/>
               </tr:panelHeader>
            </af:commandLink>
         </h:panelGroup>
      </af:iterator>
   </dt:contentListTemplateDef>
</jsp:root>
```

27.3.4.3 Using CSS3 Media Queries

The style sheet in Example 27–5 uses media queries to render the content in different ways depending on the width of the browser.

Example 27–5 Style sheet using CSS3 Media Queries (articles.css)

```
/* Default styles */
.article {
  display: block;
  float: left;
  width: 31.623931623931625%;
  margin-left: 2.564102564102564%;
  margin-bottom: 1em;
}
.article-3 {
  margin-left: 0;
  clear: both;
}
.article img {
  width: 100%;
  margin: 0 0 .25em;
  float: none;
  padding-top: 0;
  display: block;
  border: 0;
}
.article h1 {
  font-size: 1.5em;
}

@media only screen and (max-width : 480px) {
  /* up to width of iPhone (excluding iPhone 5 in landscape) */
  .article {
    margin-top: .5em;
    float: left;
    display: inline;
    width: 100%;
    margin-left: 0;
  }
  .article-3 {
    width: 100%;
    clear: none;
  }
  .article img {
    margin-right: 4%;
    width: 48%;
    float: left;
  }
  .article {
    font-size: 1em;
  }
  .article h1 {
    font-size: 1.25em;
  }
}

@media only screen and (min-width : 481px) and (max-width : 780px) {
  /* up to the width of iPad in portrait and iPhone 5 in landscape */
  .article {
    display: block;
    float: left;
    width: 48.717948717948718%;
    margin-left: 2.564102564102564%;
    clear: none;
  }
  .article-3 {
    margin-left: 2.564102564102564%;
    clear: none;
  }
  .article-2 {
    margin-left: 0;
    clear: both;
  }
  .article h1 {
    font-size: 1.25em;
  }
}

@media only screen and (min-width : 769px) and (max-width : 1024px) {
  /* up to the width of iPad in landscape */
}

@media only screen and (min-width : 1025px) {
  /* desktop */
}
```

27.3.5 Extending Responsive Templates

These section describes the steps required to modify the out-of-the-box templates if they don't meet your local requirements. For information about optimizing viewport settings for mobile devices such as smart phones and tablets, see the "Optimizing Portals for Mobile Devices" section in *Building Portals with Oracle WebCenter Portal*.

This section includes the following subsections:

- Section 27.3.5.1, "Extending the Articles View Template"
- Section 27.3.5.2, "Extending the Full Article View Template"
- Section 27.3.5.3, "Adapting the Out-of-the-Box Templates"

27.3.5.1 Extending the Articles View Template

To extend the Articles View template follow the steps below:

1. Create an empty template for displaying multiple items (see Section 27.3.3, "Defining Multiple-Item Display Templates") and copy the contents of

articles.jsff (located in the JDEVELOPER/webcenter/samples/contentpresenter/ directory) into the empty template.

2. Embed the CSS used by artices.jsff into the new template by changing:

```
<af:resource type="css"
source="/oracle/webcenter/content/templates/seeded/articles.css"/>
```

To:

```
<af:resource type="css">
/* Default styles */
.article {
  display: block;
  float: left;
  width: 31.623931623931625%;
  margin-left: 2.564102564102564%;
  margin-bottom: 1em;
}
.article-3 {
  margin-left: 0;
  clear: both;
}
.article img {
  width: 100%;
  margin: 0 0 .25em;
  float: none;
  padding-top: 0;
  display: block;
  border: 0;
}
.article h1 {
  font-size: 1.5em;
}

@media only screen and (max-width : 480px) {
  /* up to width of iPhone */
  .article {
    margin-top: .5em;
    float: left;
    display: inline;
    width: 100%;
    margin-left: 0;
  }
  .article-3 {
    width: 100%;
    clear: none;
  }
  .article img {
    margin-right: 4%;
    width: 48%;
    float: left;
  }
  .article {
    font-size: 1em;
  }
  .article h1 {
    font-size: 1.25em;
  }
}
```

```
@media only screen and (min-width : 481px) and (max-width : 780px) {
  /* up to the width of iPad in portrait */
  .article {
    display: block;
    float: left;
    width: 48.71794871794871%;
    margin-left: 2.564102564102564%;
    clear: none;
  }
  .article-3 {
    margin-left: 2.564102564102564%;
    clear: none;
  }
  .article-2 {
    margin-left: 0;
    clear: both;
  }
  .article h1 {
    font-size: 1.25em;
  }
}

@media only screen and (min-width : 769px) and (max-width : 1024px) {
  /* up to the width of iPad in landscape */
}

@media only screen and (min-width : 1025px) {
  /* desktop */
}
</af:resource>
```

3. Edit the new template to adapt it to your requirements (see Section 27.3.5.3, "Adapting the Out-of-the-Box Templates").
4. Export the new template as a Portal Resource (see Section 27.5.1, "Export a Content Presenter Display Template as a Portal Resource").
5. Upload the new template to your WebCenter Portal or Framework application (see Section 27.5.2, "Upload the New Content Presenter Display Template").

27.3.5.2 Extending the Full Article View Template

Follow the steps below to extend the Full Article View template:

1. Create an empty template for displaying a single content item (see Section 27.3.2, "Creating Single-Item Display Templates") and copy the contents of `full-article.jsff` (located in the `JDEVELOPER/webcenter/samples/contentpresenter/` directory) into the empty template.
2. Embed the CSS used by `full-artice.jsff` into the new template by changing:

   ```
   <af:resource type="css"
   source="/oracle/webcenter/content/templates/seeded/articles.css"/>
   ```

   To:

   ```
   <af:resource type="css">
   /* Default styles */
   .full-article h1 {
     font-size: 1.5em;
   ```

```
}
.full-article-image img {
  margin-left: 4%;
  width: 48%;
  float: right;
}

@media only screen and (max-width : 480px) {
  /* up to width of iPhone */
  .full-article-image img {
    margin-left: 0;
    width: 100%;
    float: none;
  }
}

@media only screen and (min-width : 481px) and (max-width : 780px) {
  /* up to the width of iPad in portrait */
}

@media only screen and (min-width : 769px) and (max-width : 1024px) {
  /* up to the width of iPad in landscape */
}

@media only screen and (min-width : 1025px) {
  /* desktop */
}
</af:resource>
```

3. Edit the new template to adapt it your requirements (see Section 27.3.5.3, "Adapting the Out-of-the-Box Templates").
4. Export the new template as a Portal Resource (see Section 27.5.1, "Export a Content Presenter Display Template as a Portal Resource").
5. Upload the new template (see Section 27.5.2, "Upload the New Content Presenter Display Template").

27.3.5.3 Adapting the Out-of-the-Box Templates

This section describes changes you may want to make to the Articles View and Full Article View templates, and outlines how you could go about making those changes. For example:

- You may want to update the templates to support a responsive layout on older browsers like Internet Explorer 8.
- You may want to update the templates to work with a different region definition.

These extensions are described in the following sections:

- Section 27.3.5.3.1, "Supporting Responsive Layouts for Older Browsers"
- Section 27.3.5.3.2, "Using Different Region Definitions"
- Section 27.3.5.3.3, "Updating the Layout in a Template"

27.3.5.3.1 Supporting Responsive Layouts for Older Browsers

The current responsive templates rely on CSS3 media queries, which are not supported by older browsers, so you may want to use a third-party JavaScript library that can take the media queries and use JavaScript to enable a responsive design.

To do this:

- Create and deploy a custom Shared Library for WebCenter Portal containing the third-party JavaScript library (see Section 55.2, "Developing Task Flows, Data Controls, and Managed Beans for WebCenter Portal").
- Add a reference to a third-party JavaScript library to the template (where `path/to/3rd/party/library.js` is the path to the JavaScript file within the Custom Shared Library):

```
<af:resource type="javascript" source="path/to/3rd/party/library.js"/>
```

27.3.5.3.2 Using Different Region Definitions

This section shows you how you can modify the region definitions in your responsive template, For example, you might have a region definition called `RD_NEWS` with four elements: `TITLE`, `LEAD`, `IMAGE`, and `BODY` (see Section 27.3.10, "Referencing Site Studio Region Elements in a Custom View"). You could then update the templates to reference this new region definition by changing references of `RD_ARTICLES` to `RD_NEWS` and changing the references of `SUMMARY` to `LEAD`.

News View

This template displays a list of news items (of type `RD_NEWS`) based on the Articles View template:

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:rah="http://xmlns.oracle.com/webcenter/resourcehandler"
          xmlns:tr="http://myfaces.apache.org/trinidad">
   <dt:contentListTemplateDef var="nodes">
      <af:resource type="css"
source="/oracle/webcenter/content/templates/seeded/articles.css"/>
      <af:iterator rows="0" var="node" varStatus="iterator" value="#{nodes}"
                   id="it0">
         <h:panelGroup styleClass="#{(iterator.index % 3 == 0) ? 'article-3 ' :
''}#{(iterator.index % 2 == 0) ? 'article-2 ' : ''}article"
                       id="pg1">
            <af:commandLink immediate="true" partialSubmit="true" id="cl2">
               <rah:resourceActionBehavior id="rah1"

serviceId="oracle.webcenter.content.presenter"
                                           resourceId="#{node.id}"
                                           resourceTitle="#{node.propertyMap['RD_
NEWS:TITLE'].asTextHtml}"

                                           useResourcePopup="never"/>
               <f:attribute name="taskFlowInstId"
                            value="a5fafea8-90e6-4972-997d-314401b6c98b"/>
               <f:attribute name="datasourceType" value="dsTypeSingleNode"/>
               <f:attribute name="datasource"

value="#{node.id.repositoryName}#dDocName:#{node.propertyMap['dDocName'].value}"/>
               <f:attribute name="templateView"
                            value="oracle.webcenter.content.templates.newsitem"/>
               <f:attribute name="regionTemplate" value="#{false}"/>
               <af:outputText value="#{node.propertyMap['RD_
NEWS:IMAGE'].asTextHtml}"
```

```
                              escape="false" id="ot4"/>
               <tr:panelHeader text="#{node.propertyMap['RD_
NEWS:TITLE'].asTextHtml}"
                               id="ph1">
                  <af:outputText value="#{node.propertyMap['RD_
NEWS:LEAD'].asTextHtml}"
                                 escape="false" id="ot3"/>
               </tr:panelHeader>
            </af:commandLink>
         </h:panelGroup>
      </af:iterator>
   </dt:contentListTemplateDef>
</jsp:root>
```

News Item View

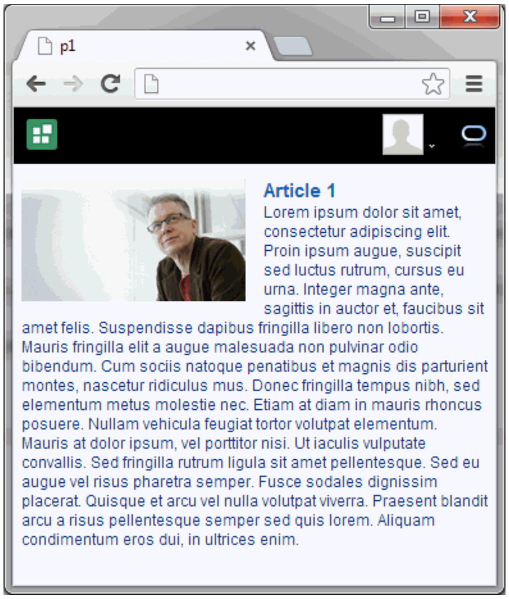
This template displays a full news item (`View ID: oracle.webcenter.content.templates.newsitem`) based on the Full Articles View template:

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:tr="http://myfaces.apache.org/trinidad">
     <dt:contentTemplateDef var="node">
        <af:resource type="css"
source="/oracle/webcenter/content/templates/seeded/articles.css"/>
        <af:panelGroupLayout id="psl1" layout="vertical">
            <tr:panelHeader text="#{node.propertyMap['RD_NEWS:TITLE'].asTextHtml}"
                            styleClass="full-article" id="ph1">
                <tr:panelGroupLayout id="pgl1" styleClass="full-article-image">
                    <af:outputText value="#{node.propertyMap['RD_
NEWS:IMAGE'].asTextHtml}"
                                   escape="false" id="ot4"/>
                </tr:panelGroupLayout>
                <af:outputText value="#{node.propertyMap['RD_
NEWS:BODY'].asTextHtml}"
                               escape="false" id="ot3"/>
            </tr:panelHeader>
        </af:panelGroupLayout>
    </dt:contentTemplateDef>
</jsp:root>
```

27.3.5.3.3 Updating the Layout in a Template

You might want to change the layout of the templates to better suit your content. For example, in the single column layout the Articles View template will flow the text of an article summary under the image if the text is sufficiently long:

Figure 27–4 Article with Wide Layout

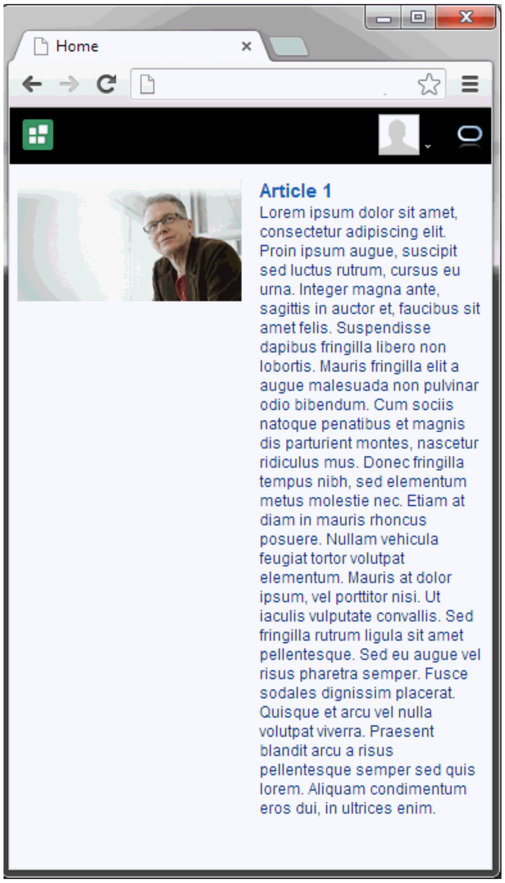


Article 1

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Proin ipsum augue, suscipit sed luctus rutrum, cursus eu urna. Integer magna ante, sagittis in auctor et, faucibus sit amet felis. Suspendisse dapibus fringilla libero non lobortis. Mauris fringilla elit a augue malesuada non pulvinar odio bibendum. Cum sociis natoque penatibus et magnis dis parturient montes, nascetur ridiculus mus. Donec fringilla tempus nibh, sed elementum metus molestie nec. Etiam at diam in mauris rhoncus posuere. Nullam vehicula feugiat tortor volutpat elementum. Mauris at dolor ipsum, vel porttitor nisi. Ut iaculis vulputate convallis. Sed fringilla rutrum ligula sit amet pellentesque. Sed eu augue vel risus pharetra semper. Fusce sodales dignissim placerat. Quisque et arcu vel nulla volutpat viverra. Praesent blandit arcu a risus pellentesque semper sed quis lorem. Aliquam condimentum eros dui, in ultrices enim.

You could change this so that the text doesn't flow under the image:

Figure 27–5 Article with Narrow Layout



Article 1

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Proin ipsum augue, suscipit sed luctus rutrum, cursus eu urna. Integer magna ante, sagittis in auctor et, faucibus sit amet felis. Suspendisse dapibus fringilla libero non lobortis. Mauris fringilla elit a augue malesuada non pulvinar odio bibendum. Cum sociis natoque penatibus et magnis dis parturient montes, nascetur ridiculus mus. Donec fringilla tempus nibh, sed elementum metus molestie nec. Etiam at diam in mauris rhoncus posuere. Nullam vehicula feugiat tortor volutpat elementum. Mauris at dolor ipsum, vel porttitor nisi. Ut iaculis vulputate convallis. Sed fringilla rutrum ligula sit amet pellentesque. Sed eu augue vel risus pharetra semper. Fusce sodales dignissim placerat. Quisque et arcu vel nulla volutpat viverra. Praesent blandit arcu a risus pellentesque semper sed quis lorem. Aliquam condimentum eros dui, in ultrices enim.

To do this, you could create a new template based on the Articles View template, add a style class to the block of text (`article-text`), and set the display CSS property for this style class to `table-cell` for the narrow layout:

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:rah="http://xmlns.oracle.com/webcenter/resourcehandler"
          xmlns:tr="http://myfaces.apache.org/trinidad">
   <dt:contentListTemplateDef var="nodes">
      <af:resource type="css">
      /* Default styles */
      .article {
        display: block;
        float: left;
        width: 31.623931623931625%;
        margin-left: 2.564102564102564%;
        margin-bottom: 1em;
      }
      .article-3 {
        margin-left: 0;
        clear: both;
      }
      .article img {
        width: 100%;
        margin: 0 0 .25em;
        float: none;
        padding-top: 0;
        display: block;
        border: 0;
      }
      .article h1 {
        font-size: 1.5em;
      }

      @media only screen and (max-width : 480px) {
        /* up to width of iPhone */
        .article {
          margin-top: .5em;
          float: left;
          display: inline;
          width: 100%;
          margin-left: 0;
        }
        .article-3 {
          width: 100%;
          clear: none;
        }
        .article img {
          margin-right: 4%;
          width: 48%;
          float: left;
        }
        .article {
          font-size: 1em;
        }
        .article h1 {
          font-size: 1.25em;
        }
        /* Set the display CSS property to table-cell for the article-text style
class in the narrow layout */
        .article-text {
          display: table-cell;
        }
      }

      @media only screen and (min-width : 481px) and (max-width : 780px) {
        /* up to the width of iPad in portrait */
        .article {
          display: block;
          float: left;
          width: 48.717948717948718;
          margin-left: 2.564102564102564%;
          clear: none;
        }
        .article-3 {
          margin-left: 2.564102564102564%;
          clear: none;
        }
        .article-2 {
          margin-left: 0;
          clear: both;
        }
        .article h1 {
          font-size: 1.25em;
        }
      }

      @media only screen and (min-width : 769px) and (max-width : 1024px) {
        /* up to the width of iPad in landscape */
      }

      @media only screen and (min-width : 1025px) {
        /* desktop */
      }
      </af:resource>
      <af:iterator rows="0" var="node" varStatus="iterator" value="#{nodes}"
                   id="it0">
         <h:panelGroup styleClass="#{(iterator.index % 3 == 0) ? 'article-3 ' :
''}#{(iterator.index % 2 == 0) ? 'article-2 ' : ''}article"
                       id="pg1">
            <af:commandLink immediate="true" partialSubmit="true" id="cl2">
               <rah:resourceActionBehavior id="rah1"

serviceId="oracle.webcenter.content.presenter"
                                           resourceId="#{node.id}"
                                           resourceTitle="#{node.propertyMap['RD_
ARTICLE:TITLE'].asTextHtml}"
                                           useResourcePopup="never"/>
               <f:attribute name="taskFlowInstId"
                            value="a5fafea8-90e6-4972-997d-314401b6c98b"/>
               <f:attribute name="datasourceType" value="dsTypeSingleNode"/>
               <f:attribute name="datasource"

value="#{node.id.repositoryName}#dDocName:#{node.propertyMap['dDocName'].value}"/>
               <f:attribute name="templateView"
```

```
value="oracle.webcenter.content.templates.sitestudio.fullarticle"/>
               <f:attribute name="regionTemplate" value="#{false}"/>
               <af:outputText value="#{node.propertyMap['RD_
ARTICLE:IMAGE'].asTextHtml}"
                              escape="false" id="ot4"/>
               <tr:panelHeader text="#{node.propertyMap['RD_
ARTICLE:TITLE'].asTextHtml}"
                               id="ph1" styleClass="article-text">
                  <af:outputText value="#{node.propertyMap['RD_
ARTICLE:SUMMARY'].asTextHtml}"
                                 escape="false" id="ot3"/>
               </tr:panelHeader>
            </af:commandLink>
         </h:panelGroup>
      </af:iterator>
   </dt:contentListTemplateDef>
</jsp:root>
```

27.3.6 Using Image Renditions in Content Presenter Display Templates

In some cases you may want to use different renditions of an image in different circumstances. For example, you might want to use a large, high resolution image when the page containing the image is displayed using a desktop browser. However, if the same page is displayed on a mobile device, a large, high resolution image might not be appropriate given the smaller screen size and possible slower download speed. For mobile devices it would be better to display a smaller, lower resolution version, or rendition, of the image. Content Presenter display templates provide the capability of specifying which rendition of an image to display under which circumstances.

To enable the use of different image renditions, you can use EL expressions in your Content Presenter display templates to determine which image renditions to use when.

Note: Image renditions are not supported through CMIS.

This section includes the following topics:

- Section 27.3.6.1, "Prerequisites"
- Section 27.3.6.2, "Retrieving Image Rendition Information for Image Documents"
- Section 27.3.6.3, "Retrieving Image Renditions for Site Studio Region Elements"

27.3.6.1 Prerequisites

For full image rendition support, the WebCenter Content where your images are checked in must have Digital Asset Management (DAM) enabled. If DAM is not enabled, there is limited support for separate `web` and `thumbnail` renditions only. For information about enabling DAM, see the "Enabling Digital Asset Manager" section in *Administering Oracle WebCenter Portal*.

When DAM is enabled, different renditions are automatically created when an image is checked in, determined by the rendition set specified during check in. DAM provides some built-in rendition sets but the WebCenter Content administrator can also create new rendition sets. The individual renditions can then be referenced by name in Content Presenter display templates by using the appropriate EL expression.

For more information about DAM and rendition sets, see the "Working with Image and Video Conversions" chapter of *Managing Oracle WebCenter Content*.

Note: WebCenter Portal supports multiple renditions for images only, not video.

In addition, the following other prerequisites must also be met:

- You must be using WebCenter Content Release 11*g*R1 (11.1.1.9.0) or later.
- WebCenter Portal and WebCenter Content must be using the same OHS front-end.
- The `webContextRoot` parameter must be set in line with the common OHS front-end so that WebCenter Portal can find WebCenter Content objects, for example, `/cs`.
- Single sign-on must be enabled across WebCenter Portal and WebCenter Content.

27.3.6.2 Retrieving Image Rendition Information for Image Documents

To retrieve image rendition information for image documents in your Content Presenter display template, use the following EL expression:

```
node.renditionsMap['renditionName:renditionProperty']
```

Where:

- *`renditionName`* is:
  - for DAM implementations, the name of the rendition from the appropriate rendition set. For example, `web`, `thumbnail`, `preview`, or `lowres`.
  - for non-DAM implementations, either `web` or `thumbnail`.

  Note: The *`renditionName`* is not case sensitive, therefore `preview` refers to the same rendition as `Preview`.

- *`renditionProperty`* is the required rendition information.

  In most cases, you will want to retrieve the URL of the image rendition so that the rendition can be displayed on a page. To do this use the `url` property.

  You can also retrieve other information about the rendition, such as `name`, `type`, `width`, `height`, `resolution`, `size`, or `contentType`.

  Note: For `web` and `thumbnail` renditions, only `size`, `contentType`, and `url` are applicable; `name` returns the name of the native file, not of the web or thumbnail rendition.

For example to display the `preview` rendition of an image, add the following to your template:

```
<af:image source="#{node.renditionsMap['preview:url']}" shortDesc="Preview
rendition" id="imageContent3"/>
```

> **Note:** Wherever possible, `url` points to a static rendition URL for the image rendition on the WebCenter Content. If the static URL cannot be determined, the `url` uses the WebCenter Portal `showProperty` servlet.

Example 27–6 shows a Content Presenter display template that displays a carousel of images. If the carousel is displayed on a desktop device (`rendered="#{DeviceAgent.desktop}`), then the `a200` rendition is used for the images (`node.renditionsMap['a200:url']`). If the carousel is displayed on a mobile device (`rendered="#{DeviceAgent.mobile}`), then the smaller `thumbnail` rendition is used (`node.renditionsMap['thumbnail:url']`).

Example 27–6 Content Presenter Template Using Image Renditions

```

      <f:facet name="nodeStamp">
        <af:carouselItem id="ci1"
                         text="#{node.isFolder ? node.name : (empty
node.propertyMap['dDocTitle'] ?
                               node.name :
node.propertyMap['dDocTitle'].value.stringValue)}"
                         shortDesc="#{not empty
node.propertyMap['xComments'].value.stringValue ?

node.propertyMap['xComments'].value.stringValue :
                                    node.primaryProperty.value.binaryValue.name}">
          <af:image id="cimg1"
                    source="#{node.primaryProperty.isImage ?
node.renditionsMap['a200:url'] :
                            node.icon.largeIcon}"
                    shortDesc="#{node.primaryProperty.value.binaryValue.name}"
                    rendered="#{DeviceAgent.desktop}"/>
          <af:image id="cimg2"
                    source="#{node.primaryProperty.isImage ?
node.renditionsMap['thumbnail:url'] : node.icon.largeIcon}"
                    shortDesc="#{node.primaryProperty.value.binaryValue.name}"
                    rendered="#{DeviceAgent.mobile}"/>

                </af:carouselItem>
            </f:facet>
        </af:carousel>
    </dt:contentListTemplateDef>
</jsp:root>
```

27.3.6.3 Retrieving Image Renditions for Site Studio Region Elements

The handling of image renditions for images in Site Studio region definitions is determined by way the region definitions are defined in Site Studio. You can either have a region definition that includes a single region element that defines the original image or a region definition that includes separate region elements for each image rendition. Your Content Presenter display template must use the appropriate EL expression according to how the region definition is set up.

For example, your region definition could have a single region element (`myimage`) for the original image, therefore to display a particular image rendition, you must use an EL expression where you can specify which rendition to retrieve from the WebCenter Content, for example, `highres` or `lowres`. Alternatively, if your region definition has separate region elements for the different image renditions, say one element (`desktop`) for a rendition suitable for desktop browsers and one (`mobile`) for a rendition more suited to mobile devices, you can use an EL expression that refers directly to the region element that defines the rendition that you want to use.

> **Tip:** If you anticipate adding further image renditions in the future, for example for new devices, it makes sense to create region definitions with single image region elements so that as new renditions are added, they can be included in your Content Presenter display templates without having to create new region elements.

- If the region definition includes a single region element that defines the original image, you can also specify which rendition of the image you want to use:

  ```
  node.propertyMap['regionDefinitionName:elementName/Rendition:renditionName'].as
  TextHtml
  ```

- To reference a region element within a region definition that defines a specific image rendition, use the following EL expression:

  ```
  node.propertyMap['regionDefinitionName:elementName'].asTextHtml
  ```

Where:

- *`regionDefinitionName`* is the name of the region definition.
- *`elementName`* is the name of the region element.
- *`renditionName`* is:
  - for DAM implementations, the name of the rendition from the appropriate rendition set. For example, `web`, `thumbnail`, `highres` or `lowres`.
  - for non-DAM implementations, either `web` or `thumbnail`.

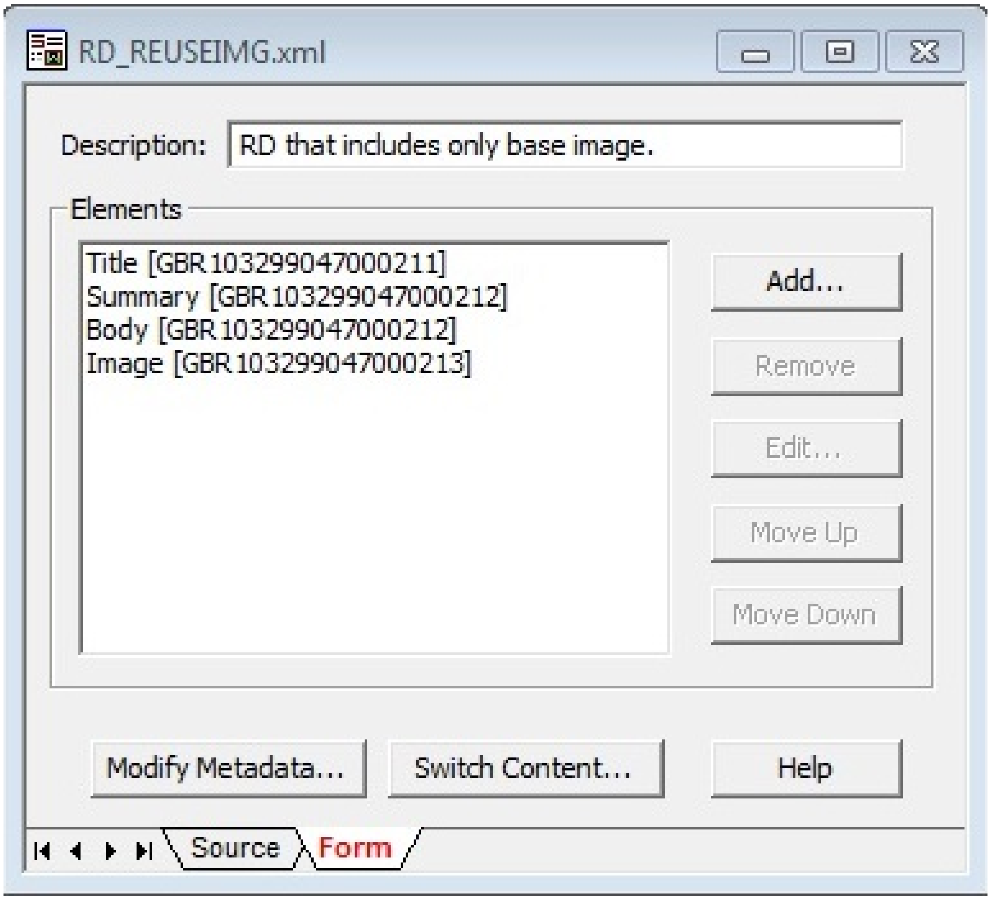
> **Note:** The *`renditionName`* is not case sensitive, therefore `preview` refers to the same rendition as `Preview`.

The EL expressions return an HTML `img` tag with a `src` element that points to the URL of the appropriate image rendition.

> **Note:** Wherever possible, the `src` URL points to a static rendition URL for the image rendition on the WebCenter Content. If the static URL cannot be determined, the `url` uses the WebCenter Portal `showProperty` servlet.

Figure 27–6 shows a Site Studio region definition (RD_REUSEIMG) for an article. The definition includes region elements for the title, summary, body and image of the article. The single image region element defines the original image (Image).

Figure 27–6 Region Definition with Single Image Region Element



RD_REUSEIMG.xml

Description: RD that includes only base image.

Elements

Title [GBR103299047000211]
Summary [GBR103299047000212]
Body [GBR103299047000212]
Image [GBR103299047000213]

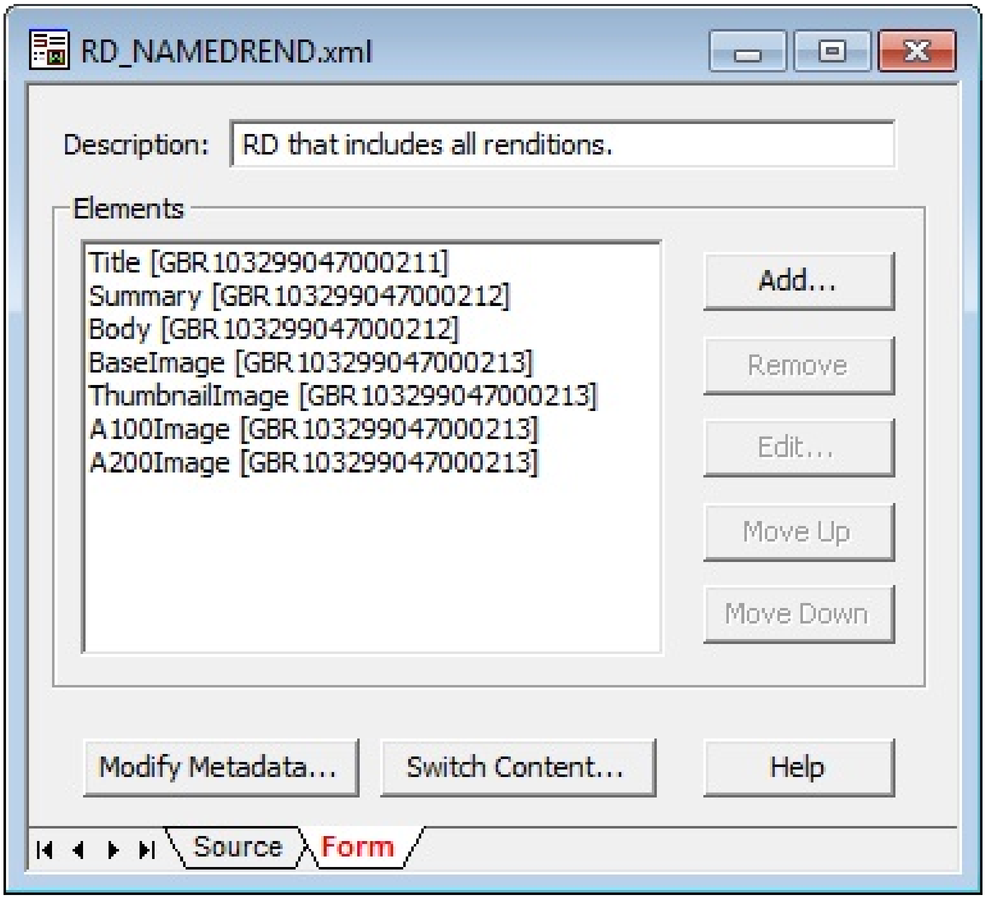
To use a lower resolution rendition (lowres) of the image on a mobile device, use the following code:

```
<af:outputText value="#{node.propertyMap['RD_
REUSEIMG:Image/Rendition:lowres'].asTextHtml}" escape="false" id="olmaget"
rendered="#{DeviceAgent.mobile}"/>
```

Note: If the specified *renditionName* does not exist for the image, the image's primary rendition is used instead.

Figure 27–7 shows a different region definition (RD_NAMEDREND) for a different article that includes separate region elements for the different possible renditions of the article image: BaseImage, ThumbnailImage, A100Image, and A200Image.

Figure 27–7   Region Definition with Region Elements for Named Renditions



RD_NAMEDREND.xml

Description: RD that includes all renditions.

Elements

Title [GBR103299047000211]
Summary [GBR103299047000212]
Body [GBR103299047000212]
BaseImage [GBR103299047000213]
ThumbnailImage [GBR103299047000213]
A100Image [GBR103299047000213]
A200Image [GBR103299047000213]

To use the `ThumbnailImage` region element to render the image on a mobile device, use the following code:

```
<af:outputText value="#{node.propertyMap['RD_
NAMEDREND:ThumbnailImage'].asTextHtml}" escape="false" id="olmaget"
rendered="#{DeviceAgent.mobile}"/>
```

Note: If you use an EL expression with a specified *`renditionName`* for an region element that explicitly references a particular image rendition (rather than the original image), the rendition defined by the region element is returned (not the rendition specified by *`renditionName`*).

Within a WYSIWYG or static list region element you can reference a specific rendition of an image using the `node.propertyMap['`*`regionDefinitionName`*`:`*`elementName`*`']` EL expression. Alternatively, you can reference original images in the WYSIWG or static list region elements and then use the `node.propertyMap['`*`regionDefinitionName`*`:`*`elementName`*`/Rendition:`*`renditionName`*`']` EL expression to use a specific rendition for all images within the element.

Example 27–7 shows how a particular rendition (`Preview`) is used for images within a static list region element (`paragraph`).

Example 27–7 Using Image Renditions within a Static List Region Element

```
<af:iterator value="#{node.propertyMap['RD_MYREGION:paragraph/Rendition:Preview'].values}"
             var="row"
             id="i1"
             rendered="#{DeviceAgent.desktop}">
  <af:showDetailItem text="#{row.nestedValue[0].value}" id="sdi1" stretchChildren="first">
    <af:panelGroupLayout layout="horizontal" id="tt" inlineStyle="padding:5px;">
      <af:outputText escape="false" value="#{row.nestedValue[1].value}" id="ld1"/>
      <af:outputText escape="false" value="#{row.nestedValue[2].value}" id="ld2"/>
    </af:panelGroupLayout>
  </af:showDetailItem>
</af:iterator>
```

In Example 27–8 `RD_MYREGION:body` corresponds to a WYSIWYG region element. All images within that WYSIWYG element will be rendered using the `A100` rendition.

Example 27–8 Using Image Renditions within a WYSIWYG Region Element

```
<af:outputText value="#{node.propertyMap['RD_MYREGION:body/Rendition:A100'].asTextHtml}"
               escape="false" id="ot5"/>
```

Note: If the WYSIWYG or static list element references an element that defines a particular image rendition, that rendition supersedes any rendition specified using the `Rendition:`*`renditionName`* syntax.

27.3.7 Using EL Expressions to Retrieve Content Item Information

This section describes the EL expressions that you can use in your Content Presenter display template definitions to retrieve and display specific information about content items.

Use the EL expressions described in the following tables as you define your Content Presenter display templates as explained in Section 27.3.2, "Creating Single-Item Display Templates" and Section 27.3.3, "Defining Multiple-Item Display Templates." These expressions are used with the JSP tags described in Table 27–1 and Table 27–2.

This section contains the following subsections:

- Section 27.3.7.1, "Retrieving Basic Information About a Content Item"
- Section 27.3.7.2, "Working with Content Item Properties and Values"
- Section 27.3.7.3, "Working with Content Item Icons and URLs"
- Section 27.3.7.4, "Working with Image Renditions"
- Section 27.3.7.5, "Working with Group Portal Information"

27.3.7.1 Retrieving Basic Information About a Content Item

The EL expressions listed in Table 27–3 let you display basic information about a content item in a display template.

Table 27–3 EL Expressions for Retrieving Basic Content Information

EL Expression	Description
`#{node.createdBy}`	Returns the user name of the node's creator.
`#{node.createdDate}`	Returns the node's creation date.
`#{node.hasParentNode}`	Returns `true` if the current node has a valid parent node ID, or a node that has no parent.
`#{node.icon}`	Returns the icon service defined in the current web application.
`#{node.id}`	Returns the node's identifier.
`#{node.isFolder}`	Returns `true` if this node is associated with a folder or container.
`#{node.isInherited}`	Returns `true` if this node is inherited by another object class definition.
`#{node.modifiedBy}`	Returns the user name of the node's last modifier.
`#{node.modifiedDate}`	Returns the node's last modification date.
`#{node.name}`	Returns the node's name.
`#{node.parentId}`	Returns the parent node's identifier.
`#{node.path}`	Returns the node's path.
`#{node.primaryProperty}`	Returns the node's primary property, if available.
`#{node.propertyMap}`	Creates and returns a map of wrapped property objects, keyed by property name. Properties can be accessed as `#{node.propertyMap['myProp']}` or `#{node.propertyMap.myProp}`.
`#{node.url}`	Returns an instance of the node property URL service for the primary property of this node (if any). By default, it resolves to `#{node.url.renderUrl}`. This is a shortcut for `#{node.primaryProperty.url}`.

27.3.7.2 Working with Content Item Properties and Values

Use the EL expression described in Table 27–4 and Table 27–5 to perform actions on content item node properties and property values.

> **Tip:** To determine the names of the properties defined for a given content type, see Section 27.3.8, "Discovering Content Type Property Names."

Table 27–4 EL Expressions for Content Item Node Properties

EL Expression	Description
`#{node.propertyMap['myProp'].asTextHtml}`	Returns this property as text or HTML if the type is text or HTML. If `isHTML` or `isPlainText` is `true`, the text or HTML is returned as a string.
`#{node.propertyMap['myProp'].hasValue}`	Returns `true` if a value is associated with this property.
`#{node.propertyMap['myProp'].icon}`	Returns the icon service defined in the current web application.
`#{node.propertyMap['myProp'].indexedName}`	Returns the indexed name of a multi-valued property. For example, if a multi-valued node property named `color` contains `blue`, `red`, `orange`, the indexed name of the `red` value is `color[1]`. The following EL expression references the color `orange` in this list: `#{node.propertyMap['color[2]'].value.stringValue}`
`#{node.propertyMap['myProp'].isAudio}`	Returns `true` if the property's mime type is '`audio/`'.

Table 27–4 (Cont.) EL Expressions for Content Item Node Properties

EL Expression	Description
`#{node.propertyMap['myProp'].isBinary}`	Returns `true` if the current property is of type `Property.BINARY`.
`#{node.propertyMap['myProp'].isBoolean}`	Returns `true` if the current property is of type `Property.BOOLEAN`.
`#{node.propertyMap['myProp'].isCalendar}`	Returns `true` if the current property is of type `Property.CALENDAR`.
`#{node.propertyMap['myProp'].isDouble}`	Returns `true` if the current property is of type `Property.DOUBLE`.
`#{node.propertyMap['myProp'].isExcel}`	Returns `true` if the property's mime type is '`application/vnd.ms-excel`', '`application/excel`', '`application/x-excel`', or '`application/x-msexcel`'.
`#{node.propertyMap['myProp'].isGIF}`	Returns `true` if the property's mime type is '`image/gif`'.
`#{node.propertyMap['myProp'].isHTML}`	Returns `true` if the property's mime type is '`text/html`'.
`#{node.propertyMap['myProp'].isImage}`	Returns `true` if the property's mime type is '`image/`'.
`#{node.propertyMap['myProp'].isJPEG}`	Returns `true` if the property's mime type is '`image/jpeg`'.
`#{node.propertyMap['myProp'].isLink}`	Returns `true` if the current property is of type `Property.LINK`.
`#{node.propertyMap['myProp'].isLong}`	Returns `true` if the current property is of type `Property.LONG`.
`#{node.propertyMap['myProp'].isMSWord}`	Returns `true` if the property's mime type is '`application/vnd.ms-word`' or '`application/msword`'.
`#{node.propertyMap['myProp'].isMultiValued}`	Returns `true` if this property is multi-valued.
`#{node.propertyMap['myProp'].isNested}`	Returns `true` if the current property is of type `Property.NESTED`.
`#{node.propertyMap['myProp'].isPDF}`	Returns `true` if the property's mime type is '`application/pdf`'.
`#{node.propertyMap['myProp'].isPlainText}`	Returns `true` if the property's mime type is '`text/plain`'.
`#{node.propertyMap['myProp'].isPNG}`	Returns `true` if the property's mime type is '`image/png`'.
`#{node.propertyMap['myProp'].isPowerPoint}`	Returns `true` if the property's mime type is '`application/vnd.ms-powerpoint`', '`application/mspowerpoint`', or '`application/x-mspowerpoint`'.
`#{node.propertyMap['myProp'].isPrimaryProperty}`	Returns `true` if this property is the primary property.
`#{node.propertyMap['myProp'].isRequired}`	Returns `true` if this property is required/mandatory.
`#{node.propertyMap['myProp'].isRetricted}`	Returns `true` if this property is restricted.
`#{node.propertyMap['myProp'].isRichText}`	Returns `true` if the property's mime type is '`text/richtext`'.
`#{node.propertyMap['myProp'].isString}`	Returns `true` if the current property is of type `Property.STRING`.
`#{node.propertyMap['myProp'].isTextBased}`	Returns `true` if this property is text-based (`isHTML`, `isPlainText`, `isString`, `isCalendar`, `isBoolean`, `isDouble`, `isLong`).
`#{node.propertyMap['myProp'].isVideo}`	Returns `true` if the property's mime type is '`video/`'.
`#{node.propertyMap['myProp'].isXML}`	Returns `true` if the property's mime type is '`text/xml`'.

Table 27–4 (Cont.) EL Expressions for Content Item Node Properties

EL Expression	Description
`#{node.propertyMap['myProp'].isZip}`	Returns `true` if the property's mime type is '`application/zip`'.
`#{node.propertyMap['myRefNode'].linkAsNode}`	Returns the `myRefNode` property as a node, where `myRefNode` is a link property type. Properties can be referenced in EL expressions. **Example**: `#{node.propertyMap['myRefNode'].linkAsNode.primaryProperty.url.renderUrl}`
`#{node.propertyMap['myProp'].name}`	Returns the property's name.
`#{node.propertyMap['myProp'].nestedProperty}`	Retrieves nested properties for this single-valued property, and returns a list of properties.
`#{node.propertyMap['myProp'].type}`	Returns the data type of this property value. For example: `String`, `Integer`, `Long`, and so on.
`#{node.propertyMap['myProp'].url}`	Returns a URL service for this property.
`#{node.propertyMap['myProp'].value}`	Returns the value service for this property.

`#{node.propertyMap['myProp'].nestedProperties}`	Returns elements from a static list. For example:
	`<af:iterator var="listItem"`
	`  value="#{node.propertyMap['ARTICLE_RGD:Paragraphs'].nestedProperties}"`
	`  varStatus="vs">`
	`  <af:outputText id="ot1" value='#{listItem[0].value}'/>`
	`  <af:outputText id="ot3" value="#{listItem[1].value}"/>`
	`  </af:iterator>`

`#node.propertyMap['regionDefName:elementName'].asTextHtml}`	Returns Site Studio data as HTML text. For example: `#node.propertyMap['RD_NEWS:LEAD'].asTextHtml}` The element name (`LEAD`) is prefixed by the Region Definition name (`RD_NEWS`). See also Section 27.3.10, "Referencing Site Studio Region Elements in a Custom View."

Table 27–5 EL Expressions for Content Item Node Property Values

EL Expression	Description
`#{node.propertyMap['myProp'].value.binaryValue}`	Returns custom attributes for a binary property type or attachment. Attributes available on `binaryValue` are: ■ `contentType` – Returns the mime type of the binary content (for example, `text` or `html`). ■ `name` – Returns the filename of the binary content (for example, `index.html`). ■ `size` – Returns the size of the binary content, or `-1` if the size is unavailable.
`#{node.propertyMap['myProp'].value.booleanValue}`	Returns the value of this property as `java.lang.Boolean`.
`#{node.propertyMap['myProp'].value.calendarValue}`	Returns the value of this property as `java.util.Calendar`.
`#{node.propertyMap['myProp'].value.doubleValue}`	Returns the value of this property as `java.lang.Double`.

Table 27–5 (Cont.) EL Expressions for Content Item Node Property Values

EL Expression	Description
`#{node.propertyMap['myProp'].value.longValue}`	Returns the value of this property as `java.lang.Long`.
`#{node.propertyMap['myProp'].value.orderedPosition}`	Returns the "index" of the property when the property is multi-valued. **Example**: `#{node.propertyMap['address[0]'].value.orderedPosition},`
`#{node.propertyMap['myProp'].value.stringValue}`	Returns the value of this property as `java.lang.String`. **Example**: `#{node.propertyMap['firstName'].value.stringValue}`

27.3.7.3 Working with Content Item Icons and URLs

Table 27–6 and Table 27–7 describe EL expressions for working with icons and URLs associated with content items and properties.

Table 27–6 EL Expressions for Content Item Node or Property Icons

EL Expression	Description

`#{node.icon.largeIcon}`
`#{node.propertyMap['myDoc'].icon.largeIcon}`
	Returns a URL to an image resource for a large icon.
	Example:
	`<af:image source="#{node.propertyMap['projectFolder'].largeIcon}"/>`

`#{node.icon.smallIcon}`
`#{node.propertyMap['myDoc'].icon.smallIcon}`
	Returns a URL to an image resource for a small icon.
	Example:
	`<af:image source="#{node.icon.smallIcon}" />`

Table 27–7 EL Expressions for Content Item Node URLs

EL Expression	Description
`#{node.url.downloadUrl}`	Creates a URL to the binary content. Forces a download, and the underlying operating system renders the content based on the content type. **Example**: `<af:goLink destination="#{node.url.downloadUrl}" targetFrame="_blank"/>`
`#{node.url.renderUrl}`	Creates a URL to the binary content. Allows the browser to render the content based on the content type. By default, `#{node.url}` resolves to `#{node.url.renderUrl}`. **Example**: `<af:goLink destination="#{node.url.renderUrl}" targetFrame="_blank"/>`

27.3.7.4 Working with Image Renditions

Table 27–8 lists the EL expressions available to retrieve information about a particular rendition of an image, including the URL to render the image using that rendition.

Table 27–9 lists the EL expressions available to retrieve different image renditions for Site Studio region elements.

For more information about image renditions, see Section 27.3.6, "Using Image Renditions in Content Presenter Display Templates."

Table 27–8 EL Expressions for Image Renditions of Image Documents

EL Expression	Description
`#{node.renditionsMap['`*`renditionName`*`:url']}`	Returns the URL of the image rendition. For example: `http://mymachine.example.com:8888/cs/groups/personalspaces/@pewebcenter/@799c4d7d-255c-46c8-80f5-0d06c848dd65/documents/document/awrf/mdax/~edisp/~extract/ID_001642~3~staticrendition/preview.gif` Wherever possible, `url` points to a static rendition URL for the image rendition on the WebCenter Content. If the static URL cannot be determined, the `url` uses the WebCenter Portal `showProperty` servlet.
`#{node.renditionsMap['`*`renditionName`*`:name']}`	Returns the name of the rendition, for example `web`, `thumbnail`, or `highres`. For `web` and `thumbnail` renditions, `name` returns the name of the native file, not of the web or thumbnail rendition.
`#{node.renditionsMap['`*`renditionName`*`:type']}`	Returns the file type of the image rendition, for example, `preview`. The `type` property is not valid for `web` and `thumbnail` renditions.
`#{node.renditionsMap['`*`renditionName`*`:width']}`	Returns the width of the image rendition in pixels, for example `250`. The `width` property is not valid for `web` and `thumbnail` renditions.
`#{node.renditionsMap['`*`renditionName`*`:height']}`	Returns the height of the image rendition in pixels, for example `34`. The `height` property is not valid for `web` and `thumbnail` renditions.
`#{node.renditionsMap['`*`renditionName`*`:resolution']}`	Returns the resolution (DPI) of the image rendition, for example `96 dpi`. The `resolution` property is not valid for `web` and `thumbnail` renditions.
`#{node.renditionsMap['`*`renditionName`*`:size']}`	Returns the file size of the image rendition, for example, `3133`.
`#{node.renditionsMap['`*`renditionName`*`:contentType']}`	Returns the MIME type of the image rendition, for example. `image/gif`.

Table 27–9 EL Expressions for Image Renditions of Site Studio Region Elements

EL Expression	Description
`#{node.propertyMap['`*`regionDefinitionName`*`:`*`elementName`*`'].asTextHtml}`	Returns an HTML `img` tag with the `src` element set to the URL of the image defined in the specified element. For example: `<img src="http://mymachine.example.com:9400/cs/idcplg?IdcService=GET_FILE&amp;dDocName=id_038497&amp;RevisionSelectionMethod=LatestReleased" alt="S3-1" class="">` Use this EL to reference a Site Studio region element that defines a specific rendition of an image. Wherever possible, the URL points to a static rendition URL for the image rendition on the WebCenter Content. If the static URL cannot be determined, the `url` uses the WebCenter Portal `showProperty` servlet.
`#{node.propertyMap['`*`regionDefinitionName`*`:`*`elementName`*`/Rendition:`*`renditionName`*`'].asTextHtml}`	Returns an HTML `img` tag with the `src` element set to the URL of the specified image rendition of the image defined in the specified element. For example: `<img src="/cs/groups/wc081512c/@sb5cdcaa4610341a8bb8387effdf21790/documents/document/awrf/mdm4/~edisp/~extract/ID_038497~1~staticrendition/preview.gif" alt="S3-1" class="">` If the specified image rendition does not exist for the image, then the URL of the original image is returned. Use this EL to reference a Site Studio region element that defines the original image for which you want to display the specified *`renditionName`*. Wherever possible, the URL points to a static rendition URL for the image rendition on the WebCenter Content. If the static URL cannot be determined, the `url` uses the WebCenter Portal `showProperty` servlet.

27.3.7.5 Working with Group Portal Information

Table 27–10 and Table 27–11 provide EL expressions you can use to work with group portal information in your content presenter template.

Table 27–10 EL Expressions for Basic Group Portal Information

EL Expression	Description

`#{spaceContext.currentSpace.metadata.createdBy}`
`#{spaceContext.space[portalName].metadata.createdBy}`
	Returns the user who created the current or specified group portal.

`#{spaceContext.currentSpace.metadata.creationDate}`
`#{spaceContext.space[portalName].metadata.creationDate}`
	Returns a `java.util.Calendar` object representing the date and time on which the current or specified portal was created.

`#{spaceContext.currentSpace.metadata.customAttributes[attributeName]}`
`#{spaceContext.space[portalName].metadata.customAttributes[attributeName]}`
	Returns the value of a specific custom attribute of the name `attributeName` for the portal.

Table 27–10 (Cont.) EL Expressions for Basic Group Portal Information

EL Expression	Description

`#{spaceContext.currentSpace.metadata.defaultLanguage}`
`#{spaceContext.space[portalName].metadata.defaultLanguage}`
	Returns the default language for the current or specified portal.

`#{spaceContext.currentSpace.metadata.description}`
`#{spaceContext.space[portalName].metadata.description}`
	Returns the description associated with the current portal with the display name in the language in which the portal was created. If the portal name has been translated, the translated name is not shown.
	Example: `#{spaceContext.space['FinanceProject'].metadata.description}`
	Evaluates to conglomeration of all teams involved in financial activities.

`#{spaceContext.currentSpace.metadata.displayName}`
`#{spaceContext.space[portalName].metadata.displayName}`
	Returns the display name associated with the current or specified portal in the language in which the portal was created. If the portal name has been translated, the name in which the portal was created will be shown.
	Example:
	If a group portal called "Web20Portal" has the display name "Web 2.0 Portal", then:
	`#{spaceContext.space['Web20Portal'].metadata.displayName}`
	will evaluate to "Web 2.0 Portal".

`#{spaceContext.currentSpace.metadata.guid}`
`#{spaceContext.space[portalName].metadata.guid}`
	Returns the unique ID associated with the current or specified portal.

`#{spaceContext.space[portalName].metadata.icon}`
`#{spaceContext.currentSpace.metadata.icon}`
	Returns a URL to the icon associated with the current or specified portal.

`#{spaceContext.currentSpace.metadata.keywords}`
`#{spaceContext.space[portalName].metadata.keywords}`
	Returns a comma-separated list of searchable keywords associated with the current or specified portal.

`#{spaceContext.currentSpace.metadata.lastUpdatedDate}`
`#{spaceContext.space[portalName].metadata.lastUpdatedDate}`
	Returns the `java.util.Calendar` object representing the date-time on which the current or specified portal was last updated.

`#{spaceContext.space[portalName].metadata.logo}`
`#{spaceContext.currentSpace.metadata.logo}`
	Returns the path to the image associated with the logo of the current or specified portal.

`#{spaceContext.currentSpace.metadata.name}`
`#{spaceContext.space[portalName].metadata.name}`
	Returns the name of the current or specified portal used generally at the back end of the portal and is used with the pretty URL.

`#{spaceContext.currentSpace.metadata.groupSpaceURI}`
`#{spaceContext.space[portalName].metadata.groupSpaceURI}`
	Returns the pretty URL of the current or specified portal.

Table 27–10 (Cont.) EL Expressions for Basic Group Portal Information

EL Expression	Description

`#{spaceContext.currentSpace.metadata.closed}`
`#{spaceContext.space[portalName].metadata.closed}`
	Returns Boolean value indicating whether the portal has been kept closed.

`#{spaceContext.currentSpace.metadata.discoverable}`
`#{spaceContext.space[portalName].metadata.discoverable}`
	Returns Boolean value indicating whether users will be able to discover the existence of the portal by searching for it or getting it listed in My Portals.

`#{spaceContext.currentSpace.metadata.offline}`
`#{spaceContext.space[portalName].metadata.offline}`
	Returns Boolean value indicating whether the portal has been taken offline.

`#{spaceContext.currentSpace.metadata.publishRSS}`
`#{spaceContext.space[portalName].metadata.publishRSS}`
	Returns Boolean value, indicating whether the portal publishes RSS feeds.

`#{spaceContext.currentSpace.metadata.selfRegistration}`
`#{spaceContext.space[portalName].metadata.selfRegistration}`
	Returns a Boolean value indicating whether users are allowed to subscribe themselves to the portal.

`#{spaceContext.currentSpace.metadata.unsubscriptionApprovalRequired}`
`#{spaceContext.space[portalName].metadata.unsubscriptionApprovalRequired}`
	Returns a Boolean value representing whether approval is required to unsubscribe from the current or specified portal.

Table 27–11 EL Expressions for Portal UI Information

EL Expression	Description

`#{spaceContext.space[portalName].metadata.uiMetadata.gsSiteTemplateId}`
`#{spaceContext.currentSpace.metadata.uiMetadata.gsSiteTemplateId}`
	Returns the ID of the page template associated with the current or specified portal.

`#{spaceContext.space[portalName].metadata.uiMetadata.rcForGSPages}`
`#{spaceContext.currentSpace.metadata.uiMetadata.rcForGSPages}`
	Returns the ID of the resource catalog associated with the current or specified portal.

`#{spaceContext.space[portalName].metadata.uiMetadata.rcForGSSiteTemplates}`
`#{spaceContext.currentSpace.metadata.uiMetadata.rcForGSSiteTemplates}`
	Returns the ID of the resource catalog associated with the page template of the current portal.

`#{spaceContext.space[portalName].metadata.uiMetadata.gsSiteStructureId}`
`#{spaceContext.currentSpace.metadata.uiMetadata.gsSiteStructureId}`
	Returns the ID of the navigation model associated with the current portal.

`#{spaceContext.space[portalName].metadata.uiMetadata.skin}`
`#{spaceContext.currentSpace.metadata.uiMetadata.skin}`
	Returns the ADF Faces skin family associated with the current portal.

Table 27–11 (Cont.) EL Expressions for Portal UI Information

EL Expression	Description

`#{spaceContext.space[portalName].metadata.uiMetadata.footerHidden}`
`#{spaceContext.currentSpace.metadata.uiMetadata.footerHidden}`
	Returns the Boolean value representing whether the footer of the portal is hidden.

`#{spaceContext.space[portalName].metadata.uiMetadata.copyrightMessage}`
`#{spaceContext.currentSpace.metadata.uiMetadata.copyrightMessage}`
	Returns the copyright message used by the portal.

`#{spaceContext.space[portalName].metadata.uiMetadata.privacyPolicyUrl}`
`#{spaceContext.currentSpace.metadata.uiMetadata.privacyPolicyUrl}`
	Returns the URL to the privacy policy document followed.

27.3.8 Discovering Content Type Property Names

As a Content Presenter display template developer, you will need to know the names of the properties defined for the associated content type so that you can define how to display the selected content item(s) on the page.

Each content item is associated with a specific *content type* defined in the WebCenter Content repository. Content types can map to WebCenter Content profile definitions and Site Studio region definitions. Types are created on the WebCenter Content and define the properties of the content item. The property names of a content item's content type, however, are different than the display names, and need to be obtained from the Content Server. For more information, see "Defining Content Types" in *Managing Oracle WebCenter Content*.

> **Note:** You can also use REST services to obtain content type property names. For more information see Chapter 31, "Content Management REST API.".

27.3.9 Referencing External Files in Display Templates

In some cases, a display template needs to reference an external file, like a CSS file. All such references must be either an absolute path or a path that is relative to the root of the web application. For example:

- **absolute path** – `http://host:port/mypath/file.css`
- **relative path** – `/webcenter/mypath/file.css`

Do not use local references to external files. Local references to external files do not work because they are not included when you upload a Content Presenter display template to a WebCenter Portal application, as explained in Section 27.5, "Making Content Presenter Display Templates Available."

27.3.10 Referencing Site Studio Region Elements in a Custom View

You can use custom display templates to display Site Studio Region Definition elements. For example, you might have a Site Studio Region Definition called `RD_NEWS` with four elements: `TITLE`, `LEAD`, `IMAGE`, and `BODY`. A Content Presenter display template can reference these elements using the node property EL expression like this:

```
#node.propertyMap['RD_NEWS:LEAD'].asTextHtml}
```

Example 27–9 illustrates how these Site Studio Region elements can be included in a `contentTemplateDef` definition:

Example 27–9 Referencing Site Studio Region Elements in a Template

```
<dt:contentTemplateDef var="node">
   <af:panelGroupLayout layout="vertical" id="pgl3">
     <af:panelGroupLayout layout="horizontal" valign="top" inlineStyle="background-color:#FFF;
padding:10px;" id="pgl4">
         <af:panelGroupLayout layout="vertical" id="pgl2" valign="top">
            <af:outputText value="#{node.propertyMap['dInDate'].value.calendarValue}" id="ot3"
styleClass="bodytext" converter="javax.faces.DateTime"/>
          </af:panelGroupLayout>
          <af:spacer width="10px;" id="s1" inlineStyle="background-color:#DDD; color:white;"/>
          <af:panelGroupLayout layout="vertical" id="pgl1" valign="top">
             <af:outputText value="#{node.propertyMap['xTargetGroup'].value}" id="ot12"
inlineStyle="background-color:#0A9FC0; color:white; text-align:left; padding:5px;"/>
            <af:goLink text="#{node.propertyMap['RD_NEWS:TITLE'].asTextHtml}" id="gil1"
                destination="#{'/faces/home/news-viewer?news_
id='}#{node.propertyMap['dDocName'].value}" styleClass="newstitle"/>
           <af:outputText value="#{node.propertyMap['RD_NEWS:LEAD'].asTextHtml}" id="ot2"
styleClass="bodytext"/>
         </af:panelGroupLayout>
       <af:panelGroupLayout layout="vertical" id="pgl32" valign="top" styleClass="newsimage">
         <af:outputText value="#{node.propertyMap['RD_NEWS:IMAGE'].asTextHtml}" escape="false"
id="ot1"  inlineStyle="max-width:100px;"/>
       </af:panelGroupLayout>
     </af:panelGroupLayout>
     <af:panelGroupLayout layout="horizontal" id="aaaa">
     </af:panelGroupLayout>
   </af:panelGroupLayout>
</dt:contentTemplateDef>
```

More On OTN

For a complete, end-to-end example illustrating how to reference Site Studio Region elements in multiple templates, see the WebCenter Architecture Team blog entry at: `http://www.ateam-oracle.com/content-presenter-cmis-complete`

27.3.11 Using a Content Presenter Display Template

For information on using a display template in a Content task flow, see Section 29.5, "Adding a Content Task Flow to a Page." See also Section 29.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates." For information on integrating a display template into a Portal Framework application, see the following section Section 27.5, "Making Content Presenter Display Templates Available."

> **Note:** If you display a wiki page in a Portal Framework application using a Content Presenter display template, by default any links within that wiki page are displayed in the Document Viewer. If you want to display wiki page links using Content Presenter, you must edit the `adf-config.xml` file. For more information, see Section 30.3.5, "Displaying Wiki Page Links Within Content Presenter."

27.4 Adding the Content Presenter Task Flow to a Page

You can add a Content Presenter task flow at design time or runtime. For information about how to add Content Presenter at design time (using JDeveloper), see Chapter 29, "Adding Content Task Flows and Document Components to a Portal Page." For information about how to add Content Presenter at runtime, see the "Publishing Content Using Content Presenter" chapter in *Building Portals with Oracle WebCenter Portal*.

27.5 Making Content Presenter Display Templates Available

This section explains how to make a Content Presenter display template available to Content Presenter in a portal or Framework application.

- Section 27.5.1, "Export a Content Presenter Display Template as a Portal Resource"
- Section 27.5.2, "Upload the New Content Presenter Display Template"
- Section 27.5.3, "Test the New Content Presenter Display Template"

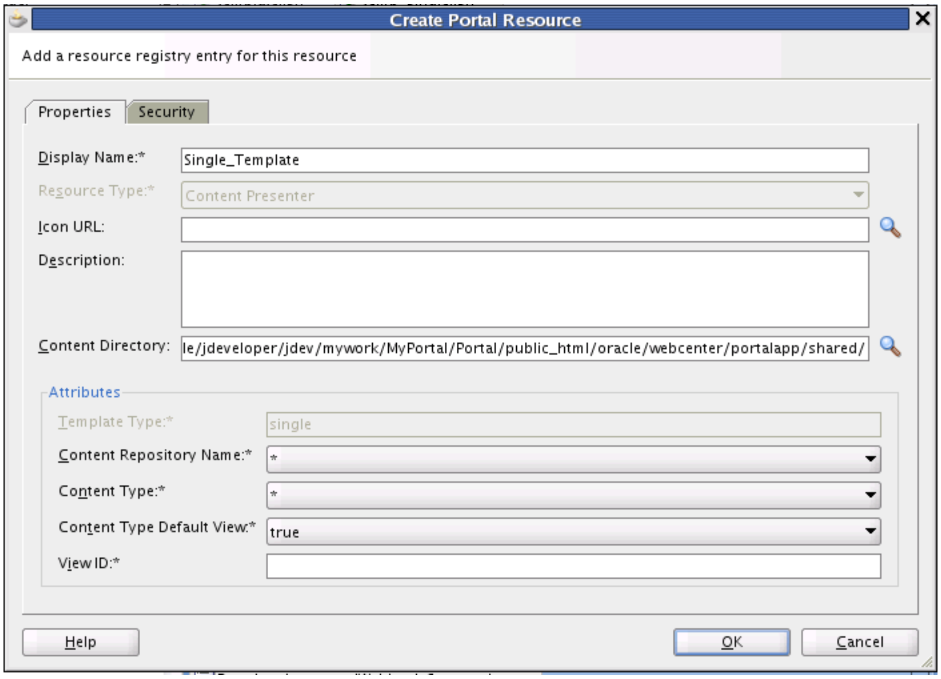
> **Note:** If you are using a locally configured JDev environment to develop a Portal Framework application, all you need to do to use a Content Presenter display template in your application is to export it as a portal resource, as explained in Section 27.5.1, "Export a Content Presenter Display Template as a Portal Resource." You do not need to perform the upload task as explained in Section 27.5.2, "Upload the New Content Presenter Display Template."

27.5.1 Export a Content Presenter Display Template as a Portal Resource

This section explains how to export a Content Presenter display template as a portal resource. This procedure is a prerequisite to adding a Content Presenter display template to a portal and to Content Presenter at runtime.

1. Create a Content Presenter display template, as explained previously in Section 27.3, "Creating Content Presenter Display Templates."
2. In the Application Navigator, right-click the Content Presenter display template file (a JSFF file) and select **Create Portal Resource**.
3. Fill in the Create Portal Resource dialog. This dialog differs depending on whether you are creating a single or multiple-item template. The dialog for a single-item template is shown in Figure 27–8. The dialog for a multiple-item template is shown in Figure 27–9.

Figure 27–8 Create Portal Resource Dialog for a Single-Item Template



Display Name:* Single_Template

Resource Type:* Content Presenter

Icon URL:

Description:

Content Directory: le/jdeveloper/jdev/mywork/MyPortal/Portal/public_html/oracle/webcenter/portalapp/shared/

Attributes

Template Type:* single

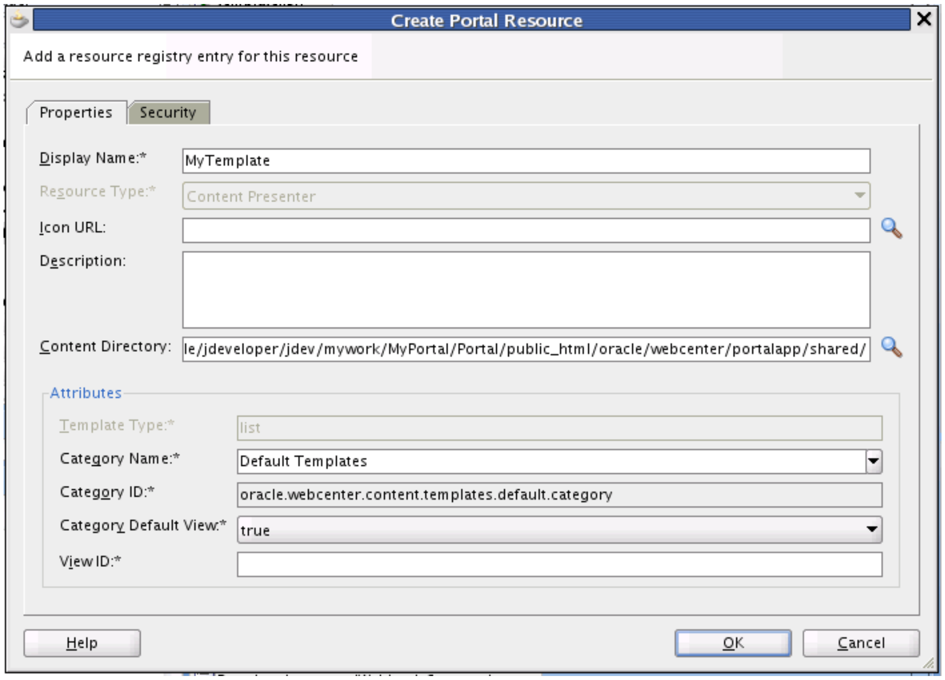
Content Repository Name:* *

Content Type:* *

Content Type Default View:* true

View ID:*

Figure 27–9 Create Portal Resource Dialog for a Multiple-Item Template



Display Name:* MyTemplate

Resource Type:* Content Presenter

Icon URL:

Description:

Content Directory: le/jdeveloper/jdev/mywork/MyPortal/Portal/public_html/oracle/webcenter/portalapp/shared/

Attributes

Template Type:* list

Category Name:* Default Templates

Category ID:* oracle.webcenter.content.templates.default.category

Category Default View:* true

View ID:*

The default settings in the Create Portal Resource dialog are generally sufficient; however, you must enter a unique value in the View ID field. The Display Name is the name that appears in the display template drop down menu at runtime.

The View ID parameter is intended to be human-readable; therefore, it is not automatically generated for you. For example, you can use the View ID to programmatically refer to one template from another. For example, a multiple content item template could render tabs for each item and also call on a single item template to be used below the selected tab to render the details of that item. As another example, you can include one template in another by passing the View ID as a parameter to the Content Presenter task flow. For a detailed example illustrating this, see the WebCenter Architecture Team blog entry at: `http://www.ateam-oracle.com/content-presenter-cmis-complete`. See also Section 27.3.10, "Referencing Site Studio Region Elements in a Custom View."

Additional Attributes in the Create Portal Resource dialog for a **single item template** include:

- **Template Type** – Reflects whether the template is single or multi-item template.
- **Content Repository Name** – By default, the portal resource uses the repository associated with the application's default content connection. If you intend to export the portal resource for use in a portal, you must pick the repository that matches the one used by the portal connection name(s).
- **Content Type** – Lets you pick a content type for which the template will be valid. The list of content types displayed in the menu depends on the selected content repository.
- **Content Type Default View** – If set to true, specifies that the display template is the default template to use for the given combination of repository and content type.
- **View ID** – A unique value that is used to refer to the template programmatically, as discussed previously in this section.

Additional Attributes in the Create Portal Resource dialog for a **multiple item template** include:

- **Template Type** – Reflects whether the template is single or multi-item template.
- **Category Name** – A name given to a category of display templates. Can be any name that describes the category or you can use the **Default Templates** category name.
- **Category ID** – An ID for the category. If you select **Default Templates** as the category name, this field will become read-only and populate with **oracle.webcenter.content.templates.default.category**. If you are creating a new category, this value can be any unique string. For example: **oracle.webcenter.content.templates.pressrelease.category**. If two resources have the same ID, they will be grouped together in the user interface.
- **View ID** – A unique value that is used to refer to the template programmatically, as discussed previously in this section.

Note: For more information on other fields in the Create Portal Resource dialog, see Section 9.6.3, "How to Export a Portal Resource from JDeveloper."

4. Click **OK** in the dialog when you are finished.
5. Right-click the Content Presenter display template (JSFF) file again, and this time select **Export Portal Resource**.

6. In the Export Portal Resource dialog, enter or browse to a directory in which to place the exported portal resource (JSPX) file. You can place this file anywhere on your file system.
7. Click **OK** in the Export Portal Resource dialog.

Now that your Content Presenter display template is exported as a portal resource, the next step is to upload it to your portal. After uploading the display template portal resource, it will be available in the list of display templates when you add a Content Presenter to your portal page.

27.5.2 Upload the New Content Presenter Display Template

You can upload a new display template to any deployed portal or Framework application that includes the Resource Manager. To upload a Content Presenter display template to a portal or Framework application, an application administrator performs the following steps:

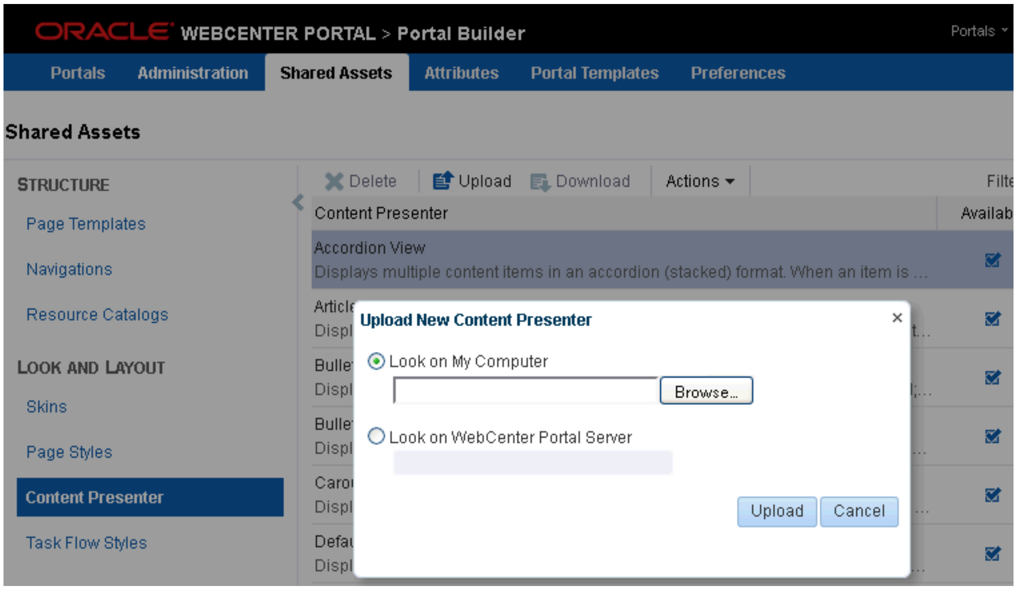
Note: The content repository connection names and details must be the same between the design time portal or Framework application in which you developed the Content Presenter display template and the destination application. Also, any references to external files in the display template must either be absolute or relative path references. See Section 27.3.9, "Referencing External Files in Display Templates."

Note: Uploading from the scope of a specific portal within WebCenter Portal instance is different than uploading from the application scope of the portal's administration tools. For more information, see the section on application-level versus portal-level resources in Section 55.1.5, "Editing WebCenter Portal Assets in JDeveloper."

1. Open your portal or Framework application.
2. Click **Administration**.

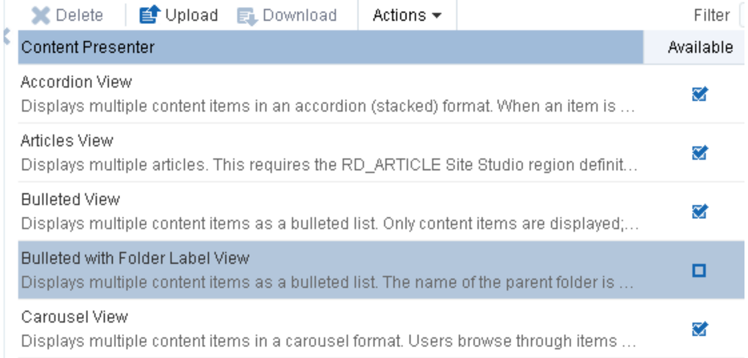
   Note that you must have administrator privileges.
3. Select **Shared Assets**.
4. Under Look and Layout, click **Content Presenter**.
5. Select **Upload**, as shown in Figure 27–10.

Figure 27–10 Uploading the Display Template Portal Resource



6. In the Upload New Content Presenter dialog, navigate to the portal resource file you saved on your file system.
7. After you've selected the template file, click **OK**. If the operation is successful, an Information dialog appears with the message "Resource uploaded successfully."
8. Locate your Content Presenter display template in the list of Content Presenter templates and select it as shown in Figure 27–11.

Figure 27–11 Toggling the Show/Hide State of a Template



Content Presenter	Available
Accordion View Displays multiple content items in an accordion (stacked) format. When an item is ...	☑
Articles View Displays multiple articles. This requires the RD_ARTICLE Site Studio region definit...	☑

Bulleted with Folder Label View Displays multiple content items as a bulleted list. The name of the parent folder is ...	□
Carousel View Displays multiple content items in a carousel format. Users browse through items ...	☑

9. To make the template visible to users and available for use in Content Presenter, check the **Available** check box.

The new Content Presenter display template is now ready to be used with Content Presenter in a portal or Framework application.

27.5.3 Test the New Content Presenter Display Template

This section explains how to test your Content Presenter display template with Content Presenter.

1. If it is not currently running, start the portal or Framework application to which you added a Content Presenter display template. This application must have a

WebCenter Content connection that Content Presenter can use. For portals, if you just completed the setup procedures described in the previous sections, click **Back to return to the Portal** link in the upper right corner of the Administration page.

2. Navigate to the portal or Framework application in which you want to use the new Content Presenter display template. Note that you'll need to be able to edit it.
3. Optionally, create a new page to test the display template. Select **Create a New Page** from the Page Actions menu. Then select **Save** and **Close**.
4. In the new or existing page, select **Edit Page** from the Page Actions menu.
5. Select an **Add Content** button in the part of the page where you want to add Content Presenter.
6. In the Add Content dialog, open the **Content Management** folder, as shown in Figure 27–12.

Figure 27–12 Opening the Content Management Folder

The Content Presenter template will be applied to the Content Presenter instance. For more information on using Content Presenter and display templates, see Section 29.2, "Understanding the Documents Task Flows" and Section 27.2, "Using the Out-of-the-Box Display Templates."

27.6 What Happens at Runtime?

This section includes these topics:

- Section 27.6.1, "Runtime Overview"
- Section 27.6.2, "Identifying Display Templates for Selected Content Items"

27.6.1 Runtime Overview

After you have defined a Content Presenter display template, you can add a Content Presenter task flow to a page in your application, specifying the content and display template in the Content Presenter task flow parameters (see Section 29.6, "Modifying Content Task Flow Parameters" and Section 27.2, "Using the Out-of-the-Box Display Templates").

If you integrate the Documents Service in your application (see Chapter 28, "Integrating Documents"), end users of your application can select content and your

Content Presenter display templates in the Content Presenter Configuration dialog to include content on editable pages of the application, as described in the "Publishing Content Using Content Presenter" chapter in *Building Portals with Oracle WebCenter Portal*. To understand how Content Presenter identifies which display templates to expose in the Content Presenter Configuration dialog, see Section 27.6.2, "Identifying Display Templates for Selected Content Items."

27.6.2 Identifying Display Templates for Selected Content Items

At runtime, after a user selects content in the Content Presenter Configuration dialog, Content Presenter checks the Resource Manager to identify the display templates that are suitable for the selected content item(s), then exposes the list of valid templates on the Template page in the Content Presenter Configuration dialog for the user to select. See also Chapter 9, "Introduction to Portal Resource Management." Note that uploaded templates must also be "available" in the list of resources for them to be selectable. See Section 27.5.2, "Upload the New Content Presenter Display Template" for more information.

For *single content item* templates, Content Presenter generates a list of valid templates using the following precedence order:

1. Check the Resource Manager for template definitions matching the content item's content repository and content type.
2. Add template definitions matching the default content repository (*) and specified content type.
3. Add template definitions matching inherited content types.
4. Add template definitions matching the default content repository (*) and default content type (*).

For *multiple content item* templates, Content Presenter generates a list of valid templates using the following precedence order:

1. Check the Resource Manager for template definitions associated with the selected template category.
2. Add template definitions associated with the default category (*).

For example, if the user selects multiple content items (such as the children of a folder, or the results of a search), the Content Presenter Configuration dialog shows a list of categories and the list of templates associated with that category and the default category, based on the repository of the content items.

> **Note:** When a user selects a template in the Content Presenter Configuration dialog, that template is used to display the selected content item(s) in the running application. If that template is later deleted from the Resource Manager for any reason, Content Presenter will automatically select a "closest match" template to display the content item(s) using the precedence order above.

27.7 Configuring Coherence as the Caching Mechanism

Content Presenter, by default, is configured to use a local (in-memory) cache. However, using Coherence for any type of production environment is strongly recommended, and is a requirement for High Availability (HA) environments. This section describes how to enable Coherence as the caching mechanism for Framework applications.

> **Note:** Your Coherence license may or may not support multi-node environments depending on the license option you have purchased. To check what your license agreement provides, see the "Oracle Coherence" section in *Licensing Information*.

You can enable content caching with Coherence for both WebCenter Portal and Framework applications by modifying the Coherence configuration file. For WebCenter Portal, only the steps described in the "Modifying Cache Settings for Content Presenter" section in *Administering Oracle WebCenter Portal* are required. For Framework applications, however, an additional step is required to add the configuration file to the application (EAR) classpath or server's system classpath.

This section contains the following subsections:

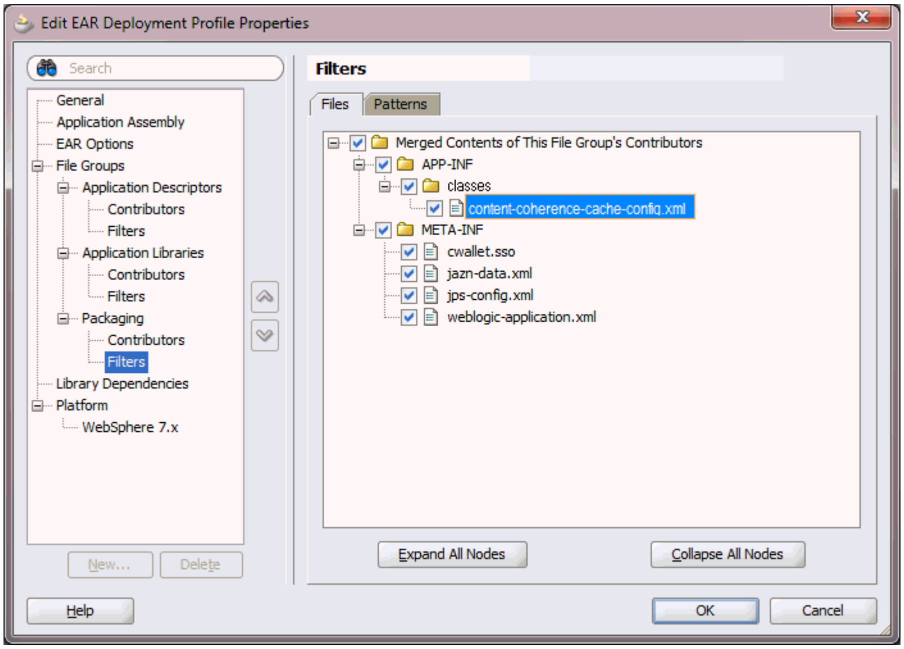
- Section 27.7.1, "Adding the Coherence Configuration File to the EAR Classpath"
- Section 27.7.2, "Verifying the Coherence Configuration"

27.7.1 Adding the Coherence Configuration File to the EAR Classpath

The following steps show how to add the XML file in the EAR classpath.

1. Complete the steps described in the "Modifying Cache Settings for Content Presenter" section in *Administering Oracle WebCenter Portal*.
2. Under the application's `src` directory (for example, `WebCenterPortalCoherence/src`), create a directory named `APP-INF/classes` and place the `content-coherence-cache-config.xml)` in it.
3. Open the application's Application Properties and select **Deployment**.
4. Edit the profile contained in the EAR file (see Figure 27–15).

Figure 27–15 Adding the XML File to the EAR Classpath



☑ Merged Contents of This File Group's Contributors
☑ APP-INF
☑ classes
☑ content-coherence-cache-config.xml
☑ META-INF
☑ cwallet.sso
☑ jazn-data.xml
☑ jps-config.xml
☑ weblogic-application.xml

5. Add a new File Group named `Packaging`. Leave the **Type** as `Packaging`.

6. Make sure `classes` and `content-coherence-cache-config.xml` file are selected in the Filters pane.
7. Deploy the application and restart the managed server on which it was deployed. After deploying your application, Coherence should be enabled.

27.7.2 Verifying the Coherence Configuration

After restarting the managed server where your application is deployed, connect to it by entering `jconsole` from the command line and choosing the process corresponding to `WC_Spaces` to open JConsole. In JConsole, check for Coherence in the MBeans tab. You should also see something like the following output in the `WC_Spaces-diagnostic.log` file:

```
2013-06-26 14:45:47.321/1278.178 Oracle Coherence GE 3.6.0.4 &lt;Info&gt;
(thread=[ACTIVE] ExecuteThread: '1' for queue: 'weblogic.kernel.Default
(self-tuning)', member=n/a): Loaded cache configuration from
"zip:/oracle/app/admin/domains/webcenter/servers/WC_CustomPortal/tmp/_WL_
user/WebCenterPortalCoherence_application1_
V2.0/i092wg/APP-INF/lib/portal-coherence.jar!/content-coherence-cache-config.xml"
```

27.8 Optimizing Performance for Content Presenter Display Templates

When content nodes are retrieved for display in a Content Presenter display template, most content item node property values are retrieved immediately along with the node, but some are loaded later only if needed. Other than the performance difference, the selective loading of node property values is transparent to the user or developer.

As a Content Presenter display template developer, you can optimize performance of your template if you are aware when different property values are loaded. For example, a typical list display template will render faster if you refer only to properties that are immediately loaded when the node is first retrieved and avoid properties that are loaded later when needed.

A secondary consideration is dependent on how the node is retrieved: through search versus fetched by parent ID. A property that may be loaded immediately on node retrieval for searches (such as "Results of a Query") may be loaded later for other retrieval methods (such as "Contents Under a Folder"). Table 27–12 shows whether or not node properties are loaded immediately upon node retrieval, by retrieval mechanism.

For information about the node properties listed in Table 27–12, see *Configuration Reference for Oracle WebCenter Content*.

Table 27–12 Loading of Node Properties By Node Retrieval Mechanism

	Loaded When Node Is First Retrieved?		
OCS Global Profile Properties	**GET BY PARENT ID ("Contents Under a Folder")**	**SEARCH ("Results of a Query")**	**GET BY UUID ("Single Content Item" and "List of Items")**

27.9 Content Presenter Tips, Tutorials and Examples

The following supplementary tutorials and examples further illustrate how Content Presenter can be used:

- *Using Content Presenter Templates* - describes how to build a region definition in Site Builder, and then use that region definition as the basis for a Content Presenter template (rather than a Site Studio region template), and finally, add the template to a Portal Framework application page.

  `http://yonaweb.be/webcenter_tutorial/using_content_presenter_templates`

- *UCM, Site Studio and Templates* - describes the components (Content Server, Site Studio, and Content Presenter) that drive content interactions in WebCenter Portal.

`http://www.ateam-oracle.com/portal-and-content-components-part-1-ucm-site-studio-and-templates-2-of-7`

- *Content Presenter-CMIS-Complete* - steps you through using Content Presenter-based pages and complex CMIS and custom templates to create a filterable content list viewer.

  `http://www.ateam-oracle.com/content-presenter-cmis-complete`

- *Portal and Content - Content Integration - Best Practices* - highlights some of the best practices to consider when integrating content into your portal.

  `http://www.ateam-oracle.com/portal-and-content-content-integration-best-practices/`

28 Integrating Documents

This chapter describes how to integrate documents into a Portal Framework application to both add content to the application, and to provide end users with content and documents task flows built into the application to manage, display, and search documents at runtime.

> **Note:** For a description of the other ways to integrate content into a WebCenter Portal Framework application, see Chapter 24, "Introduction to Integrating and Publishing Content."

This chapter includes the following topics:

- Section 28.1, "Introduction to Documents in WebCenter Portal Framework Applications"
- Section 28.2, "Setting Up Connections"
- Section 28.3, "Setting Security for the Documents Tool"
- Section 28.4, "Using the Documents Tool with Other WebCenter Services"
- Section 28.5, "Setting Parameters to Upload Files to Content Repositories"

28.1 Introduction to Documents in WebCenter Portal Framework Applications

The Documents tool provides features for accessing, adding, and managing folders and files; configuring and viewing file and folder properties; and searching file and folder content in WebCenter Content, Oracle Portal, SharePoint, or, in development environments, File System content repositories. It provides these features through documents task flows, document components (links, inline frames, and images), wikis, and blogs.

> **Note:** The availability of SharePoint as a content repository requires the installation of the SharePoint adapter, as described in Section 25.2.3.1, "Installing the Oracle WebCenter Adapter for SharePoint." Administration for SharePoint is performed using WLST commands, not Oracle Enterprise Manager Fusion Middleware Control Console.

To integrate documents into a Portal Framework application, your WebCenter Portal administrator must set up a connection to the content repository that contains the documents you want to manage. If the content repository you wish to use requires authentication, ensure that you set up an external application when you configure the connection to your content repository, as discussed in Section 28.2, "Setting Up Connections."

28.2 Setting Up Connections

Before you can use the Documents tool and task flows, you must first set up the connection to the WebCenter Content, Oracle Portal, or SharePoint content repository that contains the documents you want to manage. You can reuse connections you have created or create new ones.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can also later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, refer to the *Administering Oracle WebCenter Portal*.

The choices made for application security and content repository connection authentication need to be compatible. For example, if the connection is configured to use External Application with only Public credentials defined, then there is no requirement for the application to enforce user authentication. For detailed information about connection configuration, see Section 25.2, "Configuring Content Repository Connections."

28.3 Setting Security for the Documents Tool

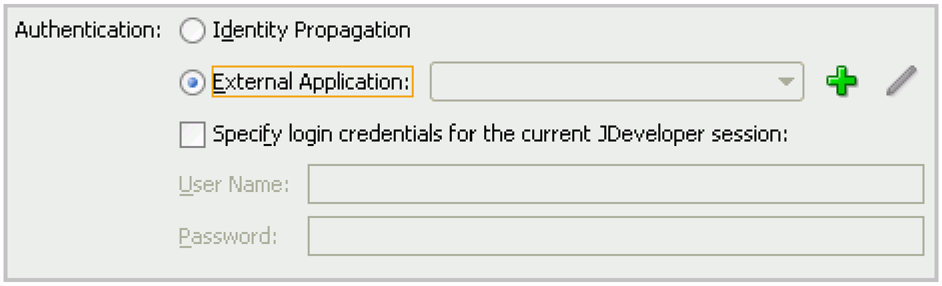
The documents task flows support the same security options that are supported by the content repository connections. This service can also use an external application with dedicated user accounts to access remote content repositories, such as an Oracle WebCenter Content or Oracle Portal. For more information about using security with content repositories, see Section 26.4, "Securing a Content Repository Data Control." For information about using external applications, see Section 74.13, "Working with External Applications."

If you are using a content repository that handles its own authentication, such as Oracle Portal or Oracle WebCenter Content, you can associate that content repository with an external application definition to allow for credential provisioning. You can modify your connection to your content repository to use an external application without shared or public credentials. When you do this, the External Application - Change Password task flow is automatically integrated to allow your end users to provide their credentials.

To register an external application for an existing content repository connection:

1. In the Application Resources pane, right-click your connection name and choose **Properties**.
2. In the Edit Content Repository Connection dialog box, under **Authentication**, select **External Application** (Figure 28–1).

Figure 28–1 Selecting External Application in the Content Repository Connection Dialog



Authentication: ○ Identity Propagation

● External Application:

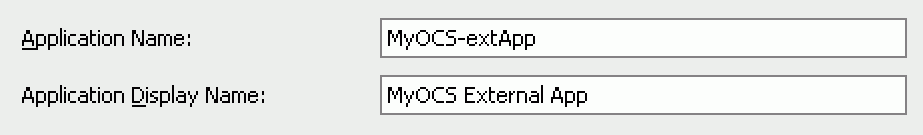
□ Specify login credentials for the current JDeveloper session:

User Name:

Password:

3. Click the green + (plus) sign to start the Register External Application wizard.
4. On the Name page, enter an **Application Name** and **Application Display Name**, (Figure 28–2) then click **Next**.

Figure 28–2 Naming the External Application

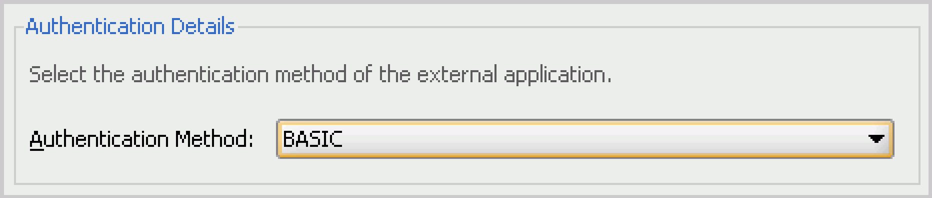


Application Name: MyOCS-extApp

Application Display Name: MyOCS External App

5. On the General page, under **Authentication Details**, choose **BASIC** from the **Authentication Method** list (Figure 28–3), then click **Next**.

Figure 28–3 Choosing the BASIC Authentication Method



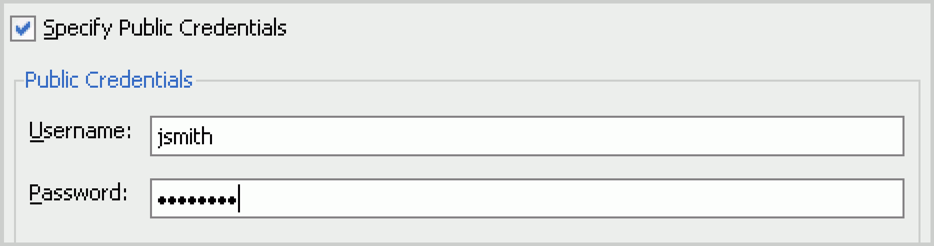
Authentication Details

Select the authentication method of the external application.

Authentication Method: BASIC

6. On the Additional Fields page, click **Next**.
7. On the Shared Credentials page, click **Next**.
8. On the Public Credentials page, select **Specify Public Credentials**, then enter the **Username** and **Password** for the content repository (Figure 28–4).

Figure 28–4 Specifying the Public Credentials



☑ Specify Public Credentials

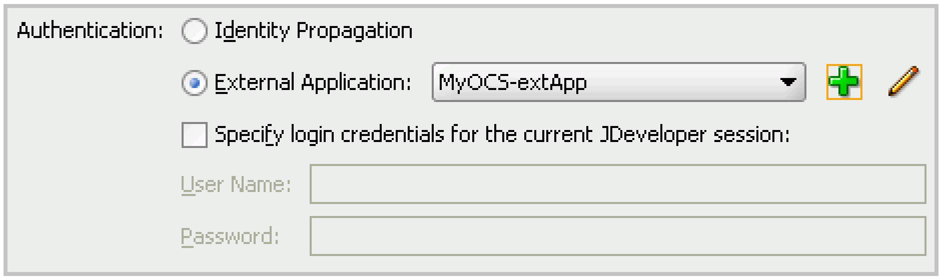
Public Credentials

Username: jsmith

Password: •••••••••

9. Click **Finish**. Notice that your connection now uses the external application for authentication (Figure 28–5).

Figure 28–5 Using the New External Application



Authentication: ○ Identity Propagation

● External Application: MyOCS-extApp

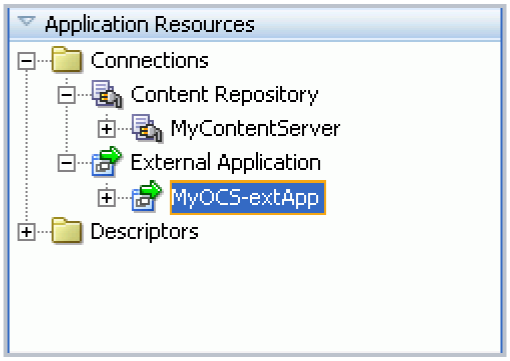
□ Specify login credentials for the current JDeveloper session:

User Name:

Password:

10. In the Edit Content Repository Connection dialog box, click **OK**. In the Application Resources panel, notice that the external application now appears (Figure 28–6).

Figure 28–6 External Application in the Application Resources Panel



```
Application Resources
⊟ Connections
    ⊟ Content Repository
        ⊞ MyContentServer
    ⊟ External Application
        ⊞ MyOCS-extApp
⊞ Descriptors
```

If you do not apply security and the content repository requires a login to access the content, the user will not be able to authenticate and thus will see only public content at runtime.

28.4 Using the Documents Tool with Other WebCenter Services

You can use the Documents tool with a variety of other WebCenter services. For example, you can add tags to documents in your content repository, search across your application and retrieve documents in the results, or track recent changes to the content repository.

You can see an example of how to use the Documents tool with the Tags service in Section 44.3.3, "Optional Way to Show Tags on Pages."

To learn more about how you can use these services together, refer to Chapter 4, "Preparing Your Application for WebCenter Portal Tools and Services,"

> **Note:** When you integrate the Documents tool with the Search service, the Search service returns results from *all* content repository connections.

28.5 Setting Parameters to Upload Files to Content Repositories

The Document Manager, Document Explorer, and Folder Viewer task flows allow you to upload files into content repositories. WebCenter Portal Framework uses Apache MyFaces Trinidad to handle file upload from a browser to the application server.

To change the default settings of Apache MyFaces Trinidad, you can add three parameters to the `web.xml` file. To edit this file, open the **ViewController** project of your application. Under **Web Content**, open the `web.xml` file. In the Overview, navigate to **Application > Context Initialization Parameters**, then click the green plus sign (**+**) to add the parameters and their values (as described in Table 28–1) or simply update the code in the Source view. After you have made your changes, save the `web.xml` file, then restart Oracle JDeveloper.

Table 28–1 Apache MyFaces Trinidad Parameters

Parameter	Description
`org.apache.myfaces.trinidad.UPLOAD_MAX_MEMORY`	The maximum amount of memory in bytes that a single file can use when uploaded
`org.apache.myfaces.trinidad.UPLOAD_MAX_DISK_SPACE`	The maximum amount of disk space in bytes that a single file can use when uploaded
`org.apache.myfaces.trinidad.UPLOAD_TEMP_DIR`	The directory in which the file being uploaded is temporarily stored

For more information, see the Apache MyFaces Trinidad documentation at `http://myfaces.apache.org/trinidad/devguide/fileUpload.html`.

29

Adding Content Task Flows and Document Components to a Portal Page

This chapter describes how to add content to a page in a Portal Framework application using the content task flows and document components. In a Portal Framework application, you can add content from one or more connected content repositories to the application, using Content Presenter or the documents task flows to display the content in a variety of ways. As you develop your application, you can view, edit, and manage that content using the content task flows, in the same way that end users of the application will do.

Note:

- For a description of the other ways to integrate content into a WebCenter Portal Framework Application, see Chapter 24, "Introduction to Integrating and Publishing Content."
- For information about viewing, editing, and managing content in content task flows, see the "Working with Documents" part in *Using Oracle WebCenter Portal*.

This chapter includes the following topics:

29.1 Understanding the Content Presenter Task Flow

Content Presenter enables you to precisely customize the selection and presentation of content in a WebCenter Portal application.

The Content Presenter task flow is available only when the connected content repository is WebCenter Content and your WebCenter Portal administrator has completed the prerequisite configuration.

See Also:

- "Prerequisites to Configuring WebCenter Content" in *Administering Oracle WebCenter Portal*
- Section 25.2.1, "Creating a Content Repository Connection Based on the Oracle Content Server Adapter"

The Content Presenter task flow allows you to select a single item of content, contents under a folder, a list of items, query for content, or select content based on the results of a Personalization Conductor scenario, and then select a template to render the content on a page in a WebCenter Portal application.

Content Presenter has no dependency on the Documents tool for adding or managing the content it displays.

To add the Content Presenter task flow to a page, see Section 29.4, "Adding a Selected Folder or File to a Page" and Section 29.5, "Adding a Content Task Flow to a Page."

Note: If a page is based on a page template that includes a Content Presenter task flow to display a content item, the page template developer must manually modify the task flow properties to display the content in the page template, as follows:

- `datasource`: `*connection_name*#dDocName:*content_ID*`
- `datasourceType`: `dsTypeSingleNode`
- `taskFlowInstId`: A unique identifier

For more information about Content Presenter task flow properties, see Table 29–4, " Content Presenter Task Flow Parameters"

For information about creating a page template, see Section 11.3, "Creating a Page Template."

29.2 Understanding the Documents Task Flows

The documents task flows provide a variety of formats to display folders and files, including wikis and blogs, on a page in a Portal Framework application. You can choose the task flows appropriate for your application to provide features for accessing, adding, and managing folders and files; configuring and viewing file and folder properties; and searching file and folder content in WebCenter Content, Oracle Portal, or SharePoint content repositories.

Note: The availability of SharePoint as a content repository requires the installation of the SharePoint adapter, as described in Section 25.2.3.1, "Installing the Oracle WebCenter Adapter for SharePoint." Administration for SharePoint is performed using WLST commands, not Oracle Enterprise Manager Fusion Middleware Control Console.

To add a documents task flow to a page in a Portal Framework application, your WebCenter Portal administrator must first integrate the Documents tool into the application by establishing a content repository connection, as described in Chapter 28, "Integrating Documents" and Chapter 25, "Configuring Content Repository Connections."

Using documents task flows and document components (such as links, previews, and images), you can add content to the application, and also provide end users with content and documents task flows built into the application to manage, display, and search documents at runtime.

Table 29–1 provides an overview of the documents task flows.

Table 29–1 Documents Task Flows

	Folder and File Listings	Individual Folders	Individual Files
Document Explorer task flow. Displays folders and files in two panes, combining the functionality of the Document Navigator and Folder Viewer task flows. It provides in-place previewing and editing, and robust management capabilities with an interface that should be familiar to users of Windows Explorer. Size: medium to full page width. See Figure 29–1.	X	X	
Document List Viewer task flow. Displays folders and files in a single pane as a flat listing. It provides preview and editing in separate window, and some management capabilities. Size: narrow to medium page width. See Figure 29–2.	X	X	
Document Manager task flow. Displays folders and files as specified by its `layout` property: `explorer`, `table`, or `treeTable`. The `explorer` layout is identical to the Document Explorer task flow, without the properties `showDocuments`, `showFolders`, and `treeNavCollapsed`. See Figure 29–3, Figure 29–4, and Figure 29–5.	X	X	
Document Navigator task flow. Displays a nested hierarchy of folders and files in a single pane, providing expand and collapse on folders to show the full hierarchy. Size: narrow to medium page width. See Figure 29–6.	X	X	
Folder Viewer task flow. Displays the contents of a folder in a single pane as a flat listing, providing in-place preview and editing, and robust document management capabilities with a straightforward interface that should be familiar to Windows users. Size: medium to full page width. See Figure 29–7.	X	X	
Recent Documents task flow. Displays a list of the files most recently created or modified files in the current folder. See Figure 29–8.	X		
Document Viewer task flow. Displays a preview of a file, or file properties for files that do not support a preview. See Figure 29–9 and Figure 29–10.		X[1]	X
Document Mini Properties task flow. Displays the Basic properties of a file in a read-only view. See Figure 29–11.		X[1]	X
Document Properties task flow. Displays both Basic and Advanced properties of a file, along with an **Edit** button to allow you to modify property values. See Figure 29–12.		X[1]	X

Table 29–1 (Cont.) Documents Task Flows

	Folder and File Listings	Individual Folders	Individual Files
Rich Text Editor task flow. Displays an HTML or wiki document in the Rich Text Editor.		X	X
Document Upload task flow. Displays the Upload dialog to allow users to upload new documents to the page.		X	X
Document Version History task flow. Displays a list of versions of a file, allowing for deletion of a selected version. See Figure 29–13 and Figure 29–14.			X
AutoVue task flow. Displays AutoVue markup for a file in a table of hyperlinked markup names (see the "Collaborating on Documents Using Oracle AutoVue" section in *Using Oracle WebCenter Portal*).			X

[1] To show folder information in a Document Viewer, Document Mini Properties, or Document Properties task flow, you must set the task flow's `resourceID` property to the ID of the target folder. See Section 29.7, "Content Task Flow Parameters."

To add a documents task flow to a page, see Section 29.4, "Adding a Selected Folder or File to a Page" and Section 29.5, "Adding a Content Task Flow to a Page."

For detailed information about each documents task flow, click the links below to display the pertinent sections in *Building Portals with Oracle WebCenter Portal*

- "Understanding the Document Explorer Task Flow"

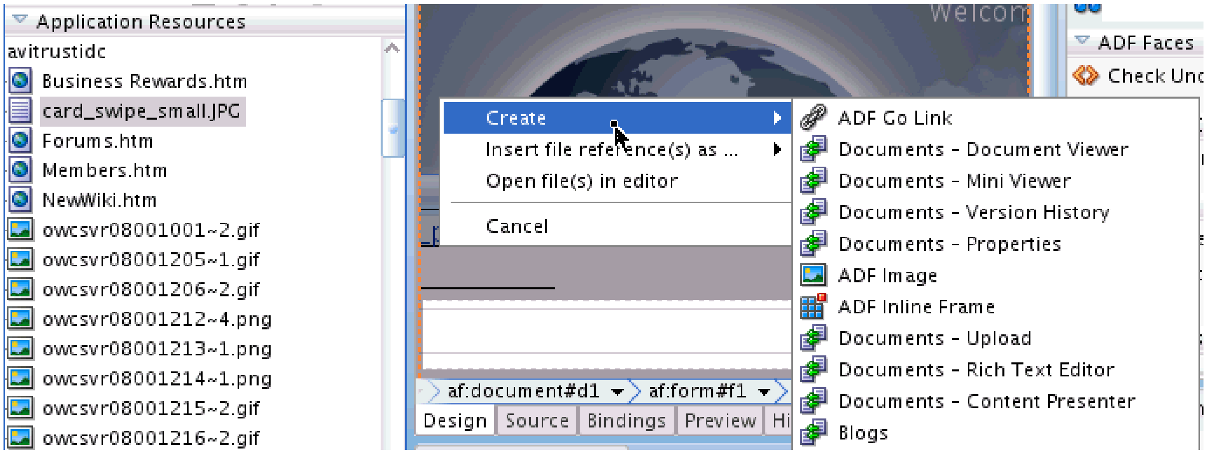
29.3 Understanding Document Components

The Documents tool provides features for adding document components to a portal page. As described in Section 29.4, "Adding a Selected Folder or File to a Page", you can add a document component to a page as a container for a selected folder or file (Figure 29–15).

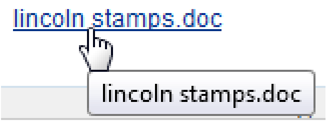
Figure 29–15 Adding a File to Portal Page



Document components enable you to display an individual file on a page in a variety of ways, depending on the file type:

- A **Link** displays the name of a selected file as a link, which end users can click to display the file content in its native application (Figure 29–16).

Figure 29–16 Link Component (for Microsoft Word file)

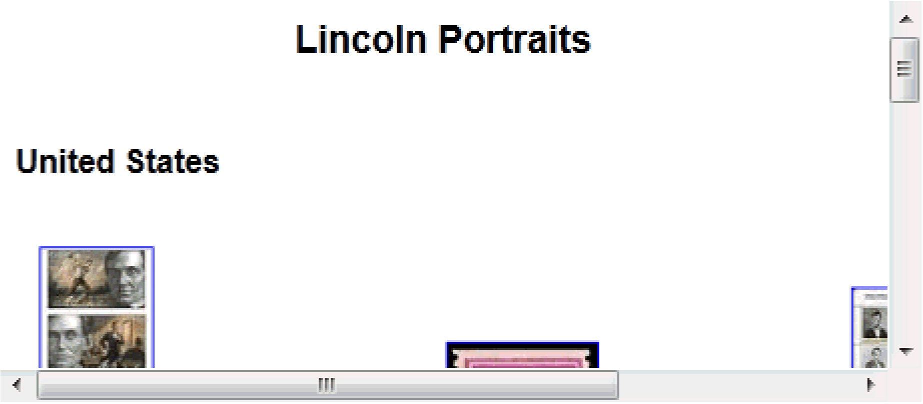


lincoln stamps.doc

lincoln stamps.doc

- An **Inline Frame** displays the content of a selected file as a preview on the page (Figure 29–17).

Figure 29–17 Inline Frame Component (for HTML file)



- An **Image** displays a selected file as an image on the page (Figure 29–18).

Figure 29–18 Image Component (for JPEG file)

To add a document component to a page in a Portal Framework application, you must first integrate the Documents tool into the application by establishing a connection to a content repository, as described in Chapter 28, "Integrating Documents."

Table 29–2 shows the document components available for the different content types.

Table 29–2 Components for Folders and FIles

Content Type	Document Components
Folder	Link (ADF Go Link)
Documents of various types (XML, PDF, JAVA, TXT, DOC, XLS, HTM)	Link (ADF Go Link)
Documents that can be rendered in a browser (HTML, flash, PDF and image)	Inline frame (ADF Inline Frame)
Images (PNG, JPG, GIF)	Link (ADF Go Link) Inline frame (ADF Inline Frame) Image (ADF Image)

To display a folder or file using one of these document components, see Section 29.4, "Adding a Selected Folder or File to a Page."

29.4 Adding a Selected Folder or File to a Page

This section describes how to display an individual folder or file from a connected content repository on a page, as shown inFigure 29–19 and Figure 29–20, by choosing the required container for the selected folder or file. If you want to add a content task flow to a page, independent of a specific folder or file, refer to Section 29.5, "Adding a Content Task Flow to a Page."

Figure 29–19 Adding a Folder to Portal Page

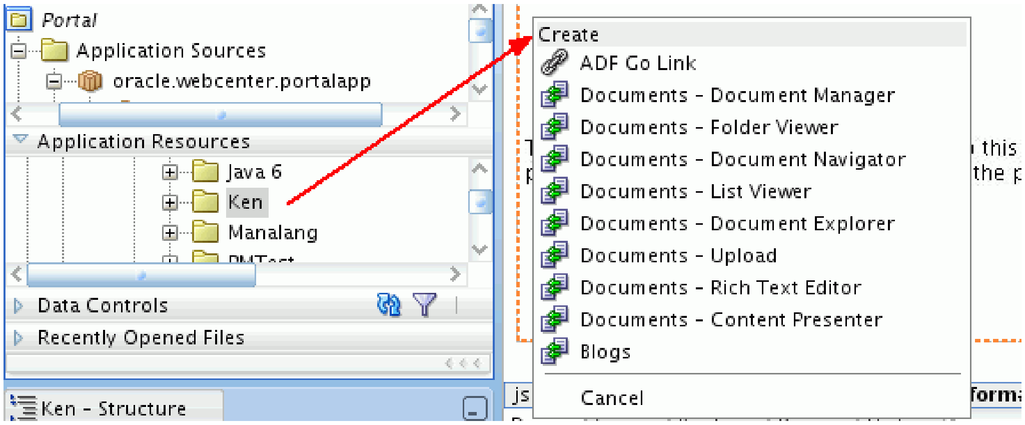


Figure 29–20 Adding a File to Portal Page

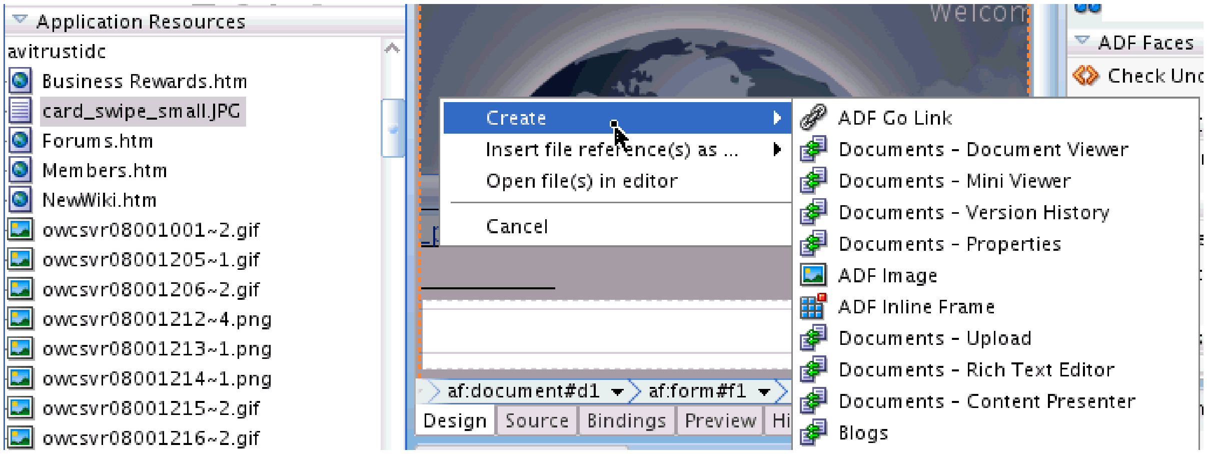

Table 29–3 lists all containers available for displaying folders and files on a portal page:

Table 29–3 Containers for Adding Individual Folders and Files to a Page

Root Folder	Folders	Individual Files
■ Document Explorer ■ Document List Viewer ■ Document Manager ■ Document Navigator ■ Folder Viewer ■ Recent Documents ■ Document Viewer[1] ■ Document Mini Properties[1] ■ Document Properties[1] ■ Document Upload ■ Rich Text Editor	■ Content Presenter ■ Document Explorer ■ Document List Viewer ■ Document Manager ■ Document Navigator ■ Folder Viewer ■ Document Viewer[1] ■ Document Mini Properties[1] ■ Document Properties[1] ■ Document Upload ■ Rich Text Editor	■ Content Presenter ■ Document Viewer ■ Document Mini Properties ■ Document Properties ■ Rich Text Editor ■ Document Upload ■ Document Version History ■ AutoVue ■ Link component ■ Inline Frame component ■ Image component

[1] To show folder information in a Document Viewer, Document Mini Properties, or Document Properties task flow, you must set the task flow's `resourceID` parameter to the ID of the target folder. See Section 29.7, "Content Task Flow Parameters."

For more information about any of the containers listed in Table 29–3, see Section 29.1, "Understanding the Content Presenter Task Flow," Section 29.2, "Understanding the Documents Task Flows," and Section 29.3, "Understanding Document Components."

Note: When an item that is stored in a content repository is dropped onto a page, the Portal Framework application instructs the browser to check whether the content is up-to-date before a cached copy, if available, displays in the browser. The default content validation process supports collaboration use cases that require real-time content exchange.

For static content or content that does not change frequently, content validation checks incur an unnecessary performance overhead. For static content, the following is recommended:

- **Oracle Content Server**: Use Content Presenter to display static content stored in WebCenter Content. Content Presenter shows only the latest released version of content; it does not show any unreleased content that is in workflow

- **Other content repositories**, such as SharePoint: Ask your administrator to override the default content cache setting by editing the Web Tier `mod_wl_ohs` configuration file (`mod_wl_ohs.conf`). This is fully explained in "Setting the Cache-Control Response Header" in the white paper "Integrating the SharePoint 2007 Adapter with WebCenter Spaces" available from Oracle Technology Network at `http://www.oracle.com/technetwork/middleware/webcenter/owcs-ps3-sharepoint-wcs-wp-335282.pdf`.

To add a selected folder or file to a page in a Portal Framework application (see Section 6.1, "Creating a New WebCenter Portal Framework Application"):

1. Follow the steps in Section 4.2.1, "How to Prepare Your Application to Consume Tools and Services" to implement security.

2. If you want to add a documents task flow, create a content repository connection, which adds the Documents tool to your application (see Chapter 28, "Integrating Documents").

3. Create or open a page in your application where you want to add the task flow (see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application").

4. Consider whether or not you want to allow end users of your application to edit the task flow that displays the folder or file:

   - To enable runtime editing of the page, see Chapter 18, "Enabling Runtime Editing of Pages Using Composer."

   - To allow end users of your application to customize a Content Presenter or Document List Viewer task flow using the **Edit** action, add the task flow inside a Show Detail Frame Component (see Section 18.1.6, "How to Enable Component Customization Using Show Detail Frame Components").

5. In the **Application Resources** panel, navigate to **Connections**, then **Content Repository**.

6. Locate the name of your connection, then expand it if desired to navigate to a specific folder or file.

7. Drag the folder or file to the page, and release the mouse button to display a menu of available task flows and document components, as shown in Figure 29–21 (root folder), Figure 29–22 (subfolder), and Figure 29–23 (individual file).

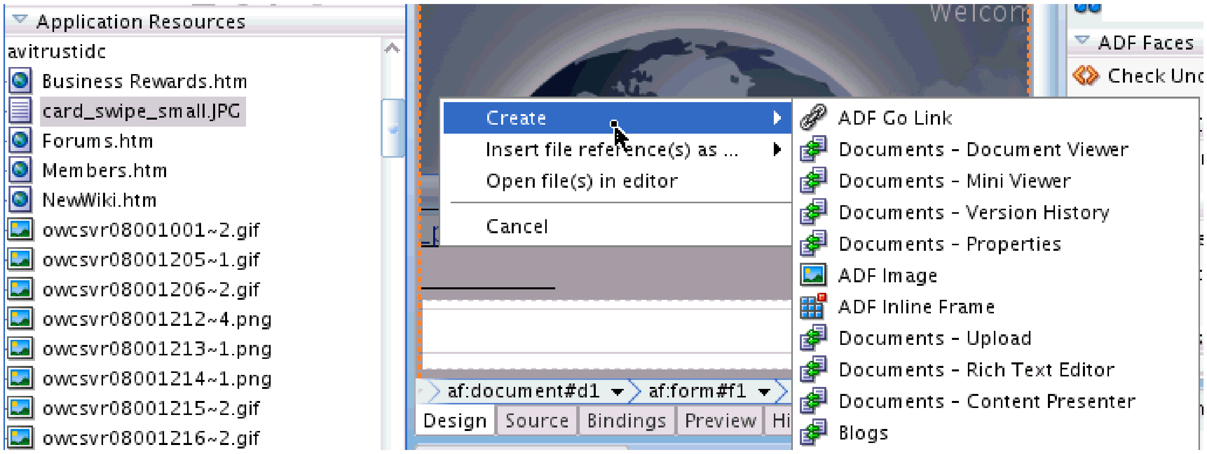
Figure 29–23 Adding a File to Portal Page



8. Choose the content task flow or document component that you want to use. If the folder or file you are adding to your page does not support a particular task flow, the task flow does not display in this menu.

> **Note:** The Content Presenter task flow is available only when the connected content repository is WebCenter Content. When you select the Content Presenter task flow, the folder or file displays in a default display template for its type.
>
> The Document Viewer, Document Mini Properties, and Document Properties task flows are not available in the **Create** menu for a folder. To show folder information in one of these task flows, you must first add an empty task flow to the page and then set the task flow's resource ID parameter to the ID of the target folder.

9. In the Edit Task Flow Binding dialog that displays when you select a task flow, click **OK** to accept the default task flow parameters, or modify the parameters as desired. For more information, see Section 29.7, "Content Task Flow Parameters."

10. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

For information about viewing, editing, and managing content in content task flows, see the "Working with Content in a Portal" part in *Building Portals with Oracle WebCenter Portal*.

29.5 Adding a Content Task Flow to a Page

You may want to add an empty content task flow to a page, containing no folders or files. For example, in cases where you do not have a content repository connection, or want to use an EL expression as a parameter to dynamically bind to a target item.

See Chapter 24, "Introduction to Integrating and Publishing Content" for information about each content task flow to help you select the task flow most appropriate for your needs.

To add a content task flow to a page in a Portal Framework application:

1. Follow the steps in Section 4.2.1, "How to Prepare Your Application to Consume Tools and Services" to implement security.
2. If you want to add a documents task flow, see Chapter 28, "Integrating Documents".
3. Create or open a page in your application where you want to add the task flow (see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application").
4. Before you add a task flow to your page, consider whether you want to allow end users of your application to edit the task flow:
   - To enable runtime editing of the page, see Chapter 18, "Enabling Runtime Editing of Pages Using Composer."
   - To allow end users of your application to customize a Content Presenter or Document List Viewer task flow using the **Edit** action, add the task flow inside a Show Detail Frame Component (see Section 18.1.6, "How to Enable Component Customization Using Show Detail Frame Components").
5. In the **Resource Palette**, expand **My Catalogs**, then **WebCenter Portal - Services Catalog**. Under **Task Flows**, select the desired content task flow and drag it onto your page (Figure 29–24).

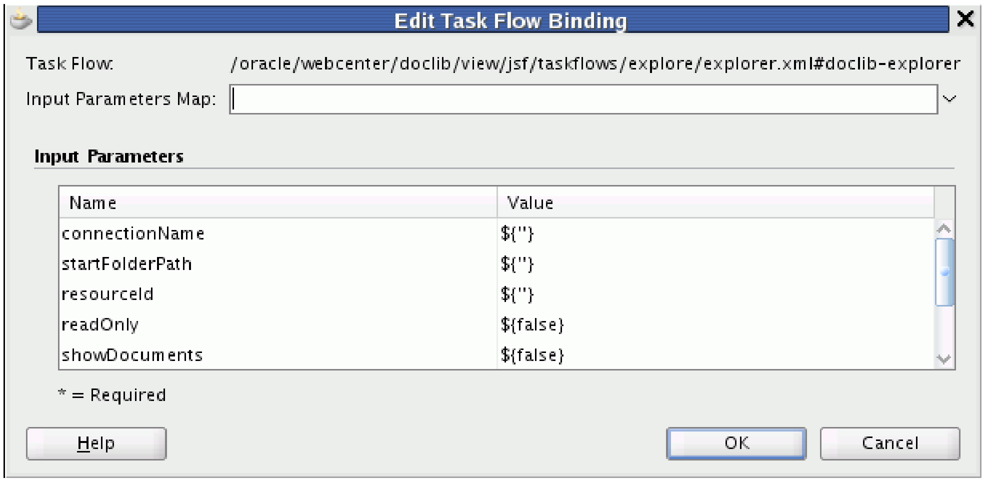
Note: To allow end users of your application to customize a Content Presenter or Document List Viewer task flow using the **Edit** action, drag the task flow inside a Show Detail Frame Component (see Section 18.1.6, "How to Enable Component Customization Using Show Detail Frame Components").

Note: If you display a wiki page in a Portal Framework application using a Content Presenter display template, by default any links within that wiki page are displayed in the Document Viewer. If you want to display wiki page links using Content Presenter, you must edit the `adf-config.xml` file. For more information, see Section 30.3.5, "Displaying Wiki Page Links Within Content Presenter."

---

6. From the menu that displays, choose **Region** to open the Edit Task Flow Binding dialog (Figure 29–25).

Figure 29–25 Specifying Parameters for Document Explorer Task Flow



Task Flow: /oracle/webcenter/doclib/view/jsf/taskflows/explore/explorer.xml#doclib-explorer

Input Parameters Map:

Input Parameters

Name	Value
connectionName	${''}
startFolderPath	${''}
resourceId	${''}
readOnly	${false}
showDocuments	${false}

* = Required

7. In the Edit Task Flow Binding dialog, click **OK** to accept the default task flow parameters, or modify the parameters as desired. For more information, see Section 29.7, "Content Task Flow Parameters."
8. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

After you add a content task flow to a page, you can subsequently modify the parameters if required. See Section 29.6, "Modifying Content Task Flow Parameters."

For information about viewing, editing, and managing content in content task flows, see the "Working with Content in a Portal" part in *Building Portals with Oracle WebCenter Portal*.

Note: For information about adding custom actions to task flows, see Section 20.3.2, "How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow."

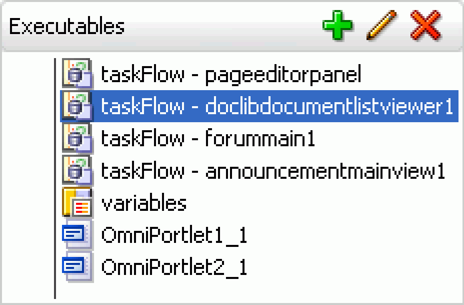
Note: By default, the task flow displays as full screen at runtime. You can use ADF layout components to modify this layout. To learn more about ADF layout components, refer to the *Web User Interface Developer's Guide for Oracle Application Development Framework*.

29.6 Modifying Content Task Flow Parameters

To modify the parameters of a content task flow after you have created the region:

1. Go to the Bindings view of your page (click the **Bindings** tab next to the **Source** tab).
2. Under **Executables**, select the task flow you added. Figure 29–26 shows an example of a Document List Viewer task flow in the **Executables** section.

Figure 29–26 Document List View Task Flow in the Bindings View



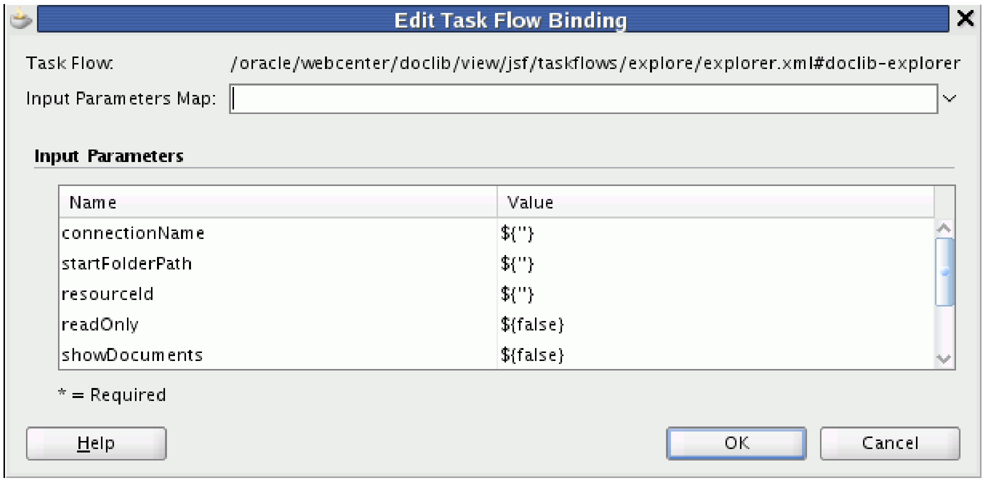
Executables
taskFlow - pageeditorpanel
taskFlow - doclibdocumentlistviewer1
taskFlow - forummain1
taskFlow - announcementmainview1
variables
OmniPortlet1_1
OmniPortlet2_1

3. Next to the **Executables** heading, click the pencil icon to display the Edit Task Flow Binding dialog.
4. In the Edit Task Flow Binding dialog, specify parameter settings for the task flow. For more information, see Section 29.7, "Content Task Flow Parameters."

Note: For a Content Presenter task flow:

- If you want to allow end users of your application to select the content and display template using the Content Presenter Configuration dialog at runtime, you can leave all parameter values blank except for `taskFlowInstId`. Enter a task flow instance ID that is unique to your application (for example, `contentPresenterInstance1`).
- If you specify the content and a display template, note that Content Presenter does not support non-ASCII characters in files that are encoded using the non-UTF-8 character encoding. When users preview such files in Content Presenter, non-ASCII characters appear garbled.

Figure 29–27 Task Flow Binding Parameters



Task Flow: /oracle/webcenter/doclib/view/jsf/taskflows/explore/explorer.xml#doclib-explorer

Input Parameters Map:

Input Parameters

Name	Value
connectionName	${''}
startFolderPath	${''}
resourceId	${''}
readOnly	${false}
showDocuments	${false}

* = Required

5. Click **OK** to add the parameters.

29.7 Content Task Flow Parameters

Each content task flow has its own set of parameters. You configure these values when you add the task flow to a page.

The following sections describe the parameters for the content task flows:

- Section 29.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates"
- Section 29.7.2, "Document Explorer Task Flow Parameters"
- Section 29.7.3, "Document List Viewer Task Flow Parameters"
- Section 29.7.4, "Document Manager Task Flow Parameters"
- Section 29.7.5, "Document Navigator Task Flow Parameters"
- Section 29.7.6, "Folder Viewer Task Flow Parameters"
- Section 29.7.7, "Recent Documents Task Flow Parameters"
- Section 29.7.8, "Document Viewer Task Flow Parameters"
- Section 29.7.9, "Document Mini Properties Task Flow Parameters"
- Section 29.7.10, "Document Properties Task Flow Parameters"
- Section 29.7.11, "Rich Text Editor Task Flow Parameters"
- Section 29.7.12, "Document Upload Task Flow Parameters"
- Section 29.7.13, "Document Version History Task Flow Parameters"

29.7.1 Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates

The Content Presenter task flow is available when the connected content repository is WebCenter Content. This task flow displays selected documents in out-of-the-box or custom display templates.

See Also:

- Section 29.1, "Understanding the Content Presenter Task Flow"
- Section 29.5, "Adding a Content Task Flow to a Page"

Table 29–4 describes the Content Presenter task flow parameters. Table 29–5 and Table 29–6 describe the out-of-the-box display templates for single and multiple content items, which can be specified as values for the `templateView` and `templateCategory` parameters.

Note: When you specify the content and a display template, note that Content Presenter does not support non-ASCII characters in files that are encoded using the non-UTF-8 character encoding. When users preview such files in Content Presenter, non-ASCII characters appear garbled.

If you want to allow end users of your application to select the content and display template using the Content Presenter Configuration dialog at runtime, you can leave all parameter values blank except for `taskFlowInstId`. Enter a task flow instance ID that is unique to your application (for example, `contentPresenterInstance1`).

At runtime, the parameters of a Content Presenter task flow on an editable page can be edited in two ways by end users with appropriate permissions:

- Click the configuration **Edit** icon for the task flow to display the Content Presenter Configuration dialog, where they can specify content and a display template. For information about the Content Presenter Configuration dialog at runtime, see the "Publishing Content Using Content Presenter" chapter in *Building Portals with Oracle WebCenter Portal*.
- Click the properties **Edit** icon for the task flow to display the Component Properties dialog where they can set and modify task flow parameters. Parameters set in this way are generally intended for use at design time by developers creating a Portal Framework application, or for advanced users who want to bind a parameter to an EL expression. If an end user modifies a parameter value in the Component Properties dialog, the new value overrides the value specified in the Content Presenter Configuration dialog.

Table 29–4 Content Presenter Task Flow Parameters

Parameter	Description
`datasource`	The data source of the content. The value depends on the value of `datasourceType`: ■ When `datasourceType=dsTypeSingleNode`, set `datasource` to a single document node identifier in the format: *connection_name*#dDocName:*content_id* Example: `xmlns.oracle.com#dDocName:STAN_IDC-007619` ■ When `datasourceType=dsTypeFolderContents`, set `datasource` to a single folder node identifier in the format: *connection_name*#dCollectionID:*collection_id* Example: `xmlns.oracle.com#dCollectionID:45535` ■ When `datasourceType=dsTypeQueryExpression`, set `datasource` to a CMIS search expression. **Note:** Using a CMIS query as the `datasource` requires a valid taskFlowInstId. Examples: `select * from cmis:document where cmis:name like \'test%\'` connectionName=*connection_name*#select * from cmis:document where cmis:createdBy = \'weblogic\' **Note:** If `connectionName` is not specified, then the primary connection will be used. For more information about how to format the query and for more examples, see Chapter 31, "Content Management REST API.". ■ When `datasourceType=dsTypeMultiNode`, set `datasource` to a set of comma-delimited document node identifiers in the format: *connection_name*#dDocName:*content_id*, *connection_name*#dDocName:*content_id*, ... Example: `myconn#dDocName:DOCUMENT_ID_12345,myconn#dDocName:DOCUMENT_ID_56789`

Table 29–4 (Cont.) Content Presenter Task Flow Parameters

Parameter	Description
`datasource` (cont'd)	■ When `datasourceType=dsTypeScenarioResults`, set `datasource` to point to a scenario in the format: `conductor-connection-name=`*`conductor_conn_name`*`,`*`namespace=scenario_namespace`*`,scenario-name=`*`scenario_name`*`,`*`inputparm1=value1,inputparm2=value2`*`,` ... Example: `conductor-connection-name=ConductorServiceLocal,namespace=CPNamespace,scenario-name=GetRelatedDocsScenario,topic=outdoors,interests=hiking` Where: *`connection_name`* = the name of the content repository connection. *`content_id`* = the `Content ID` for the content specified on the content information page for the item in WebCenter Content. *`collection_id`* = the `dCollectionID` found in the URL for the folder information page in WebCenter Content, or the `CollectionID` value on the content server. *`conductor_connection_name`* = the name of the URL connection that points to the Personalization Conductor (this name must start with `Conductor`). This value must match the `Reference name` attribute value in the `connections.xml` file for this URL connection. For more information, see the "Configuring Content Presenter" chapter in *Administering Oracle WebCenter Portal* and Appendix A, "WebCenter Portal Files" (for details about `connections.xml`). *`namespace`* = the name of the namespace that contains the specified scenario. *`scenario_name`* = the name of the scenario that Content Presenter will be using. For information about the Personalization Conductor and scenarios, see Chapter 66, "Personalizing Oracle WebCenter Portal Applications."
`datasourceType`	The data source type of the content. Valid values are: ■ `dsTypeSingleNode`: A single content item. ■ `dsTypeFolderContents`: The contents of a folder. ■ `dsTypeQueryExpression`: The results of a query. ■ `dsTypeMultiNode`: An ordered list of content items. ■ `dsTypeScenarioResults`: The results of the specified scenario. See Chapter 66, "Personalizing Oracle WebCenter Portal Applications."
`maxResults`	The maximum number of results to display when `datasourceType` is `dsTypeQueryExpression`. Default: `100`

Table 29–4 (Cont.) Content Presenter Task Flow Parameters

Parameter	Description
`regionTemplate`	Specifies whether the display template is a Site Studio region definition template. This value is valid only with WebCenter Content 11*g* or higher: - Selected: Display template is a Site Studio region definition template. The `templateView` value is set to the Content ID of the region template. - Cleared (default): Display template is not a Site Studio region definition template. For information about creating and using Site Studio region templates, see the "Publishing Content Using Content Presenter" chapter in *Building Portals with Oracle WebCenter Portal* and the Oracle Site Studio documentation library.
`taskFlowInstId`	The unique identifier of this task flow instance, used internally to maintain the association of the task flow instance with its customization and personalization settings and to manage saved queries. The value is generated automatically when you add individual files or the content of folders to your page from the Application Resources Panel, displaying the content in a Content Presenter task flow. The value is blank when you add a Content Presenter task flow onto your page from the Resource Palette. Enter or edit this value to set the unique identifier for the task flow. **Note:** Using a CMIS query as the `datasource` requires a valid taskFlowInstId.
`templateCategory`	The display template category ID to use in rendering results for multiple content items. This ID may reference the default template category for an out-of-the-box display template (Table 29–6) or a custom category created for a display template for multiple content items that has been defined as described in Section 27.3, "Creating Content Presenter Display Templates".
`templateView`	The display template view ID to use in rendering results for single content items. Enter the view ID of a template that is configured in the Resource Manager for a specific content type, or for list-based templates by category ID. This ID may reference one of the out-of-the-box display templates (Table 29–5), a custom display template that has been defined as described in Section 27.3, "Creating Content Presenter Display Templates", or set to the contentID of a region template if the content is a region.

The out-of-the-box display templates provided by Oracle WebCenter are listed in Table 29–5 and Table 29–6.

Table 29–5 Out-of-the-Box Templates for Displaying Single Content Items

Single Content Item Display Templates	View ID	Description
Default Document Details View	`oracle.webcenter.content.templates.default.document.details`	Displays detailed information about any single content item including creation date, modification date, created by username, modified by username, path and any comments.

Table 29–5 (Cont.) Out-of-the-Box Templates for Displaying Single Content Items

Single Content Item Display Templates	View ID	Description
Default List Item View	`oracle.webcenter.content.templates.default.list.item`	Used by multiple content item views to display each individual item. Displays a single line with an icon and item name as a link that either displays or downloads the item when clicked.
Default View (default when no template is selected)	`oracle.webcenter.content.templates.default.detail`	Displays any single content item, either directly in the browser (images, HTML, text) or as a link that downloads the associated file when clicked.
Full Article View	`oracle.webcenter.content.templates.sitestudio.fullarticle`	Displays a full article, including the Title, Image, and Body of an article. This is a *responsive template*, meaning that it CSS3 media queries to produce a responsive layout—a layout that adjusts to the width of the browser. For more information, see Section 27.3.4, "Using Responsive Templates." This template requires Site Studio to be enabled on the WebCenter Content, as it uses the `RD_ARTICLE` Site Studio region definition.

Table 29–6 Out-of-the-Box Templates for Displaying Multiple Content Items

Multiple Content Item Display Templates	View ID	Description
Accordion View	`oracle.webcenter.content.templates.default.list.panel.accordion`	Displays multiple content items in an accordion format, where each item can be expanded to display its details.
Articles View (under the Site Studio Template category)	`oracle.webcenter.content.templates.sitestudio.articles`	Displays the summaries of multiple articles, including the Title, Image, and Summary of articles. This is a *responsive template*, meaning that it CSS3 media queries to produce a responsive layout—a layout that adjusts to the width of the browser. For more information, see Section 27.3.4, "Using Responsive Templates." This template requires Site Studio to be enabled on the WebCenter Content, as it uses the `RD_ARTICLE` Site Studio region definition.
Bulleted View	`oracle.webcenter.content.templates.default.list.bulleted`	Displays multiple content items in a bulleted list format. Only content items will be displayed; folder items will be omitted.

Table 29–6 (Cont.) Out-of-the-Box Templates for Displaying Multiple Content Items

Multiple Content Item Display Templates	View ID	Description
Bulleted with Folder Label View	`oracle.webcenter.content.templates.default.list.bulleted.label`	Displays multiple content items in a bulleted list format. The name of the folder containing the first item in the list will display as a label above the list. This template is intended to be used when datasourceType is set to dsTypeFolderContents to ensure that all items have the same parent folder. Only content items will be displayed; folder items will be omitted.
Carousel View	`oracle.webcenter.content.templates.default.list.carousel`	Displays multiple content items in a carousel format, where items can be browsed by moving a slider left or right.
Icon View	`oracle.webcenter.content.templates.default.list.tile`	Displays multiple content items in a tiled format with large icons and file names.
List View (default when no template is selected)	`oracle.webcenter.content.templates.default.list.simple`	Displays multiple content items in a simple list.
List with Details Panel View	`oracle.webcenter.content.templates.default.list.details.panel`	Displays multiple content items in a list on the left, with a panel to the right displaying the details of a selected item.
Sortable Table View	`oracle.webcenter.content.templates.default.list.tabular`	Displays multiple content items in a sortable table that includes the document name, date created, and date modified.
Tabbed View	`oracle.webcenter.content.templates.default.list.panel.tabbed`	Displays multiple content items as tabs that can be selected to display item details. content items in a simple list.

29.7.2 Document Explorer Task Flow Parameters

The Document Explorer task flow displays a list of folders and files in two panes: the left pane shows folders, and the right pane show the contents of the currently selected folder. It is a feature-rich documents task flow for viewing, managing, and collaborating on folders and files.

See Also:

- "Understanding the Document Explorer Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Explorer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–7 describes the Document Explorer task flow parameters.

Table 29–7 Document Explorer Task Flow Parameters

Parameter	Description
connectionName	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see the "Registering Content Repositories" chapter in *Administering Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.
featuresOff	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: checkin, checkout, clipboard, close, delete, download, dnd, editwiki, editoffice, newfolder, newwiki, rename, upload, multifile-upload, profile-upload, search, advancedSearch, workflow, properties, history, comments, likes, links, tags, recommendations, autovue, title, related-items, social, sidebars, ils. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
pageSize	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: 27 Typical scenarios where you may want to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note:** If you set pageSize to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
readOnly	Specifies whether to disable and hide all content management operations: ■ ${true}: Disable content management. ■ ${false} (default): Expose content management to users.
resourceId	The currently focused resource. This value can be a folder ID or a document ID. The resourceId value is checked for coherence with the connectionName and startFolderPath values, and influences their default values when they are not explicitly specified. For example, if resourceId alone is specified, the connectionName value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.
showDocuments	Specifies whether the navigation tree shows documents and folders, or folders only: ■ ${true}: Show documents and folders. ■ ${false} (default): Show folders and hide documents.
showFolders	Specifies whether the navigation tree shows documents and folders, or documents only: ■ ${true} (default): Show folders and documents. ■ ${false}: Show documents and hide folders.

Table 29–7 (Cont.) Document Explorer Task Flow Parameters

Parameter	Description
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current portal's default root folder. But it is useful, for example, when you want the start folder to be other than a portal's default root folder and when you want to display content from another portal. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current portal.
`treeNavCollapsed`	Specifies whether to collapse or expand the panel containing the tree navigation: ■ `${true}` (default): Collapse panel. ■ `${false}`: Expand panel.

29.7.3 Document List Viewer Task Flow Parameters

The Document List Viewer task flow displays folders and files in a single pane as a flat listing. In this task flow, users can navigate a folder hierarchy, and customize search queries. While this task flow may be useful for a specific need, its search functionality is replicated and enhanced by the Content Presenter task flow.

See Also:

- "Understanding the Document List Viewer Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document List Viewer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–8 describes the Document List Viewer task flow parameters.

Table 29–8 Document List Viewer Task Flow Parameters

Task Flow Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see the "Registering Content Repositories" chapter in *Administering Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.

Table 29–8 (Cont.) Document List Viewer Task Flow Parameters

Task Flow Parameter	Description
`createdAfter`	A filtering value to limit the display of task flow content to folders and files created after a specified date and time. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZ'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`createdBefore`	A filtering value to limit the display of task flow content to folders and files created before a specified date and time. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZ'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`creator`	A filtering value to limit the display of task flow content to folders and files created by a particular user. Enter the user name as specified by the user login credentials. Only one user name may be entered. If no value is entered, then content created by any user is shown. Example: `${'monty'}`
`lastModifiedAfter`	A filtering value to limit the display of task flow content to folders and files last modified after a specified date and time. If no value is entered, then content modified in the last three months is shown. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01.00'}`
`lastModifiedBefore`	A filtering value to limit the display of task flow content to folders and files modified before a specified date and time. If no value is entered, then the last modification date is applied. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`lastModifier`	A filtering value to limit the display of task flow content to folders and files last modified by a particular user. Enter the user name as specified by the user login credentials. Only one user name may be entered. If no value is entered, then all modified documents are shown. Example: `${'monty'}`
`pageSize`	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: `15` Typical scenarios where you may want to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note:** If you set `pageSize` to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.

Table 29–8 (Cont.) Document List Viewer Task Flow Parameters

Task Flow Parameter	Description
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current portal's default root folder. But it is useful, for example, when you want the start folder to be other than a portal's default root folder and when you want to display content from another portal. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current portal.
`showFolders`	Specifies whether to show documents and folders, or documents only: ■ `${true}`: show folders and documents ■ `${false}` (default): show documents and hide folders
`taskFlowInstId`	The unique identifier for this task flow instance, used internally to maintain the association of the task flow instance with its customization and personalization settings and to manage saved queries. The value is generated automatically when you add individual files or the content of folders to your page from the Application Resources Panel, displaying the content in a Document List Viewer task flow. The value is blank when you add a Document List Viewer task flow onto your page from the Resource Palette. Enter or edit this value to set the unique identifier for the task flow.

[1] "TZ" is the time zone indicator. If the time being described is in UTC (Coordinated Universal Time), then the time zone indicator is "Z". If the time is from any other time zone, then TZ describes the offset from UTC of the time zone. For example, if the time is in California in December (Pacific Standard Time, PST), then the TZ indicator would be "-08:00".

29.7.4 Document Manager Task Flow Parameters

The Document Manager task flow provides comprehensive document management functionality, such as copying, moving, pasting, and deleting folders and files, as well as the ability to configure the task flow layout. The Document Manager task flow displays folders and files as specified by its `layout` parameter: it can display folders and files in two panes (`explorer` layout), or a single pane showing only the content of the current folder (`table` layout), or a single pane showing the folder hierarchy starting from the root folder (`treeTable` layout). The `explorer` layout is identical to the Document Explorer task flow, without the properties `showDocuments`, `showFolders`, and `treeNavCollapsed`.

See Also:

- "Understanding the Document Manager Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Manager task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–9 describes the Document Manager task flow parameters.

Table 29–9 Document Manager Task Flow Parameters

Task Flow Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see the "Registering Content Repositories" chapter in *Administering Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`layout`	A target layout for the task flow. Select from: ■ `${'explorer'}` (default): Displays folders and files in two panes; the left pane shows folders, and the right pane shows the contents of the currently selected folder. This layout looks identical to the Document Explorer task flow, without the parameters `showDocuments`, `showFolders`, and `treeNavCollapsed`. See Figure 29–3. ■ `${'table'}`: Displays only the contents of the current folder in a single pane, with the capability to click a folder to drill down, refreshing the pane with the folder contents. See Figure 29–4. ■ `${'treeTable'}`: Displays the folder hierarchy in a single pane, beginning with the root folder, with the capability to expand and collapse folders. See Figure 29–5.
`pageSize`	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: `27` Typical scenarios where you may want to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note:** If you set `pageSize` to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
`readOnly`	Specifies whether to disable and hide all content management operations: ■ `${true}`: Disable content management. ■ `${false}` (default): Expose content management to users.

Table 29–9 (Cont.) Document Manager Task Flow Parameters

Task Flow Parameter	Description
`resourceId`	The currently focused resource. This value can be a folder ID or a document ID. The `resourceId` value is checked for coherence with the `connectionName` and `startFolderPath` values, and influences their default values when they are not explicitly specified. For example, if `resourceId` alone is specified, the `connectionName` value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current portal's default root folder. But it is useful, for example, when you want the start folder to be other than a portal's default root folder and when you want to display content from another portal. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current portal.

29.7.5 Document Navigator Task Flow Parameters

The Document Navigator task flow displays folders and files in a single pane, with the capability to expand and collapse folders to view folder hierarchy within the current folder. There are no menu options available to the end user for this task flow.

See Also:

- "Understanding the Document Navigator Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Navigator task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–10 describes the Document Navigator task flow parameters.

Table 29–10 Document Navigator Task Flow Parameters

Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see the "Registering Content Repositories" chapter in *Administering Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.

Table 29–10 (Cont.) Document Navigator Task Flow Parameters

Parameter	Description
featuresOff	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: checkin, checkout, clipboard, close, delete, download, dnd, editwiki, editoffice, newfolder, newwiki, rename, upload, multifile-upload, profile-upload, search, advancedSearch, workflow, properties, history, comments, likes, links, tags, recommendations, autovue, title, related-items, social, sidebars, ils. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
pageSize	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: 27 Typical scenarios where you may want to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note:** If you set pageSize to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
readOnly	Specifies whether to disable and hide all content management operations: ■ ${true}: Disable content management. ■ ${false} (default): Expose content management to users.
resourceId	The currently focused resource. This value can be a folder ID or a document ID. The resourceId value is checked for coherence with the connectionName and startFolderPath values, and influences their default values when they are not explicitly specified. For example, if resourceId alone is specified, the connectionName value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.
showDocuments	Specifies whether the navigation tree shows documents and folders, or folders only: ■ ${true} (default): Show documents and folders. ■ ${false}: Show folders and hide documents.

Table 29–10 (Cont.) Document Navigator Task Flow Parameters

Parameter	Description
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current portal's default root folder. But it is useful, for example, when you want the start folder to be other than a portal's default root folder and when you want to display content from another portal. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current portal.

29.7.6 Folder Viewer Task Flow Parameters

The Folder Viewer task flow displays a listing of the contents of a folder in a single pane as a flat listing.

See Also:

- "Understanding the Folder Viewer Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Folder Viewer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–11 describes the Folder Viewer task flow parameters.

Table 29–11 Folder Viewer Task Flow Parameters

Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see the "Registering Content Repositories" chapter in *Administering Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.

Table 29–11 (Cont.) Folder Viewer Task Flow Parameters

Parameter	Description
featuresOff	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: checkin, checkout, clipboard, close, delete, download, dnd, editwiki, editoffice, newfolder, newwiki, rename, upload, multifile-upload, profile-upload, search, advancedSearch, workflow, properties, history, comments, likes, links, tags, recommendations, autovue, title, related-items, social, sidebars, ils. Example: ${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}
pageSize	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: 27 Typical scenarios where you may want to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note:** If you set pageSize to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
readOnly	Specifies whether to disable and hide all content management operations: ■ ${true}: Disable content management. ■ ${false} (default): Expose content management to users.
resourceId	The currently focused resource. This value can be a folder ID or a document ID. The resourceId value is checked for coherence with the connectionName and startFolderPath values, and influences their default values when they are not explicitly specified. For example, if resourceId alone is specified, the connectionName value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.
showFolders	Specifies whether the navigation tree shows documents and folders, or documents only: ■ ${true} (default): Show folders and documents. ■ ${false}: Show documents and hide folders.

Table 29–11 (Cont.) Folder Viewer Task Flow Parameters

Parameter	Description
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current portal's default root folder. But it is useful, for example, when you want the start folder to be other than a portal's default root folder and when you want to display content from another portal. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. See Section G.9, "ELs Related to Documents." Default: The root folder of the content repository configured with the specified connection for the current portal.

29.7.7 Recent Documents Task Flow Parameters

The Recent Documents task flow displays a listing of the most recently created or modified files by the current user.

See Also:

- "Understanding the Recent Documents Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Recent Documents task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–12 describes the Recent Documents task flow parameters.

Table 29–12 Recent Documents Task Flow Parameters

Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see the "Registering Content Repositories" chapter in *Administering Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.

Table 29–12 (Cont.) Recent Documents Task Flow Parameters

Parameter	Description
`groupSpace`	(Used in WebCenter Portal only) The name of a portal that is the source of the recently created or modified documents listed in the task flow. Valid values are: ■ no value or `${null}` (default): Displays documents for the entire connected content repository. ■ Display name or ID of a specific portal: Displays documents in that portal. ■ `${'all'}`: Displays documents from any portal, excluding non-portal documents.
`lastModifiedAfter`	A filtering value to limit the display of task flow content to folders and files last modified after a specified date and time. If no value is entered, then content modified in the last three months is shown. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01.00'}`
`lastModifiedBefore`	A filtering value to limit the display of task flow content to folders and files modified before a specified date and time. If no value is entered, then the last modification date is applied. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`lastModifier`	A filtering value to limit the display of task flow content to folders and files last modified by a particular user. Enter the user name as specified by the user login credentials. Only one user name may be entered. If no value is entered, then all modified documents are shown. Example: `${'monty'}`
`maxDocuments`	The maximum number of files to show. If no value or 0 is entered, then up to 10 of the most recently accessed documents are shown. Example: `${10}` Note that there is no single quote surrounding the value. Default: `${null}`
`mostRecentFirst`	Specifies the sort order of files in the task flow: ■ `${true}` (default): Most recent documents listed first. ■ `${false}`: Oldest documents listed first.

[1] "TZ" is the time zone indicator. If the time being described is in UTC (Coordinated Universal Time), then the time zone indicator is "Z". If the time is from any other time zone, then TZ describes the offset from UTC of the time zone. For example, if the time is in California in December (Pacific Standard Time, PST), then the TZ indicator would be "-08:00".

29.7.8 Document Viewer Task Flow Parameters

The Document Viewer task flow displays the contents of a folder or a preview of an individual file in the default template for its file type.

See Also:

- "Understanding the Document Viewer Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Viewer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–13 describes the Document Viewer task flow parameters.

Table 29–13 Document Viewer Task Flow Parameters

Parameter	Description
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`initialSidebar`	Specifies the tabbed pane to have initial focus in the Document Viewer. Valid values are: ▪ `${'comments'}` (default). Displays the **Comments** pane (see the "Commenting on Items" section in *Using Oracle WebCenter Portal*). ▪ `${'tags'}`. Displays the **Tags** pane (see the "Managing Tags on Files" section in *Using Oracle WebCenter Portal*). ▪ `${'history'}`. Displays the **History** pane (see the "Viewing and Deleting File Version History" section in *Using Oracle WebCenter Portal*). ▪ `${'docInfo'}`. Displays the **Info** pane (see the "Working with Folder and File Properties" section in *Using Oracle WebCenter Portal*). ▪ `${'tags'}`. Displays the **Links** pane (see the "Managing Document Links" section in *Using Oracle WebCenter Portal*). ▪ `${'autovue'}`. When Oracle AutoVue is installed, displays an **AutoVue** pane showing the AutoVue markup for the current document in a table of hyperlinked markup names (see "Collaborating on Documents Using Oracle AutoVue" section in *Using Oracle WebCenter Portal*).
`readOnly`	Specifies whether to disable and hide all content management operations: ▪ `${true}`: Disable content management. ▪ `${false}` (default): Expose content management to users.
`resourceID`	The currently focused resource. This value can be a folder ID or a document ID.

29.7.9 Document Mini Properties Task Flow Parameters

The Document Mini Properties task flow displays the basic properties of a selected file in a read-only view. This task flow is available for all file types.

See Also:

- "Understanding the Document Mini Properties Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Mini Properties task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–14 describes the Document Mini Properties task flow parameters.

Table 29–14 Document Mini Properties Task Flow Parameters

Parameter	Description
`resourceID`	The ID of the document for which to display basic properties.

29.7.10 Document Properties Task Flow Parameters

The Document Properties task flow displays both Basic and Advanced properties of a selected file, along with an **Edit** button to modify property values. This choice is available for all file types.

See Also:

- "Understanding the Document Properties Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Properties task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–15 describes the Document Properties task flow parameters.

Table 29–15 Document Properties Task Flow Parameters

Parameter	Description
`resourceID`	The ID of the document for which to display basic and advanced properties.
`readOnly`	Specifies whether or not to allow end user to edit document properties: ■ `${true}`: Do not display **Edit** button in Basic and Advanced properties panes, thus disabling the ability for the end user to edit document properties. ■ `${false}` (default): Display **Edit** button in Basic and Advanced properties panes, allowing end users to edit document properties.

29.7.11 Rich Text Editor Task Flow Parameters

The Rich Text Editor task flow displays an HTML or wiki document in the Rich Text Editor.

See Also:

- "Using the Rich Text Editor (RTE)" in *Using Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Rich Text Editor task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–18 describes the Rich Text Editor task flow parameters.

Table 29–16 Rich Text Editor Task Flow Parameters

Parameter	Description
`destinationID`	The currently focused resource. This value can be a folder ID to create a new document in that folder, or a document ID (as shown in the properties pane of the Document Viewer task flow) to edit an existing document.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`initialSidebar`	Specifies a pane to display in the sidebar of the Document Viewer. Valid values are: ■ `${'comments'}` (default). Displays a **Comments** pane (see the "Commenting on Items" section in *Using Oracle WebCenter Portal*) ■ `${'tags'}`. Displays a **Tags** pane (see the "Managing Tags on Files" section in *Using Oracle WebCenter Portal*) ■ `${'history'}`. Displays a **History** pane (see the "Viewing and Deleting File Version History" section in *Using Oracle WebCenter Portal*) ■ `${'docInfo'}`. Displays a **Properties** pane (see the "Working with Folder and File Properties" section in *Using Oracle WebCenter Portal*) ■ `${'links'}`. Displays a **Links** pane (see the "Managing Document Links" section in *Using Oracle WebCenter Portal*) ■ `${'recommendations'}`. Displays a **Recommendations** pane (see the "Viewing Document Recommendations" section in *Using Oracle WebCenter Portal*) **Note:** Values are case-sensitive.

29.7.12 Document Upload Task Flow Parameters

The Document Upload task flow displays the Upload dialog to allow users to upload new documents to the page.

See Also:

- "Uploading Files" in *Using Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Upload task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–18 describes the Document Upload task flow parameters.

Table 29–17 Document Upload Task Flow Parameters

Parameter	Description
`destinationID`	The currently focused resource. This value specifies a folder ID to upload a document into that folder.
`destinationSelectionEnabled`	Specifies whether or not the destination folder can be changed: - `${true}`: Display destination folder as an input text box along with a **Browse** button. - `${false}` (default): Display destination folder as read only text.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`

29.7.13 Document Version History Task Flow Parameters

The Document Version History task flow displays a list of versions of a selected file in a read-only view. This task flow is available for all file types.

See Also:

- "Understanding the Document Version History Task Flow" in *Building Portals with Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Version History task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–18 describes the Document Version History task flow parameters.

Table 29–18 Version History Task Flow Parameters

Parameter	Description
`horizontalLayout`	Specifies the layout orientation for the version history information: - `${vertical}` (default): Vertical orientation (see Figure 29–13). - `${horizontal}`: Horizontal orientation (see Figure 29–13).
`resourceID`	The ID of the document for which to display version history.

Table 29–18 (Cont.) Version History Task Flow Parameters

Parameter	Description
`readOnly`	Specifies whether to disable and hide all content management operations: - `${true}`: Disable content management. `${false}` (default): Expose content management to users.

29.7.14 AutoVue Task Flow Parameters

The AutoVue task flow integrates the Oracle AutoVue functionality to allow users to review and collaborate on a document.

See Also:

- "Collaborating on Documents Using Oracle AutoVue" in *Using Oracle WebCenter Portal*
- Section 29.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the AutoVue task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 29–19 describes the AutoVue task flow parameters.

Table 29–19 AutoVue Task Flow Parameters

Parameter	Description
`resourceId`	The ID of the document to display in the AutoVue task flow.

30 Integrating Wikis and Blogs

This chapter describes how to integrate the wiki and blog functionality into your WebCenter Portal Framework applications to enable your application end users to collaborate and share content and ideas.

This chapter includes the following topics:

- Section 30.1, "Introduction to Wikis and Blogs"
- Section 30.2, "Requirements for Wikis and Blogs"
- Section 30.3, "Integrating Wikis"
- Section 30.4, "Integrating Blogs"

30.1 Introduction to Wikis and Blogs

A wiki is a collection of useful content or information that users can browse, update, and remove, sometimes without the need for registration. This ease of interaction and the variety of operations make wiki an effective tool for collaborative authoring, where multiple people create written content together.

Blogs are typically personal records of an individual user's experience and opinions. They provide a useful tool for discussing and/or evangelizing any type of idea, strategy, or point of view. Blogs may be projected out to a select group of people or to a wider audience. Typically, each blog contains various blog posts, with the most recently added blog post displayed at the top. Blogs invite readers to comment on the overall concepts.

You can integrate wikis and blogs into your Portal Framework applications through the Documents tool. There is no limitation on the number of wiki pages or blogs that you can expose in an application.

30.2 Requirements for Wikis and Blogs

To support the wiki and blog functionality, the Documents tool relies on WebCenter Content. For wiki and blog functionality to be available in your Portal Framework applications, the following prerequisites must be met:

- WebCenter Content 11*g* must be installed and configured as the default content repository for WebCenter Portal. Wiki and blog functionality is not available with WebCenter Content 10*g*. For information about installing and configuring WebCenter Content 11*g*, see the "Managing Content Repositories" chapter in *Administering Oracle WebCenter Portal*.

- A connection to WebCenter Content 11*g* must be established. For information, see Section 25.2.1, "Creating a Content Repository Connection Based on the Oracle Content Server Adapter."
- Complete the steps covered in Section 4.2, "Preparing Your Framework Application for Tools and Services," as needed. For example, you can use the Activity Stream feature to track activities such as when a blog or wiki document is created or updated. End users can add comments on wiki documents and blog posts to express their views. To enable the Comments and Activities Stream features, you must register a connection to a database that has the `WebCenter` schema installed.

After completing these requirements, you can use the Documents tool to add wikis and blogs to your Portal Framework applications:

- To add wikis to your application, you will need to add a documents task flow that provides the **Add Wiki Document** action (such as the Document Explorer task flow). See Section 30.3, "Integrating Wikis."
- To add blogs to your application, you use the blog tasks flows. See Section 30.4, "Integrating Blogs."

If you want to convert wikis and blogs in your Portal Framework applications into PDF, your application administrator must configure the WebCenter Conversion component, as described in the "Enabling the Conversion of Wikis and Blogs into PDFs" section in *Administering Oracle WebCenter Portal*.

30.3 Integrating Wikis

This following sections provide the information you need to add wiki documents to your Portal Framework applications:

- Section 30.3.1, "About Integrating Wikis"
- Section 30.3.2, "Adding the Document Explorer Task Flow to Provide the Wiki Functionality"
- Section 30.3.3, "Modifying Document Explorer Task Flow Parameters"
- Section 30.3.4, "What Happens at Runtime"
- Section 30.3.5, "Displaying Wiki Page Links Within Content Presenter"

30.3.1 About Integrating Wikis

To provide your end users with the ability to add and manage wiki documents at runtime, you need to add the Document Explorer task flow to your Portal Framework application. When you add this task flow at design time, it is built into the application for end users, and enables them to work with wiki documents at runtime.

The Document Explorer task flow has associated parameters. For information, see Section 29.7.2, "Document Explorer Task Flow Parameters."

30.3.2 Adding the Document Explorer Task Flow to Provide the Wiki Functionality

To prepare your Portal Framework application and add the Document Explorer task flow for enabling the wiki functionality:

1. Ensure that you have completed the requirements listed in Section 30.2, "Requirements for Wikis and Blogs."

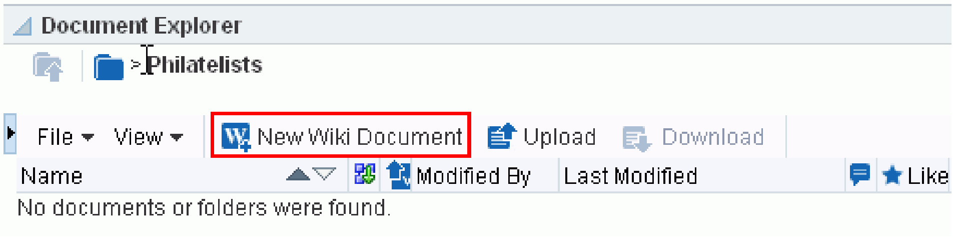
> **Note:** While setting up the connection, you must choose an authentication method. If you choose identity propagation, you must implement ADF security in your application and configure secure socket layer (SSL) on WebCenter Content.
>
> If you choose external application, you must specify the external application you want to use for authenticating users to WebCenter Content.
>
> For information, see Section 4.2.1.1, "Implementing Security for Tools and Services."

2. Create or open the JSF page on which you want to provide the wiki functionality (see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application").
3. Choose a method for adding the Document Explorer task flow to the page:
   - To add the Document Explorer task flow prepopulated with a selected folder or file, see Section 29.4, "Adding a Selected Folder or File to a Page."
   - To add the Document Explorer task flow standalone as an "empty" task flow that you can populate using the task flow menus and actions, see Section 29.5, "Adding a Content Task Flow to a Page."

   For information about the parameters that you can set for the Document Explorer task flow, see Section 29.7.2, "Document Explorer Task Flow Parameters."

   When you run the page, the Document Explorer task flow displays in your default browser, as shown in Figure 30–1. End users can create a wiki document by clicking **New Wiki Document**. For more information, see Section 30.3.4, "What Happens at Runtime."

Figure 30–1 Creating a New Wiki Document



No documents or folders were found.

30.3.3 Modifying Document Explorer Task Flow Parameters

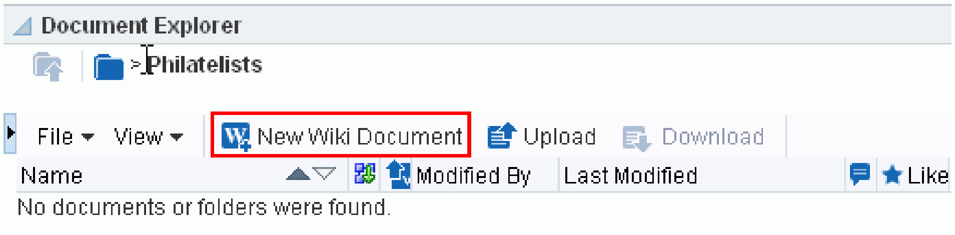
The way you modify parameters of a Document Explorer task flow is the same as any other documents task flow. For information, see Section 29.6, "Modifying Content Task Flow Parameters." For information about the specific parameters that you can modify, see Section 29.7.2, "Document Explorer Task Flow Parameters."

30.3.4 What Happens at Runtime

At runtime, authorized users can create wiki documents in a Portal Framework application in which the wiki functionality has been exposed. Users can also edit, download, rename, share, and subscribe to a wiki document and view its history and properties.

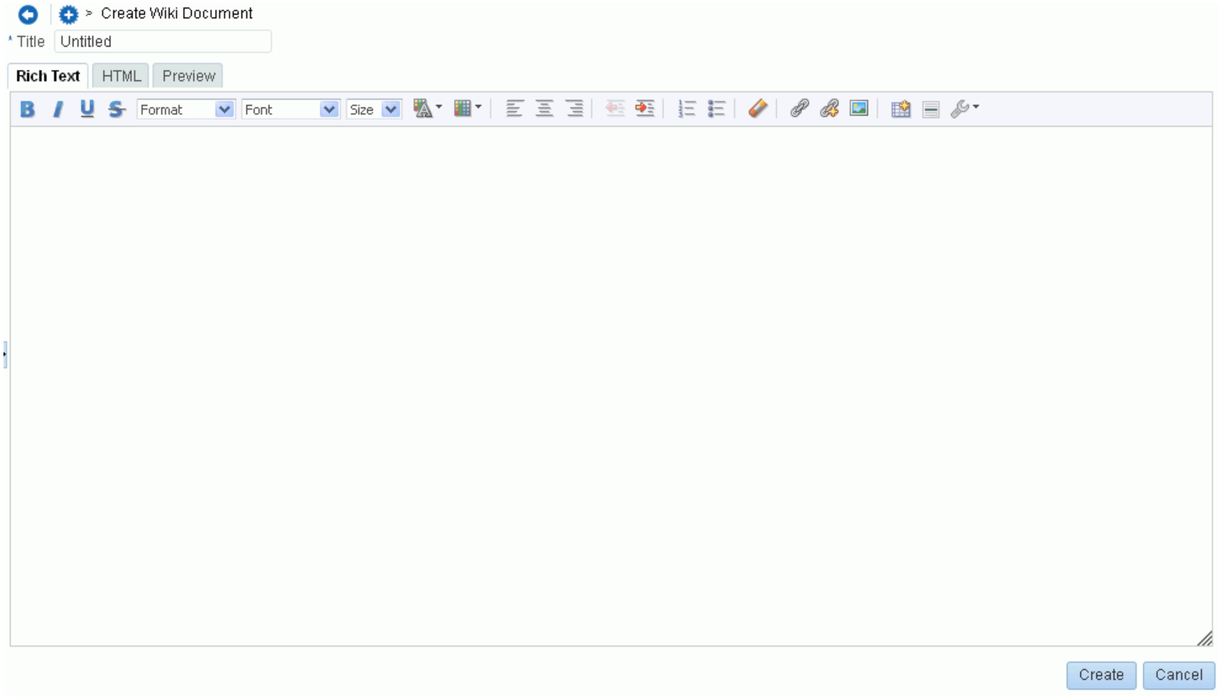
At runtime, the folder that you exposed through the Document Explorer task flow is shown as the root folder. End users can create a wiki document by clicking **New Wiki Document** (Figure 30–2), which opens the Rich Text Editor (RTE) (Figure 30–3), displaying a blank wiki document.

Figure 30–2 Creating a New Wiki Document



Users can add and edit wiki content using the Rich Text Editor (RTE), which is a fully-integrated HTML text editor (Figure 30–3).

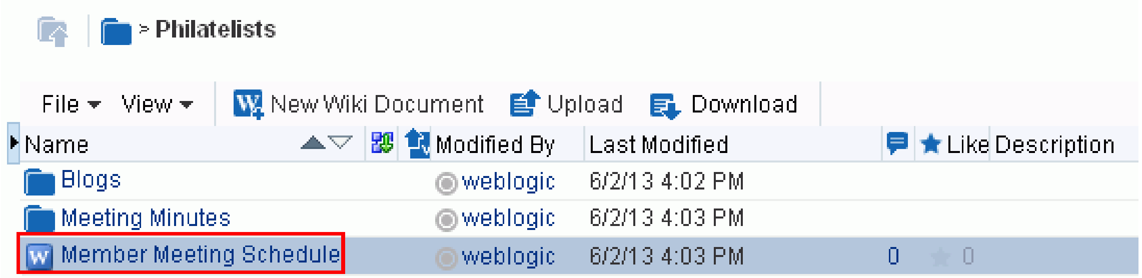
Figure 30–3 Rich Text Editor Displaying New Wiki Document



Note: By default, the **Wiki Markup** tab is hidden in the RTE. To show and hide the **Wiki Markup** tab, your system administrator can edit a configuration file, as described in the "Showing and Hiding the Wiki Markup Tab in the Rich Text Editor" section in *Administering Oracle WebCenter Portal*.

By default, all wiki documents are created directly under the root folder (Figure 30–4).

Figure 30–4 Wiki Document Created Using New Wiki Document Action



Name	Modified By	Last Modified		Like	Description
Blogs	weblogic	6/2/13 4:02 PM			
Meeting Minutes	weblogic	6/2/13 4:03 PM			
Member Meeting Schedule	weblogic	6/2/13 4:03 PM	0	0	

The runtime procedures for adding and managing wiki documents in a Portal Framework application are the same as those in WebCenter Portal. For generic information, refer to the "Working with Wikis" chapter in *Using Oracle WebCenter Portal*.

30.3.5 Displaying Wiki Page Links Within Content Presenter

At runtime, users can choose to display an existing wiki document using Content Presenter, as described in the "Adding a Selected Folder or File to a Page" section in *Building Portals with Oracle WebCenter Portal*.

When a wiki document is displayed using a Content Presenter display template, by default the links present in the wiki document render in the Document Viewer. You can configure your application to display link targets within Content Presenter.

To open the targets of links present in a wiki document within Content Presenter rather than the Document Viewer:

1. Open the `adf-config.xml` file. This file is located under `Descriptors/ADF META-INF` in the **Application Resources** section of the Application Navigator.

2. Update the `Namespace` entry as follows:

   ```
   xmlns:wpsC="http://xmlns.oracle.com/webcenter/framework/service"
   ```

3. Update the `ResourceActionHandler` entry as follows:

   ```
   <wpsC:adf-service-config
   xmlns="http://xmlns.oracle.com/webcenter/framework/service">
         <resource-handler
   class="oracle.webcenter.portalframework.sitestructure.handler.NavigationResourc
   eActionHandler"/>
   </wpsC:adf-service-config>
   ```

4. Save `adf-config.xml`.

30.4 Integrating Blogs

When you integrate the blogs functionality into your Portal Framework application, authorized end users can create and manage blog posts. To enable the blog functionality, you need to add the blog task flows.

This following sections provide the information you need to add blogs to a Portal Framework application:

- Section 30.4.1, "Understanding the Blog Task Flows"
- Section 30.4.2, "Adding a Blog to a Page"

- Section 30.4.5, "Blog Task Flow Parameters"
- Section 30.4.4, "Modifying Blog Task Flow Parameters"
- Section 30.4.3, "What Happens at Runtime"

30.4.1 Understanding the Blog Task Flows

If you want to include a blog on a page, along with other page components, you can use the blog task flows to add one or more elements of a blog to a page. Table 30–1 lists and describes the blog task flows:

Table 30–1 Blog Task Flows

Blog Task Flow	Description	Example as Exposed on a Page
Blog Archives	Displays a composite list of blogs based on dates.	 Archives 2013 (2) June (2)
Blog Banner	Displays a banner for the blog.	 MyBlog
Blog Digest	Displays a blog or blog post.	 New Post Philatelists Club? If you are interested in joining the online Philatelists Club, check out my web site: www.arisite/philatclub Created on 6/17/13 6:04 PM by Ari Spice - 0 comments - ☆ 0
Recent Blog Posts	Displays a list of most recent blog posts.	 Recent Posts Philatelists Club? Presidential Stamps

Table 30–1 (Cont.) Blog Task Flows

Blog Task Flow	Description	Example as Exposed on a Page
Blogs	Displays a blog or blog post with a default design.	 MyBlog New Post Archives 2013 (2) June (2) Philatelists Club? If you are interested in joining the online Philatelists Club, check out my web site:

30.4.2 Adding a Blog to a Page

To add a blog to a page in your Portal Framework application:

1. Ensure that you have completed the requirements listed in Section 30.2, "Requirements for Wikis and Blogs."

   > **Note:** While setting up the connection, you must choose an authentication method. If you choose identity propagation, you must implement ADF security in your application and configure secure socket layer (SSL) on WebCenter Content.
   >
   > If you choose external application, you must specify the external application you want to use for authenticating users to WebCenter Content.
   >
   > For information, see Chapter 4.2.1.1, "Implementing Security for Tools and Services."

2. Create or open a page in your application where you want to expose the blog functionality (see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application").
3. Before you add a blog task flow to your page, consider whether or not you want to allow your end users to edit the task flow. To enable runtime editing of the page, see Chapter 18, "Enabling Runtime Editing of Pages Using Composer."
4. Add a blog to the page using an existing folder to create a default blog page, or by creating a custom blog by selecting component blog task flows:
   - Section 30.4.2.1, "Adding a Blog Using an Existing Folder"
   - Section 30.4.2.2, "Adding a Custom Blog to a Page Using the Blog Task Flows"

30.4.2.1 Adding a Blog Using an Existing Folder

If you have an existing folder, perhaps already containing blog posts, you can establish that folder as the source of blog posts for a blog, instead of creating a new "empty" blog (see Section 30.4.2.2, "Adding a Custom Blog to a Page Using the Blog Task Flows"). At runtime, the blog displays the blog posts in that folder.

To expose a selected folder and its contents as a blog on a page:

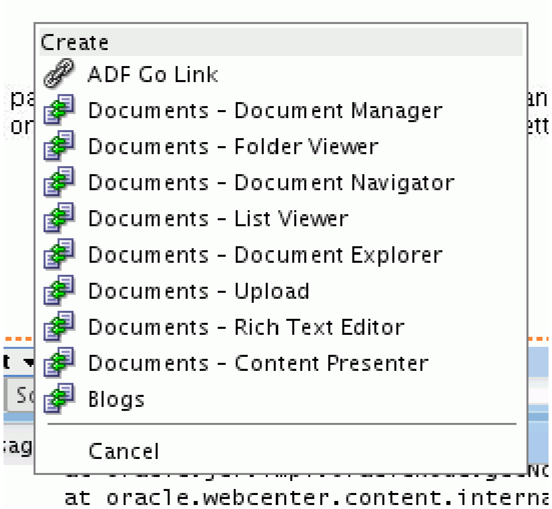
1. In the **Application Resources** panel, navigate to **Connections**, then **Content Repository**.

2. Locate the name of your WebCenter Content connection, then expand it to navigate to the folder that you want to establish as the blog folder.

   > **Tip:** You can expose any folder as a blog. To better organize your blogs, you may consider storing each blog folder in a parent folder; for example, a folder named **Blogs**. You can create a folder using either a documents task flow or the WebCenter Content console.
   >
   > Files stored in the blog folder are identified as blog posts in their metadata `Type` field, which is set to `Blog Post`. Uploading an HTML file into a blog folder does not expose it as a blog post, unless you set its `Type` to `Blog Post`.

3. Drag the folder onto the page, and release the mouse button to display a menu listing all available task flows (Figure 30–5).

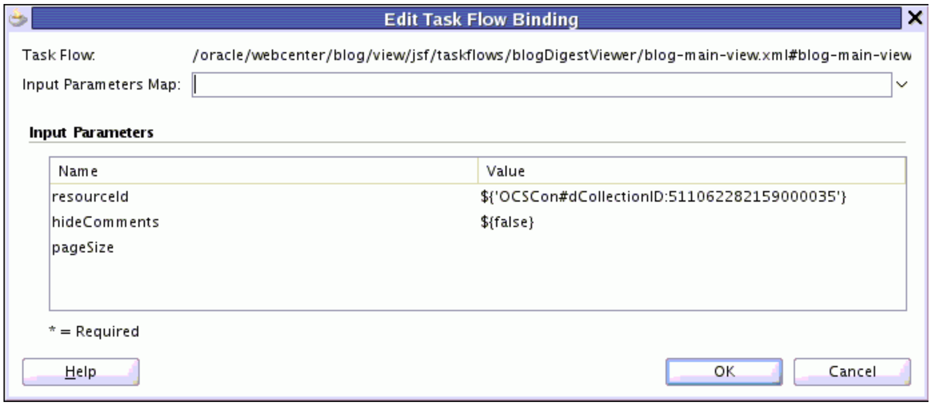
Figure 30–5 Menu of Available Task Flows for Selected Folder



Create
ADF Go Link
Documents - Document Manager
Documents - Folder Viewer
Documents - Document Navigator
Documents - List Viewer
Documents - Document Explorer
Documents - Upload
Documents - Rich Text Editor
Documents - Content Presenter
Blogs
Cancel
at oracle.webcenter.content.interna

4. From the menu, choose **Blogs** to open the Edit Task Flow Binding dialog (Figure 30–6).

Figure 30–6 Specifying Parameters for Blogs Task Flow



Task Flow: /oracle/webcenter/blog/view/jsf/taskflows/blogDigestViewer/blog-main-view.xml#blog-main-view

Input Parameters Map:

Input Parameters

Name	Value
resourceId	${'OCSCon#dCollectionID:511062282159000035'}
hideComments	${false}
pageSize	

* = Required

5. In the Edit Task Flow Binding dialog, the `resourceId` value is automatically populated with the resource ID of the selected folder. Click **OK** to accept the default task flow parameters, or modify the parameters as desired. For more information, see Section 30.4.5.5, "Blogs Task Flow Parameters."

6. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

The new blog is given the same name as the selected folder. Existing files under the folder become blog posts if the `Type` property of the file is set to `Blog Post`. As posts are added to the blog at runtime, the blog posts are stored in this folder. See Section 30.4.3, "What Happens at Runtime."

30.4.2.2 Adding a Custom Blog to a Page Using the Blog Task Flows

You may want to add an "empty" blog task flow onto your page, either as one component on a page, or as the entire page. For example, in cases where you do not have a content repository connection, or want to use an EL expression as a parameter to dynamically bind to a target item, you may want to use this method instead of the method described in Section 30.4.2.1, "Adding a Blog Using an Existing Folder." Additionally, the individual blog task flows enable you to customize the appearance of a blog.

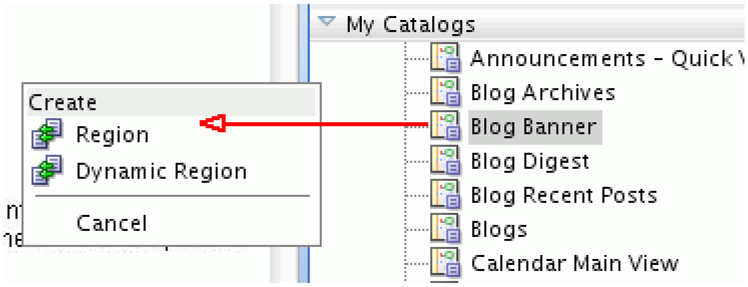
To add a customized blog task flow to a page:

1. In the **Resource Palette**, expand the **WebCenter Portal - Services Catalog**. Under **Task Flows**, select the blog task flow that you want to add, drag it onto your page, and release the mouse button.

   For information about each of the five blog task flows, see Section 30.4.1, "Understanding the Blog Task Flows."

2. From the menu that displays, choose **Region** (Figure 30–7).

Figure 30–7 Adding Blog Task Flow Using Resource Palette



3. In the Edit Task Flow Binding dialog, click **OK** to accept the default task flow parameters, or modify the parameters as desired. For information, see Section 30.4.5, "Blog Task Flow Parameters."

4. Repeat these steps for each blog task flow that you want to comprise your blog.

5. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

Internally, the new blog is given the same name as the folder specified by the `resourceID`; however, the name visible on the page is the value you specify in the `Title` parameter of the Blog Banner task flow. Existing files under the folder become blog posts if the `Type` property of the file is set to `Blog Posts`. As posts are added to the blog at runtime, the blog posts are stored in this folder. See Section 30.4.3, "What Happens at Runtime."

30.4.3 What Happens at Runtime

At runtime, the folder specified by the `resourceID` parameter for the blog task flow is exposed as a blog on the page:

- If you created a blog as described in Section 30.4.2.1, "Adding a Blog Using an Existing Folder," then the name of the folder that you exposed as a blog is displayed as the name of your blog in the blog banner.
- If you created a blog as described in Section 30.4.2.2, "Adding a Custom Blog to a Page Using the Blog Task Flows," then the name of the folder that you specified in the `resourceID` parameter of the blog task flow is the name of your blog internally; however, the name visible on the page is the value that you specified in the `Title` parameter of the Blog Banner task flow.

Authorized users can create blog posts, and the posts are displayed on the blog page. Users can perform tasks such as edit, download, comment upon blog posts, and so on.

On the default blog page (Figure 30–8), and in the Blog Archives task flow, the **Archives** section provides links to blog posts by year and by month. Clicking a month displays all blog posts created during that month.

Figure 30–8 A Default Blog Page

Presidential Stamps

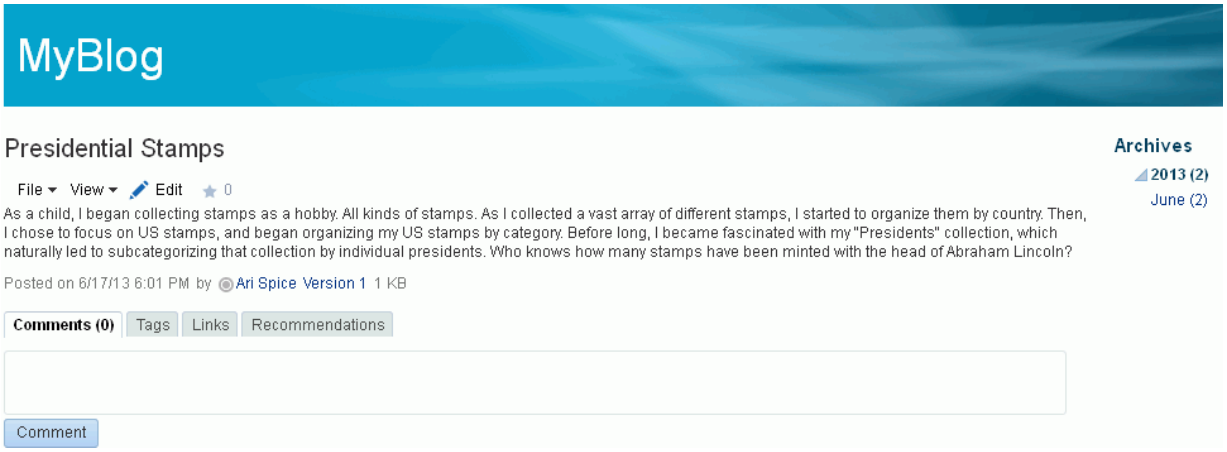
As a child, I began collecting stamps as a hobby. All kinds of stamps. As I collected a vast array of different stamps, I started to organize them by country. Then, I chose to focus on US stamps, and began organizing my US stamps by category. Before long, I became fascinated with my "Presidents" collection, which naturally led to subcategorizing that collection by individual presidents. Who knows how many stamps have been minted with the head of Abraham Lincoln?

Created on 6/17/13 6:01 PM by Ari Spice - 0 comments - 0

A blog displays various details for each blog post. These include the blog post title, the blog post content, date of creation or modification, name of the user who created or last modified the post, and the number of comments on the blog post. Authorized users can click the **Edit Post** icon to edit a post, and click the **Post comments** link to enter comments on a blog post.

Clicking a blog post title opens the blog post to occupy the entire the blog page (Figure 30–9), providing controls to manage the blog post.

Figure 30–9 A Blog Post



Presidential Stamps

As a child, I began collecting stamps as a hobby. All kinds of stamps. As I collected a vast array of different stamps, I started to organize them by country. Then, I chose to focus on US stamps, and began organizing my US stamps by category. Before long, I became fascinated with my "Presidents" collection, which naturally led to subcategorizing that collection by individual presidents. Posted on 6/17/13 6:01 PM by Ari Spice Version 1 1 KB

When public users (not logged in) view a blog post in a Portal Framework application, they will not see the profile photos associated with each blog post because the `anonymous-role` that is assigned to public users is not granted permission to view profiles by default (see Table 74–2, " Automated Security Grants for Portal Framework Applications"). Your system administrator can use the `grantPermission` WLST command (see the "grantPermission" section in the *WebLogic Scripting Tool Command Reference*) to allow public users to view profile photos for blog posters. For example:

```
grantPermission(appStripe=<app-name>,
  principalClass="oracle.security.jps.internal.core.principals.JpsAnonymousRoleI
mpl",
  principalName="anonymous-role",
permClass="oracle.webcenter.peopleconnections.profile.security.ProfilePermission",
  permTarget="/oracle/webcenter/peopleconnections/profile/s8bba98ff_4cbb_40b8_
beee_296c916a23ed/.*",
  permActions="view")
```

The procedures for managing blogs at runtime in a Portal Framework application are the same as those for managing blogs in WebCenter Portal. For information, see the "Working with Blogs" chapter in *Using Oracle WebCenter Portal*.

30.4.4 Modifying Blog Task Flow Parameters

The procedure for modifying the parameters of a Blogs task flow is the same as any other documents task flow. For information, see Section 29.6, "Modifying Content Task Flow Parameters." For information about the specific parameters that you can modify, see Section 30.4.5, "Blog Task Flow Parameters."

30.4.5 Blog Task Flow Parameters

Each blog task flow has its own set of parameters. You can configure these values when you add the task flow to your page, or modify the values at any time.

The following sections describe the parameters for the blog task flows:

- Section 30.4.5.1, "Blog Archives Task Flow Parameters"
- Section 30.4.5.2, "Blog Banner Task Flow Parameters"
- Section 30.4.5.3, "Blog Digest Task Flow Parameters"
- Section 30.4.5.4, "Blog Recent Posts Task Flow Parameters"
- Section 30.4.5.5, "Blogs Task Flow Parameters"

30.4.5.1 Blog Archives Task Flow Parameters

The Blog Archives task flow displays a composite list of blogs based on dates.

> **See Also:** Section 30.4.1, "Understanding the Blog Task Flows"

Parameters that are unique to the Blog Archives task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 30–2 describes the Blog Archives task flow parameters.

Table 30–2 Blog Archives Task Flow Parameters

Parameter	Description
`resourceId`	The resource ID of the blog folder (see Figure 30–6), which can be specified in the following formats: ■ *`connection_name/path_to_folder`* where *`connection_name`* is the name of the WebCenter Content connection, and *`path_to_folder`* is the path to the folder on WebCenter Content that you want to expose as a blog. ■ *`connection_name`*`#dCollectionID:`*`dCollectionId`* where *`connection_name`* is the name of the WebCenter Content connection, and *`dCollectionId`* is the collection ID of the folder on WebCenter Content that you want to expose as a blog.

30.4.5.2 Blog Banner Task Flow Parameters

The Blog Banner task flow task flow displays a banner for the blog.

> **See Also:** Section 30.4.1, "Understanding the Blog Task Flows"

Parameters that are unique to the Blog Banner task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 30–3 describes the Blog Banner task flow parameters.

Table 30–3 Blog Banner Task Flow Parameters

Parameter	Description
`resourceId`	The resource ID of the blog folder (see Figure 30–6), which can be specified in the following formats: ■ *`connection_name/path_to_folder`* where *`connection_name`* is the name of the WebCenter Content connection, and *`path_to_folder`* is the path to the folder on WebCenter Content that you want to expose as a blog. ■ *`connection_name`*#`dCollectionID`:*`dCollectionId`* where *`connection_name`* is the name of the WebCenter Content connection, and *`dCollectionId`* is the collection ID of the folder on WebCenter Content that you want to expose as a blog.
`imageURL`	(Optional) The background image to be used in the blog banner. When not specified, the background image will default to an image provided by the current skin.
`title`	(Optional) The title to be used for the blog banner. Default: The blog folder name.

30.4.5.3 Blog Digest Task Flow Parameters

The Blog Digest task flow displays a blog or blog post.

> **See Also:** Section 30.4.1, "Understanding the Blog Task Flows"

Parameters that are unique to the Blog Digest task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 30–4 describes the Blog Digest task flow parameters.

Table 30–4 Blog Digest Task Flow Parameters

Parameter	Description
`resourceId`	The target blog resource to display. This can be either a folder ID, in which case the blog listing for this folder will display, or a document ID, in which case the blog post will display. A folder can be specified in the following formats: ■ *`connection_name/path_to_folder`* where *`connection_name`* is the name of the WebCenter Content connection, and *`path_to_folder`* is the path to the folder on WebCenter Content that you want to expose as a blog. ■ *`connection_name`*#`dCollectionID`:*`dCollectionId`* where *`connection_name`* is the name of the WebCenter Content connection, and *`dCollectionId`* is the collection ID of the folder on WebCenter Content that you want to expose as a blog. **Note**: To allow users to add new blog posts (by clicking **New Post** in the task flow), the specified folder must have a security group assigned in WebCenter Content.
`year`	A four-digit number specifying the target year used to filter blog entries. Example: `2012`
`month`	A number from 1 to 12 specifying the target month used to filter blog entries. For this parameter to take effect, the Filter Year parameter must also be specified. Example: `10` (October)
`hideComments`	Specifies whether the Comments feature is exposed: ■ Selected: Hide the Comments link and pane. ■ Deselected (default): Show the Comments link and pane.
`pageSize`	The number of blog posts displayed in the Blog Digest Viewer before the Next and Previous icons are enabled. Default: `10`

30.4.5.4 Blog Recent Posts Task Flow Parameters

The Blog Recent Posts task flow displays a list of most recent blog posts.

> **See Also:** Section 30.4.1, "Understanding the Blog Task Flows"

Parameters that are unique to the Blog Recent Posts task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 30–5 describes the Blog Recent Posts task flow parameters.

Table 30–5 Blog Recent Posts Task Flow Parameters

Parameter	Description
`resourceId`	The resource ID of the blog folder (see Figure 30–6), which can be specified in the following formats: - *`connection_name/path_to_folder`* where *`connection_name`* is the name of the WebCenter Content connection, and *`path_to_folder`* is the path to the folder on WebCenter Content that you want to expose as a blog. - *`connection_name`*`#dCollectionID:`*`dCollectionId`* where *`connection_name`* is the name of the WebCenter Content connection, and *`dCollectionId`* is the collection ID of the folder on WebCenter Content that you want to expose as a blog.
`recentPostListSize`	The number of recent posts to display. Default: `10`

30.4.5.5 Blogs Task Flow Parameters

The Blogs task flow displays a blog or blog post with a default design.

See Also: Section 30.4.1, "Understanding the Blog Task Flows"

Parameters that are unique to the Blogs task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 30–6 describes the Blogs task flow parameters.

Table 30–6 Blogs Task Flow Parameters

Parameter	Description
`resourceId`	The target blog resource to display. This can be either a folder ID, in which case the blog listing for this folder will display, or a document ID, in which case the blog post will display. A folder can be specified in the following formats: - *`connection_name/path_to_folder`* where *`connection_name`* is the name of the WebCenter Content connection, and *`path_to_folder`* is the path to the folder on WebCenter Content that you want to expose as a blog. - *`connection_name`*`#dCollectionID:`*`dCollectionId`* where *`connection_name`* is the name of the WebCenter Content connection, and *`dCollectionId`* is the collection ID of the folder on WebCenter Content that you want to expose as a blog. **Note**: To allow users to add new blog posts (by clicking **New Post** in the task flow), the specified folder must have a security group assigned in WebCenter Content.
`hideComments`	Specifies whether the Comments feature is exposed: - Selected: Hide the Comments link and pane. - Deselected (default): Show the Comments link and pane.
`pageSize`	The number of blog posts displayed in the Blogs task flow before the Next and Previous icons are enabled. Default: `10`

Content Management REST API

This chapter supplements the OASIS CMIS specification, and provides details on the specific implementation of the Content Management REST Service.

The OASIS CMIS (Content Management Interoperability Services) Technical Committee works to standardize a Web services interface specification that will enable greater interoperability of Enterprise Content Management (ECM) systems. For more information, see the OASIS CMIS site:

`http://www.oasis-open.org/committees/cmis/`

Before continuing, all users should review the OASIS CMIS specification. This chapter references the Content Management Interoperability Services (CMIS) Version 1.0, which can be viewed at the following URL:

`http://docs.oasis-open.org/cmis/CMIS/v1.0/cmis-spec-v1.0.html`.

The Content Management REST Service provides a server that uses the CMIS RESTful AtomPub server binding to provide access to Oracle Content Server repositories configured in your application.

The specification includes the domain model and two server bindings. As mentioned above, only the RESTful AtomPub binding is currently implemented by the Content Management REST Service. Users should be familiar with Atom and AtomPub, which are the default formats for responses.

> **Note:** CMIS provides a lowest common denominator for a wide range of different content systems; it is not aligned directly with Oracle WebCenter Content functionality. Refer to the Content Management REST Service service document to identify available functionality.

This chapter includes the following sections:

- Section 31.1, "CMIS Domain Model"
- Section 31.2, "CMIS Part II: RESTful AtomPub Binding"
- Section 31.3, "Content Management REST Service Best Practices and Examples"

31.1 CMIS Domain Model

Section 2: Domain Model in the CMIS specification defines a domain model that can be used by applications to work with one or more Content Management repositories.

- Section 31.1.1, "Data Model"

- Section 31.1.2, "Services"

31.1.1 Data Model

The Content Management REST Service service document consists of AtomPub workspaces. Each workspace maps to a content connection (only Oracle WebCenter Content repositories are supported by the Content Management REST Service). For details on the service document, see the next section, Section 31.2, "CMIS Part II: RESTful AtomPub Binding".

31.1.1.1 Repository

For this release, some of the optional capabilities listed in section 2.1.1 have not been implemented. Versioning, ACL, Policies, Relationships, Change Log, Folder Descendants/Tree, and Renditions will be considered for future releases.

Specifically, the Content Management REST Service implementation has the following optional capabilities:

```
capabilityGetDescendants = true
capabilityGetFolderTree = false
capabilityContentStreamUpdatability = anytime
capabilityChanges = none
capabilityRenditions = none
capabilityMultifiling = false
capabilityUnfiling = false
capabilityVersionSpecificFiling = false
capabilityPWCUpdateable = false
capabilityPWCSearchable = false
capabilityAllVersionsSearchable = false
capabilityJoin = none
capabilityACL = none
capabilityQuery = none, metadataonly, or both combined
```

31.1.1.2 Object

The Content Management REST Service supports document and folder objects. In CMIS the `cmis:baseTypeId` for a Node will be `cmis:folder` or `cmis:document`. Also, the `cmis:baseId` for a Type will be `cmis:folder` or `cmis:document`.

31.1.1.3 Object-Type

A CMIS Object-Type contains fields mapped from the Oracle WebCenter Content: WebCenter Content metadata field definitions and Oracle WebCenter Content's Site Studio region definitions.

The mapping from Oracle WebCenter Content metadata fields to CMIS property definitions is as follows:

Table 31–1 WebCenter Content Metadata Mappings

Oracle WebCenter Content Metadata	CMIS Property Definition
TEXT metadata field with option list configured with select list validated and YesNoView or TrueFalseView view	cmis:propertyBoolean
All other TEXT metadata fields	cmis:propertyString
LONG TEXT metadata field	cmis:propertyString
MEMO metadata field	cmis:propertyString
INTEGER metadata field	cmis:propertyInteger

Table 31–1 (Cont.) WebCenter Content Metadata Mappings

Oracle WebCenter Content Metadata	CMIS Property Definition
DATE metadata field	cmis:propertyDateTime
DECIMAL metadata field	cmis:propertyDecimal

The mapping from Site Studio region definition fields to CMIS property definitions is as follows:

Table 31–2 Site Studio Region Definition Mappings

Site Studio Region Definition	CMIS Property Definition
Image Element Definition fields	cmis:propertyString
WYSIWYG Element Definition fields	cmis:propertyString
Plain Text Element Definition fields	cmis:propertyString
Static List Element Definition fields	cmis:propertyString

31.1.1.4 Document Object

Document Objects are the elementary information entities managed by the repository. As defined by the CMIS specification, Document Objects may be version-able, file-able, query-able, control-able and ACLControl-able. As stated earlier, the Content Management REST Service does not support versioning, multi-filing, Policies or ACL for this release.

If a Node is determined to be a Document (not a Folder) then any children it has will not be exposed through CMIS. In CMIS, each Document Object is associated with a single content stream, and for WebCenter CMIS REST, this stream is the Oracle WebCenter Content: WebCenter Content binary associated with the document.

31.1.1.5 Folder Object

The CMIS specification states that Folder Objects do not have a content-stream and are not version-able. If a Node is determined to be a Folder, then the Content Management REST Service exposes it in this manner. (In Oracle WebCenter Content, folders do not have a content stream and are not versionable).

31.1.1.6 Relationship Object

Section 2.1.6: Relationship Object in the CMIS specification is not applicable; the Content Management REST Service does not support Relationships for this release.

31.1.1.7 Policy Object

Section 2.1.7: Policy Object in the CMIS specification is not applicable; the Content Management REST Service does not support Policies for this release.

31.1.1.8 Access Control

Most of *Section 2.1.8: Access Control* in the CMIS specification is not applicable; the Content Management REST Service does not support ACL for this release. See the next section for details on allowable actions.

31.1.1.8.1 AllowableActions Mapping This section lists allowable actions defined for Objects. Because of how this release is implemented, some of these are hard-coded for all objects. Other allowable actions will be set based on the repository configuration.

- canGetObjectRelationships = false
- canCreateRelationship = false
- canGetDescendants = false
- canGetFolderTree = false
- canCheckOut = false (versioning)
- canCancelCheckOut = false (versioning)
- canCheckIn = false (versioning)
- canAddObjectToFolder = false (multi-filing)
- canRemoveObjectFromFolder = false (unfiling/multi-filing)
- canApplyPolicy = false
- canGetAppliedPolicies = false
- canRemovePolicy = false
- canCreatePolicy = false
- canApplyACL = false
- canGetACL = false
- canGetRenditions = false
- canDeleteTree = true
- canGetAllVersions = false (versioning)

31.1.1.9 Versioning

Section 2.1.9: Versioning in the CMIS specification is not applicable; the Content Management REST Service does not support versioning for this release.

31.1.1.10 Query

CMIS queries return a Result Set where each Entry object will contain only the properties that were specified in the query. The Content Management REST Service does not support JOINs in queries, so each result entry will represent properties from a single node. Common searches use a query like "SELECT * FROM …".

- The FROM clause specifies a content-type to be searched.
  - FROM cmis:document ==> any Oracle WebCenter Content document (for example, IDC:GlobalProfile)
  - FROM cmis:folder ==> any Oracle WebCenter Content folder (for example, IDC:Folder)
  - FROM typeQueryName ==> type's cmis queryName, as long as the type is queryable (for example, ora:t:IDC!;GlobalProfile)
- The cmis:document and cmis:folder types are always queryable. Other types will be queryable if they are searchable in the repository.
- The IN_FOLDER predicate is implemented as the folder ID specified, being the parent of the results.
- The IN_TREE predicate is implemented as the folder ID specified, being a parent in the folder structure of the results.
- The CONTAINS() predicate is a full-text query expression operator.

- Properties of cmis:document and cmis:folder will be queryable and orderable if their corresponding Oracle WebCenter Content system property is searchable and sortable. The system property mappings are:
  - cmis:createdBy ==> dDocAuthor
  - cmis:lastModifiedBy ==> dDocCreator
  - cmis:creationDate ==> dCreateDate
  - cmis:lastModificationDate ==> dLastModifiedDate (for 10g, folders map to dLastModifiedDate and documents map to dCreateDate)
  - cmis:name ==> dOriginalName (for a document) or dCollectionName (for a folder)
  - cmis:contentStreamFileName ==> dOriginalName
  - cmis:contentStreamLength ==> VaultFileSize
  - cmis:contentStreamMimeType ==> dFormat
  - cmis:objectId ==> dDocName
  - cmis:objectTypeId ==> Oracle WebCenter Content profile name or SiteStudio Region Definition name

    Note: cmis:objectTypeId is never orderable.

  - cmis:path ==> use IN_FOLDER or IN_TREE predicate

    Note: Some repositories may have capabilities that are not representable in a CMIS query, and some repositories may have restrictions which will limit the CMIS-query predicates (or combinations of predicates) that can be used in a query. Use the mappings above to translate repository capabilities and restrictions into corresponding considerations for CMIS queries.

- Nested properties are not queryable or orderable.
- The Content Management REST Service implementation reports as orderable any properties which Oracle WebCenter Content specifies as sortable. This list can include properties which Oracle WebCenter Content cannot actually sort on. To allow ordering on a field for which Oracle WebCenter Content reports a sort error, follow the steps below to make the specified Oracle WebCenter Content field sortable:
  1. Go to **Administration** and open **Admin Applets**.
  2. Open the Configuration Manager applet and click **Advanced Search Design.**
  3. Edit the field you wish to make orderable and select **Is sortable**.
  4. Save your changes and exit Administration.

The table that follows lists specific search considerations and recommendations. For example queries, see Section 31.3, "Content Management REST Service Best Practices and Examples."

Table 31–3 Search Considerations and Recommendations

Consideration	Recommendation
Oracle WebCenter Content provides limited support for querying on null or non-null values.	Be aware of the differences in search behavior and do not write search expressions that depend on unsupported criteria.
Recursive search for folders is not supported by Oracle WebCenter Content, but is supported for documents if configured on the Oracle WebCenter Content server as described to the right.	Scope the search to only include documents (add a select clause like `select * from cmis:document`). Set the search path on the Search object (add a where clause like "`where IN_TREE('/StellentRepository/IDC:Folder/2`'). Configure the `folders_g CollectiveSearchRecursiveContent` and related settings like `CollectionMaxBranch` in the Oracle WebCenter Content config.cfg file.
Multivalued property operators perform substring matches. This is true for `ANY <multiValuedQueryName> IN (<literal>, ...)` or `<literal> = ANY < multiValuedQueryName>`. In Oracle WebCenter Content, a field with an option list stores values in a comma-delimited manner. For example, if you have values "A", "B", and "C", these will be represented as "A, B, C". Using an ANY or ANY IN search for 'A, B' will find this item.	Be aware of the differences in search behavior and consider changing the Oracle WebCenter Content option list delimiter character in the Configuration Manager applet to reduce the potential for finding extra matches.
When searching folders (`FROM cmis:folder`), at most one value can be specified per criteria. Each criteria is logically ANDed with the others to make a more selective query. There is no support for `OR` or `NOT` operators when searching folders.	Do not use `OR` and `NOT` in Oracle WebCenter Content folder search.
Not all properties are searchable, and if the search encounters a property that is not searchable, it will return a ParseException (400 error).	Understand which properties are searchable for a given content type by examining the Oracle WebCenter Content Configuration Manager information fields section, or by reviewing the ContentType definition. Examine the URL for the `isSearchable` field setting Example URLS: `http://myContentServer/idc/idcplg?IdcService=VCR_GET_CONTENT_TYPE&vcrContentType=IDC:Folder&IsSoap=1` Or, examine the specific type through CMIS.
Not all ContentTypes are searchable. An attempt to search for a non-searchable ContentTypes will throw an exception. For example, the `IDC:FileReference` ContentType is not searchable.	Be aware that not all ContentTypes are searchable.
Only String multi-valued properties can be searched.	Do not specify search for multi-valued property types other than String.
The `NOT` operator cannot be used for `LONG` properties.	Try to restructure the query using supported syntax.
Only one sort criteria is supported.	Do not write search expressions that use more than a single sort criteria.

Table 31–3 (Cont.) Search Considerations and Recommendations

Consideration	Recommendation
Sorting on non-indexed fields results in an exception. Searching on a non-indexed field throws an exception, with the embedded exception code of, for example, "DRG-10837: section dStatus does not exist".	Understand which fields have been indexed before using them as sort criteria. Examine the URL for the `isSortable` field definition. Example URL: `http://myContentServer/idc/idcplg?IdcService=GET_ADVANCED_SEARCH_OPTIONS&IsSoap=1,` Or examine the type through CMIS to see if the property definition is queryable.
Empty values are not allowed in a search query.	Do not use a criteria such as `cmis:name != ''..`
The `Notequals` operator is not supported for non-String properties	Be aware of the differences in search behavior and do not write search expressions that depend on unsupported criteria.
Multiple search paths on the same Oracle WebCenter Content repository are not supported.	Be aware of the differences in search behavior and do not write search expressions that depend on unsupported criteria.
When searching for documents, recursive search (folder tree search) is supported if Oracle WebCenter Content is configured properly. If the search path is not set, then all documents in the repository will be searched (both filed and unfiled).	Configure the content server `folders_g CollectionSearchRecursiveContent` and related settings like `CollectionMaxBranch` in the Oracle WebCenter Content config.cfg file. These settings are described in the Oracle WebCenter Content documentation. To perform a document search scoped to a folder tree, use the IN_TREE predicate.
When searching for documents and using the `LIKE` operator, wildcards (`%`) are only supported in the last path element.	Be aware of the differences in search behavior and do not write search expressions that depend upon unsupported criteria.
When searching documents (select * from cmis:document), it is not possible to limit the search to more than just a single content type; for example, this is not supported: `select * from IDC:MyProfile, IDC:AnotherProfile` because it has multiple explicit content types and `JOINS` are not supported.	If you need to limit the search to more than just a single content type, issue multiple queries to achieve the same behavior. If you want to search across all types, use cmis:document in the select statement.
Oracle WebCenter Content search does not support `OR` when `cmis:objectTypeId` is specified in a query; other parameters can be ANDed with this criteria, but `OR` is not supported.	If this functionality is necessary, issue multiple queries to achieve the same behavior.
The `cmis:objectTypeId` criteria only supports `==`, `!=`, and `like`. Use of `!=` is restricted to the case of excluding folders (which behaves the same as adding `select * from cmis:document`).	Be aware of the valid operators when using `cmis:objectTypeId` criteria.
Queries may be case-sensitive depending on the selected Oracle WebCenter Content search engine.	Be aware that the Oracle WebCenter Content search engine selection can affect case-sensitivity. Metadata searches using OracleTextSearch as the search engine are generally case-insensitive. Metadata searches using `DATABASE.FULLTEXT` as the search engine are generally case-sensitive. The exact behavior sometimes varies by metadata field.

31.1.2 Services

The methods described in *Section 2.2 Services* of the CMIS specification are implemented by the Content Management REST Service; specific implementation details are covered in Section 31.2, "CMIS Part II: RESTful AtomPub Binding."

31.2 CMIS Part II: RESTful AtomPub Binding

Section 3: RESTful AtomPub Binding in the CMIS specification defines a specification based on AtomPub that can be used by applications to work with one or more Content Management Repositories. REST services are available through a portal instance.

31.2.1 Service Document

All navigation of a repository begins with the AtomPub Service Document. From this document, all accessible content in a repository can be discovered through the collections, links, and templates.

The URI to the service document, relative to the CMIS web application's context-root, is /rest/cmis/repository.

Therefore, if an application is deployed with a library-context-root-override as in the example above, the service document would be accessed through the following URL:

```
http://hostname:port/rest/cmis/repository
```

> **Note:** The REST application is only available with portals and not with Portal Framework applications. However, you can make HTTP requests from your Framework application to access the REST and CMIS resources that are available in a portal. You must make sure that the portal instance is configured with the relevant content connections that you wish to access.

By default, this document will contain a workspace for each configured Oracle WebCenter Content repository (only Oracle WebCenter Content repositories are supported by CMIS REST in Oracle WebCenter Portal). A service document for a single repository can be obtained by using the `repositoryId` query parameter, as described in section 3.6.2.1 of the CMIS AtomPub binding specification.

As noted in the previous section, the service document consists of AtomPub workspaces. Each workspace maps to a Oracle WebCenter Portal WebCenter Content connection.

Specific URIs beyond the service document are not published; it is assumed that users will start at the service document and navigate the collections and links down expected paths. The relationships of the links and the titles and types of the collections are all defined in the CMIS specification, and thus can be commonly navigated by a client implementation. There are also templates defined for each repository, for easier access of objects by path, object by ID, type by ID, and queries. The format of the variables for the path and ID templates can be discovered by viewing the Entries of Folders and Documents.

31.2.2 Response Formats

Section 3.1.3: Response Formats in the CMIS specification indicates that Atom/AtomPub style formats will be returned by default unless overridden by a supported media type expressed in the Accept header.

A generic AtomPub feed reader can walk through any of the feeds returned by the CMIS REST server. It will not see all the CMIS specifics, but will be able to navigate through links. In general, to set up a feed reader, you need to know the URI of a particular feed, which can be discovered by navigating through the service document, for example, the workspace link for "typesdescendants".

For details on query syntax, see the CMIS specification. For Content Management REST Service best practices and examples, see Section 31.3, "Content Management REST Service Best Practices and Examples."

31.2.3 Additional Functionality

The Content Management REST Service provides the following additional functionality beyond the CMIS specification.

- Section 31.2.3.1, "Folder Children Collection"
- Section 31.2.3.2, "Document Entry"
- Section 31.2.3.3, "Content Stream"

31.2.3.1 Folder Children Collection

The specification defines the following CMIS services:

- GET: getChildren
- POST: createDocument
  or createFolder
  or createPolicy
  or moveObject
  or addObjectToFolder

The Content Management REST Service provides the following additional services:

- POST: create
  This service has five query parameters: uid, fileName, contentId, comments, simpleResponse, and one header parameter: Slug. This service is meant to be used as a simple binary request upload. A new document is created with this service. Slug and fileName are used to name the binary that is attached to the request (using both parameters is optional; only one needs to be defined and fileName is checked first). The comments parameter is optional and contentId is optional if Oracle WebCenter Content is set up to auto-generate the dDocName.
- POST: create Content-Type: multipart/form-data
  This service has a single query parameter: uid, which is the uid of the folder in which the document is to be created. The boolean query parameter simpleResponse will return a response of media type: application/atom+xml;type=entry, if set to false. If set to true, a response of media type: text/html will be returned with a URI pointing to the newly created document. The comments and simpleResponse parameters are both optional, contentId is optional if Oracle WebCenter Content is set up to auto-generate the dDocName, and the name "fileUpload" is required.

```
<html>
<head>
    <title>simple post</title>
</head>
<body>
<form
action="http://<host>:<port>/rest/api/cmis/children/StellentRepository?uid=IDC:
```

```
Folder/2"
      method="POST"
      enctype="multipart/form-data">
    Select a document to upload: <input type="file" name="fileUpload"/><br>
     <input type="hidden" name="comments" value="this is just a comment"/>
     <input type="hidden" name="contentId" value="uniqueID1"/>
     <input type="hidden" name="simpleResponse" value="true"/>
    <input type="submit" value="Submit"/>
</form>
</body>
</html>
```

31.2.3.2 Document Entry

The specification defines the following CMIS services:

- GET: getObject, getObjectOfLatestVersion (getObject)
- PUT: updateProperties
- DELETE: deleteObject

The Content Management REST Service provides the following additional services:

- POST: postToDelete
  This service has two query parameters: uid and _method, and allows a document to be deleted through POST.

  ```
  http://<host>:<port>/rest/api/cmis/document/repoName?uid=ABC&_method="delete"
  ```

31.2.3.3 Content Stream

The specification defines the following CMIS services:

- GET: getContentStream
- PUT: setContentStream
- DELETE: deleteContentStream

The Content Management REST Service provides the following additional services:

- POST: postTunnelContentStream
  This service has five query parameters: uid, overwriteFlag, fileName, comments, _ method, and one header parameter: Slug. This service is meant to be used as a simple binary request upload or delete through POST. A document must already exist for this service. Slug and fileName are used to name the binary that is attached to the request (using both parameters is optional; only one needs to be defined and fileName is checked first). The overwriteFlag parameter defaults to true, the comments parameter is optional and valid values for _method are "delete" or "put" (not case sensitive).

  ```
  http://<host>:<port>/rest/api/cmis/stream/repoName?uid=ABC&_method="delete"
  ```

- POST: postTunnelContentStream
  Content-Type: multipart/form-data
  This service has a single query parameter: uid and is meant to be used as a simple html multipart/form-data upload or delete through POST. A document must already exist for this service. The attribute name="fileUpload" is required, "comments" is optional, and valid values for "_method" are "delete" or "put" (not case sensitive).

  ```
  <form
  action="http://<host>:<port>/rest/api/cmis/stream/repoName?uid=WDOC019113"
  ```

```
          method="POST"
          enctype="multipart/form-data">
        Select a document to upload: <input type="file" name="fileUpload"/><br>
         <input type="hidden" name="comments" value="this is just a comment"/>
         <input type="hidden" name="_method" value="PUT"/>
        <input type="submit" value="Submit"/>
    </form>
```

31.3 Content Management REST Service Best Practices and Examples

This section provides best practices and examples using the Content Management REST Service. For details on query syntax, see the CMIS specification.

This section includes the following subsections:

- Section 31.3.1, "Best Practices"
- Section 31.3.2, "Content Management REST Service Examples"

31.3.1 Best Practices

The following list provides suggested best practices for repositories that use the Content Management REST Service.

- To determine the types that can be used in the "FROM" portion of a query, see the types collection from the AtomPub service document. The type must be queryable and the query name of that type must be used.

  For example, IDC:GlobalProfile might have type information similar to the following:

  ```
  <cmis:localName>IDC:GlobalProfile</cmis:localName>
  <cmis:displayName>IDC:GlobalProfile</cmis:displayName>
  <cmis:queryName>ora:t:IDC!;GlobalProfile</cmis:queryName>
  <cmis:queryable>true</cmis:queryable>
  ```

  An example query for the type information above could be: "SELECT * FROM ora:t:IDC!;GlobalProfile".

- To determine the properties that can be used in the "SELECT" and "WHERE" portions of a query, see the entry for the associated type. Each property definition of that type will be listed and will have a setting for queryable and orderable. The cmis:queryname will be the value to be used in the query.

  For example, IDC:GlobalProfile might have property definition information similar to the following:

  ```
  <cmis:propertyStringDefinition>

  <cmis:id>/stanl18-ucm11g/IDC:GlobalProfile.ora:p:dDocName</cmis:id>
                <cmis:localName>dDocName</cmis:localName>
                <cmis:displayName>dDocName</cmis:displayName>
                <cmis:queryName>ora:p:dDocName</cmis:queryName>
                <cmis:description>Content ID</cmis:description>
                <cmis:propertyType>string</cmis:propertyType>
                <cmis:cardinality>single</cmis:cardinality>
                <cmis:updatability>readwrite</cmis:updatability>
                <cmis:inherited>false</cmis:inherited>
                <cmis:required>false</cmis:required>
                <cmis:queryable>true</cmis:queryable>
                <cmis:orderable>true</cmis:orderable>
              </cmis:propertyStringDefinition>
  ```

An example query for the property definition information above could be: "SELECT ora:p:dDocName FROM ora:t:IDC!;GlobalProfile"

- To keep queries more readable, avoid non-alphanumeric characters in ContentType and PropertyDefinition names.

31.3.2 Content Management REST Service Examples

This section provides some example queries. For details on query syntax, see the CMIS specification. (To get the full URI for a query, see the query URI template in the service document.)

- SELECT * from cmis:folder
- SELECT cmis:name, cmis:contentStreamFileName, cmis:contentStreamMimeType, cmis:contentStreamLength FROM cmis:document WHERE cmis:contentStreamFileName = 'BinaryName' AND cmis:contentStreamMimeType = 'text/html' AND cmis:contentStreamLength > 1
- SELECT cmis:name, cmis:creationDate, cmis:lastModificationDate FROM cmis:folder WHERE cmis:name = 'Trash' AND cmis:lastModificationDate > TIMESTAMP '2008-05-18T10:32:44.703-06:00'
- SELECT * FROM cmis:document WHERE cmis:name LIKE 'baker%'
- SELECT * FROM cmis:document WHERE cmis:name NOT IN ('nodeBoolean', 'nodeLong')
- SELECT cmis:name from cmis:document where IN_TREE('/StellentRepository')
- SELECT * FROM ora:t:IDC:GlobalProfile WHERE ora:p:xBooleanTestField = FALSE ORDER BY ora:p:dDocTitle ASC
- SELECT ora:p:xMultiValuedDelimiterTest FROM ora:t:IDC:GlobalProfile WHERE ANY ora:p:xMultiValuedDelimiterTest NOT IN ('four')
- SELECT cmis:name FROM ora:t:IDC:GlobalProfile WHERE CONTAINS('test') ORDER BY ora:p:dInDate DESC
- SELECT * FROM cmis:document where IN_TREE('/StellentRepository/IDC:Folder/2')

Part V

Enabling Communication and Collaboration

Part V contains the following appendixes:

32

Integrating Announcements

This chapter explains how to integrate announcements into a Portal Framework application at design time.

This chapter includes the following sections:

- Section 32.1, "Introduction to Announcements"
- Section 32.2, "Basic Configuration for Announcements"
- Section 32.3, "Advanced Information for Using Announcements"

For more information about managing and including announcements, see:

- the "Managing Announcements and Discussions" chapter in *Administering Oracle WebCenter Portal*
- the "Working with Announcements" chapter in *Using Oracle WebCenter Portal*

32.1 Introduction to Announcements

With portals and Framework applications, you can create and expose announcements on your application pages. Access to announcements boosts community participation, problem resolution, and knowledge sharing.

Note that while for portals, announcements can show either forum-level announcements or global announcements (that is, system announcements not specific to a forum), for Framework applications only global announcements are shown.

This section includes the following subsections:

- Section 32.1.1, "Understanding Announcements"
- Section 32.1.2, "Requirements for Announcements"
- Section 32.1.3, "What Happens at Runtime"

32.1.1 Understanding Announcements

With WebCenter Portal, you can do the following:

- Create announcements
- Edit and delete existing announcements
- Mail announcements
- Personalize the way in which announcements are viewed. You can select to display all announcements or only announcements sent today, this week, or this month. You can also view future, active, or expired announcements.

- Manage announcements, such as publishing announcements on a later date and specifying auto-expire on certain dates.

Announcements are integrated with many other WebCenter Portal features, such as activities, RSS feeds, and instant messaging and mail, and you can link announcements to other WebCenter Portal features such as events and discussions. For example, suppose your company is announcing a new product, you can link from the announcement directly to a discussion forum, where potential customers can ask other customers about the product, or link to an instant messaging tool to speak directly with a customer service representative to find out about or purchase the product.

32.1.2 Requirements for Announcements

To use announcements in a Framework application you must have installed and configured the discussions server that comes with Oracle Fusion Middleware.

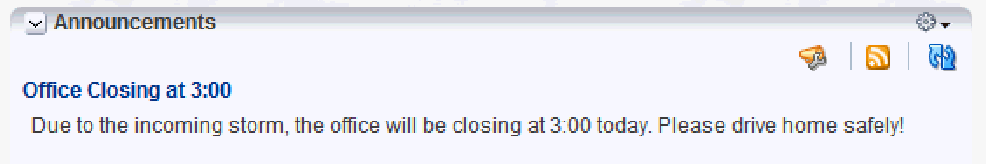
See Also: *Installation Guide for Oracle WebCenter Portal*

32.1.3 What Happens at Runtime

At runtime, users who have been granted the `Create Announcements` permission can post announcements, and these announcements are visible to all users who have `View Announcements` permission. For example, an application specialist can use announcements to showcase the availability of a new feature or the plan to shut down the application temporarily for maintenance.

Figure 32–1 shows a sample announcement at runtime.

Figure 32–1 Sample Announcement in the Announcements - Quick View Task Flow



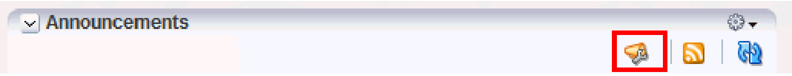
Announcements

Office Closing at 3:00

Due to the incoming storm, the office will be closing at 3:00 today. Please drive home safely!

To view announcements in the Announcement Manager, ensure that the Announcements task flow has been added to your Framework application. Then log in to your application and click the **Open Announcement Manager** icon in the Announcements task flow (Figure 32–2).

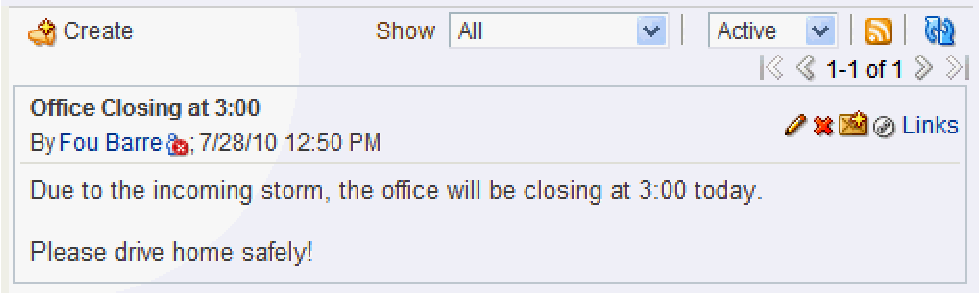
Figure 32–2 Open Announcement Manager Icon



Note: The **Open Announcement Manager** icon does not display if the user does not have the required privileges.

Figure 32–3 shows the sample announcement in the Announcement Manager.

Figure 32–3 Sample Announcement in the Announcement Manager



Office Closing at 3:00

By Fou Barre; 7/28/10 12:50 PM

Due to the incoming storm, the office will be closing at 3:00 today.

Please drive home safely!

Application administrators in Framework applications can access the Announcement Manager, which provides **Create**, **RSS**, and **Refresh** icons, and **Show** dropdown lists to control the display of announcements on the page. **Edit**, **Delete**, **Mail**, and **Links** icons are available for each announcement in the list.

Depending on the privileges users have on the page and what has been made available in WebCenter Portal and is configured in the application, users may see only a subset of these options in the Announcement Manager. For example, the **Delete** icon is displayed only to users with administrative privileges.

For more information about announcements at runtime, see the "Working with Announcements" chapter in *Using Oracle WebCenter Portal*.

32.2 Basic Configuration for Announcements

This section describes required steps for adding announcements to your Framework application. It includes the following subsections:

- Section 32.2.1, "Setting Up a Connection for Announcements"
- Section 32.2.2, "Adding Announcements at Design Time"
- Section 32.2.3, "Setting Security for Announcements"

32.2.1 Setting Up a Connection for Announcements

To take advantage of announcements, you must first create a connection to the discussions server from your application. To do so, ensure that you have the connection information for the discussions server.

32.2.1.1 Announcements Connections

Announcements requires a Discussion Forum connection to the discussions server. You can register additional Discussion Forum connections, but only one connection is active at a time.

When you create a Discussion Forum connection or set a connection as active, both announcements and discussions use this same connection. If you have an existing connection, then you can skip this section and see Section 32.2.2, "Adding Announcements at Design Time."

If you do not have an existing connection, then you must create a new Discussion Forum connection.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, see *Administering Oracle WebCenter Portal*.

32.2.1.2 How to Set Up Connections for Announcements

To set up the Announcements connection:

1. In Oracle JDeveloper, open the application in which you plan to consume Announcements.

   > **Note:** If you created a Discussion Forum connection for announcements, then that is used by default for announcements. No extra configuration is required.

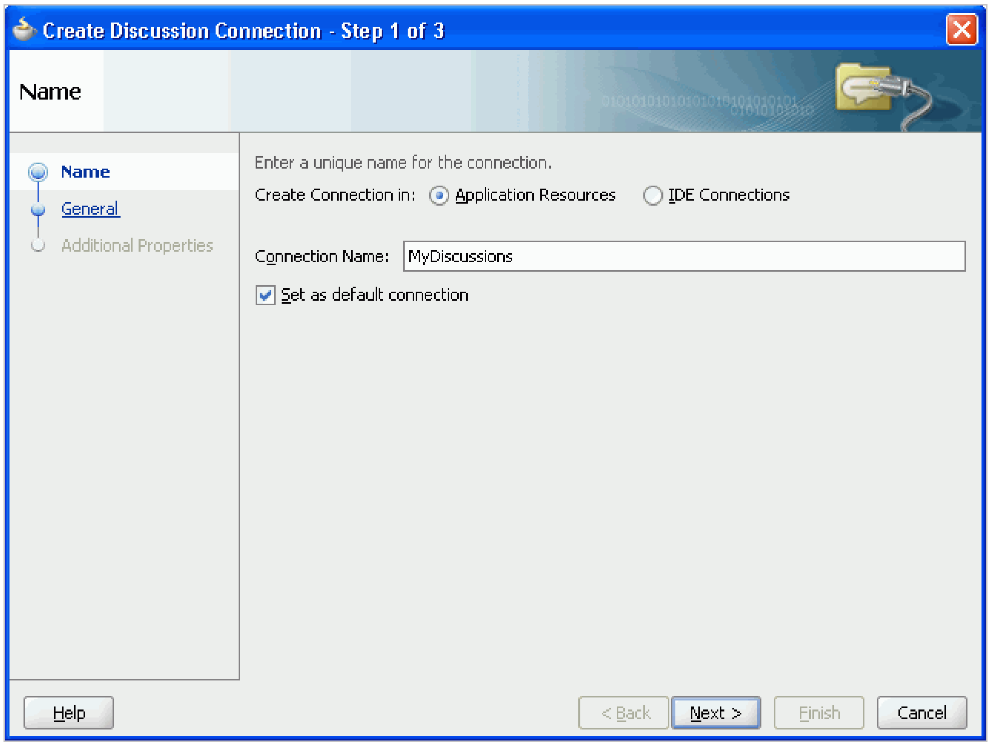
2. In the Application Navigator, under Application Resources, right-click **Connections**, then select the new connection **Discussion Forum** from the list.
3. On the **Name** page, select to create the connection in **Application Resources**. (A connection in Application Resources is available only for that application, while a connection in IDE Connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE Connections so you do not need to re-create it.)

   > **Note:** If you create a connection in IDE and not in the application, then the connection must be added to the application. For example, in the Resource Palette under IDE Connections, right-click the connection and select **Add to Application**.

4. For **Connection Name**, enter a meaningful name; for example, `MyDiscussions`.
5. Select the **Set as default connection** check box. You can have multiple connections, but only one can be active (default). If you have different discussions servers (for example, for each page in your application), then do not select the check box, but one connection must be marked as the active connection (Figure 32–4).

   > **Note:** After you create a connection as the active connection, you cannot edit it so that it is *not* the default. To use a different default connection, you must create a new connection and mark that as the default connection.

Figure 32–4 Create Discussion Connections, Step 1



Create Discussion Connection - Step 1 of 3

Name

Enter a unique name for the connection.

Create Connection in: ● Application Resources ○ IDE Connections

Connection Name: MyDiscussions

☑ Set as default connection

6. Click **Next**.

7. On the **General** page, enter values for the required parameters:

   - `URL`: Enter the URL of the discussions server; for example: `http://discussions.example.com:8888/owc_discussions`.
   - `Admin User`: The user name of your discussions server administrator; for example, `admin`. This account is used by discussions and announcements to perform administrative operations on behalf of WebCenter Portal users.

     In WebCenter Portal, this account is mostly used for managing portal-related discussions and announcements. It is not necessary for this user to be a super admin. However, the user must have administrative privileges on the current root category for WebCenter Portal, that is, the category (on the discussions server) under which all portal-related discussions and announcements are stored.

8. Optionally, enter a value for the other parameters:

   - `Connection Timeout`: Specify a suitable timeout for the connection. This is the length of time (in seconds) the application waits for a response from the discussions server before issuing a connection timeout message. The default is -1, which means that a default value of 10 seconds is used.
   - `Policy URI for Authenticated Access`: Select the SAML token client policy this connection uses for authenticated access to the discussions server Web service. SAML (Security Assertion Markup Language) is an XML-based standard for passing security tokens defining authentication and authorization rights. An attesting entity (that has trust relationship with the receiver) vouches for the verification of the subject by method called sender-vouches. Options available are:

- WSS 1.0 SAML Token Client Policy (oracle/wss10_saml_token_client_policy)
- WSS 1.1 SAML Token With Message Protection Client Policy (oracle/wss11_saml_token_with_message_protection_client_policy)

The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServiceAuthenticated` endpoint in the discussions server. Out-of-the-box, the default service policy is WSS 1.0 SAML Token Service Policy (oracle/wss10_saml_token_service_policy).

- `Policy URI for Public Access`: Select the client policy this connection uses to enforce message security and integrity for public access to the discussions server Web service. Options available are:

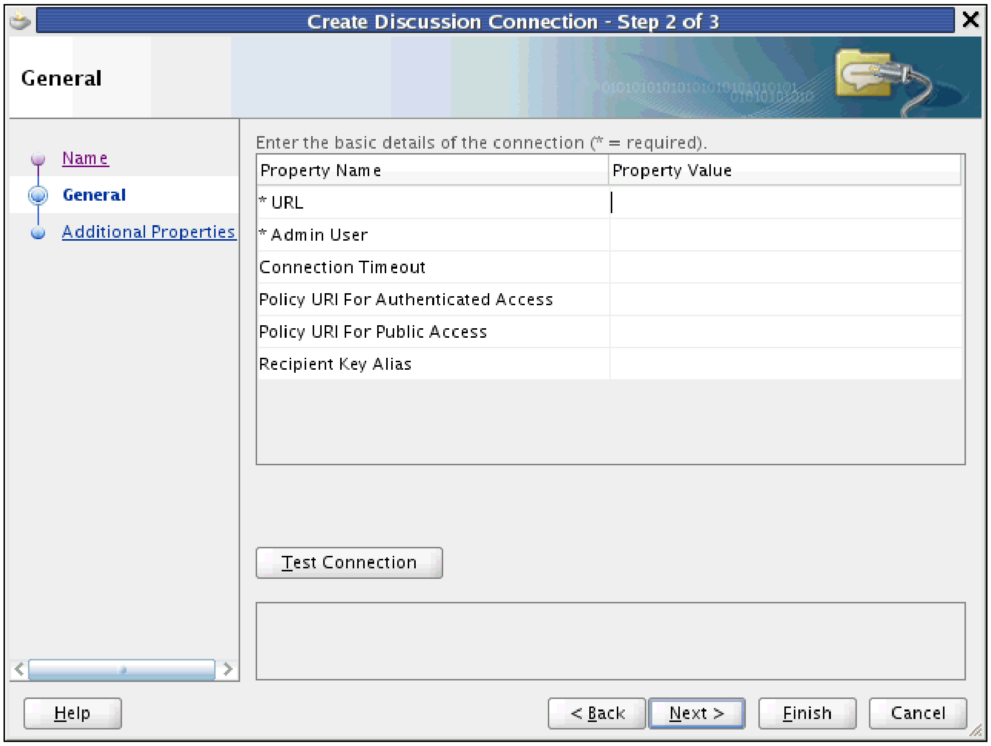
  - None - This is the default setting.
  - WSS 1.1 Message Protection Client Policy (oracle/wss11_with_message_protection_client_policy)

  The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServicePublic` endpoint in the discussions server. Out-of-the-box, a service policy is not configured for public access.

- `Recipient Key Alias`: Enter the recipient key alias to be used for message protected policies (applicable to the `OWCDiscussionsServicePublic` and `OWCDiscussionsServiceAuthenticated` endpoints). This is the alias to the certificate that contains the public key of the discussions server in the configured keystore.

  For more information, see the "Configuring WS-Security" chapter in *Administering Oracle WebCenter Portal*.

Figure 32–5 Create Discussions Connection, Step 2



Create Discussion Connection - Step 2 of 3

General

Enter the basic details of the connection (* = required).

Property Name	Property Value
* URL	
* Admin User	
Connection Timeout	
Policy URI For Authenticated Access	
Policy URI For Public Access	
Recipient Key Alias	

9. Click **Test Connection**, and if it is successful, then click **Next**.
10. On the **Create Discussion Connection - Step 3 of 3** page, you can configure additional parameters. For example:

    `application.root.category.id`: (WebCenter Portal only) The application root category ID on the discussions server under which all discussion forums are stored. For example, if set to 3, then all forums are stored inside the category 3.

    > **Note:** To encrypt property values, such as passwords, click **Add Secured Property**.

11. Click **Finish**. Your connection should now appear as a node under **Application Resources - Connections**.

32.2.2 Adding Announcements at Design Time

This section explains how announcements can be incorporated at design time.

32.2.2.1 Announcements Task Flows

Both the Announcements and the Announcements - Quick View task flows display current announcements. The Announcements task flow additionally offers tools for managing announcements within the task flow. With the Announcements - Quick View task flow, you must click the **Open Announcement Manager** icon to manage announcements, and administrators can configure this task flow to remove all announcement management functionality.

Table 32–1 Announcements Task Flows

Task Flow	Description
Announcements	This task flow displays a view that allows the user to see all current announcements and perform operations based on their privileges. For a Moderator, all command buttons are shown, but for a Reader, only the refresh and personalization options are shown. The personalization option lets users select the number of days to display announcements. The `parentId` parameter is the forum ID in the discussions server under which announcements are maintained. Each Framework application should create a forum on the discussions server.
Announcements - Quick View	This task flow displays a view that shows various categories of quick links to announcements. The `parentId` parameter is the forum ID in the discussions server under which announcements are maintained. Each Framework application should create a forum on the discussions server. The look and feel of this view changes with the optional parameter values given for rendering the task flow region. For information on how to add this task flow, see Section 32.3.1, "How to Add the Announcements - Quick View Task Flow."

32.2.2.2 How to Add Announcements to Your Page

The Announcements task flow provides a complete view of your announcements. To add the Announcements task flow to your Framework application:

1. Follow the steps described in Chapter 2, "Setting Up Your Development Environment" to implement security and create a new customizable page in your application.
2. Open the page on which you want to add an announcement.
3. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
4. Drag **Announcements** from the Resource Palette and drop it onto the page inside of the `af:form` `begin` and `end` tags.
5. When prompted, select **Region** as the way to create the task flow (and confirm with **Add Library**). This operation may take a moment to complete.
6. In the Edit Task Flow Binding dialog, enter a value for the `parentId` parameter.

   The discussions server could be shared with multiple Framework applications. Each Framework application should create a forum on the discussions server. Enter that forum ID here as the `parentId`; for example, `${2}`.
7. Click **OK**.
8. Save and run your page.

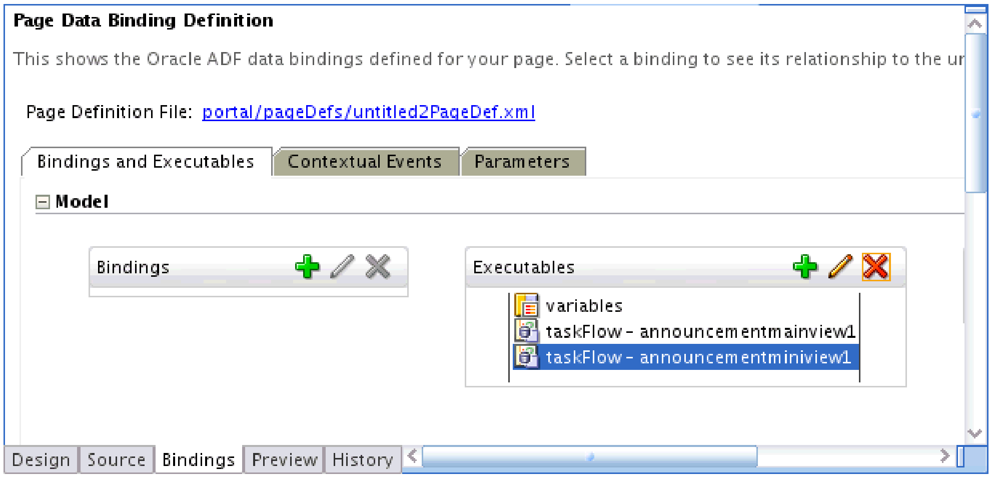
32.2.2.3 How to Modify Announcement Task Flow Parameters

The announcements task flows have required and optional task flow binding parameters.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:

1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 32–6 shows an example of a Search task flow in the Executables section.

Figure 32–6 Page Data Binding Definition



Page Data Binding Definition

This shows the Oracle ADF data bindings defined for your page. Select a binding to see its relationship to the ur

Page Definition File: portal/pageDefs/untitled2PageDef.xml

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.

4. In the Edit Task Flow Binding dialog Figure 32–7, revise the binding parameter values as required.

freeFlowView	
expandedAnnouncements	
truncateAt	
pageSize	

* = Required

5. When you are finished, click **OK.**

6. Save and run your page to see the results.

Table 32–2 describes the properties that are unique to announcements task flows.

Table 32–2 Announcement Task Flow Parameters

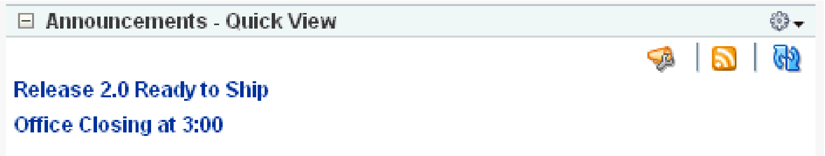
Property	Description	Task Flow
`parentId`	The forum ID in the discussions server under which announcement objects are maintained. Each Framework application should create a forum on the discussions server. Enter that forum ID here; for example, `${2}`. If this parameter is not specified, then announcements default to global announcements.	Announcements Announcements - Quick View
`freeFlowView`	A Boolean value representing whether to remove the announcement title (subject) and show the announcement body as is. The default value is `${false}`, which means that the announcement list displays the title and body in plain text and the `truncateAt` and `expandedAnnouncements` parameters control it. Enter `${true}` to remove the announcement title and ignore the values for `truncateAt` and `expandedAnnouncements`.	Announcements - Quick View
`expandedAnnouncements`	The number of announcements to display announcement details (that is, the body of the announcement). Users can click the title to display the full announcement content in rich text mode. The value you enter for `expandedAnnouncements` is ignored if `freeFlowView` is set to `true`.	Announcements - Quick View

Table 32–2 (Cont.) Announcement Task Flow Parameters

Property	Description	Task Flow
`truncateAt`	For announcements that display announcement body, this value specifies how many characters to display for each announcement. Enter an Expression Language (EL) expression. For example, when the value is set to the EL expression `${50}`, following their titles, announcements display no more than 50 characters. Users can click announcement titles to display the full announcement. If no value is specified, then it displays 200 characters. If a non-valid positive integer value is specified, then it displays all characters in plain text. This parameter takes effect with `expandedAnnouncements`. The value you enter for `truncateAt` is ignored if `freeFlowView` is set to `true`.	Announcements - Quick View
`pageSize`	The number of announcements to show in a page on Extended Quick View.	Announcements - Quick View
`visibleAnnouncements`	The number of announcements to show in the Quick View.	Announcements - Quick View
`hideToolbar`	A Boolean value representing whether to display the task flow personalization feature.	Announcements - Quick View
`navigateToAnnouncementViewer`	A Boolean value representing whether to launch the announcement in a popup or navigate to the Announcement Manager. The default behavior is to launch in a popup. Enter `true` to navigate to the Announcement Manager.	Announcements - Quick View
`expandAllAnnouncements`	A Boolean value representing whether to display details for all announcements in extended quick view. Default value is `false`, in which case announcements display the announcement title only.	Announcements - Quick View

You can change the look and feel of the Announcements - Quick View task flow using parameter values. For example, Figure 32–12 shows the Announcements - Quick View task flow at runtime with the `freeFlowView` parameter set to false (or empty).

Figure 32–8 Announcements - Quick View with Optional Parameters



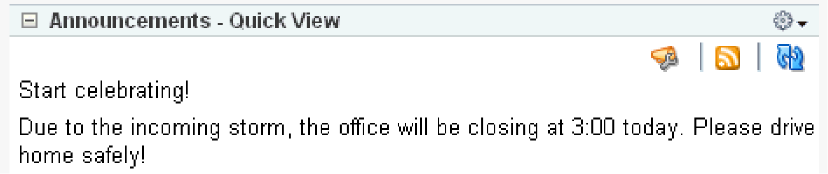
Announcements - Quick View

Release 2.0 Ready to Ship

Office Closing at 3:00

Figure 32–13 shows the Announcements - Quick View task flow at runtime with the `freeFlowView` parameter set to `${true}`.

Figure 32–9 Announcements - Quick View with freeFlowView Parameter



Announcements - Quick View

Start celebrating!

Due to the incoming storm, the office will be closing at 3:00 today. Please drive home safely!

32.2.3 Setting Security for Announcements

By default, authenticated users of Framework applications can view and participate in announcements. Any user who has logged in to a WebCenter Portal application can view announcements, and users with sufficient permissions can create announcements. To create announcements, you must be a moderator or administrator on the back-end discussions server.

In an unsecured Framework application, identity propagation cannot happen. A user is a *guest* (or *anonymous*) user who can view only public categories and forums. In an unsecured application, the `parentId` (forum ID) from which announcements are fetched should be a public forum. If the forum is not public, then an error is reported. If the `parentId` parameter is not specified at all, then WebCenter Portal cannot fetch global announcements (that is, announcements not scoped to a forum): global announcements are not available for public users. Rather than relying to global announcements, each Framework application should reserve its own forum ID.

In an ADF-secured Framework application, identity propagation is enabled. Based on the identity, appropriate permissions are matched and corresponding actions are enabled. The user name that you use to log in to the application is used to log in to the discussions server. The recommended approach is to have the discussions server and the Framework application point to the same identity store. This way, your users can log in to the application one time and automatically connect to the discussions server.

Note: Announcements requires an external LDAP-based identity store; that is, you cannot use the out-of-the-box embedded LDAP with announcements.

ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 74.3, "Configuring ADF Security."

32.3 Advanced Information for Using Announcements

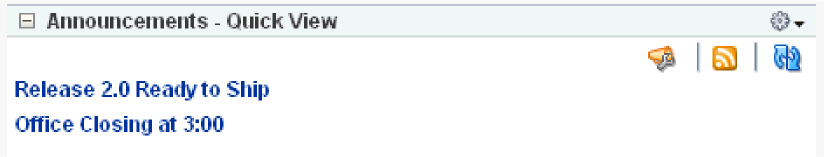
This section describes optional features available with announcements. It includes the following subsections:

- Section 32.3.1, "How to Add the Announcements - Quick View Task Flow"
- Section 32.3.2, "Customizing Announcements Views"
- Section 32.3.3, "Obtaining a Portal RSS News Feed URL for Announcements"

32.3.1 How to Add the Announcements - Quick View Task Flow

The Announcements - Quick View task flow provides a snapshot (dashboard) view of the announcements (Figure 32–10).

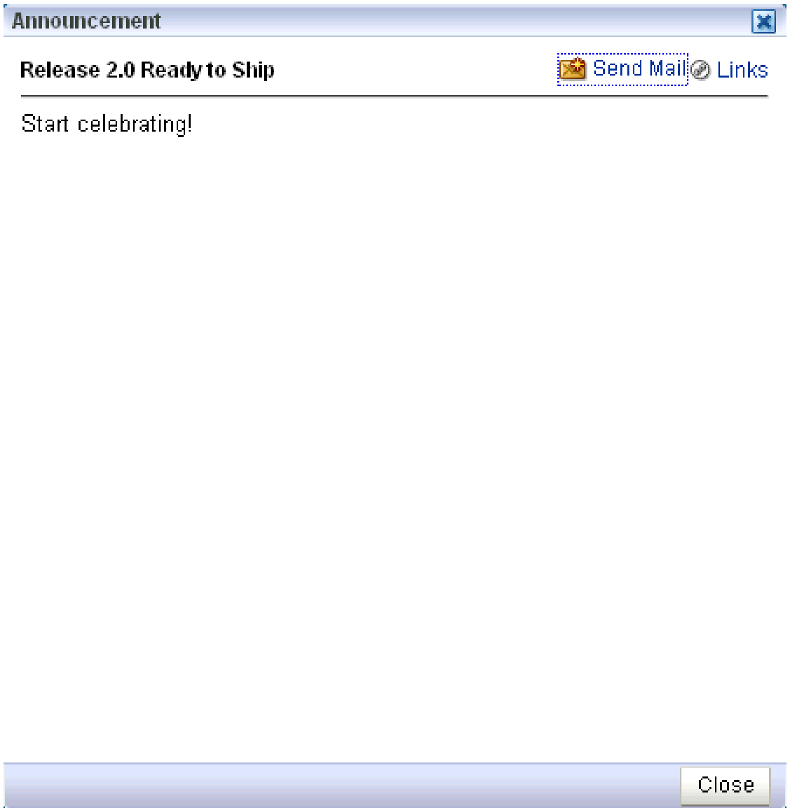
Figure 32–10 Announcements - Quick View



By default, announcements in the Announcements - Quick View task flow show announcement titles as links. But you can configure the task flow to display only announcement titles, titles with some amount of content, or only content.

Click an announcement to view it in a popup. From there, you can select the **Mail** icon to mail the announcement to anyone you choose or select the **Links** icon to link to this announcement (Figure 32–10).

Figure 32–11 Announcement Popup



Announcement

Release 2.0 Ready to Ship

Start celebrating!

The Announcements - Quick View task flow includes numerous parameters to customize your view. For example, you can remove the link to the Announcement Manager, to present announcements to end users where manage controls are not needed. The task flow lists 10 announcements by default, but you can change this number and how much of the announcement is displayed. The **More Announcements ...** link launches a popup containing the complete list of all announcements with pagination behavior. This is called the Extended Quick View (or Mini View).

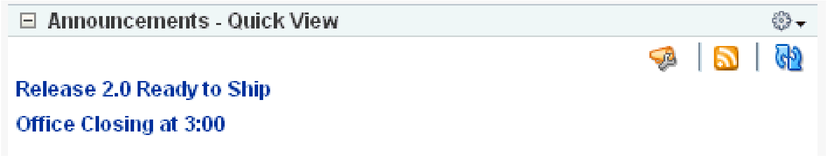
To add the Announcements - Quick View to your Framework application, follow the same instructions that you did for the Announcements task flow in Section 32.2.2, "Adding Announcements at Design Time," but drag and drop Announcements - Quick View onto the page.

Table 32–2 describes the Announcements - Quick View parameters. The look and feel of the Announcements - Quick View changes with the values provided for these parameters. For more information, see Section 32.2.2.3, "How to Modify Announcement Task Flow Parameters."

32.3.2 Customizing Announcements Views

You can change the look and feel of the Announcements - Quick View with the parameter values. For example, Figure 32–12 shows the Announcements - Quick View at runtime with the freeFlowView parameter set to false (or empty).

Figure 32–12 Announcements - Quick View with Optional Parameters

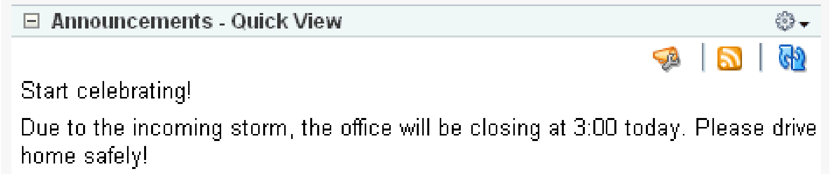


Release 2.0 Ready to Ship

Office Closing at 3:00

Figure 32–13 shows the Announcements - Quick View task flow at runtime with the freeFlowView parameter set to ${true}.

Figure 32–13 Announcements - Quick View task flow with freeFlowView Parameter



Start celebrating!

Due to the incoming storm, the office will be closing at 3:00 today. Please drive home safely!

32.3.3 Obtaining a Portal RSS News Feed URL for Announcements

You can expose WebCenter Portal functionality in a Framework application so that your Framework application users can find out what is happening in a specific portal through RSS news feeds.

Configure RSS news feeds for the announcements to enable users to view portal announcements from within a Framework application. To obtain the portal RSS news feed URL for the announcements, use either of the following WebCenter Portal API methods:

- getServiceRSSFeedURL
- getServiceRSSFeedURLbyGuid

To obtain an RSS feed URL, you must identify the portal (by name or GUID) and specify the service required (by service ID). The service ID for the announcements is GroupSpaceWSClient.ANNOUNCEMENT_SERVICE_ID.

For information about how to use these APIs, see Section 56.1.5.3.9, "Retrieving RSS Feed URLs for WebCenter Portal Tools and Services."

33

Integrating Discussions

This chapter explains how to integrate discussions in a Portal Framework application at design time.

This chapter includes the following topics:

- Section 33.1, "Introduction to Discussions"
- Section 33.2, "Basic Configuration for Discussions"
- Section 33.3, "Advanced Information for Discussions"

For more information about managing and including discussions, see:

- the "Managing Announcements and Discussions" chapter in *Administering Oracle WebCenter Portal*
- the "Working with Discussions" chapter in *Using Oracle WebCenter Portal*

33.1 Introduction to Discussions

You can expose discussion forums on your application pages, so users can create forums, post questions, and search for answers. For example, customers can share product reviews, or a customer service department can answer questions online. Discussion forums additionally provide the means to preserve and revisit discussions.

The back-end discussions server manages content in a hierarchy. At the top of the hierarchy are *categories*, below that are *forums*, and then *topics*. Within each topic are messages, and messages can be nested within messages.

Where categories are exposed in your application, authorized users can create multiple forums within a given scope and multiple topics under those forums. Where categories are not exposed, authorized users can create multiple topics under one forum within a given scope.

33.1.1 Understanding Discussions

With discussions, users can do the following (according to your permissions):

- Create a new discussion forum or a new topic.
- Navigate into a forum from a list of available forums.
- Edit, reply to, or delete an existing discussion forum, topic, or message.
- View the number of replies for a topic on the main forum view.
- Drill into a topic to read all replies by clicking the topic name.
- Add a "watch" to a topic or forum.

- View the following in a quick view:
  - Watched topics
  - Watched forums
  - Most popular (frequently viewed) topics
  - Most recent topics

Note: In a secured application, discussions permissions are allotted according to an individual user's assigned user role. A user can be a moderator, participant, or viewer. Some activities require moderator or participant roles. For more information, see Section 33.2.3, "Setting Security for Discussions."

Discussions is integrated with many WebCenter Portal components, such as instant messaging and presence, RSS, and search (to search within forums). Mail can be archived into discussions as threads. You can also link to a discussion from any WebCenter Portal object.

33.1.2 Requirements for Discussions

Discussions requires a discussions server. Install and configure the discussions server that comes with Oracle Fusion Middleware.

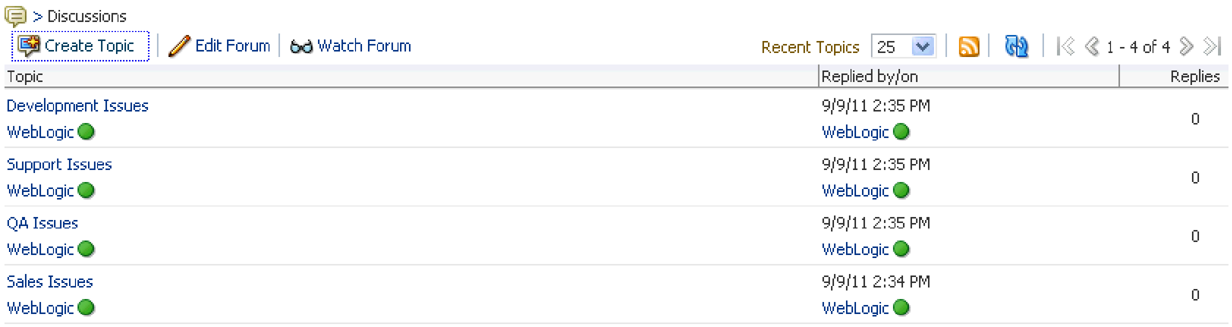
See Also: *Installation Guide for Oracle WebCenter Portal*

33.1.3 What Happens at Runtime

To create forums in Framework applications, you must be a moderator or administrator on the back-end discussions server. For more information, see the "Granting Administrator Role on the Discussions Server" section in *Administering Oracle WebCenter Portal*.

Figure 33–1 shows a discussion forum at runtime.

Figure 33–1 Discussion Forums Task Flow at Runtime



Topic	Replied by/on	Replies
Development Issues WebLogic ●	9/9/11 2:35 PM WebLogic ●	0
Support Issues WebLogic ●	9/9/11 2:35 PM WebLogic ●	0
QA Issues WebLogic ●	9/9/11 2:35 PM WebLogic ●	0
Sales Issues WebLogic ●	9/9/11 2:34 PM WebLogic ●	0

For more information about discussions at runtime, see the "Viewing and Participating in Discussions" chapter in *Using Oracle WebCenter Portal*.

33.2 Basic Configuration for Discussions

This section describes required steps for adding discussions to your application. It includes the following subsections:

- Section 33.2.1, "Setting up Connections for Discussions"
- Section 33.2.2, "Adding Discussions Functionality at Design Time"
- Section 33.2.3, "Setting Security for Discussions"

33.2.1 Setting up Connections for Discussions

You must create a connection to the discussions server in your WebCenter Portal Framework application. You can register additional Discussion Forum connections, but only one connection is active at a time.

When you create a Discussion Forum connection or set a connection as active, both announcements and discussions use this same connection. If you have an existing connection, then you can skip this section and see Section 33.2.2, "Adding Discussions Functionality at Design Time."

If you do not have an existing connection, then you must create a new Discussion Forum connection.

33.2.1.1 Discussions Connections

Discussions requires a Discussion Forum connection to the discussions server.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle Developer, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, see *Administering Oracle WebCenter Portal*.

33.2.1.2 How to Set Up Connections for Discussions

Follow these steps to set up the discussions connection.

1. In Oracle JDeveloper, open the application in which you plan to consume discussion forums.

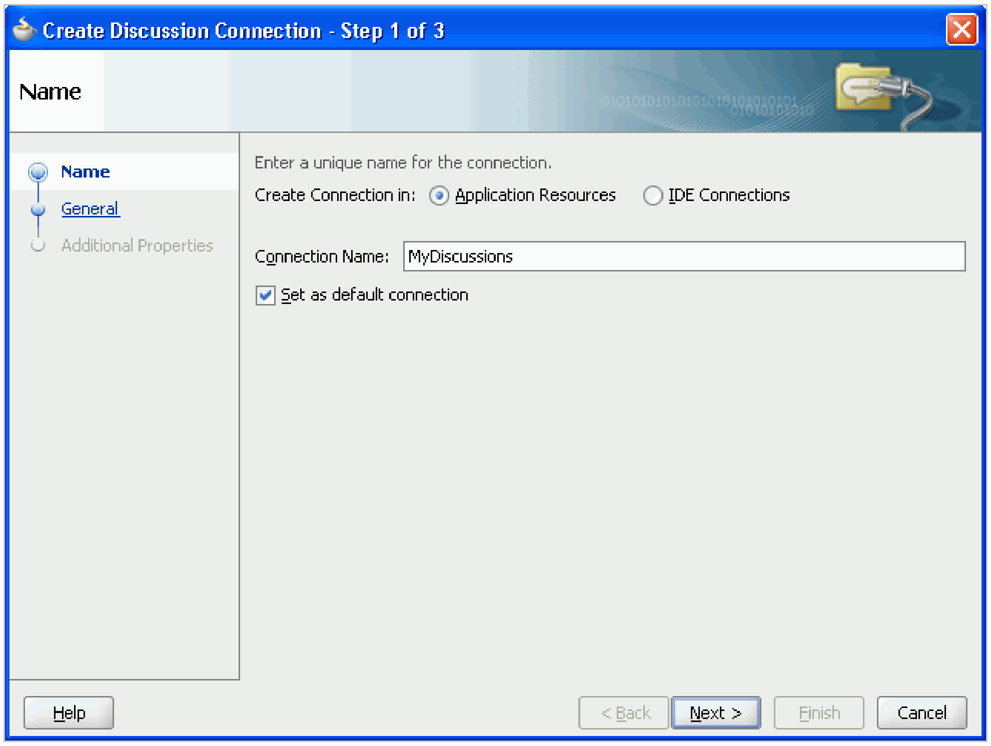
   > **Note:** If you created a Discussion Forum connection for announcements, then that is used by default for discussions. No extra configuration is required.

2. In the Application Navigator, under Application Resources, right-click **Connections**, then select the new connection **Discussion Forum** from the list.
3. On the **Name** page, select to create the connection in **Application Resources**. (A connection in Application Resources is available only for that application, while a connection in IDE Connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE Connections so you do not need to re-create it.)
4. For **Connection Name**, enter a unique name; for example, `MyDiscussions`.
5. Select the **Set the default connection** check box. You can have multiple connections, but only one can be active (default). If you have different discussions

servers (for example, for each page in a portal), then do not select the checkbox, but one connection must be marked as the default connection (Figure 33–2).

Note: After you create a connection and set it as the default connection, you cannot reset it so that it is *not* the default. That is, the **Set as default connection** option cannot be unchecked. To use a different default connection, you must create a new connection and set that as the default connection.

Figure 33–2 Create Discussion Connections, Step 1



Create Discussion Connection - Step 1 of 3

Name

Enter a unique name for the connection.

Create Connection in: ● Application Resources ○ IDE Connections

Connection Name: MyDiscussions

☑ Set as default connection

6. Click **Next**.

7. On the **General** page, enter values for the required parameters:

   - `URL`: Enter the URL of the discussions server hosting discussion forums and announcements. For example: `http://discuss-example.com:8888/owc_discussions`

   - `Admin User`: The user name of your discussions server administrator; for example, `admin`. This account is used by discussions and announcements to perform administrative operations on behalf of WebCenter Portal users.

     In Portal, this account is mostly used for managing portal-related discussions and announcements. It is not necessary for this user to be a super admin. However, the user must have administrative privileges on the current root category for Portal, that is, the category (on the discussions server) under which all portal-related discussions and announcements are stored.

Note: If your Framework application does not include portal-related functionality, then the administrator's user name is not required.

---

8. Optionally, enter a value for the other parameters:

   - `Connection Timeout`: Specify a suitable timeout for the connection. This is the length of time (in seconds) the application waits for a response from the discussions server before issuing a connection timeout message. The default is -1, which means that the default is used. The default is 10 seconds.
   - `Policy URI for Authenticated Access`: Select the SAML token client policy this connection uses for authenticated access to the discussions server Web service. SAML (Security Assertion Markup Language) is an XML-based standard for passing security tokens defining authentication and authorization rights. An attesting entity (that has trust relationship with the receiver) vouches for the verification of the subject by method called sender-vouches. Options available are:

     – WSS 1.0 SAML Token Client Policy (oracle/wss10_saml_token_client_policy)

     – WSS 1.1 SAML Token With Message Protection Client Policy (oracle/wss11_saml_token_with_message_protection_client_policy)

     The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServiceAuthenticated` endpoint in the discussions server. Out-of-the-box, the default service policy is WSS 1.0 SAML Token Service Policy (oracle/wss10_saml_token_service_policy).

   - `Policy URI for Public Access`: Select the client policy this connection uses to enforce message security and integrity for public access to the discussions server Web service. Options available are:

     – None - This is the default setting.

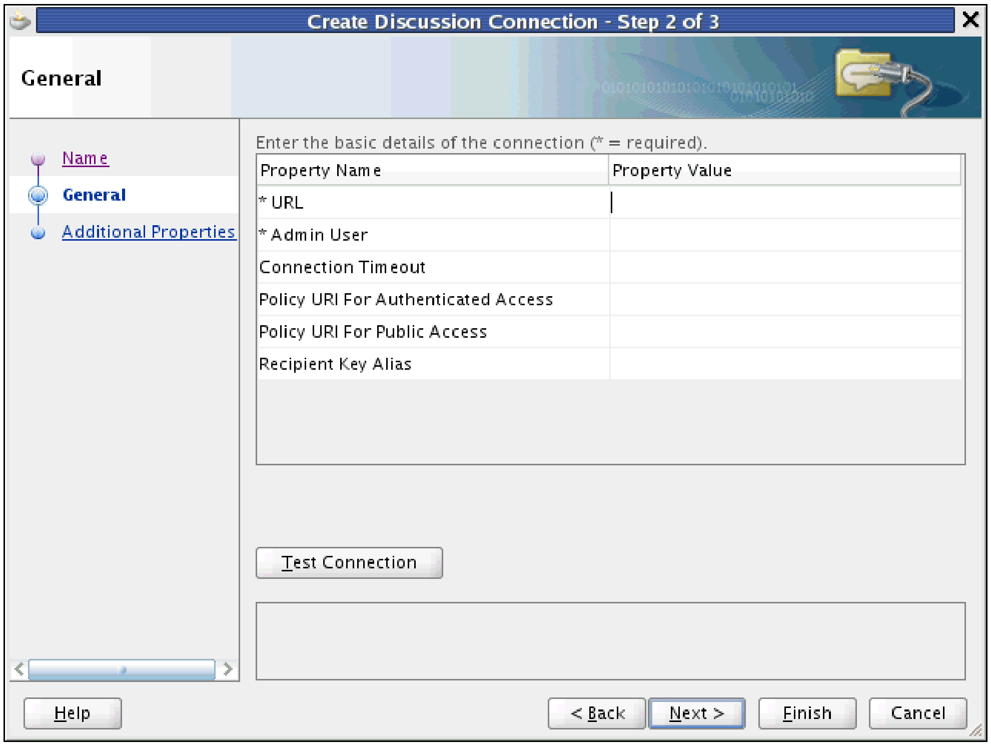
     – WSS 1.1 Message Protection Client Policy (oracle/wss11_with_message_protection_client_policy)

     The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServicePublic` endpoint in the discussions server. Out-of-the-box, a service policy is not configured for public access.

   - `Recipient Key Alias`: Enter the recipient key alias to be used for message protected policies (applicable to the `OWCDiscussionsServicePublic` and `OWCDiscussionsServiceAuthenticated` endpoints). This is the alias to the certificate that contains the public key of the discussions server in the configured keystore.

     For more information, see the "Configuring WS-Security" chapter in *Administering Oracle WebCenter Portal*.

Figure 33–3 Create Discussions Connection, Step 2



Create Discussion Connection - Step 2 of 3

General

Enter the basic details of the connection (* = required).

Property Name	Property Value
* URL	
* Admin User	
Connection Timeout	
Policy URI For Authenticated Access	
Policy URI For Public Access	
Recipient Key Alias	

9. Click **Test Connection**, and if it is successful, then click **Next**.

10. On the **Create Discussion Connection - Step 3 of 3** page, you can configure additional parameters.

    `application.root.category.id`: (WebCenter Portal only) The application root category ID on the discussions server under which all discussion forums are stored. For example, if set to 3, then all forums are stored inside the category 3.

    > **Note:** To encrypt property values, such as passwords, click **Add Secured Property**.

11. Click **Finish**. Your connection should now appear as a node under **Application Resources - Connections**.

33.2.2 Adding Discussions Functionality at Design Time

This section explains a basic incorporation of discussions.

33.2.2.1 Discussions Task Flows

There are several task flows (Table 33–1) to provide discussions in a form that best suits your needs.

Table 33–1 Discussions Task Flows

Task Flow	Description
Discussion Forums	This task flow displays the Discussion Forums view, which allows the user to see all the discussions and their respective replies. It also allows users to perform various operations based on their privileges. A Moderator can perform create, read, update, and delete operations on all objects. A Participant can create a topic, edit a topic that has been created by him, and reply to a topic. A Viewer can only view objects. All watched forums and topics are accessible from this task flow. The Watched Forums and Watched Topics task flows provide more focussed views of watched forums or watched topics. The parameters alter the way the view appears. For more information, see Section 33.2.2.3, "How to Modify the Discussions Task Flow Parameters."
Discussions - Popular Topics	This task flow provides a view that allows users to see the most frequently viewed topics in the application under a given category ID or forum ID. For more information, see Section 33.3.1, "Adding the Discussions - Popular Topics Task Flow."
Discussions - Recent Topics	This task flow displays a view that allows users to see all the recent topics in the application given a category ID or forum ID. For more information, see Section 33.3.2, "Adding the Discussions - Recent Topics Task Flow."
Discussions - Watched Forums	This task flow displays a view that allows users to see all of their watched forums in the application under a given category ID. For more information, see Section 33.3.3, "Adding the Discussions - Watched Forums Task Flow."
Discussions - Watched Topics	This task flow displays a view that allows users to see all their watched topics in the application under a given category ID or forum ID. For more information, see Section 33.3.4, "Adding the Discussions - Watched Topics Task Flow."
Discussions - Quick View	This task flow displays a combined view of the Popular Topics, Recent Topics, Watched Topics, and Watched Forums task flows. Instead of adding four separate task flows, this single task flow presents all four views with a dropdown list so that end users can personalize it For more information, see Section 33.3.5, "Adding the Discussions - Quick View Task Flow."

33.2.2.2 How to Add Discussions to a Page

The Discussion Forums task flow provides a complete view of your discussions. To add the Discussion Forums task flow to your Framework application, follow these steps.

1. Follow the steps described in Section 4.2.1, "How to Prepare Your Application to Consume Tools and Services" to implement security and create a new customizable page in your application.
2. Open the page on which you want to add discussions.
3. In the Resource Palette, expand **My Catalogs**, **WebCenter - Framework Services Catalog**, and **Task Flows**.

4. Drag **Discussions** from the Resource Palette and drop it onto the page.
5. When prompted, select **Region** as the way to create the task flow.
6. You may be prompted to add the discussions library to your project. If so, then click **Add Library**. This operation may take a moment to complete.
7. In the Edit Task Flow Binding dialog box, enter values for the parameters, and click **OK**. Table 33–2 describes the parameters.
8. Save and run your page.

> **Notes:** If you created a connection in IDE and not in the application, then the connection must be added to the application. For example, in the Resource Palette under IDE Connections, right-click the connection and select **Add to Application**.
>
> All instances of the Discussion Forums task flow in an application run against the same discussions server: it is unnecessary to add multiple Discussion Forums task flow instances. This is true for all task flows that require connections to back-end servers, such as task flows from announcements or mails.

The Discussion Forums main view contains some features that require other components in your application.

- For the links in the main view to work, you must have configured the Links service. For more information, see Chapter 43, "Integrating Links."
- For users' presence indicators to work, you must have configured the WebCenter Portal Presence service. For more information, see Chapter 34, "Integrating Instant Messaging and Presence."
- Oracle recommends that the discussions server and WebCenter Portal point to the same identity store. If the Framework application and the discussions page are configured to be secure, then upon logging in to the application, then discussions respects those credentials in the discussions server.

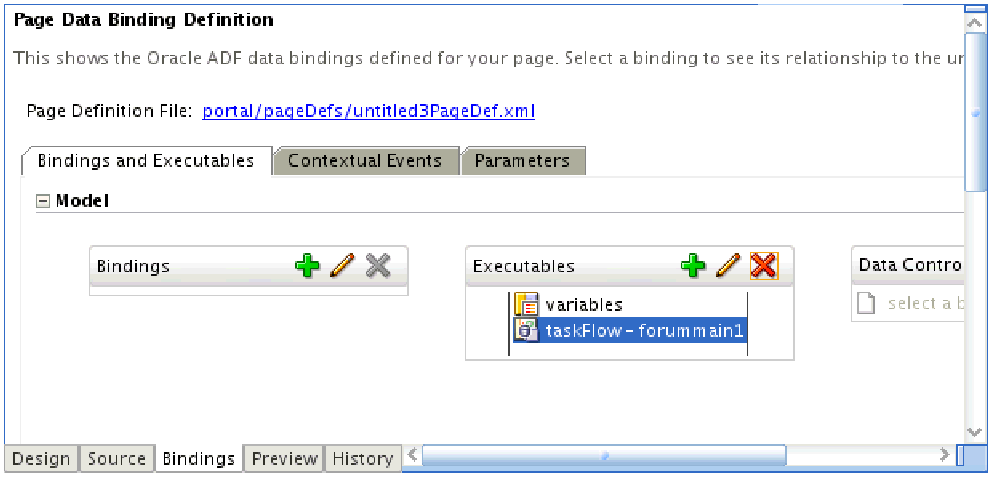
33.2.2.3 How to Modify the Discussions Task Flow Parameters

Discussions task flows have optional task flow binding parameters.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:

1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 33–4 shows an example of a Search task flow in the Executables section.

Figure 33–4 Page Data Binding Definition



Page Data Binding Definition

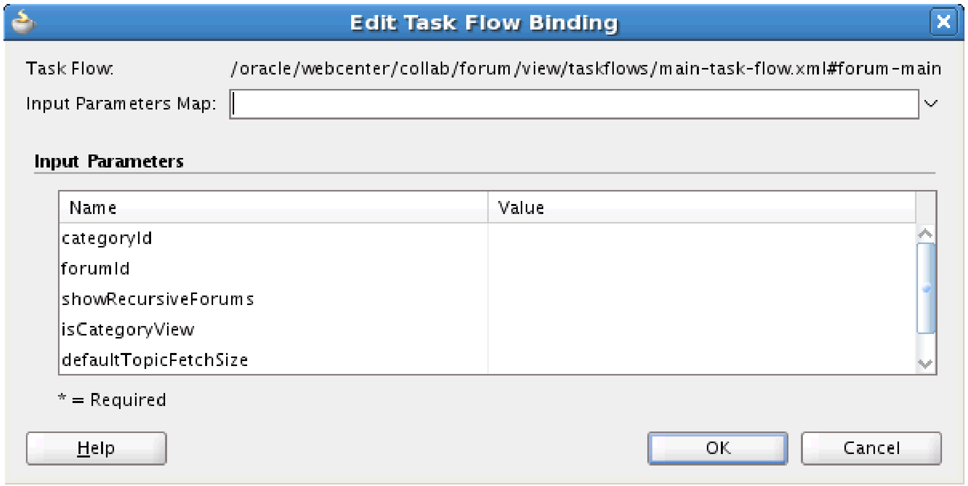
This shows the Oracle ADF data bindings defined for your page. Select a binding to see its relationship to the ur

Page Definition File: portal/pageDefs/untitled3PageDef.xml

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.

4. In the Edit Task Flow Binding dialog Figure 33–5, revise the binding parameter values as required.

Figure 33–5 Edit Task Flow Binding Dialog for Discussion Forums Task Flow



Edit Task Flow Binding

Task Flow: /oracle/webcenter/collab/forum/view/taskflows/main-task-flow.xml#forum-main

Input Parameters Map:

Input Parameters

Name	Value
categoryId	
forumId	
showRecursiveForums	
isCategoryView	
defaultTopicFetchSize	

* = Required

5. When you are finished, click **OK.**

6. Save and run your page to see the results.

Table 33–2 describes the properties that are unique to the discussions task flows.

Table 33–2 Discussions Task Flow Parameters

Property	Description	Task Flow
`categoryId`	This optional parameter is an identifier for an existing category in Oracle WebCenter Portal's Discussion Server to which the view should be scoped. When no value is supplied, it defaults to the appropriate root category of the discussions server. (This root category ID can be overridden by supplying an additional property named `application.root.category.id` in the connection.) For testing purposes, you may want to create a category through the discussions server administrator interface and then reference that category identifier here.	■ Discussion Forums ■ Discussions - Quick View ■ Popular Topics ■ Recent Topics ■ Watched Forums ■ Watched Topics
`forumId`	This parameter is an identifier for an existing forum in your discussions server for which popular topics should be fetched. If both `categoryId` and `forumId` are given, then only `categoryId` is honored.	■ Discussion Forums ■ Popular Topics ■ Recent Topics ■ Watched Topics
`disableToolbar`	This parameter indicates whether the toolbar, including the Refresh icon, should be displayed. It can be `${true}`, `${false}`, or undefined. If you leave this parameter undefined, then the default behavior (false) is to show the toolbar.	■ Popular Topics ■ Recent Topics ■ Watched Forums ■ Watched Topics
`showRecursiveForums`	This parameter determines if you show forums either in a category only or in subcategories. True means all forums under a given category/subcategory are shown; false means only the category's direct child forums are shown. The default value is false. Note: A value of true can impact performance.	Discussion Forums
`isCategoryView`	A means of showing the forums grouped under the Category ID category or the topics specified under the Forum ID forum. True means you want the task flow to display the forums classified under `categoryId`; false, the default value, means you want the task flow to display the topics associated with the specified `forumId`. This parameter value works in combination with other parameters.	Discussion Forums
`defaultTopicFetchSize`	Sets the number of visible topics	Discussion Forums
`doNotAllowSelectingPageSize`	If set to true, users are not allowed to change the number of visible topics.	Discussion Forums
`visibleTopicsFetchSize`	Sets the number of visible watched topics.	■ Recent Topics ■ Watched Topics
`visibleForumsFetchSize`	Sets the number of visible watched forums.	Watched Forums
`doNotShowMoreLink`	If set to true, the **More** link is not visible.	■ Discussions - Quick View ■ Recent Topics ■ Watched Forums ■ Watched Topics

You can customize the look and feel of **Discussion Forums** views by changing parameter values. The following combinations are possible:

> **Note:** A *bidirectional link* connects back and forth. For example, when you create a link from a discussion topic to a document, a link from the document back to the topic also is created. Similarly, when you delete the link from the discussion topic to a document, the link from the document back to the topic automatically is deleted.

- `categoryId`: This displays the forums list view if there are multiple forums. If there is only one forum, then it drills into the forum and lists all topics with a bidirectional link enabled.
- `categoryId` and `forumId`: This displays the topics list view with a bidirectional link enabled.
- `isCategoryView` is set to `true`: This displays the topics list view with a bidirectional link enabled.
- `categoryId` and `forumId` and `isCategoryView` is set to `false`: This displays the topics list view, but a bidirectional link is not enabled.
- `categoryId` and `isCategoryView` is set to `true`: This displays the forums list view if there are multiple forums. If there is only one forum, then it displays that forum with a bidirectional link enabled.
- `forumId` and `isCategoryView` is set to `false`: This displays the topics list view, but a bidirectional link is not enabled.
- `categoryId` and `isCategoryView` is set to `false`: This is similar to when `categoryId` alone is given.
- `forumId` and `isCategoryView` is set to `true`: This is similar to when `forumId` and `isCategoryView` is set to false.
- `isCategoryView` = `true` or `false`: This is ignored. It goes with the default scope (that is, all forums listed under the root category) in a Framework application.
- `forumId`: This is similar to `forumId` and `isCategoryView` is set to false.

33.2.3 Setting Security for Discussions

By default, authenticated users of WebCenter Portal applications can view and participate in discussion forums. Any user who has logged in to a WebCenter Portal application can view discussions, and users with sufficient permissions can create forums and topics. To create forums, you must be a moderator or administrator on the back-end discussions server that provides the discussions.

In an unsecured Framework application, the user identity is not propagated to the discussions server; consequently, users are identified as GUEST (that is, as anonymous users) and can view only public categories and forums.

> **Note:** *Categories* and *forums* are server-side classifications that move from *category* to *forum* to *topic*. That is, a category can head a collection of forums, just as a forum can head a collection of topics.

In a secured Framework application, discussions permissions are allotted according to an individual user's assigned user role. For example, a user can be a moderator, participant, or viewer. A forum moderator can edit and delete any topics and messages within a forum. A forum participant can create topics and edit his or her own topics. A forum viewer can view topics and messages.

In an unsecured Framework application, identity propagation cannot happen. A user is a *guest* (or *anonymous*) user who can view only public categories and forums.

In an ADF-secured Framework application, identity propagation is enabled. Based on the identity, appropriate permissions are matched and corresponding actions are enabled. The user name that you use to log in to the application is used to log in to the discussions server. The recommended approach is to have the discussions server and the application point to the same identity store. When you run the page, you are presented with a login page for user credentials. Enter the credentials with the required privileges in the discussions server.

Note: Discussions requires that the identity store be LDAP-based; that is, not file-based with `jazn-data.xml`.

ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 74.3, "Configuring ADF Security."

33.3 Advanced Information for Discussions

This section describes optional features available with discussions. It includes the following subsections:

- Section 33.3.1, "Adding the Discussions - Popular Topics Task Flow"
- Section 33.3.2, "Adding the Discussions - Recent Topics Task Flow"
- Section 33.3.3, "Adding the Discussions - Watched Forums Task Flow"
- Section 33.3.4, "Adding the Discussions - Watched Topics Task Flow"
- Section 33.3.5, "Adding the Discussions - Quick View Task Flow"
- Section 33.3.6, "Obtaining Portal RSS News Feed URL for Discussions"
- Section 33.3.7, "Using Custom Discussions APIs"
- Section 33.3.8, "Using the Discussions REST API"
- Section 33.3.9, "Troubleshooting Discussions"

33.3.1 Adding the Discussions - Popular Topics Task Flow

The Discussions - Popular Topics task flow provides a view that allows users to see the most frequently viewed discussion topics under a given category ID or forum ID.

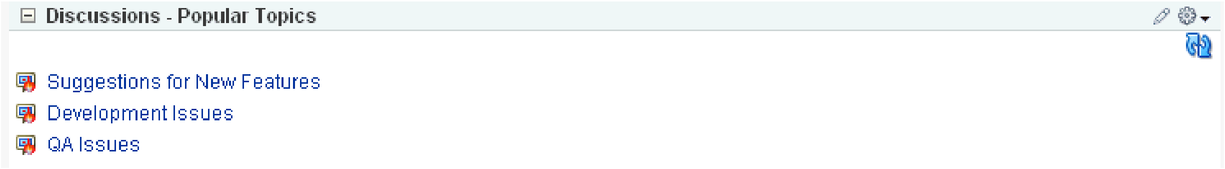
Note: Popular topics are based on topic replies. The administrator is not able to determine popularity.

To add the Discussions - Popular Topics task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 33.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Popular Topics onto the page.

Table 33–2 describes the available parameters for this task flow.

Figure 33–6 shows how the Discussions - Popular Topics task flow looks at runtime.

Figure 33–6 Discussions - Popular Topics View at Runtime



Discussions - Popular Topics

Suggestions for New Features

Development Issues

QA Issues

33.3.2 Adding the Discussions - Recent Topics Task Flow

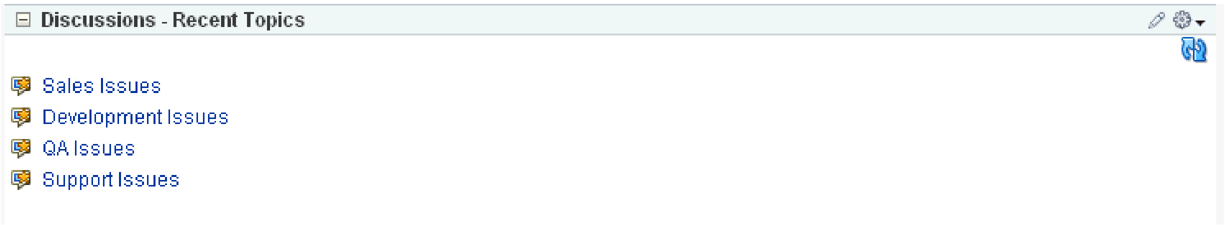
The Discussions - Recent Topics task flow displays a view that allows users to see all the recent topics (that is, topics posted within the past two days) given a category ID or forum ID.

To add the Discussions - Recent Topics task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 33.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Recent Topics onto the page.

Table 33–2 describes the available parameters for this task flow.

Figure 33–7 shows how the Discussions - Recent Topics task flow looks at runtime. To view a topic post, simply click the relevant topic.

Figure 33–7 Discussions - Recent Topics View at Runtime



Discussions - Recent Topics

Sales Issues

Development Issues

QA Issues

Support Issues

33.3.3 Adding the Discussions - Watched Forums Task Flow

The Discussions - Watched Forums task flow displays a view that allows users to see all of their watched forums under a given category ID.

You can watch discussion forums and topics to keep a close eye on the information most current and relevant to your efforts. The forums and topics you select to watch are personal, in that your selections appear on your view of watch lists. No other user is affected by the forums and topics you choose to watch.

When a user places a watch on a forum or a topic, in addition to it appearing in their watched forums or topics list, the user receives an mail notification whenever other users add to that forum or topic.

All watched forums and topics are accessible from the Forums task flow. The Watched Forums and Watched Topics task flows provide more focussed views of watched forums or watched topics.

To add the Discussions - Watched Forums task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 33.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions -

Watched Forums onto the page.

Table 33–2 describes the available parameters for this task flow.

Figure 33–8 shows how the Discussions - Watched Forums task flow looks at runtime.

Figure 33–8 Discussions - Watched Forums View at Runtime

- portalspace
- ProjectSpace
- DiscussionSpace
- gs33
- May - June Service Requests

For information on how to watch a forum or topic at runtime, see the "Working with Discussions" chapter in *Using Oracle WebCenter Portal.*

33.3.4 Adding the Discussions - Watched Topics Task Flow

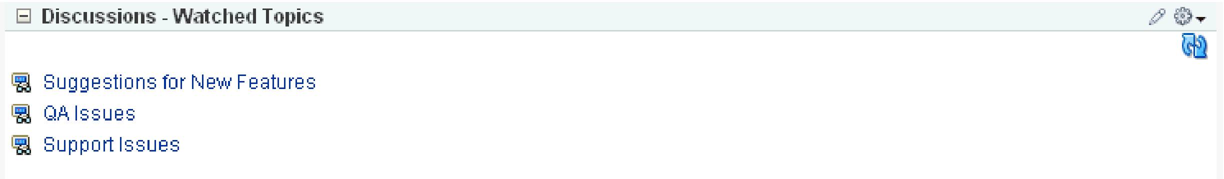
Similar to the Discussions - Watched Forums task flow, the Discussions - Watched Topics task flow displays a view that allows users to see all their watched topics under a given category ID or forum ID.

To add the Discussions - Watched Topics task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 33.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Watched Topics onto the page.

Table 33–2 describes the available parameters for this task flow.

Figure 33–9 shows how the Discussions - Watched Topics task flow looks at runtime.

Figure 33–9 Discussions - Watched Topics View at Runtime



Discussions - Watched Topics

- Suggestions for New Features
- QA Issues
- Support Issues

For information on how to watch a forum or topic at runtime, see the "Working with Discussions" chapter in *Using Oracle WebCenter Portal.*

33.3.5 Adding the Discussions - Quick View Task Flow

The Discussions - Quick View task flow displays a combined view of the Popular Topics, Recent Topics, Watched Topics, and Watched Forums task flows. Instead of adding four separate task flows, this single task flow presents all four views with a dropdown list so that end users can personalize it.

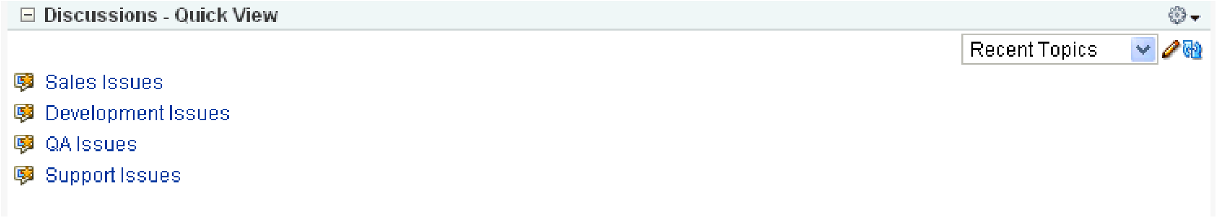
By default, Watched Topics are displayed. This task flow takes only one parameter: `categoryId`.

To add the Discussions - Quick View task flow to your WebCenter Portal Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 33.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Quick View onto the page.

Table 33–2 describes the available parameters for this task flow.

Figure 33–10 shows how the Discussions - Quick View task flow looks at runtime.

Figure 33–10 Discussions - Quick View at Runtime



33.3.6 Obtaining Portal RSS News Feed URL for Discussions

You can expose portal functionality in a Framework application. Your Framework application users can find out what is happening in a specific portal through RSS news feeds.

Configure RSS news feeds for discussions to enable users to view portal discussions from within a Framework application. To obtain the portal RSS news feed URL for discussions, use either of the following WebCenter Portal API methods:

- `getServiceRSSFeedURL`
- `getServiceRSSFeedURLbyGuid`

To obtain an RSS feed URL, you must identify the portal (by name or GUID) and specify the component required (by service ID). The service ID for discussions is `GroupSpaceWSClient.DISCUSSION_SERVICE_ID`.

For information about how to use these methods, see Section 56.1.5.3.9, "Retrieving RSS Feed URLs for WebCenter Portal Tools and Services."

33.3.7 Using Custom Discussions APIs

The back-end discussions server includes APIs to further customize your application. To learn more about them, see the Jive Forums documentation on the Oracle Fusion Middleware documentation library (in the WebCenter Portal product area).

33.3.8 Using the Discussions REST API

WebCenter Portal provides a REST API to support discussions. Use the discussions REST API to post, read, update, and delete discussion forums, topics, and messages.

This section describes the REST API methods associated with discussions. It includes the following subsections:

- Section 33.3.8.1, "Discussions Entry Point"
- Section 33.3.8.2, "Discussions Resource Type Taxonomy"
- Section 33.3.8.3, "Security Considerations"
- Section 33.3.8.4, "Discussions Resource Types"

For an introduction to the REST APIs, see Chapter 53, "Using Oracle WebCenter Portal REST APIs."

33.3.8.1 Discussions Entry Point

Each REST service has a link element within the Resource Index that provides the entry point for that service. To find the entry point for discussions, find the link element with a `resourceType` of:

```
urn:oracle:webcenter:discussions:forums
```

The corresponding `href` or `template` element provides the URI entry point. The client sends HTTP requests to this entry point to work with discussions.

For more information about the Resource Index, see Section 53.5.1, "Using the Resource Index."

For more information about resource types, see Section 53.5.2.1, "Resource Type."

33.3.8.2 Discussions Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 53.5.2.1, "Resource Type."

The taxonomy for discussions is:

```
urn:oracle:webcenter:discussions:forums
   urn:oracle:webcenter:discussions:forum
   urn:oracle:webcenter:discussions:forum:topics
      urn:oracle:webcenter:discussions:forum:topic
      urn:oracle:webcenter:discussions:forum:topic:messages
         urn:oracle:webcenter:discussions:forum:topic:message
```

Beyond the service entry points, URL templates allow clients to pass query parameters to customize their requests and control the form of returned data.

Collection resources in the discussions resources support pagination (`startIndex` and `itemsPerPage`). Other query parameters are not supported (that is, `search` and `projection`).

33.3.8.3 Security Considerations

There are no specific security considerations for discussions. For general security considerations, see Section 53.8, "Security Considerations for WebCenter Portal REST APIs."

33.3.8.4 Discussions Resource Types

This section provides the information about each resource type. It includes the following subsections:

- Section 33.3.8.4.1, "urn:oracle:webcenter:discussions:forums"
- Section 33.3.8.4.2, "urn:oracle:webcenter:discussions:forum"
- Section 33.3.8.4.3, "urn:oracle:webcenter:discussions:forum:topics"
- Section 33.3.8.4.4, "urn:oracle:webcenter:discussions:forum:topic"
- Section 33.3.8.4.5, "urn:oracle:webcenter:discussions:forum:topic:messages"
- Section 33.3.8.4.6, "urn:oracle:webcenter:discussions:forum:topic:message"

33.3.8.4.1 urn:oracle:webcenter:discussions:forums Use this resource type to identify the URI to use to read (GET) and write (POST) discussion forums. The response from a GET operation includes each forum in this collection of forums, and each forum includes links used to operate on that forum. The response from a POST operation includes the forum that was created in this collection of forums and a link to operate on that forum.

Navigation Paths to forums

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
```

Supported Methods for forums

The following methods are supported by this resource:

- GET
  - **request - body:** none, **Parameters**: startIndex, itemsPerPage (pagination)
  - **response - body:** forums
- POST
  - **request - body:** forum
  - **response - body:** forum

Note that the number of forums displayed per page defaults to 10. For more information, see Section 53.5.2.5, "Templates."

Resource Types Linked to From forums

Table 33–3 lists the resource types that the client can link to from this resource.

Table 33–3 Related Resource Types for forums

rel	resourceType
self	urn:oracle:webcenter:discussions:forums
	urn:oracle:webcenter:discussions:forum

33.3.8.4.2 urn:oracle:webcenter:discussions:forum Use this resource type to identify the URI to use to read (GET), update (PUT), and delete (DELETE) a specific discussion forum. The response from a GET operation includes the specific forum identified by the URI. The response from a PUT operation includes the modified version of the forum identified by the URI. The response from a DELETE operation is a 204.

Navigation Paths to forum

This section shows how the client can navigate through the hypermedia to access this resource:

resourceindex
   activities
      forum
```

Supported Methods for forum

The following methods are supported by this resource:

- GET
  - **request - body:** none
  - **response - body:** forum
- PUT
  - **request - body:** forum
  - **response - body:** forum
- DELETE
  - **request - body:** none
  - **response - body:** none

Writable Elements for forum

Table 33–4 lists the writable elements for this resource.

Table 33–4 Writable Elements for forum

Element	Type	Required	Constraints	Description
`name`	String	Yes	1 or more characters	Name of the forum
`displayName`	String	No	1 or more characters	Name used in presentation
`description`	String	No	1 or more characters	Description of the forum

Read-only Elements for forum

Table 33–5 lists the read-only elements for this resource.

Table 33–5 Read-only Elements for forum

Element	Type	Description
`id`	Integer	ID of the forum
`parentId`	Integer	ID of the parent category
`createdBy`	String	ID of the user that created the forum
`author`	personReference	User information about the user that created the forum, including GUID, ID, display name, and a link to the profile icon (same user as `createdBy`)
`createdOn`	Date	Date on which the forum was created

Table 33–5 (Cont.) Read-only Elements for forum

Element	Type	Description
`updatedBy`	String	ID of the user that performed the last modification
`modifiedBy`	personReference	User information about the user that performed the last modification, including GUID, ID, display name, and a link to the profile icon (same user as `updatedBy`)
`updatedOn`	Date	Date on which the forum was last modified
`webUrl`	String	URL for direct access to the discussions server
`topicCount`	Integer	Number of topics
`messageCount`	Integer	Number of messages
`locked`	Boolean	True if this forum is locked
`favorite`	Boolean	True if this forum is marked as a favorite

Resource Types Linked to From forum

Table 33–6 lists the resource types that the client can link to from this resource.

Table 33–6 Related Resource Types for forum

rel	resourceType
self	`urn:oracle:webcenter:discussions:forum` `urn:oracle:webcenter:discussions:forum:topics`

33.3.8.4.3 urn:oracle:webcenter:discussions:forum:topics Use this resource type to identify the URI to use to read (`GET`) and write (`POST`) discussion topics. The response from a `GET` operation includes each topic in this collection of topics, and each topic includes links used to operate on that topic. The response from a `POST` operation includes the topic that was created in this collection of topics and a link to operate on that topic.

Navigation Paths to topics

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums
      topics

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
            topics
```

Supported Methods for topics

The following methods are supported by this resource:

- `GET`
  - **request - body:** none, **Parameters:** `startIndex`, `itemsPerPage` (pagination)
  - **response - body:** topics

- POST
  - **request - body:** topic
  - **response - body:** topic

For more information, see Section 53.5.2.5, "Templates."

Resource Types Linked to From topics

Table 33–7 lists the resource types that the client can link to from this resource.

Table 33–7 Related Resource Types for topics

rel	resourceType
self	`urn:oracle:webcenter:discussions:forum:topics` `urn:oracle:webcenter:discussions:forum:topic`

33.3.8.4.4 urn:oracle:webcenter:discussions:forum:topic Use this resource type to identify the URI to use to read (`GET`), update (`PUT`), and delete (`DELETE`) a specific discussion topic. The response from a `GET` operation includes the specific topic identified by the URI. The response from a `PUT` operation includes the modified version of the topic identified by the URI. The response from a `DELETE` operation is a 204.

Navigation Paths to topic

This section shows how the client can navigate through the hypermedia to access this resource:

```

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
            topics
               topic

resourceindex
   activities
      topicT
```

Supported Methods for topic

The following methods are supported by this resource type:

- GET
  - **Request—Body:** none
  - **Response—Body:** topic
- PUT
  - **Request—Body:** topic
  - **Response—Body:** topic
- DELETE
  - **Request—Body:** none

- **Response—Body:** none

Writable Elements for topic

Table 33–8 lists the writable elements for this resource type.

Table 33–8 Writable Elements for topic

Element	Type	Required	Constraints	Description
`subject`	String	Yes	1 or more characters	Subject of the topic
`body`	String	No	0 or more characters	Contents of the topic

Read-only Elements for topic

Table 33–9 lists the read-only elements for this resource type.

Table 33–9 Read-only Elements for topic

Element	Type	Description
`id`	Integer	Identifier for the topic
`parentId`	Integer	Identifier for the parent message
`forumId`	Integer	Identifier for the forum under which this topic is posted
`topicId`	Integer	Identifier for the topic under which this topic is posted
`createdBy`	String	ID of the user who created the topic
`author`	personReference	User information about the user who created the topic, including GUID, ID, display name, and a link to the profile icon (same user as `createdBy`)
`createdOn`	Date	Date on which the topic was created
`updatedBy`	String	User who lasted updated the topic
`updatedOn`	Date	Date on which the topic was last updated
`webUrl`	String	URL for direct access to the discussions server
`depth`	Integer	Depth in the hierarchy of messages
`messageCount`	Integer	Number of child messages under this topic
`numberOfReplies`	Integer	Number of replies to this topic
`favorite`	Boolean	Whether the topic is marked as a favorite for the user
`locked`	Boolean	Whether the topic is locked
`hidden`	Boolean	Whether the topic is hidden
`hasAttachment`	Boolean	Whether the topic has attachments

Resource Types Linked to From topic

Table 33–10 lists the resource types that the client can link to from this resource.

33.3.9 Troubleshooting Discussions

This section describes common problems and solutions for discussions.

Problem

It can take several minutes to fetch data from recursive forums. For example, if you drop the Discussions task flow on the page with the categoryId and forumId parameters left blank and you set the showrecursive parameter to ${'true'}, then it could take several minutes to scroll through all the forums.

Solution

The option to show recursive forums is not recommended for performance reasons.

Problem

Users can log on to the Framework application but cannot log on to the discussions server.

Solution

Make sure that discussions server is configured to use the same identity store as the Framework application. Contact your administrator for details. For information about configuring the identity store, see the "Configuring the Identity Store" section in *Administering Oracle WebCenter Portal*.

Problem

When you access a discussions forum from your Framework application, the following error message is displayed:

```
No default or active connection available for: Discussion Forum
```

Solution

Ensure the following:

- Ensure that you have created a Discussion Forum connection.
- Ensure the required Discussion Forum connection is marked as the default connection.

Problem

While performing certain operations on Discussions Forums task flows, you encounter error messages like "Forum not found" or "Topic not found."

Solution

Check the following:

- Ensure that the discussions server is up and running.
- Ensure the forum or topic exist on the discussions server.
- Ensure that you have the required privileges for the forum or topic that you are editing.

If all of these settings are fine and the problem persists, contact your administrator for details.

Problem

If you change the connection to use a different discussions server, and if you change the application root category ID from administrator-services-discussions, then you could see exceptions like, "Category Not Found."

Solution

Restart the managed server on which the Framework application is deployed.

34

Integrating Instant Messaging and Presence

This chapter explains how to integrate instant messaging and presence (IMP) in a Portal Framework application at design time.

This chapter includes the following topics:

- Section 34.1, "Introduction to Instant Messaging and Presence"
- Section 34.2, "Basic Configuration for IMP"
- Section 34.3, "Advanced Information for IMP"

For more information about managing and including instant messaging and presence, see:

- the "Managing Instant Messaging and Presence" chapter in *Administering Oracle WebCenter Portal*
- the "Using Instant Messaging and Presence Viewer" chapter in *Using Oracle WebCenter Portal*

34.1 Introduction to Instant Messaging and Presence

Instant messaging and presence (IMP) enables users to observe the presence status (online, offline, busy, or away) of other authenticated application users. It provides instant access to interaction options, such as instant messages and mails. Additionally, if your enterprise presence is unavailable (for example, when you are traveling), you can connect to a third-party network presence service, such as Yahoo! Messenger.

Tools and services within WebCenter Portal that have user names with the same identity can integrate with IMP; for example, discussions, documents, or mail.

This section provides an overview of IMP features and requirements. It includes the following subsections:

- Section 34.1.1, "Understanding Instant Messaging and Presence"
- Section 34.1.2, "Requirements for Instant Messaging and Presence"

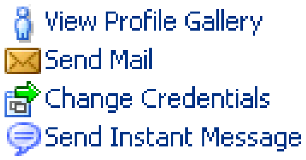
34.1.1 Understanding Instant Messaging and Presence

Figure 34–1 shows the Presence icon indicating a user who is online.

Figure 34–1 Presence Icon (Online)

Wherever a user is indicated, for example as the author of a document in the document library, you can click the icon to invoke a context menu (Figure 34–2).

Figure 34–2 Presence Icon Context Menu



The context menu can include the following actions:

- View Profile (This opens the selected user's profile page, with information such as mail ID and contact numbers.)
- Send Mail (This opens a compose window for the mail client set, either WebCenter Portal's Mail or a local mail client.)
- Change Credentials (This works as an alternative to using an external application, visible only to the current user.)
- Send Instant Message (This opens the instant message client running on the computer, Microsoft Communicator.)

Next to a contact name is an icon that indicates the presence state of each contact.

For detailed information about IMP at runtime, including screen shots and descriptions of the presence status options, see the "Using Instant Messaging and Presence Viewer" chapter in *Using Oracle WebCenter Portal*.

34.1.2 Requirements for Instant Messaging and Presence

IMP requires a back-end presence server. WebCenter Portal is certified with Microsoft Office Live Communications Server (LCS) 2005, Microsoft Office Communications Server (OCS) 2007, and Microsoft Lync 2010.

> **Note:** Oracle Beehive Server connections are not supported in this release.

34.2 Basic Configuration for IMP

This section describes the steps required for adding IMP to your application. It includes the following subsections:

- Section 34.2.1, "Setting up Connections for IMP"
- Section 34.2.2, "Adding IMP Functionality at Design Time"
- Section 34.2.3, "Setting Security for IMP"

34.2.1 Setting up Connections for IMP

After the presence server is properly installed and running, you must add a connection to it. This section describes how. It includes the following subsections:

- Section 34.2.1.1, "Instant Messaging and Presence Connections"
- Section 34.2.1.2, "How to Set Up Microsoft LCS Connections for IMP"

- Section 34.2.1.3, "How to Set Up Microsoft OCS and Microsoft Lync Connections for IMP"

34.2.1.1 Instant Messaging and Presence Connections

Instant Messaging and Presence requires an **Instant Messaging and Presence** connection to the presence server (Microsoft LCS, Microsoft OCS, or Microsoft Lync).

When WebCenter Portal interacts with an application that handles its own authentication, you can associate that application with an external application definition to allow for credential provisioning. An external application is mandatory.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Fusion Middleware Control. For more information, see *Administering Oracle WebCenter Portal*.

34.2.1.1.1 Mapping User Names to IM Addresses The im.address.resolver.class handles the resolver implementation used to map user names to IM addresses and IM addresses to user names. This implementation looks for IM addresses in the following places and order:

1. User Preferences - If the user has entered his or her IM address in the Presence Preferences page, then the user's IM address is found in the user's preferences.
2. User Credentials - If an external application is configured, then an account field provides the user's IM address.
3. User Profiles - If the user has not supplied preferences and WebCenter Portal cannot fetch the IM address from the external application, then WebCenter Portal reads the IM address from LDAP (that is, the user's profile). The default LDAP property read is the BUSINESS_EMAIL attribute. Users can change this default with im.address.profile.attribute.

To use your own resolver implementation, extend from IMPAddressResolver class and implement two methods: resolveAddress and resolveUsername.

- The resolveAddress method takes in user name and returns the corresponding IM address.
- The resolveUsername method takes in the IM address and returns the corresponding user name.

To plug in the new resolver class, change the property im.address.resolver.class from the default oracle.webcenter.collab.rtc.IMPAddressResolverImpl to your resolver implementation. Example 34–1 shows a sample IMPAddressResolver implementation, where the resolver appends the domain string @example.com to the user name to construct the address and removes the same domain string from the address to construct the user name.

Example 34–1 Resolver Implementation

```
public class SampleAddressResolver extends IMPAddressResolver
{
  private String DOMAIN = "@example.com";

  public SampleAddressResolver()
  {
    super();
  }

  //Append DOMAIN to the username to construct the IM address
  public String resolveAddress(String username)
  {
    String imAddress = username;
    if(!imAddress.endsWith(DOMAIN))
    {
      imAddress = imAddress + DOMAIN;
    }

    return imAddress;
  }

  //Remove DOMAIN from the IM address to construct the username
  public String resolveUsername(String imAddress)
  {
    String username = imAddress;
    if(username.endsWith(DOMAIN))
    {
      int index = username.indexOf(DOMAIN);
      username = username.substring(0, index);
    }

    return username;
  }
}
```

> **See Also:** The "setIMPServiceProperty" section in the *WebLogic Scripting Tool Command Reference*

34.2.1.2 How to Set Up Microsoft LCS Connections for IMP

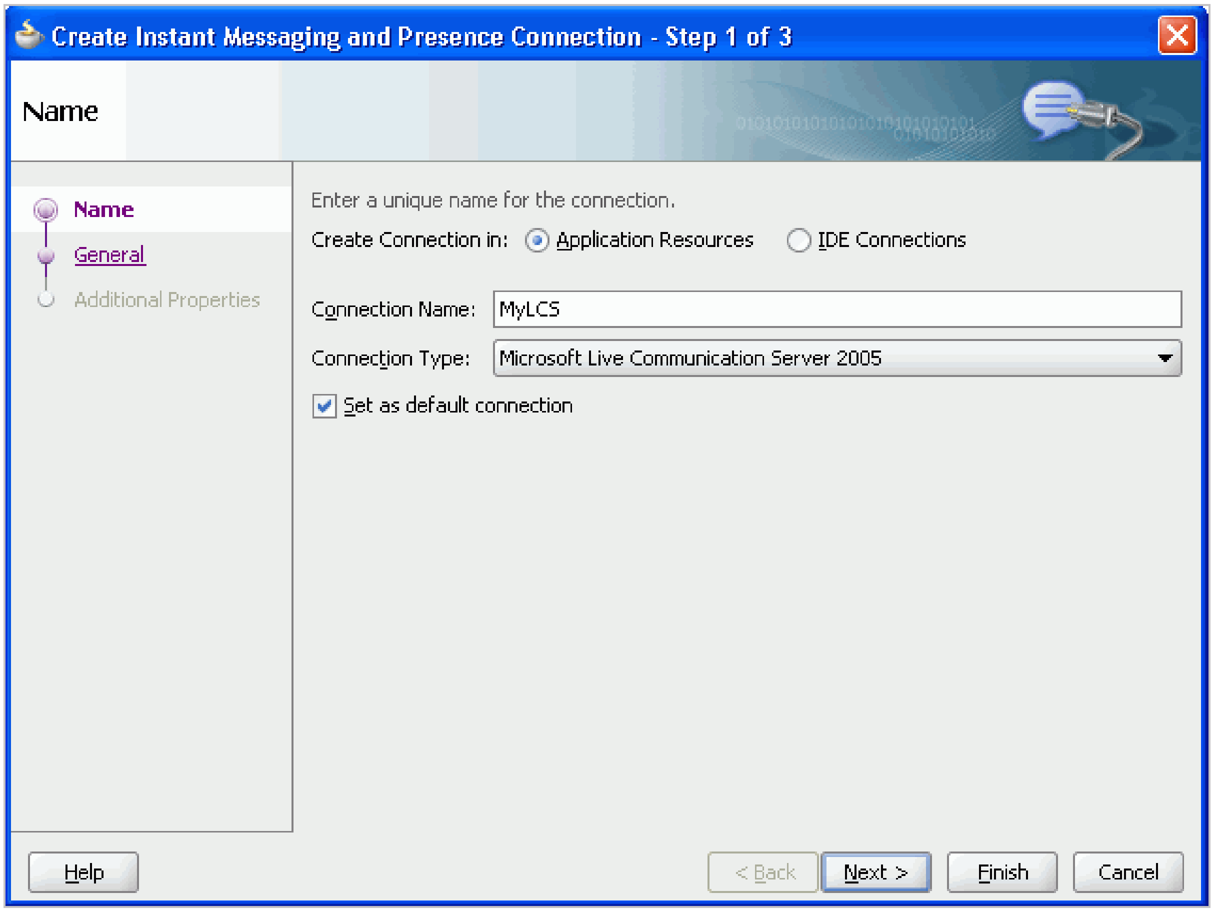
To set up the connection to the LCS presence server:

1. In Oracle JDeveloper, open the application in which to consume instant messaging and presence.
2. In the Application Navigator, under Application Resources, right-click **Connections**, then select **Instant Messaging and Presence** from the list.
3. In the Create Instant Messaging and Presence connection dialog box, select to create the connection in **Application Resources**.

   A connection in Application Resources is available only for that application, while a connection in IDE connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE connections to avoid having to re-create it.
4. On the **Name** page, for **Connection Name**, enter a unique name for your connection.

   No other connection should have the same name.
5. From the **Connection Type** list, select **Microsoft Live Communication Server 2005**.
6. Select the **Set as default connection** checkbox to use this as the default connection, as shown in Figure 34–3.

Figure 34–3 Create LCS Instant Messaging and Presence Connection, Step 1



Enter a unique name for the connection.

Create Connection in: ● Application Resources ○ IDE Connections

Connection Name: MyLCS

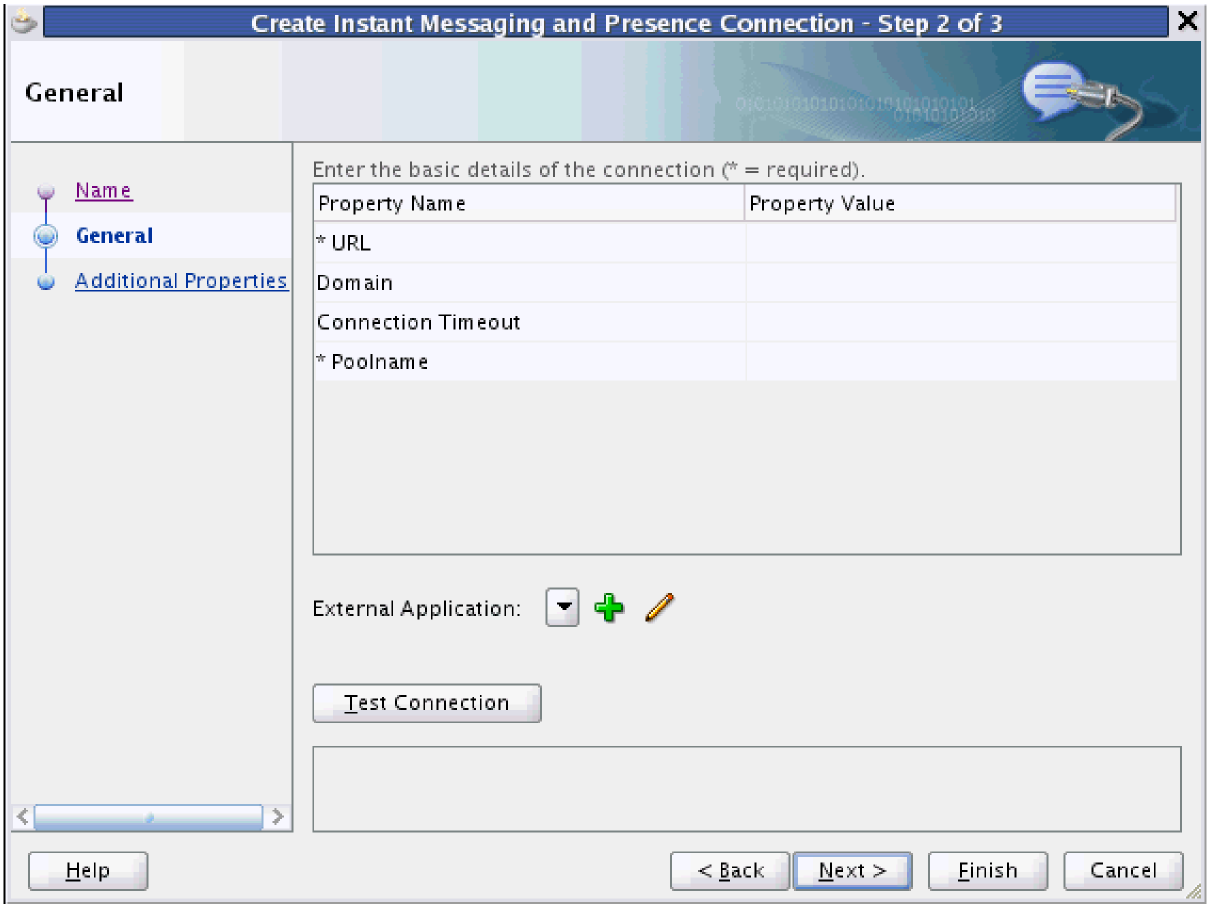
Connection Type: Microsoft Live Communication Server 2005

☑ Set as default connection

7. Click **Next**

8. On the **General** page (Figure 34–4), enter the information for your Microsoft LSC instance.

Figure 34–4 Create LCS Instant Messaging and Presence Connection, Step 2



Create Instant Messaging and Presence Connection - Step 2 of 3

General

Enter the basic details of the connection (* = required).

Property Name	Property Value
* URL	
Domain	
Connection Timeout	
* Poolname	

For example:

- The Url could be http://host:port/RTC where RTC is the virtual directory name under which the server side module is deployed. (See the Microsoft Live Communications Server 2005 documentation for more information.)
- The Domain property is maintained for backward compatibility. It should be left blank.
- The Connection Timeout property is optional. It represents the time (in seconds) WebCenter Portal should wait for the server to respond while making the connection. If the presence server does not respond in the given time, then it aborts the connection and reports an error.
- For PoolName, enter the name of the pool under which Microsoft Communications Server components are deployed. (See the Microsoft Live Communications Server documentation for more information.)

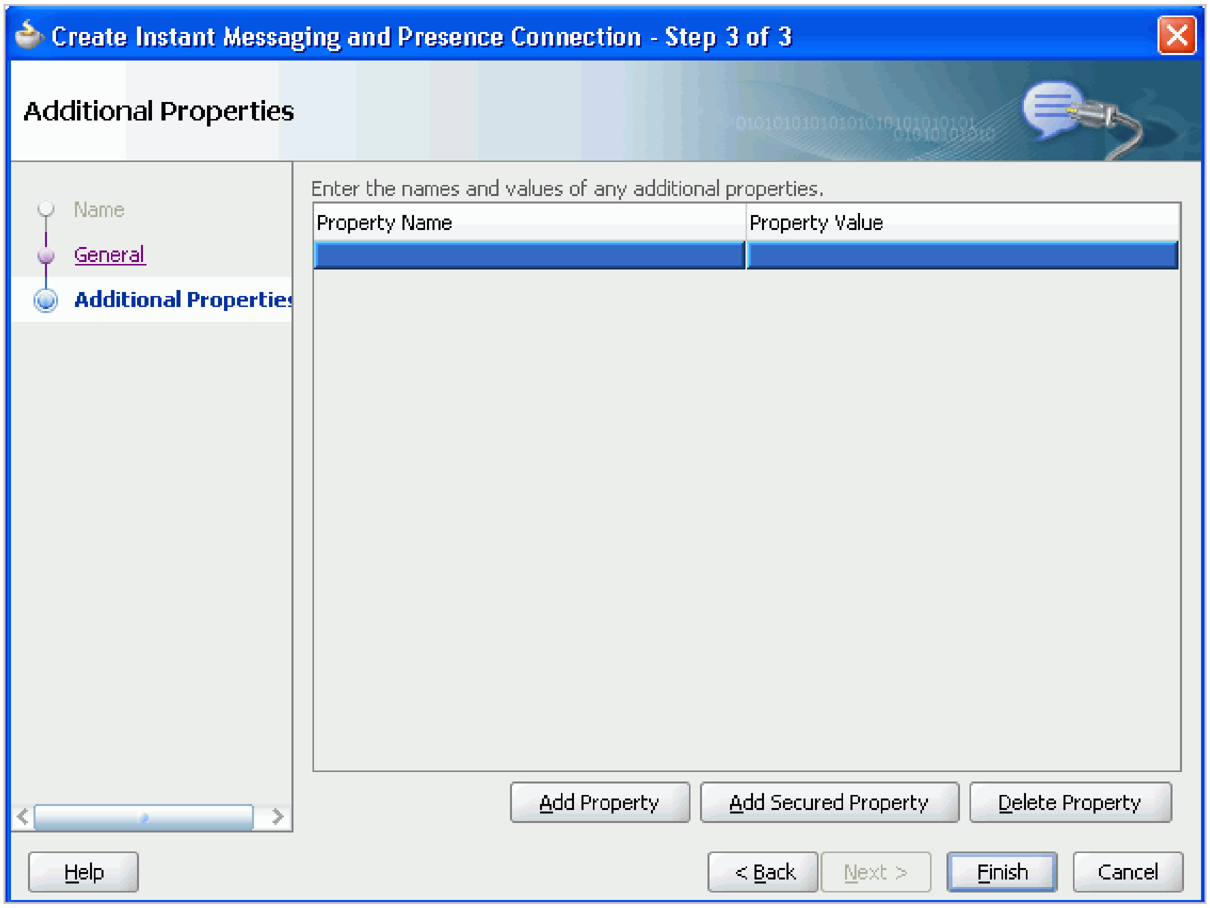
9. On the same page, select an **External Application** to leverage the authentication mechanism (user names and passwords) on the presence server.

   For LCS connections, an external application is mandatory. The application maps the presence server user to the application user such that end users do not have to enter their user names and passwords each time they need information. For detailed information about configuring an external application for IMP, see Section 34.2.3, "Setting Security for IMP."

10. Click **Test Connection** to confirm that the connection is good.

11. Click **Next** to create the connection.
12. On the **Additional Properties** page (Figure 34–5), you can optionally add parameters.

Figure 34–5   Create LCS Instant Messaging and Presence Connection, Step 3



Create Instant Messaging and Presence Connection - Step 3 of 3

Additional Properties

Enter the names and values of any additional properties.

Property Name	Property Value

13. Click **Finish**.

You can see the new IM and presence connection under **Application Resources - Connections**.

34.2.1.3 How to Set Up Microsoft OCS and Microsoft Lync Connections for IMP

To set up the connection to the Microsoft OCS or Microsoft Lync presence server:

1. In Oracle JDeveloper, open the Framework application in which you plan to consume instant messaging and presence.
2. In the Application Navigator, under Application Resources, right-click **Connections**, then select **Instant Messaging and Presence** from the list.
3. In the Create Instant Messaging and Presence connection dialog box, select to create the connection in **Application Resources**.

   A connection in Application Resources is available only for that application, while a connection in IDE connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE connections to avoid having to re-create it.

4. On the **Name** page, for **Connection Name**, enter a unique name for your connection.

   No other connection should have the same name.

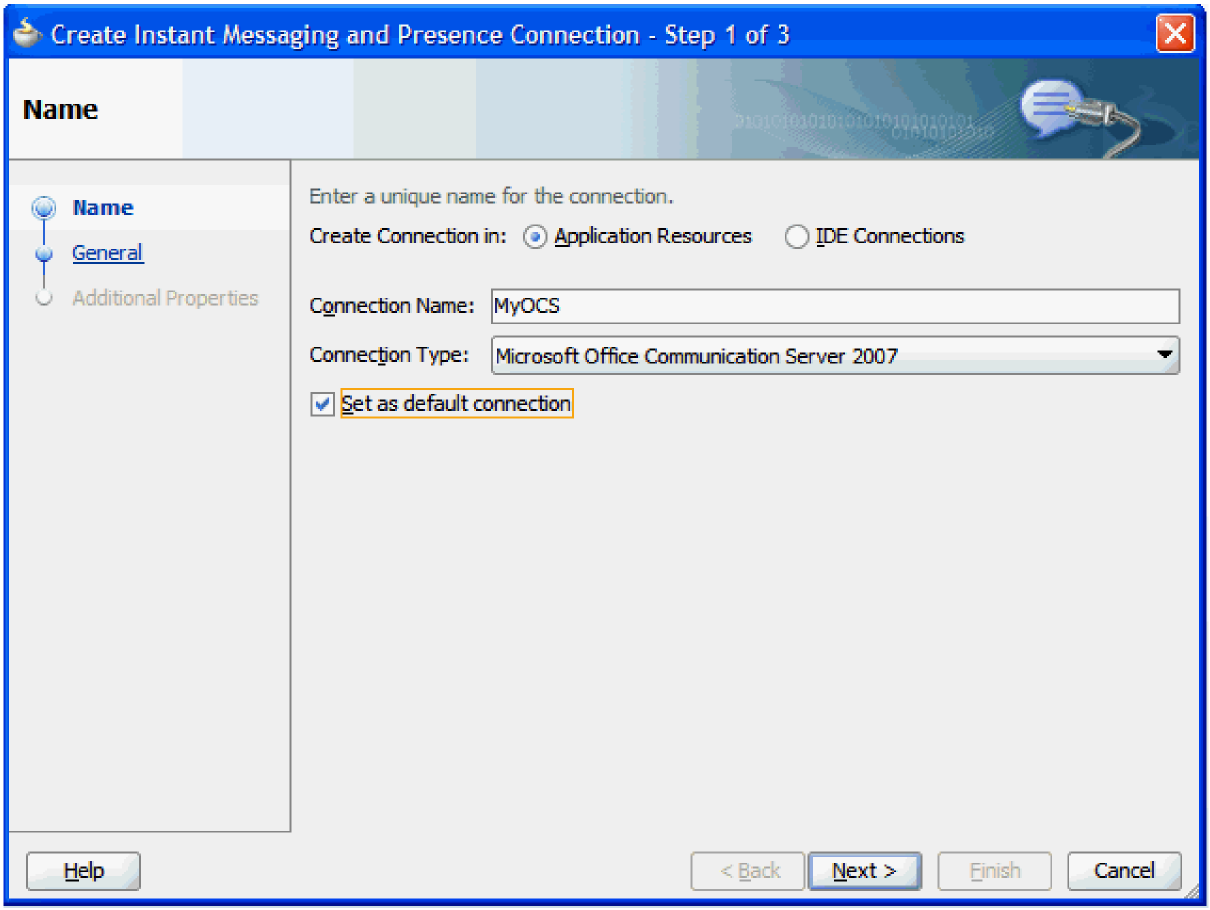
5. From the **Connection Type** list, select **Microsoft Office Communications Server 2007**.

   > **Note:** Microsoft Lync connections use the Microsoft Office Communications Server 2010 connection type.

6. Select the **Set as default connection** checkbox.

   One connection must be marked as the default connection, as shown in Figure 34–6.

Figure 34–6 Create Microsoft OCS or Microsoft Lync IMP Connection, Step 1



Create Instant Messaging and Presence Connection - Step 1 of 3

Name

Enter a unique name for the connection.

Create Connection in: ● Application Resources ○ IDE Connections

Connection Name: MyOCS

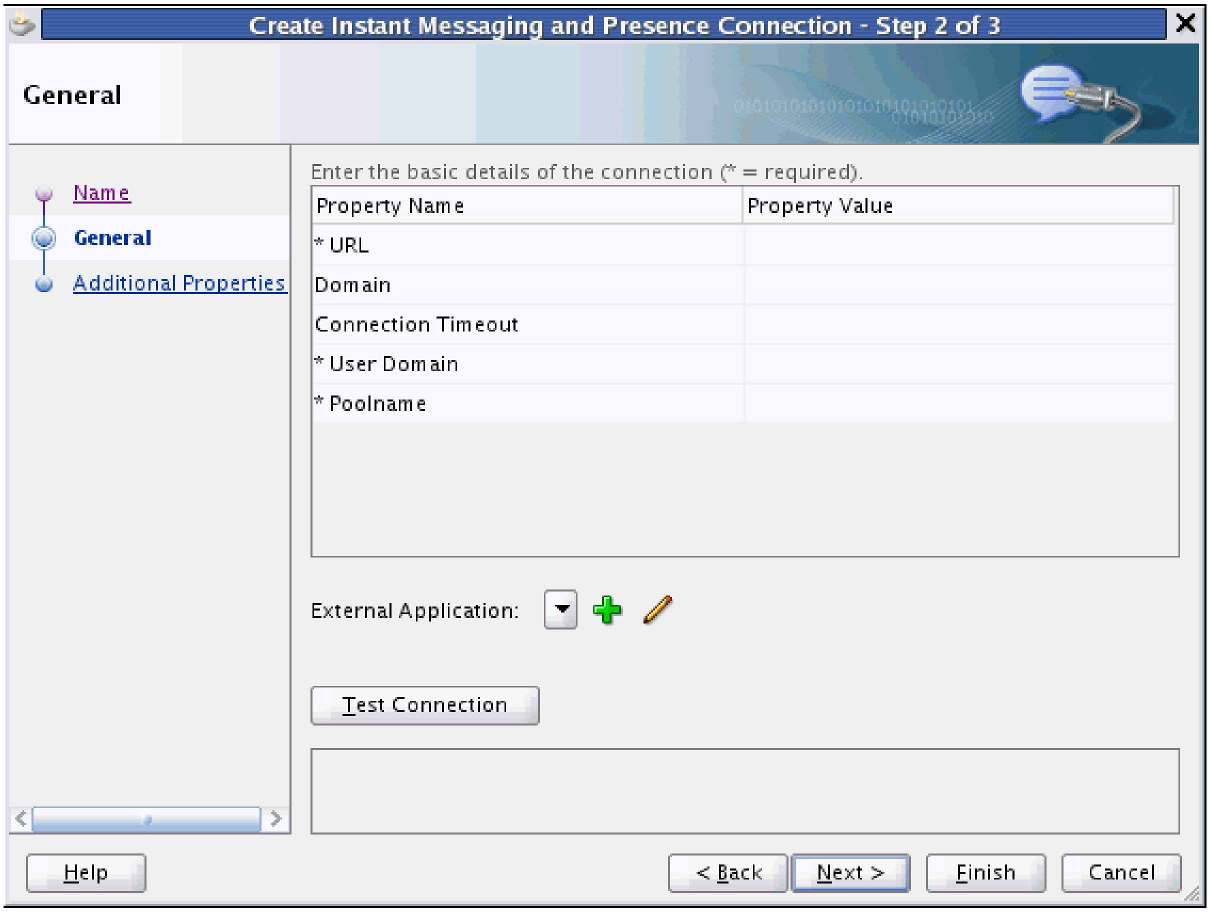
Connection Type: Microsoft Office Communication Server 2007

☑ Set as default connection

7. Click **Next**.

8. On the **General** page (Figure 34–7), enter the parameters for your Microsoft OCS or Microsoft Lync instance.

Figure 34–7 Create Microsoft OCS or Microsoft Lync IMP Connection, Step 2



Create Instant Messaging and Presence Connection - Step 2 of 3

General

Enter the basic details of the connection (* = required).

Property Name	Property Value
* URL	
Domain	
Connection Timeout	
* User Domain	
* Poolname	

External Application:

For example:

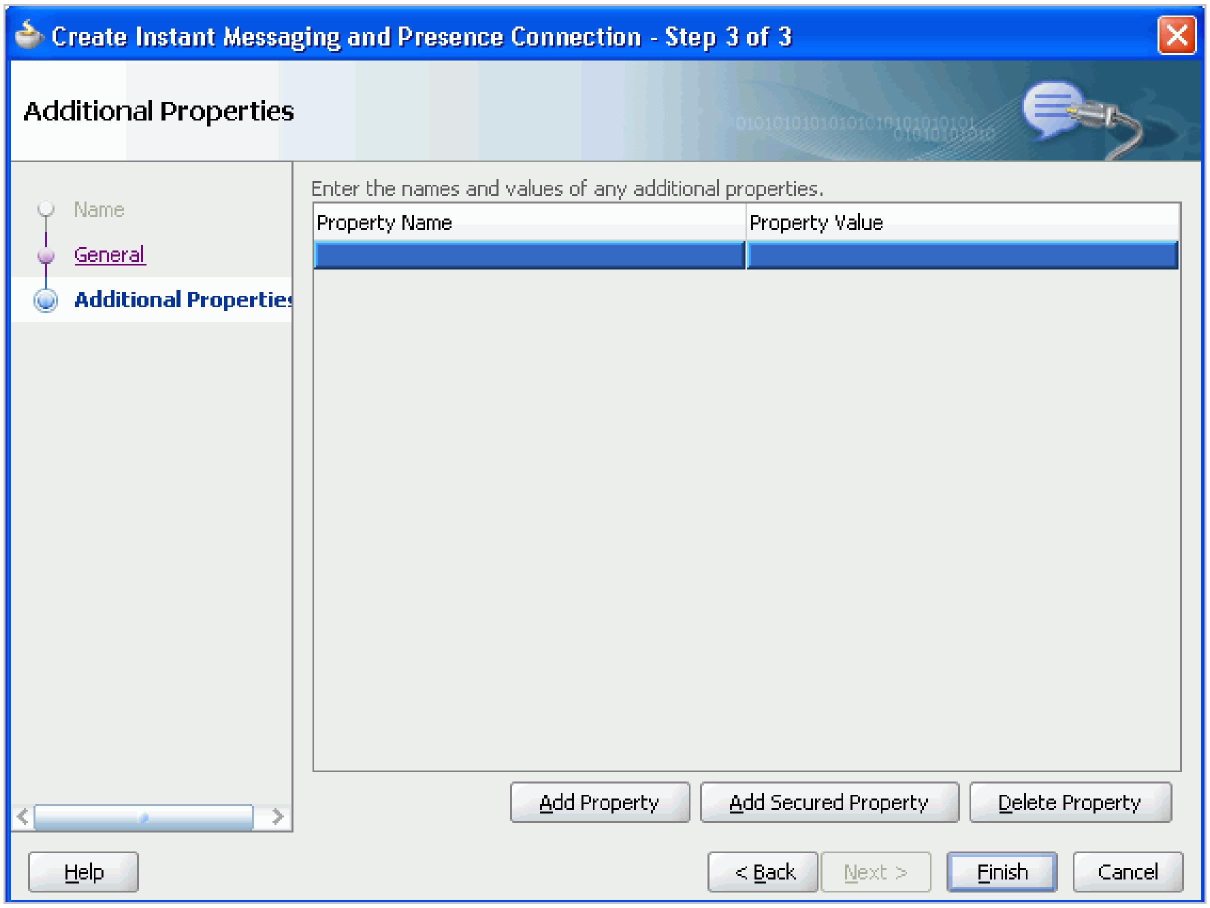
- The URL is the location of your Microsoft OCS or Lync instance. This could be http://host:port/RTC where RTC is the virtual directory name under which the server side module is deployed. (See the Microsoft documentation for more information.)
- The Domain property is maintained for backward compatibility. It should be left blank.
- The Connection Timeout property is optional. It represents the time (in seconds) WebCenter Portal should wait for the server to respond while making the connection. If the presence server does not respond in the given time, then it aborts the connection and reports an error.
- The User Domain is the Active Directory domain on Microsoft OCS or Lync. This parameter is mandatory.
- For Poolname, enter the name of the pool under which Microsoft Communications Server components are deployed. This parameter is mandatory. (See the Microsoft documentation for more information.)

9. On the same page, select an **External Application** to leverage the authentication mechanism (user names and passwords) on the presence server.

   For Microsoft OCS and Microsoft Lync connections, an external application is mandatory. The application maps the presence server user to the application user such that end users do not have to enter their user names and passwords each time they need information. For detailed information about configuring an external application for IMP, see Section 34.2.3, "Setting Security for IMP."

10. Click **Test Connection** to confirm that the connection is good.
11. Click **Next**.
12. On the **Additional Properties** page (Figure 34–5), you can optionally add parameters.

Figure 34–8 Create Microsoft OCS or Microsoft Lync IMP Connection, Step 3



13. Click **Finish**.

You can see the new IM and presence connection under **Application Resources - Connections**.

34.2.2 Adding IMP Functionality at Design Time

This section explains a basic incorporation of IMP into your application. It includes the following subsections:

- Section 34.2.2.1, "IMP Task Flows"
- Section 34.2.2.2, "How to Add IMP Functionality to your Application"

34.2.2.1 IMP Task Flows

IMP does not include any task flows.

34.2.2.2 How to Add IMP Functionality to your Application

To add IMP to your Framework application:

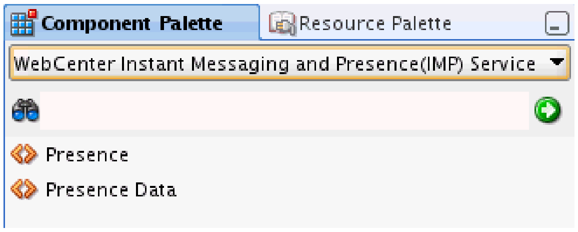
1. Follow the steps described in Chapter 2, "Setting Up Your Development Environment" to create a customizable page in your application.

2. Open the page on which you want to add IMP.

3. Ensure that you have configured your application to connect to the presence server. See Section 34.2.1, "Setting up Connections for IMP."

4. In the Component Palette, drag and drop the **Presence** component to the page to add the Presence icon (Figure 34–9).

Figure 34–9 Component Palette - IMP Components



WebCenter Instant Messaging and Presence(IMP) Service

Presence

Presence Data

Use the **Presence** icon anywhere you want to display a user, for example, as the author of a discussion topic, the sender/recipient of a mail, or the owner of a document.

5. In the resulting dialog box, enter the user name of a user that exists in the back-end server that is linked to in the IM and Presence connection.

   You can add numerous presence components to the application page.

   For information about optional **Presence** component parameters, see Section 34.3.2, "Customizing IMP Views."

6. Click **Finish**.

7. From the Component Palette, drag and drop **Presence Data** to the end of the page (that is, before the `<af:document>` tag).

   This component does not have any attributes.

   The **Presence Data** component provides the status information for all **Presence** components on the page, such as online, offline, or busy. It verifies that all presence information corresponding to the user on the whole page shows consistent status information. Without this component, all users appear offline.

   Because the **Presence Data** component makes a call to the back-end server, for best performance, ensure that this is the last tag on the page. To avoid adding this tag to every page in your application, consider using a page template with **Presence Data** as the last component; that is, before the end of the `</af:form>` tag.

> **Note:** You can create new pages at runtime on which you can add components, such as forums, mail, or documents. Many components have **Presence** tags, but users do not have a handle to add the **Presence Data** tag to the page. To see presence on custom pages, you must manually add the **Presence Data** tag to the underlying template.

8. If **External Application** in IDE connections was selected when you created the connection, then drag and drop the **External Application - Change Password** task flow into your application from the Resource Palette or Component Palette.

   This task flow enables the end user to set the appropriate user name and password for the external application.

9. Save your project, and then run your page to a browser to see the Presence component.

   Figure 34–10 shows the runtime Presence component with the display name of user Monty Montasaurus111.

Figure 34–10 WebCenter Portal Presence Icon - Online

34.2.3 Setting Security for IMP

IMP requires user identity. ADF security is configured by default if you created your application using the WebCenter Portal - Framework Application template. For information about configuring ADF security, see Section 74.3, "Configuring ADF Security."

Credentials are read from the external application (public credentials) and used to log on to the presence server. If you do not apply ADF security or if you do not have an external application configured, then users cannot authenticate and do not see any content at runtime.

> **Note:** The presence server and the Framework application should point to the same identity store. The identity store must be LDAP-based; that is, not file-based with `jazn-data.xml`.

To access the presence server, IMP can use an external application with dedicated user accounts.

Microsoft LCS, OCS, and Lync support external application connections. With a secured application, users get presence status. The Change Credentials option works as an alternative to using an external application. Logged-in users can click their own Presence context menu and select **Change Credentials**. Security should be on a private trusted network.

To use an external application for authentication:

1. On the General page of the Create Instant Messaging and Presence connection wizard, click the **+** icon next to External Application.

   This brings up the Register External Application wizard. The application maps the presence server user to the application user such that end users do not have to enter their user names and passwords each time.

   > **Note:** External application credential provisioning is built into the IMP connection. You do not need to drop **External Application - Change Password** task flow on a page.

2. On the Name page:

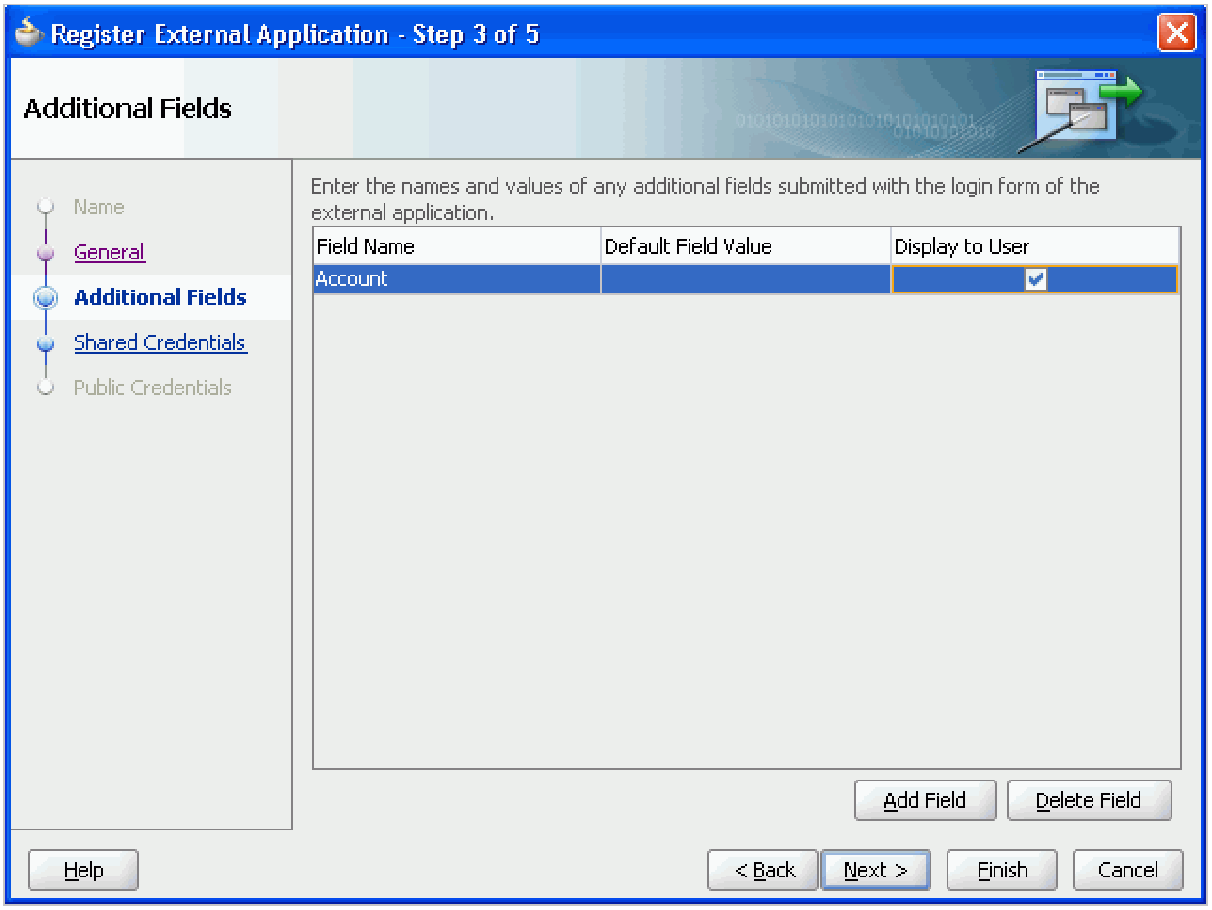
- For **Application Name**, enter a unique name to identify the application. This name must be unique within the Framework application, and among other connections as well. Note that you cannot edit this field afterward.
- For **Display Name**, enter a name for the application that end users see in the credential provisioning screens.

3. Click **Next**.
4. On the General page, leave the following properties with the default values.
   - **Login URL**
   - **User Name/ID Field Name**
   - **Password Field Name**
5. From the **Authentication Method** list, select **POST**. This submits login credentials within the body of a form. The external application for IMP requires this authentication method.
6. Click **Next**.
7. On the Additional Fields page:

   Click **Add Field**, and add an extra field with the name "Account." Make sure to select the **Display to User** checkbox, as shown in Figure 34–11.

> **Note:** The external application for IMP requires this additional field. It must be displayed to users.

Figure 34–11 Account Additional Field



Enter the names and values of any additional fields submitted with the login form of the external application.

Field Name	Default Field Value	Display to User
Account		☑

8. External applications allow different types of credentials to be associated with a connection:

   - When shared credentials are specified, every *authenticated* user uses the same credentials to access the external application; that is, the user name and password you can define here. A single presence session is created for all logged-in users. This is not accessible to public users.
   - With public credentials, without authenticating your Framework application, you can view presence from a certain presence ID for all *unauthenticated* (public) users. Public credentials are used whenever an application is not secured or the user has not yet logged in. A single presence session is created for all public users.
   - With private credentials, each user must authenticate to an *individual* ID (that is, each application user must specify his own credentials). One presence session is created for each user.

9. Click **Finish** to have the external application use private credentials, or click **Next** to set up shared or public credentials.

10. *For Shared Credentials Only*: On the Shared Credentials page, ensure that **Specify Shared Credentials** is selected, then enter the shared user credentials and ID.

11. *For Public Credentials Only*: On the Public Credentials page, ensure that **Specify Public Credentials** is selected, then enter the user credentials and ID for public use.

12. Click **Finish** to register the external application.
13. In the IMP connection wizard, ensure that this newly-created external application connection for IMP is selected.

For information about using external applications, see Section 74.13, "Working with External Applications."

34.3 Advanced Information for IMP

This section describes optional features available with IMP. It includes the following subsections:

- Section 34.3.1, "Enabling Network Presence"
- Section 34.3.2, "Customizing IMP Views"
- Section 34.3.3, "Troubleshooting IMP"

34.3.1 Enabling Network Presence

When WebCenter Portal presence is not available (for example, if your enterprise uses a Jabber/XMPP presence server or has federated presence servers with users distributed across identity management systems), you can connect to a third-party network presence service.

Out-of-the-box, WebCenter Portal supports Yahoo! Messenger on network presence. However, the network presence model can be extended to include other providers, such as ICQ.

This section includes the following subsections:

- Section 34.3.1.1, "Setting Up Yahoo! Messenger Presence"
- Section 34.3.1.2, "Setting Up Other Network Presence Providers"

34.3.1.1 Setting Up Yahoo! Messenger Presence

WebCenter Portal Framework allows end users to set their IM preferences to their Yahoo! Messenger presence. Portal developers enable this functionality by leveraging the `rtcPresenceHandler` bean.

Follow these steps to include Yahoo! Messenger presence in your Framework application.

1. On the Source tab for your JPSX page, add the user interface for users to enter their Yahoo! Messenger credentials: **Display Name** and **IM Address** input boxes and a **Save IM Preferences** button.

   Example 34–2 shows the two `af:inputText` components for users to enter Display Name and IM Address and an `af:commandButton` component for users to save the preferences.

   Setting the `inputText` value with this EL sets the `displayName` and `imAddress` in the preferences bean. To save the values, users click the button, which invokes a method from the bean to save the preferences.

Example 34–2 User Interface for Yahoo! Messenger Presence

```
      <af:inputText label="Display Name"
value="#{rtcPreferenceHandler.displayName}" id="it1"/>
      <af:inputText label="IM Address"
value="#{rtcPreferenceHandler.imAddress}" id="it2"/>
```

```
                        <af:commandButton text="Save IM Preferences" id="cb1"
                 actionListener="#{rtcPreferenceHandler.savePreferences}"/>
```

Example 34–3 shows the full source code for the page, with the user interface included.

Example 34–3 Source Code for the Page with Yahoo Presence

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:rtc="http://xmlns.oracle.com/webcenter/collab/rtc">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <f:view>
    <af:document id="d1">
      <af:form id="f1" usesUpload="true">
        <af:panelStretchLayout id="psl1">
          <f:facet name="bottom"/>
          <f:facet name="center">
            <af:panelGroupLayout layout="scroll"
                                 xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
                                 id="pgl1">
              <rtc:presence username="#{rtcPreferenceHandler.imAddress}"
displayName="#{rtcPreferenceHandler.displayName}" id="p1"/>
              <rtc:presenceData id="pd1"/>
              <af:inputText label="Display Name" value="#{rtcPreferenceHandler.displayName}"
id="it1"/>
              <af:inputText label="IM Address" value="#{rtcPreferenceHandler.imAddress}" id="it2"/>
              <af:commandButton text="Save IM Preferences" id="cb1"
                                actionListener="#{rtcPreferenceHandler.savePreferences}"/>

            </af:panelGroupLayout>
          </f:facet>
          <f:facet name="start">
            <af:spacer width="10" height="10" id="s1"/>
          </f:facet>
          <f:facet name="end">
            <af:spacer width="10" height="10" id="s2"/>
          </f:facet>
          <f:facet name="top"/>
        </af:panelStretchLayout>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

2. Run the JPSX page to see that now users can enter their Yahoo! Messenger credentials (Figure 34–12).

Figure 34–12 User Interface to Enter Yahoo! Messenger Credentials

34.3.1.2 Setting Up Other Network Presence Providers

To use a different network presence provider, deploy your application that contains the `PresenceNetworkAgent` implementation class for that service and an `imp-pna.config` file listing that implementation class into a jar file.

For example, suppose the new Presence Network Agent is called SamplePNA. You must create two files: the `Project1.SamplePNA` class file and the `imp-pna.config` file.

- `Project1.SamplePNA.java`: This class implements `oracle.webcenter.collab.rtc.PresenceNetworkAgent`. It must implement three methods:
  - `isSupported(PNAContext context)`: The method should return true if the PNA supports the user for which presence is requested. The `PNAContext` object supplied contains the user information. For example, if the PNA supports all IM addresses with the domain `example.com`, then it can get the imAddress from the `PNAContext` object and check for the domain `example.com`.
  - `getURL(PNAContext context)`: The method should return the fully qualified URL to reach to the user's Presence icon. Again, it gets the user information from the `PNAContext` object.
  - `getChatURI(PNAContext context)`: The method should return the browser compatible URI to invoke the chat client (for example, `sip:user@example.com`).

  Example 34–3 shows this SamplePNA class file.

Example 34–4 SamplePNA Class File

```
public class SamplePNA implements PresenceNetworkAgent
{
private String DOMAIN = "@example.com";

public SamplePNA()
{
super();
}

//Returns true if the imAddress ends with DOMAIN
public Boolean isSupported(PNAContext context)
{
String imAddress = context.getIMAddress();
if(imAddress.endsWith(DOMAIN))
{
return true;
}

return false;
}

//Returns the URL to the icon representing the current status of a user
public String getURL(PNAContext context)
{
String imAddress = context.getIMAddress();
Strung url = "http://www.example.com?address=" + imAddress;
return url;
}

//Returns the browser compatible chat uri to invoke the thick client
public String getChatURI(PNAContext context)
{
String imAddress = context.getIMAddress();
String chatURI = "sip:" + imAddress;
return chatURI;
}
}
```

- META-INF/imp-pna.config: This file lists the available PNAAgent classes. In this case, it contains only the following line:

  ```
  Project1.SamplePNA
  ```

Whenever a Presence tag is encountered with an IM address as *user@example.com*. The URL configured appears on the user interface as the Presence icon.

```
<rtc:presence username="user1@example.com" resolveAddress="false"/>
```

34.3.2 Customizing IMP Views

Table 34–1 lists the attributes supported by the **Presence** component. Only the username attribute is required; all other attributes are optional. You can update these attributes in the Property Inspector.

Table 34–1 Presence Component Description

Attribute	Description
username	The user whose presence information you want to add to the application page. This attribute is required.
display	How the component should display. Takes one of the following values: ▪ icon: Display only the Presence icon; do not render the name. ▪ name: Display the user name; do not display the Presence icon. ▪ both (default): Display both the icon and the user name.
displayName	By default, the **Presence** component displays the user name. If the flag get.display.name.from.user.profile is set to true in service-config.xml *and* if this displayName attribute is not supplied, then the **Presence** component tries to look up a user's display name from the User Profile.
iconPosition	The position for the icon. Possible values are begin and end. The default value is begin.
controlsEnabled	A Boolean value that defines whether the component should provide rich interactions to the end user. If this attribute is set to false, then the Presence component does not do anything when clicked.
id	A unique identifier for the component on the page. The identifier must follow a subset of the syntax allowed in HTML: ▪ Must not be a zero-length String. ▪ First character must be an ASCII letter (A-Z, a-z) or an underscore ('_'). ▪ Subsequent characters must be an ASCII letter or digit (A-Z, a-z, 0-9), an underscore ('_'), or a dash ('-').
smallIcon	A Boolean value that defines whether to use the small 12x12 icon set (true) or to use the default 16x16 icon set (false). The default value is false.
rendered	A Boolean value that defines whether to render this component. The default value is true.
binding	An EL reference to store the component instance on a bean. Use this to give programmatic access to a component from a backing bean or to move creation of the component to a backing bean.
inlineStyle	The CSS styles to use for this component. Manually enter any style in compliance with CSS version 2.0 or later, or expand this node to specify style elements. This is intended for basic style changes.

Table 34–1 (Cont.) Presence Component Description

Attribute	Description
`styleClass`	A CSS style class to use for this component.
`resolveToAddress`	A Boolean value that defines whether to resolve the supplied `username` to an IM address. The default value is `true`. However, if the supplied `username` is an IM address, then you can set this value to `false`, and IMP uses `username` as the IM address.

34.3.3 Troubleshooting IMP

This section describes common problems and solutions for IMP.

Problem

The Presence icon is not visible in your Framework application.

Solution

Ensure that an IMP connection exists in your application and has been set as active.

Problem

Changes in the presence status of users are not visible in your Framework application.

Solution

For each logged-in user's session, IMP fetches the presence information from the presence server and stores it in the presence cache. For presence requests, IMP returns the data from the cache until the cache expires. The default cache expiry period is 60 seconds.

To view the updated presence status, you can wait for the cache to expire and retrieve the latest presence status.

You can also change the cache expiry time by setting the `rtc.cache.time` configuration property to the desired value (in seconds). Update `adf-config.xml` to include the highlighted entry, which shows the sample value as 30 seconds. Example 34–5 shows an example.

Example 34–5 Setting the rtc.cache.time Expiration Value in adf-config.xml

```
<adf-collaboration-config xmlns="http://xmlns.oracle.com/webcenter/collab/config">
<service-config serviceId="oracle.webcenter.collab.rtc">
<property name="rtc.cache.time" value="30"/></service-config>
</adf-collaboration-config>
```

Problem

A number of options, such as Send Instant Message, are not available in the IMP context menu in your Framework application.

Solution

Ensure that IMP is configured in your Framework application. Also, ensure the following settings for the various context menu options:

- **View Profile** option unavailable: Ensure that your application is secured.
- **Send Instant Message** option unavailable: Ensure that IMP is configured in the application.

Problem

You are unable to send a message from your Framework application. Clicking the **Send Instant Message** option returns an error.

Solution

Ensure that your SIP client is supported by the presence server and you have logged on as an authenticated user. The supported SIP client is Microsoft Communicator.

35

Integrating Mail

This chapter explains how to integrate email functionality in a Portal Framework application at design time.

This chapter includes the following sections:

- Section 35.1, "Introduction to Mail"
- Section 35.2, "Basic Configuration for Mail"
- Section 35.3, "Advanced Information for Mail"

Note: WebCenter Portal Mail supports only the Inbox. No other folders (or moving of messages) are supported.

For more information about managing and including mail, see:

- the "Managing Mail" chapter in *Administering Oracle WebCenter Portal*
- the "Working with Mail" chapter in *Using Oracle WebCenter Portal*

35.1 Introduction to Mail

This section provides an overview of WebCenter Portal mail features and requirements. It includes the following subsections:

- Section 35.1.1, "Understanding Mail"
- Section 35.1.2, "Requirements for Mail"

35.1.1 Understanding Mail

Mail functionality enables users to access the inbox of a mail server that supports Internet Message Access Protocol4 (IMAP4) and Simple Mail Transfer Protocol (SMTP). Additionally, it enables users to compose a new mail message from within the application (with attachments) and delete, reply to, and forward messages.

This mail does not replace users' mail clients; it simply enables users to access and compose mail in a single, collaborative environment.

With mail, you can do the following:

- Read a message by clicking the linked mail subject.
- View sender details (including date) by expanding the **From** field.
- Scroll down to see the other messages not in the view. You can navigate among the fetched messages as cached messages.

- Attach a file to a message by expanding the attachment section within the mail dialog and clicking **Attach**. Specify an attachment in the new dialog pop-up. Remove an attachment from the mail by clicking the **Remove Attachment** icon.
- Reply to a message by clicking the **Reply** or **Reply All** icon.
- Forward a message by clicking the **Forward** icon.
- Cancel an operation (for example, sending a mail) by clicking **Cancel**.

Figure 35–1 shows the Mail task flow at runtime. At the top of the view are three elements: a dropdown list that shows the number of mail messages to display (here, **All**), the **Compose** icon, and the **Refresh** icon. The **Refresh** icon provides a means of manually checking for new messages in the inbox.

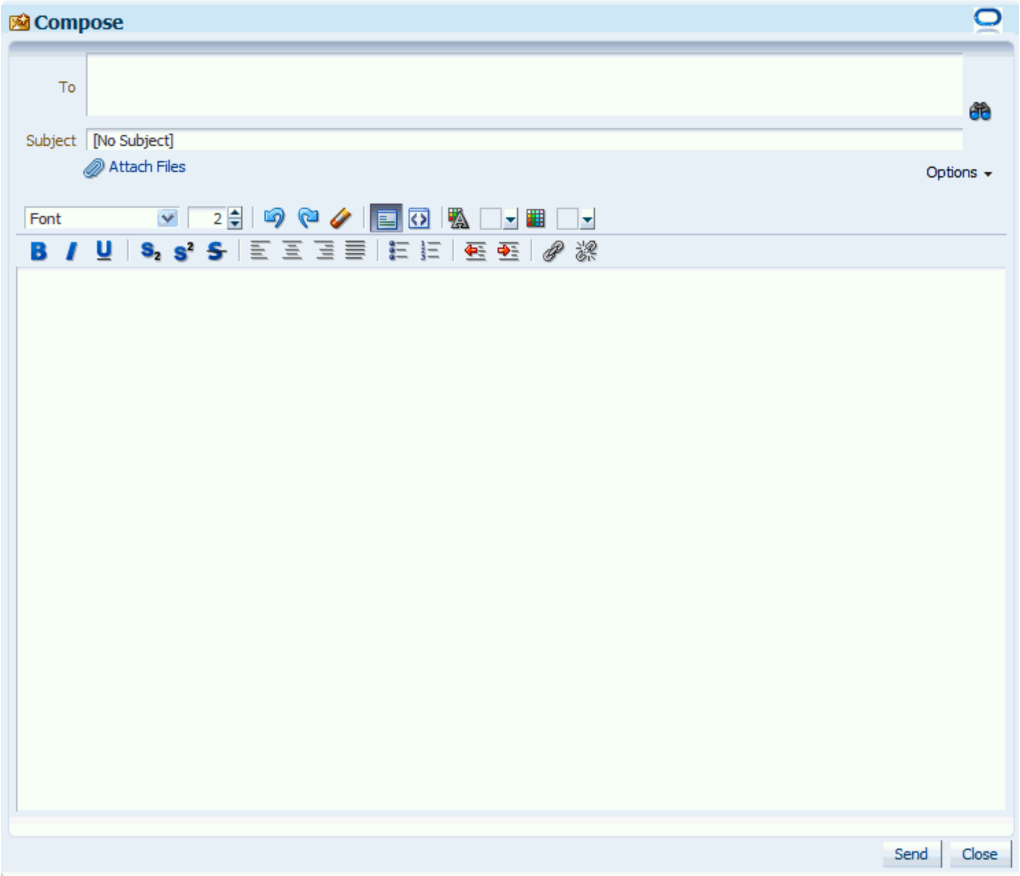
This Month

Note: By default, `All` displays the 50 most recent messages. For information on how to increase this amount, see Section 35.3.2, "Configuring the Number of Mail Messages Displayed."

Click the **Compose** icon next to the dropdown list to compose a new message right from your application. Clicking this icon displays the Compose page, as shown in Figure 35–3.

Figure 35–3 Compose Mail



Use the **Search** icons to find mail addresses and contacts of users in the LDAP store that the Framework application uses. For any user not in the LDAP store, you must enter an explicit mail address.

For more information about mail at runtime, see the "Working with Mail" section in *Using Oracle WebCenter Portal*.

35.1.2 Requirements for Mail

Mail requires a mail server that supports IMAP4 and SMTP. The Microsoft Exchange mail server is required for automatic creation of distribution lists when portals are created. In a Portal Framework application, this feature may not be desirable. To disable it, do not provide the LDAP (Active Directory) server details in the mail connection.

35.2 Basic Configuration for Mail

This section describes the steps required for adding mail functionality to your application. It includes the following subsections:

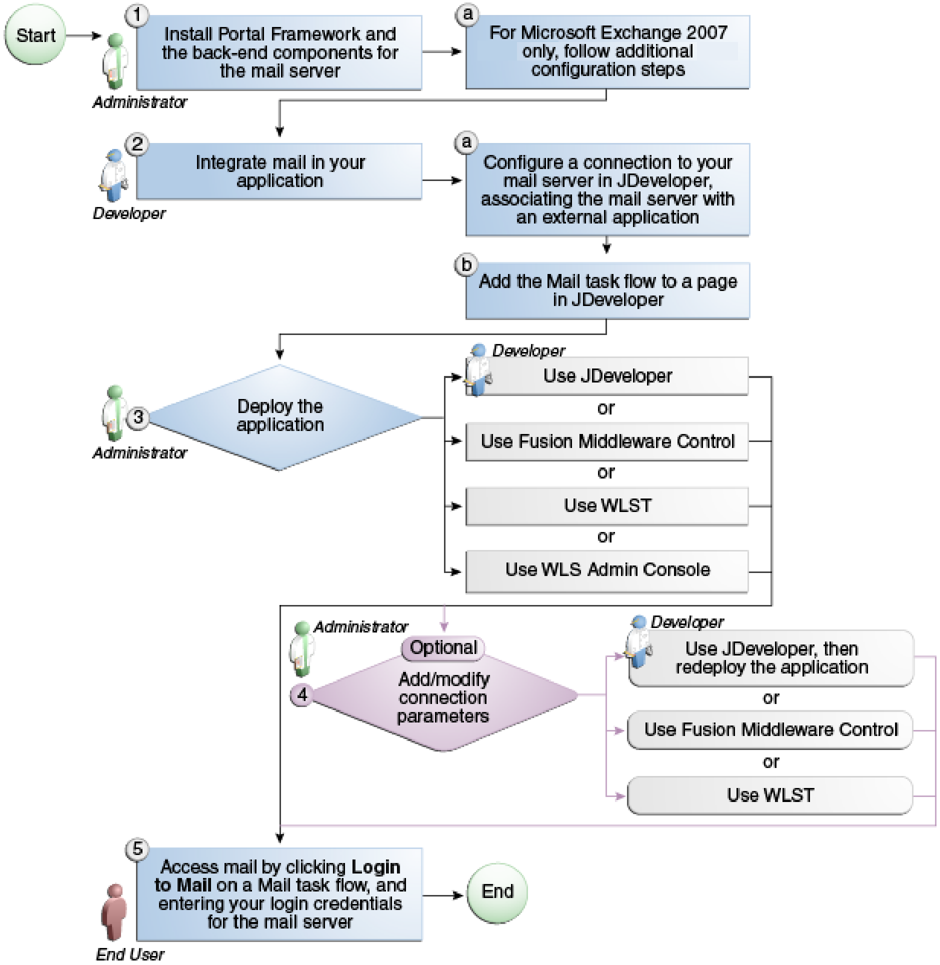
- Section 35.2.1, "Configuration Roadmap - Mail"
- Section 35.2.2, "Setting up Connections for Mail"
- Section 35.2.3, "Adding Mail Functionality at Design Time"
- Section 35.2.4, "Setting Security for Mail"

35.2.1 Configuration Roadmap - Mail

Use the roadmap in this section as a guide through the configuration process.

Figure 35–4 and Table 35–1 provide an overview of the prerequisites and tasks required to get mail working in Portal Framework applications.

Figure 35–4 Configuring Mail for Portal Framework Applications



Start
1
Administrator
Install Portal Framework and the back-end components for the mail server
a
For Microsoft Exchange 2007 only, follow additional configuration steps
2
Developer
Integrate mail in your application
a
Configure a connection to your mail server in JDeveloper, associating the mail server with an external application
b
Add the Mail task flow to a page in JDeveloper
3
Administrator
Deploy the application
Developer
Use JDeveloper
or
Use Fusion Middleware Control
or
Use WLST
or
Use WLS Admin Console
Administrator
Optional
4
Add/modify connection parameters
Developer
Use JDeveloper, then redeploy the application
or
Use Fusion Middleware Control
or
Use WLST
5
Access mail by clicking Login to Mail on a Mail task flow, and entering your login credentials for the mail server
End User
End

Table 35–1 Configuring Mail for Portal Framework Applications

Actor	Task	Sub-task
Administrator	1. Install WebCenter Portal and the back-end components for mail	1.a For Microsoft Exchange 2007 only, follow additional configuration steps
Developer	2. Integrate mail in your Portal Framework application	2.a Configure a connection to your mail server in JDeveloper, associating the mail server with an external application
		2.b Add the Mail task flow to a page in JDeveloper

Table 35–1 (Cont.) Configuring Mail for Portal Framework Applications

Actor	Task	Sub-task
Developer or Administrator	3. Deploy the Portal Framework application using one of the following tools: ■ JDeveloper (Developer) ■ Fusion Middleware Control (Administrator) ■ WLST (Administrator) ■ WLS Admin Control (Administrator)	
Developer or Administrator	4. (Optional) Add/modify connection parameters using one of the following tools: ■ JDeveloper, then redeploy the application (Developer) ■ Fusion Middleware Control (Administrator) ■ WLST (Administrator)	
End User	5. Access mail by clicking **Login to Mail** on a Mail task flow, and entering your login credentials for the mail server	

35.2.2 Setting up Connections for Mail

Before you can use mail, you must first set up the connection to your mail server. This can be any mail server based on IMAP4 and SMTP protocol.

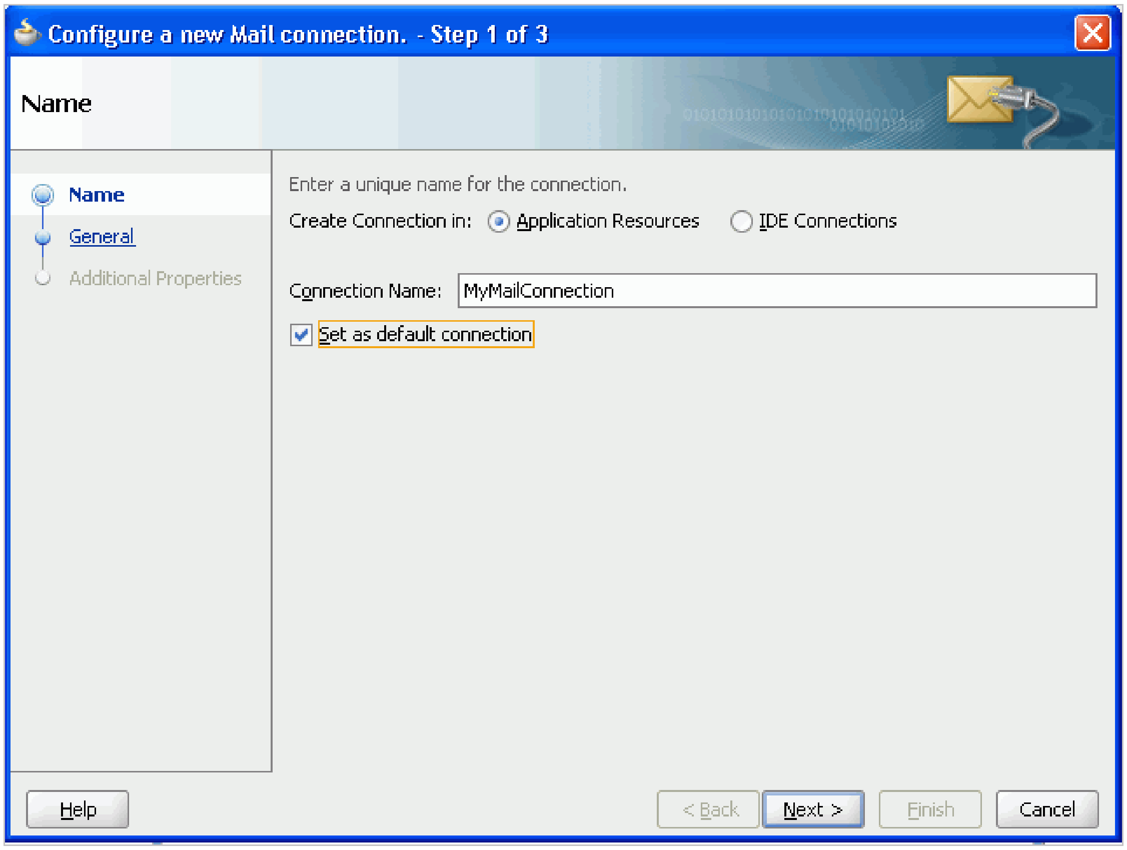
> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, see *Administering Oracle WebCenter Portal*.

To create a connection to your mail server from the application:

1. In Oracle JDeveloper, open the application in which to consume mail.
2. In your application, under Application Resources, right-click **Connections**, then select **Mail** from the list.
3. Select to create the Mail connection in **Application Resources**.

   A connection in Application Resources is available only for that application; while a connection in IDE Connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE Connections to avoid having to re-create it.
4. In the **Connection Name** field, enter a unique name for the connection.
5. When configuring a single mail account, select the **Set as default connection** checkbox to use this as the active connection (Figure 35–5).

Figure 35–5 Configure a New Mail Connection, Step 1



Enter a unique name for the connection.

Create Connection in: ● Application Resources ○ IDE Connections

Connection Name: MyMailConnection

☑ Set as default connection

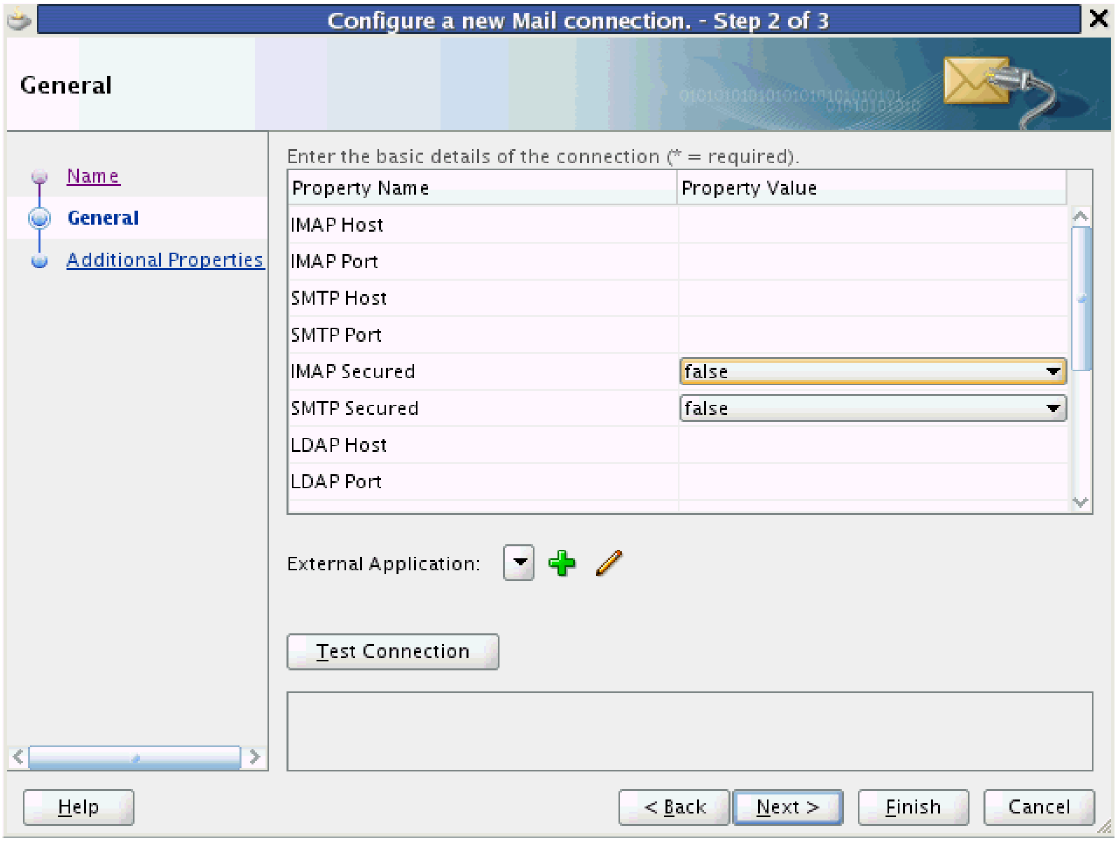
When configuring multiple mail accounts, you are not necessarily required to select this as the default connection. Keep in mind, however, that one connection must be marked as the default connection.

Note: After you create a connection as the default connection, you cannot edit it so that it is *not* the default. To use a different default connection, you must create a new connection and mark that as the default connection.

---

6. On the **General** page, enter values for the parameters (Figure 35–6).

Figure 35–6 Configure a New Mail Connection, Step 2



Configure a new Mail connection. - Step 2 of 3

General

Enter the basic details of the connection (* = required).

Property Name	Property Value
IMAP Host	
IMAP Port	
SMTP Host	
SMTP Port	
IMAP Secured	false
SMTP Secured	false
LDAP Host	
LDAP Port	

External Application:

- `IMAP Host`: The location of your IMAP server
- `IMAP Port`: The IMAP server port number (default is -1)
- `SMTP Host`: The location of your SMTP server
- `SMTP Port`: The SMTP server port number (default is -1)
- `IMAP Secured`: Indicates (true/false) a secure SSL connection (default is false)
- `SMTP Secured`: Indicates (true/false) a secure SSL connection (default is false)
- `LDAP Host` and `LDAP Port`: These, and all other LDAP values, are required only if Microsoft Exchange is the mail server. For mail to create distribution lists reliably, the WebCenter Portal application should use the same Active Directory server as Microsoft Exchange.
- `Connection Timeout`: The connection timeout (in seconds).

7. Click **Test Connection** to check that the host and port are available.
8. You must select an existing external application or create a new external application to proceed:

   a. For **External Application**, click the **+** icon to open the Register External Application wizard

   The application maps the mail server user to the application user so that end users are not required to enter their user names and passwords each time.

   For more information on external applications, see Section 74.13, "Working with External Applications."

Note: External application credential provisioning is built into the mail connection. You do not need to drop the **External Application - Change Password** task flow on a page.

b. On the Name page:

For **Application Name**, enter a unique name to identify the application. This name must be unique not only within the Framework application, but also among other connections. Note that you cannot edit this field afterward.

For **Display Name**, enter a name for the application that end users see in the credential provisioning screens.

c. Click **Next**.

d. On the General page, you can *optionally* enter values if you want the external application for mail to participate in Click Through Login.

For **Login URL**, enter the URL to which the HTML login page is submitted. View the HTML source of the application's login form to retrieve this URL.

For **User Name/ID Field Name**, enter the label that the application uses for the user name field, for example, User Name.

For **Password Field Name** field, enter the label that the application uses for the password field, for example Password.

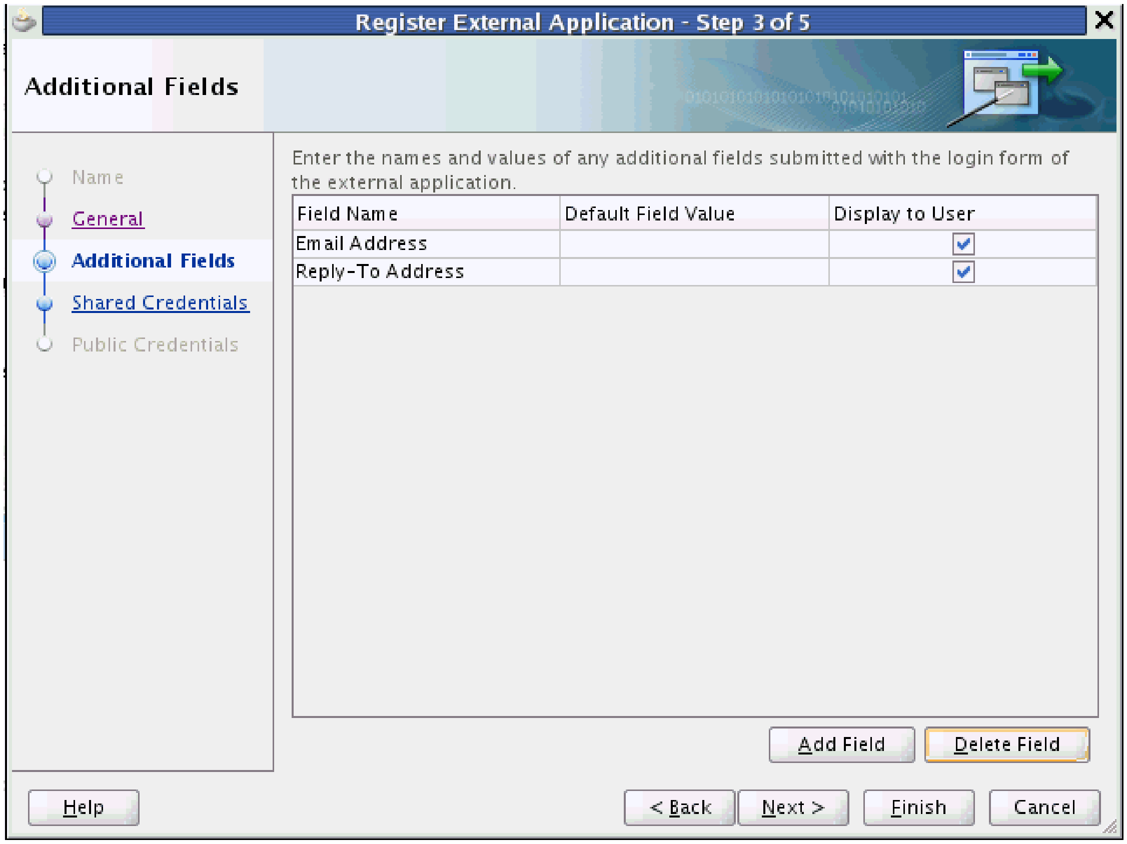
From the **Authentication Method** list, select **POST**. This submits login credentials within the body of a form. The external application for mail requires this authentication method.

e. Click **Next**.

f. On the Additional Fields page, click **Add Field**, and add an extra field with the name `Email Address`. This field captures the user's mail address, so that when the user sends mail, the sender address is this mail address. Select the **Display to User** checkbox.

Additionally, to specify that replies to the user's mail should go to different mail address than the `Email Address` field, click **Add Field** again, and add an extra field with the name `Reply-To Address`. Select the **Display to User** checkbox, as shown in Figure 35–7.

Figure 35–7 Email Address and Reply-To Additional Fields



Enter the names and values of any additional fields submitted with the login form of the external application.

Field Name	Default Field Value	Display to User
Email Address		☑
Reply-To Address		☑

Note: The external application for mail requires the `Email Address` field, and it must be shown to users. Fields for `Display Name` and `Reply-To Address` also are leveraged when sending mail.

---

g. External applications allow different types of credentials to be associated with a connection.

When shared credentials are specified, every *authenticated* user uses the same credentials to access the external application; that is, the user name and password you define here.

With public credentials, without authenticating your Framework application, you can view mail from a certain mail ID for all *unauthenticated* (public) users. Public credentials are used whenever an application is not secured or the user has not yet logged in.

Note: Public credentials are required to send mail from a self-registration page.

With private credentials, each user must authenticate to an *individual* mail ID. That is, each application user must specify his own credentials.

h. Click **Finish** to have the external application use private credentials, or click **Next** to set up shared or public credentials.

i. *For Shared Credentials Only*: On the Shared Credentials page, ensure that **Specify Shared Credentials** is selected and then enter the shared user credentials and mail ID.

j. *For Public Credentials Only*: On the Public Credentials page, ensure that **Specify Public Credentials** is selected and then enter the user credentials and mail ID for public use.

k. Click **Finish** to register the external application.

9. Back on the Mail connection wizard, ensure that this newly-created external application connection for mail is selected.

10. Optionally, you can add LDAP parameter values for the Active Directory server to manage portal distribution lists.

For detailed parameter information, see Table 35–2.

> **Note:** For WebCenter Portal and mail to share an identity management system for setting up portal mailing lists, you must use Active Directory. For information about installing and configuring mail servers as the WebCenter Portal administrator, see *Administering Oracle WebCenter Portal*.

Table 35–2 LDAP Directory Server Configuration Parameters

Field	Description
LDAP Host	Enter the host name of the computer where the LDAP directory server is running.
LDAP Port	Enter the port on which the LDAP directory server listens.
LDAP Base DN	Enter the base distinguished name for the LDAP schema. For example, CN=Users,DC=oracle,DC=com.
LDAP Domain	Enter the domain to be appended to distribution list names. For example, if the domain value is set to `oracle.com`, then the Finance Project portal maintains a distribution list named `FinanceProject@oracle.com`.
LDAP Administrator User Name	Enter the user name of the LDAP directory server administrator. A valid user with privileges to make entries into the LDAP schema.
LDAP Administrator Password	Enter the password for the LDAP directory server administrator. The password is stored in a secured store.
LDAP Default User	Enter a comma-delimited list of user names to whom you want to grant moderator capabilities. These users become members of every portal distribution list that is created. The users specified must exist in the base LDAP schema (specified in the `LDAP Base DN` field).
`ldap.secured`	Indicate whether a secured connection (SSL) is required between the Framework application and the LDAP directory server. If LDAP is configured to run in secure mode, then add this property (set to true/false) to use LDAP while creating distribution lists.

11. Click **Finish**.

You can see the new mail connection under **Application Resources - Connections**.

35.2.3 Adding Mail Functionality at Design Time

This section explains a basic incorporation of mail functionality. It includes the following subsections:

- Section 35.2.3.1, "Mail Task Flows"
- Section 35.2.3.2, "How to Add Mail to your Application"

35.2.3.1 Mail Task Flows

The Mail task flow displays a mail inbox.

35.2.3.2 How to Add Mail to your Application

To add mail to your application:

1. Follow the steps described in Chapter 2, "Setting Up Your Development Environment" to create a customizable page in your application.
2. Ensure that you have configured your application to connect to the mail server.
3. If you configured your external application for private or shared credentials, then the Framework application must be made secure using ADF security. ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 74.3, "Configuring ADF Security."
4. Open the page on which to add mail functionality.
5. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
6. Drag and drop the **Mail** task flow on to the page.
7. In the Create list, select **Region** to add the task flow to your page.
8. The resulting Edit Task Flow Binding dialog displays the optional `tabularView` parameter. If this parameter is set to `true`, then mail messages appear in a table, like an Inbox on any mail client. If this parameter is set to `false`, then mail messages render in a list view.

   Note: If you created a connection in IDE and not in the application, then the connection must be added to the application. For example, in the Resource Palette under IDE Connections, right-click the connection and select **Add to Application**.

9. Save your page and run it to the browser.
10. When you run the page with the Mail task flow for the first time, you are prompted to enter external application mail credentials from within the Mail task flow.

    Enter the credentials, then click **Submit**.

Notes:

- All instances of the Mail task flow in an application run against the same mail server, and it serves no purpose to add multiple Mail task flow instances. This is true for all task flows that require connections to back-end servers, such as task flows from discussions or announcements.
- After an application has been accessed with saved credentials, those credentials are persisted even after redeployment. To ignore saved credentials from previous deployments, edit `appUID` in `adf-config.xml` before redeploying the application. Edit the following value in bold to specify a modified value; for example, add 1 to the last value to update it as `WCApp1-1235`).

```
 <adf:adf-properties-child
xmlns="http://xmlns.oracle.com/adf/config/properties">
     <adf-property name="adfAppUID" value="WCApp1-1234"/>
 </adf:adf-properties-child>
```

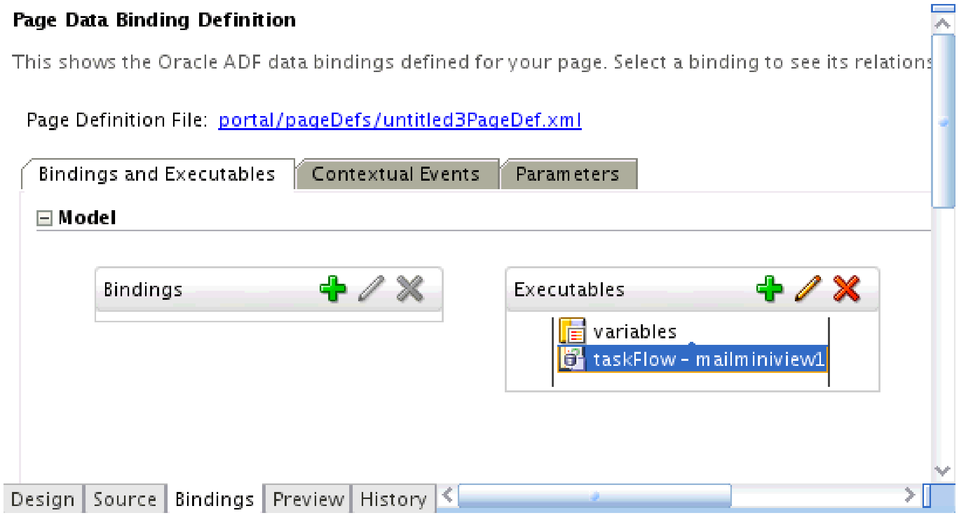
35.2.3.3 How to Modify the Mail Task Flow Parameters

The Mail task flow has an optional task flow binding parameter.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:

1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 35–8 shows an example of a Search task flow in the Executables section.

Figure 35–8 Page Data Binding Definition



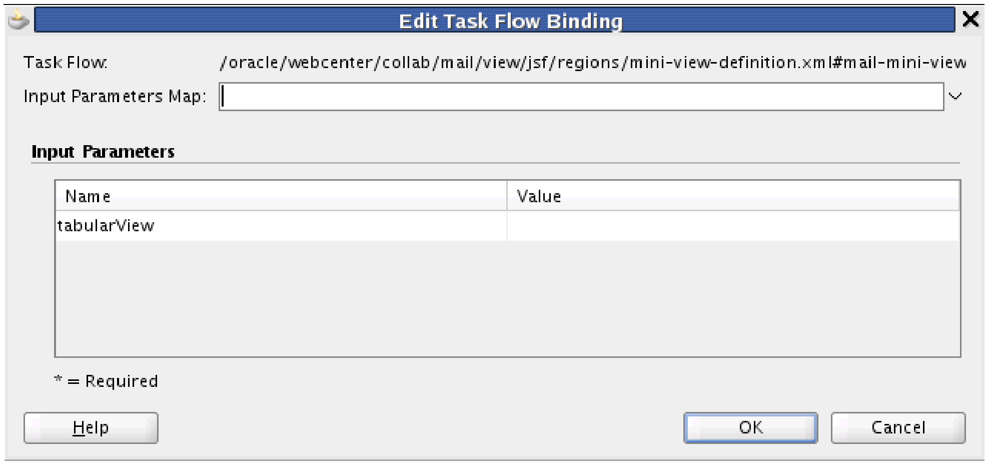
Page Data Binding Definition

This shows the Oracle ADF data bindings defined for your page. Select a binding to see its relations

Page Definition File: portal/pageDefs/untitled3PageDef.xml

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.
4. In the Edit Task Flow Binding dialog Figure 35–9, revise the binding parameter values as required.

Figure 35–9 Edit Task Flow Binding Dialog for Mail Task Flow



Task Flow: /oracle/webcenter/collab/mail/view/jsf/regions/mini-view-definition.xml#mail-mini-view

Input Parameters Map:

Input Parameters

Name	Value
tabularView	

* = Required

5. When you are finished, click **OK.**
6. Save and run your page to see the results.

Table 35–3 describes the properties that are unique to the Mail task flow.

Table 35–3 Mail Task Flow Parameters

Property	Description	Task Flow
`tabularView`	Using the EL value type, enter a value of true to display the information associated with a mail message, such as its subject, sender, and, date sent, in a tabular format. If this parameter is set to false, then mail messages render in a list view.	Mail

Figure 35–10 depicts the Mail task flow where the region parameter `tabularView` is set to true.

35.2.4 Setting Security for Mail

Mail requires security to fetch mail for each logged-in user. ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 74.3, "Configuring ADF Security."

The external application credentials for the user name used to log in to the application are fetched and used to log in to the mail server. The recommended approach is to have the mail server and the application point to the same identity store.

Note: Even if the application and the mail server share the same identity store, mail does not support identity propagation. Single sign-on functionality is enabled through the external application mechanism.

Mail works in a non-secured application if, and only if, the external application connection is configured with public credentials. If you do not apply security, and if mail requires a login to access the content, then users are not able to authenticate and do not see any content at runtime.

For information about using external applications, see Section 74.13, "Working with External Applications."

35.3 Advanced Information for Mail

This section describes optional features available with mail. It includes the following subsections:

- Section 35.3.1, "Invoking the Mail Compose Page"
- Section 35.3.2, "Configuring the Number of Mail Messages Displayed"
- Section 35.3.3, "Troubleshooting Mail"

35.3.1 Invoking the Mail Compose Page

The **Mail Compose** page enables users to determine how they want to compose individual messages within the application.

Invoke the **Mail Compose** page directly with a navigation rule that directs the user to the full page (Example 35–1).

Example 35–1 Invoking the Mail Compose Page

```
/oracle/workplace/collab/mail/view/jsf/pages/ComposeView.jspx
```

When you cannot provision mail accounts for all users within a portal but want to provide the ability for portal members to send mail to other members, then specify a shared (public) mail connection with the `useConnection` parameter. (Specify the connection name as a region input parameter to the mail-service compose view.) The end user Mail Preferences does not display mail connections with shared credentials.

You can pass optional parameters to seed the compose message. For example, you can pass parameters to pre-populate fields like To, Cc, Bcc, From, Subject, and Content. Set parameters only for items you want to pre-populate. If you require an empty `ComposeView.jspx`, then no `setActionListener` is necessary. You must set all parameters on `pageFlowScope`.

Use the `scope` parameter to set the scope within which the compose view should be launched.

Use the `sendMailToGSMembers` parameter to select the option to send mail to all portal members.

Example 35–2 shows some parameters for the Mail Compose page (`ComposeView.jspx`):

Example 35–2 Parameters of the Mail Compose Page

```
<af:commandLink text="Compose Mail" action="sendMail">

    <af:setActionListener from="#{'john.doe@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.toList']}"/>
    <af:setActionListener from="#{'Mail......'}"
to="#{pageFlowScope['collab.mail.compose.subject']}"/>
    <af:setActionListener from="#{'Mail Service'}"
to="#{pageFlowScope['collab.mail.compose.content']}"/>
    <af:setActionListener from="#{'ruby@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.ccList']}" />
    <af:setActionListener from="#{'ruby@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.bccList']}" />
    <af:setActionListener from="#{'monty@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.from']}" />
    <af:setActionListener from="#{'text/html'}"
to="#{pageFlowScope['collab.mail.compose.contentType']}" />
    <af:setActionListener from="Shared-mail-connection-name"
to="${pageFlowScope['collab.mail.compose.useConnectionName']}" />

</af:commandLink>
```

Example 35–3 shows how to hide the recipients fields (like **To**, **Cc** and **Bcc**) by setting the following action listener in `ComposeView.jspx`:

Example 35–3 Hiding Recipient Fields in the Mail Compose Page

```
    <af:setActionListener from="#{'false'}"
to="#{pageFlowScope['collab.mail.message.showrecipients']}" />
```

35.3.2 Configuring the Number of Mail Messages Displayed

By default, the 50 most recent mail messages are displayed from your Inbox folder. Providing that your mail server supports the increase in memory cache that fetching additional mail requires, the administrator can change this to a higher number in the `adf-config.xml` file.

Add the `mail.messages.fetch.size` property as shown in Example 35–4:

Example 35–4 Increasing the Number of Mail Messages Displayed

```
<adf-collaboration-config xmlns="http://xmlns.oracle.com/webcenter/collab/config">

<service-config
serviceId="oracle.webcenter.collab.mail">
<property name="mail.messages.fetch.size" value="500"/>
</service-config>

</adf-collaboration-config>
```

Alternatively, your Fusion Middleware administrator can increase this value with the WLST command `setMailServiceProperty`.

This change applies to all users; that is, following Example 35–4, all users see 500 recent mail messages in their Inbox in the Framework application. Increasing the number of messages shown correspondingly increases the cache size on the Framework application. Take care to set this to a reasonable size.

35.3.3 Troubleshooting Mail

This section describes common problems and solutions for mail.

Problem

Users are not able to retrieve their mail messages or send mail messages from within the Portal Framework application.

Solution

Ensure the following:

- Ensure that a Mail connection exists in your application.
- Ensure that the required Mail connection is marked as the default connection.
- Ensure the mail server configured in the connection is up and running. You can try connecting from any other mail client to ensure that the connection details are correct.

Problem

The mail within your Portal Framework application requires users to log in, but users are not able to authenticate and do not see any content at runtime. When users access mail, it throws an ExtApp Authorization Exception.

Solution

Mail works in a non-secured Portal Framework application if, and only if, the Mail connection is configured to use an external application connection with public credentials. If your application is running in non-secured mode, then ensure that you have configured public credentials for your external application.

If you want your Portal Framework application to run in secure mode, then you must configure ADF security for your application.

Problem

When users receive mail in Portal Framework applications, message content is shown as an attachment (named `content.html`) rather than within the message body. This can occur if the mail server is running Microsoft Exchange Server 2007 and the "*Update Rollup 3 for Microsoft Exchange Server 2007*" is not yet installed.

Solution

Mail server administrators must download and install "*Update Rollup 3 for Microsoft Exchange Server 2007*" which fixes this issue. For more information, see `http://support.microsoft.com/kb/930468`.

36

Integrating Polls

This chapter explains how to integrate polling functionality into a Portal Framework application at design time.

This chapter includes the following topics:

- Section 36.1, "Introduction to Polls"
- Section 36.2, "Basic Configuration for Polls"
- Section 36.3, "Advanced Information for Polls"

For more information about using polls, see the "Adding Polls to a Portal" chapter in *Building Portals with Oracle WebCenter Portal*.

36.1 Introduction to Polls

WebCenter Portal and Framework application users can create, edit, and take online polls on your application pages. Polls let you survey your audience (such as their opinions and their experience level), check whether they can recall important information, and gather feedback on the efficacy of presentations.

This section includes the following subsections:

- Section 36.1.1, "Understanding Polls"
- Section 36.1.2, "Requirements for Polls"
- Section 36.1.3, "What Happens at Runtime"

36.1.1 Understanding Polls

In addition to taking available polls, users can do the following:

- Quickly create and publish polls.
- Customize an existing poll; for example, add or change questions, and publish (open) and close the poll
- Take a specific or the most recently-published poll
- View poll results
- See the status of all polls and available actions for each poll, such as edit, delete, publish, analyze, and clear results

Polls is integrated with instant messaging and presence in the Polls Manager.

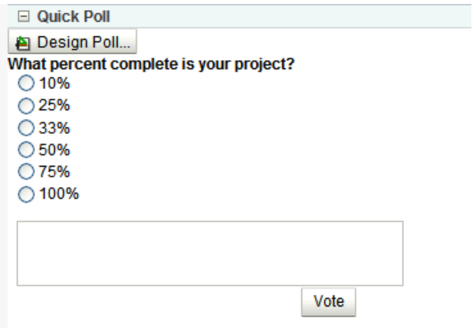
36.1.2 Requirements for Polls

In a Framework application, polls requires a connection to the WebCenter Portal database schema. For details about setting up a database connection, see Section 4.2.2, "Setting Up a Database Connection."

36.1.3 What Happens at Runtime

At runtime, users can quickly create polls with just a name and a question. Figure 36–1 shows a sample quick poll.

Figure 36–1 Quick Poll



⊟ Quick Poll

Design Poll...

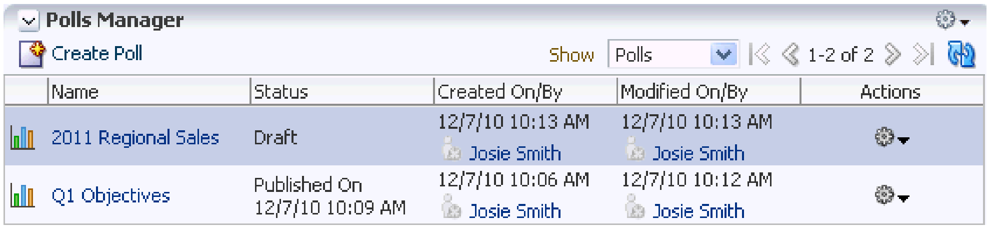
What percent complete is your project?

○ 10%
○ 25%
○ 33%
○ 50%
○ 75%
○ 100%

Vote

WebCenter Portal application administrators can access the Polls Manager, which lets you create polls with multiple questions or with templates. The Actions dropdown list lets continue designing the poll, publish polls, analyze results, clear results, and delete the poll (Figure 36–2).

Figure 36–2 Polls Manager



Polls Manager

Create Poll   Show Polls   1-2 of 2

Name	Status	Created On/By	Modified On/By	Actions
2011 Regional Sales	Draft	12/7/10 10:13 AM Josie Smith	12/7/10 10:13 AM Josie Smith	⚙
Q1 Objectives	Published On 12/7/10 10:09 AM	12/7/10 10:06 AM Josie Smith	12/7/10 10:12 AM Josie Smith	⚙

Polls created through the Polls Manager must be published and open to be taken. Users cannot take unpublished or closed polls.

For more information about using polls at runtime, see the "Adding Polls to a Portal" chapter in *Building Portals with Oracle WebCenter Portal*.

36.2 Basic Configuration for Polls

This section describes required steps for adding this to your application. It includes the following subsections:

- Section 36.2.1, "Setting up Connections for Polls"
- Section 36.2.2, "Adding Polls Functionality at Design Time"
- Section 36.2.3, "Setting Security for Polls"

36.2.1 Setting up Connections for Polls

Polls requires a connection to the database where the WebCenter Portal schema is installed. For details about setting up a database connection, see Section 4.2.2, "Setting Up a Database Connection."

36.2.2 Adding Polls Functionality at Design Time

This section explains a basic incorporation of polls. It includes the following sections:

- Section 36.2.2.1, "Polls Task Flows"
- Section 36.2.2.2, "How to Add the Quick Poll Task Flow to Your Page"
- Section 36.2.2.3, "How to Modify the Polls Task Flow Parameters"

36.2.2.1 Polls Task Flows

Polls task flows are described in Table 36–1.

Table 36–1 Polls Task Flows

Task Flow	Description
Poll - Quick Poll	This task flow displays a view that enables users to create one-question polls to be published immediately. Each quick poll needs its own Quick Poll task flow on the page.
Polls - Polls Manager	This task flow allows users to perform administrative operations on polls. Any user who has access to this task flow can perform the administrative operations, such as edit or delete the poll.
Polls - Take Polls	This task flow displays the most recently-published available poll, unless it is set to a specific poll in the `pollId` parameter.
Polls - View Poll Results	This task flow displays the results of a poll as a graph for the supplied `pollId`. This task flow works only if `pollId` is supplied.

36.2.2.2 How to Add the Quick Poll Task Flow to Your Page

The Quick Poll task flow display polls and provides tools to create, edit, and delete polls. It also provides controls for determining when a poll when it expires. This task flow lets you present polls to end users where manage controls are not needed.

To add the Quick Poll task flow to your WebCenter Portal Framework application:

1. Open the page on which you want to add polls functionality.
2. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
3. Drag **Polls - Quick Poll** from the Resource Palette and drop it onto the page inside of the `af:form` `begin` and `end` tags.
4. When prompted, select **Region** as the way to create the task flow (and confirm with **Add Library**). This operation may take a moment to complete.
5. Click **OK**.
6. Save and run your page.

36.2.2.3 How to Modify the Polls Task Flow Parameters

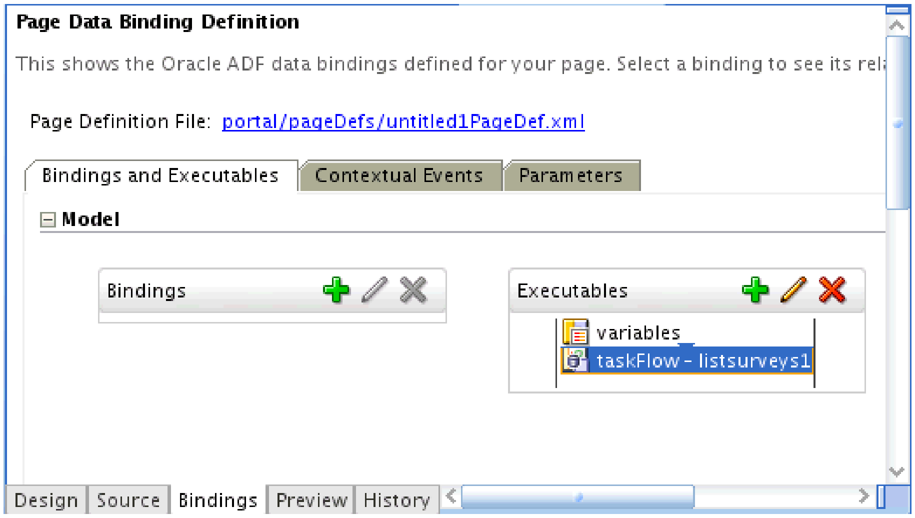
Polls task flows have optional task flow binding parameters.

In addition to providing required values for successful task flow rendering, you can use task flow parameters to customize the appearance and behavior of a task flow instance. For example, you can use parameter values to set which poll to display.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:

1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 36–4 shows an example of a Search task flow in the Executables section.

Figure 36–3 Page Data Binding Definition



Page Data Binding Definition

This shows the Oracle ADF data bindings defined for your page. Select a binding to see its rel

Page Definition File: portal/pageDefs/untitled1PageDef.xml

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.
4. In the Edit Task Flow Binding dialog Figure 36–4, revise the binding parameter values as required.

* = Required

5. When you are finished, click **OK.**
6. Save and run your page to see the results.

Table 36–2 describes the properties that are unique to the Polls task flows.

Table 36–2 Polls Task Flow Parameters

Property	Description
`scope`	The portal name from which polls are to be fetched. If this is supplied, then polls of that particular portal are shown. On the Home portal, when this parameter is not supplied, it fetches polls from all portals. This parameter appears in the properties for the Polls Manager task flow.
`showUserDataOnly`	This parameter determines whether to display all polls or only those polls created by the user. The default (No) is to show all polls. Set to Yes to display only those polls created by the user. If the `scope` parameter is specified, then this parameter works the same but within only that scope. This parameter appears in the properties for the Polls Manager task flow.
`pollId`	The poll to display. This parameter appears in the properties for the following task flows. ■ Take Polls ■ View Poll Results
`showInEditMode`	This parameter determines whether users can edit a quick poll. When a quick poll is in Edit mode, a Design Poll box for editing the poll appears. When a quick poll is not a Edit mode, the Design Poll box for editing is not visible. This parameter appears in the properties for the Quick Poll task flow.

36.2.3 Setting Security for Polls

Polls do not require security. Administrators control access to Polls task flows through the Resource Catalog, where they define the users and groups privileged to see polls. Security is driven by the page security on which the task flow exists or by the task flow permissions on that page. Any user who can see the task flow can edit the poll.

ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 74.3, "Configuring ADF Security."

36.3 Advanced Information for Polls

This section describes optional features available with polls. It includes the following subsections:

- Section 36.3.1, "How to Add the Polls Manager Task Flow"
- Section 36.3.2, "How to Add the Take Polls Task Flow"
- Section 36.3.3, "How to Add the View Poll Results Task Flow"
- Section 36.3.4, "Using the Polls Data Controls"

36.3.1 How to Add the Polls Manager Task Flow

The Polls Manager task flow provides a complete view of polls and perform actions on them.

To add this to your Framework application, follow the same instructions that you did for the Quick Poll task flow in Section 36.2.2, "Adding Polls Functionality at Design Time," but drag and drop Polls Manager onto the page.

36.3.2 How to Add the Take Polls Task Flow

This task flow displays published polls for users to take. It displays the most recently-published available poll, unless it is set to display a specific poll with the `pollId` parameter. After a user submits a response for that poll, it displays the next most recently-published poll.

To add this to your Framework application, follow the same instructions that you did for the Quick Poll task flow in Section 36.2.2, "Adding Polls Functionality at Design Time," but drag and drop Polls - Take Polls onto the page.

36.3.3 How to Add the View Poll Results Task Flow

The View Poll Results task flow displays the results of a poll as a graph for the poll supplied with the required `pollId` parameter.

To add this task flow to your Framework application, follow the same instructions that you did for the Quick Poll task flow in Section 36.2.2, "Adding Polls Functionality at Design Time," but drag and drop Polls - View Poll Results onto the page.

36.3.4 Using the Polls Data Controls

Use the Polls data controls to build a customized user interface for polls with a Framework application or a custom task flow.

Polls includes two data controls to customize the user interface:

- Take Poll Data Control
- Polls Manager Data Control

> **See Also:** Section 4.1.3, "Using WebCenter Portal Data Controls" for information on how to consume data controls

36.3.4.1 Take Poll Data Control

The Take Poll data control contains the following methods:

- createResponse
- createResponseForLatestAvailablePoll
- getPublishedPolls
- getResults
- saveResponse

36.3.4.1.1 createResponse This method lets users respond to a particular poll. Table 36–3 describes the required parameters for this method.

Table 36–3 createResponse Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

36.3.4.1.2 createResponseForLatestAvailablePoll This method lets users respond to the most recently-published poll. It has no parameters.

36.3.4.1.3 getPublishedPolls Table 36–4 describes the required parameters for this method.

Table 36–4 getPublishedPolls Input Parameters

Parameter	Type	Description
`startIndex`	Integer	The index of the first matching result that should be included in the result set (0-n ... zero based). This is used for pagination.
`numResults`	Integer	The number or results to display.

36.3.4.1.4 getResults This method gets the poll results for a particular poll. Table 36–5 describes the required parameters for this method.

Table 36–5 getResults Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

36.3.4.1.5 saveResponse Table 36–6 describes the required parameters for this method.

Table 36–6 saveResponse Input Parameters

Parameter	Type	Description
`response`	Response	The response object acquired from the data control calls to `createResponse` or `createResponseForLatestAvailablePoll`.

36.3.4.2 Polls Manager Data Control

The Polls Manager data control contains the following methods:

- addQuestion
- addQuestion
- closePoll
- closePollAfterDate
- closePollAfterDays
- closePollAfterResponses
- createPoll
- deletePoll
- editPoll
- editPoll
- findPoll
- getPolls
- getPollsByUser
- getPollsByUserCount
- publishPoll

- publishPollOnDate

36.3.4.2.1 addQuestion This method creates polls with multiple choice questions. Table 36–7 describes the required parameters for this method.

Table 36–7 addQuestion Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`question`	String	The text of the question; for example, What is your favorite color?
`rowOptions`	String	Corresponding list of options for the question. This should be line-separated list of options.
`allowMultipleSelection`	Boolean	True to allow multiple options to be selected; false to allow only a single option selection.

36.3.4.2.2 addQuestion This method creates complex polls with matrix-type questions. Table 36–8 describes the required parameters for this method.

Table 36–8 addQuestion Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`questionType`	Question Type	Question type, either: ■ Matrix of choices (only one answer per row) ■ Matrix of choices (multiple answers per row)
`question`	String	The text of the question; for example, What is your favorite color?
`rowOptions`	String	Corresponding list of options for the question. This should be line-separated list of options.
`columnOptions`	String	Column options.
`isOptional`	Boolean	True if the question is optional (that is, users can ignore answering it); false if question is mandatory.
`commentLabel`	String	Enables a comment field for users to provide feedback or enter personalized text with their answers.
`commentFieldHeight`	Integer	Size for the comment field. To capture feedback, set this to 3; otherwise, set it to 1. This parameter value depends on the type of answer expected in the comment field.

36.3.4.2.3 closePoll This method closes a particular poll. Table 36–9 describes the required parameters for this method.

Table 36–9 closePoll Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

36.3.4.2.4 closePollAfterDate This method closes a poll on a specific date. Table 36–10 describes the required parameters for this method.

Table 36–10 closePollAfterDate Input Parameters

Parameter	Type	Description
pollId	String	The poll to display.
date	Date	Date at which the poll should close.

36.3.4.2.5 closePollAfterDays This poll closes a poll at a set number of days after the poll is published. Table 36–11 describes the required parameters for this method.

Table 36–11 closePollAfterDays Input Parameters

Parameter	Type	Description
pollId	String	The poll to display.
days	Integer	Number of days, after the publish date, at which the poll should close.

36.3.4.2.6 closePollAfterResponses This method closes as poll after a set number of responses have been collected. Table 36–12 describes the required parameters for this method.

Table 36–12 closePollAfterResponses Input Parameters

Parameter	Type	Description
pollId	String	The poll to display.
responses	Integer	Number of responses at which the poll should close.

36.3.4.2.7 createPoll This method creates a quick poll. Table 36–13 describes the required parameters for this method.

Table 36–13 createPoll Input Parameters

Parameter	Type	Description
name	String	Name of the poll.
description	String	Description of the poll.

36.3.4.2.8 deletePoll This method deletes a particular poll. Table 36–14 describes the required parameters for this method.

Table 36–14 deletePoll Input Parameters

Parameter	Type	Description
pollId	String	The poll to display.

36.3.4.2.9 editPoll Table 36–15 describes the required parameters for this method.

Table 36–15 editPoll Input Parameters

Parameter	Type	Description
pollInstance	Poll	If a poll instance is directly edited, then that instance can be supplied for editing.

36.3.4.2.10 editPoll This method edits a particular poll. Table 36–16 describes the required parameters for this method.

Table 36–16 editPoll Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`name`	String	Name of the poll.
`description`	String	Description of the poll.

36.3.4.2.11 findPoll This method finds a particular poll. Table 36–17 describes the required parameters for this method.

Table 36–17 findPoll Input Parameters

Parameter	Type	Description
`id`	String	Poll instance ID

36.3.4.2.12 getPolls This method displays all polls, as defined in its parameters. Table 36–18 describes the required parameters for this method.

Table 36–18 getPolls Input Parameters

Parameter	Type	Description
`startIndex`	Integer	The index of the first matching result that should be included in the result set (0-n ... zero based). This is used for pagination.
`numResults`	Integer	The number or results to display.

36.3.4.2.13 getPollsByUser This method displays polls created by a particular user. Table 36–19 describes the required parameters for this method.

Table 36–19 getPollsByUser Input Parameters

Parameter	Type	Description
`createdBy`	String	User name of the person who created the poll.
`startIndex`	Integer	The index of the first matching result that should be included in the result set (0-n ... zero based). This is used for pagination.
`numResults`	Integer	The number or results to display.

36.3.4.2.14 getPollsByUserCount Table 36–20 describes the required parameters for this method.

Table 36–20 getPollsByUserCount Input Parameters

Parameter	Type	Description
`createdBy`	String	User name of the person who created the poll.

36.3.4.2.15 publishPoll This method publishes a particular poll. Table 36–21 describes the required parameters for this method.

Table 36–21 publishPoll Input Parameters

Parameter	Type	Description
pollId	String	The poll to display.

36.3.4.2.16 publishPollOnDate This method publishes a poll on a specific date. Table 36–22 describes the required parameters for this method.

Table 36–22 publishPollOnDate Input Parameters

Parameter	Type	Description
pollId	String	The poll to display.
date	Date	Date at which the poll should be published.

Part VI

Working with People Connections

Part VI contains the following chapters:

37

Introducing the People Connections Service

This chapter describes the task flows associated with the People Connections service. The People Connections service provides social networking tools that enhance connection and communication in a project team and throughout an enterprise. The service provides its social networking features through Activity Stream, Connections, Feedback, Message Board, Profile, and Publisher task flows.

This chapter includes the following topics:

- Section 37.1, "Overview of the People Connections Service"
- Section 37.2, "Troubleshooting the People Connections Service"

37.1 Overview of the People Connections Service

The People Connections service provides social networking tools for creating, interacting with, and tracking the activities of one's connections. The following features enable users to manage their personal profiles, access the profiles of other users, provide ad hoc feedback, post messages, track activities, and connect with others:

- **Activity Stream** for viewing user activities generated through application or social networking actions.
- **Connections** for connecting to other application users to share information, comment on performance, exchange messages, and track activity
- **Feedback** for giving *ad hoc* performance feedback to other users
- **Message Board** for posting messages to other users
- **Profile** for entering personal contact information and viewing the contact information of other users
- **Publisher** for publishing status messages and posting files and links

In a production environment, an enterprise can leverage its back-end identity store as a means of providing People Connections with a population of potential connections. In a development environment, developers can add test-users to the `jazn-data.xml` file.

> **See Also:** For information about connecting to a back-end (LDAP) identity store for the production version of your application, see the "Configuring the Identity Store" chapter in *Administering Oracle WebCenter Portal*. For information about creating test users in `jazn-data.xml`, see Section 22.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File."

This section provides an overview of the People Connections service. It includes the following subsections:

- Section 37.1.1, "People Connections Service Task Flows"
- Section 37.1.2, "People Connections Service Requirements"

37.1.1 People Connections Service Task Flows

The features of the People Connections service fall into five categories. Each category includes a set of task flows that expose People Connections features to your end users. The Publisher task flow does not belong to these categories, but rather, works in concert with the Activity Stream.

This section introduces these categories. It includes the following subsections:

- Section 37.1.1.1, "Activity Stream"
- Section 37.1.1.3, "Feedback"
- Section 37.1.1.4, "Message Board"
- Section 37.1.1.2, "Connections"
- Section 37.1.1.5, "Profile"
- Section 37.1.1.6, "The Publisher Task Flow"

> **See Also:** For information about the People Connections service at runtime, see the associated chapters in *Using Oracle WebCenter Portal*.
>
> For information about People Connections task flows, see Section 37.1.1, "People Connections Service Task Flows."

37.1.1.1 Activity Stream

The Activity Stream feature tracks the application activities of a user's connections. Table 37–1 lists the types of activities that can be tracked by the Activity Stream.

Table 37–1 Activities Tracked by Activity Stream

Service	Tracked Activities
Announcements	■ Create announcement ■ Edit announcement
Blogs	■ Create blog ■ Update blog
Connections	■ Invitations to connect ■ People are connected
Discussions	■ Create forum ■ Create topic ■ Reply to topic
Documents	■ Create document ■ Edit document ■ Add tag ■ Remove tag
Events	■ Create an event ■ Edit an event

Table 37–1 (Cont.) Activities Tracked by Activity Stream

Service	Tracked Activities
Feedback	■ Feedback left ■ Feedback received
Lists	■ Create a list ■ Add a row to a list ■ Edit a list row
Message Board	■ Message left ■ Message received
Pages	The following activities are tracked when they are performed within the service framework scope (for example, if a user creates pages under `/myapp/mypages/`, the page operations are not tracked): ■ Create page ■ Edit page ■ Delete page ■ Add tag
Profiles	■ Photo updated ■ Profile updated ■ Personal status note updated
Tagging	■ Add tag ■ Remove tag

Activity Stream compares somewhat to the Recent Activities service, which also tracks and reports on application activities (for more information, see Chapter 51, "Integrating Recent Activities"). Both track the application activities of integrated services, though Activity Stream tracks a broader range of services. For example, Recent Activities tracks the Documents (including wikis and blogs), Announcements, Discussions, and Page services. Activity Stream tracks these services as well as People Connections. Recent Activities tracks activities no matter who performs the action. Activity Stream tracks activities performed by a user's connections and includes information about who performed the activity. Recent Activities does not include names.

The basic difference between these two services can be summarized as follows: Recent Activities provides an overview of what is happening in an application. Activity Stream provides an overview of what is happening with a user's connections.

The Publisher task flow works in concert with Activity Stream to provide content in the form of user messages. A message posted through the Publisher task flow is published to the Activity Streams of the user who entered it and that user's connections.

Activity Stream messages may include attachments, such as a file or a link. Depending on a file's mime type, Activity Stream allows for displaying a preview of such attachments. Activity Stream previews files through either a native web format or through UCM slide rendition. The previewer used depends on the mime type of the file to be previewed.

The mime types that use the native web format include:

- `image`

- `htm`
- `text`

The mime types that use UCM slide rendition include:

- `pdf`
- `powerpoint`
- `powerpnt`
- `pptx`

> **Note:** PDF file previews are available in Activity Stream when the mime type is `pdf`, `webContextRoot` is specified in the UCM connection, and the WebCenter Portal application is accessed through an Oracle HTTP Server.

The mime types shown in these bullet lists are the only mime types that are previewed. Other mime types appear as links. The mime types `docx` and `xlsx` are *not* previewed in Activity Stream. You can set a parameter associated with an Activity Stream task flow instance to omit file previews (for more information, see Section 39.3, "People Connections Task Flow Binding Parameters").

Two Activity Stream task flows are available through the Resource Palette:

- Activity Stream—Provides users with the main view of the most recent activities of their connections (Figure 37–1).

Figure 37–1 Activity Stream Task Flow

> **See Also:** For information about Activity Stream task flows at runtime, see the "Tracking Portal Activities" chapter in *Using Oracle WebCenter Portal*.

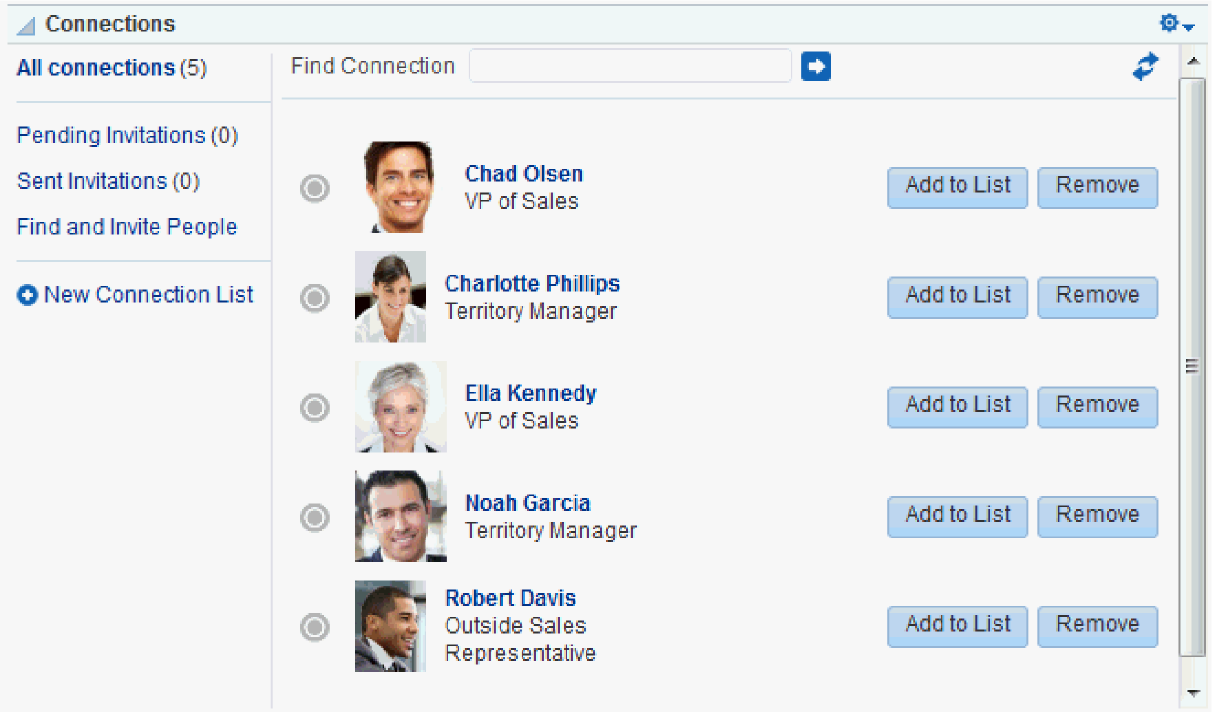
37.1.1.2 Connections

Connections provides users with a means of managing their own connections and viewing the connections of others. Use Connections to collect business friends and contacts into one or more smaller social groups. Use connections lists to manage the way your connections are displayed.

The following Connections task flows are available through the Resource Palette:

- Connections—Provides users with a means of viewing and managing their connections, creating connections lists, and sending and responding to invitations to connect (Figure 37–3).

Figure 37–3 Connections Task Flow

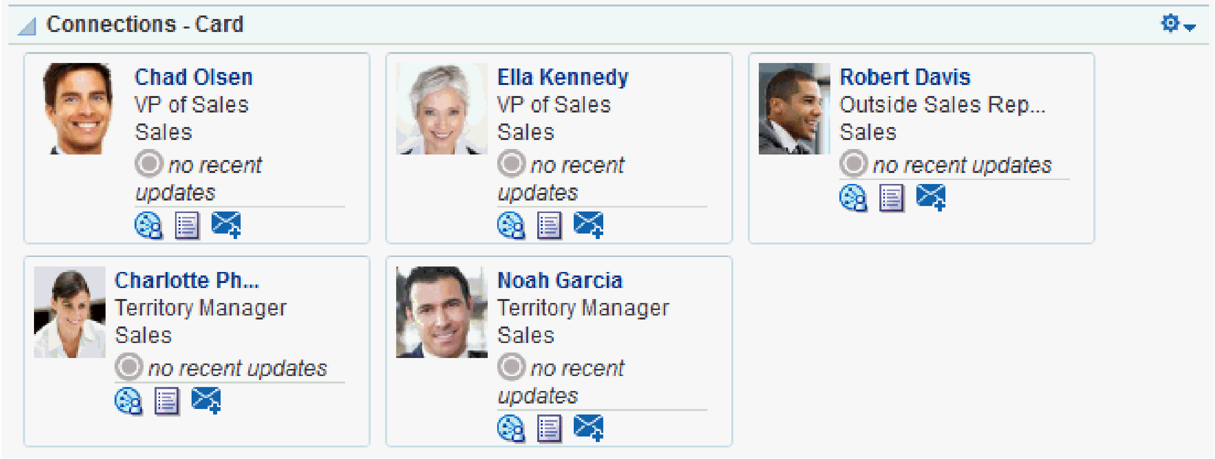


- Connections - Card—Provides a choice of the following views:
  - `vcard` displays a connection's photo, job title, and status message (Figure 37–4).
  - `iconic` displays a connection's photo and user name.
  - `list` displays connections in a list, with each list row showing the profile photo, user name, job title, and an **Add to List** button.
  - `tiled` renders the connection's personal Profile photo and shows the user name and job title beside the photo.

  Tip: In all views, the name links to a summary view of the user's Profile.

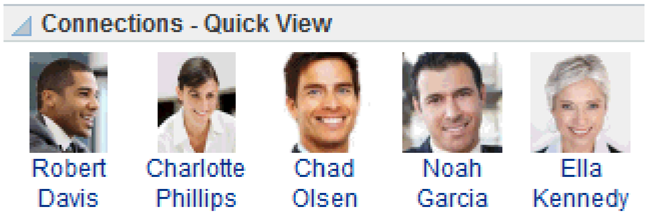
  Select one of these views through task flow bindings (for more information, see Chapter 39, "People Connections Task Flow Binding Parameters").

Figure 37–4 Connections - Card Task Flow



- Connections - Quick View—Provides users with a view of their connections' uploaded profile photos and a link to a summary view of their Profiles (Figure 37–5).

Figure 37–5 Connections - Quick View Task Flow



> **See Also:** For information about Connections task flows at runtime, see the "Managing Your Contacts" chapter in *Using Oracle WebCenter Portal*.

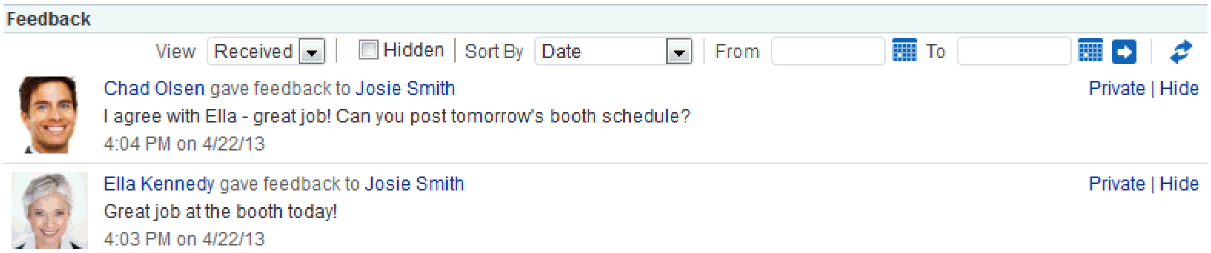
37.1.1.3 Feedback

Feedback provides users with a means of viewing, posting, and managing feedback. By default, users can view feedback in their own Feedback views. Users can view and post feedback in other users' Feedback views when given the proper permissions.

Two Feedback task flows are available through the Resource Palette:

- Feedback—Provides users with the main view of the Feedback task flow. The main view contains controls for viewing, posting, sorting, and filtering Feedback—both given and received—and for hiding received Feedback (Figure 37–6).

Figure 37–6 Feedback Task Flow



Feedback

View Received | □ Hidden | Sort By Date | From To

Chad Olsen gave feedback to Josie Smith Private | Hide
I agree with Ella - great job! Can you post tomorrow's booth schedule?
4:04 PM on 4/22/13

Ella Kennedy gave feedback to Josie Smith Private | Hide
Great job at the booth today!
4:03 PM on 4/22/13

- Feedback - Quick View—Provides users with a truncated view of the Feedback task flow, where only the most recent posts are shown (Figure 37–7). When there are more posts than can be displayed in the initial view, users can click a **More** link to navigate to the main view of the Feedback task flow. When user `A` accesses user `B`'s view of Feedback - Quick View, user `A` additionally sees an **Add Feedback** option.

> **See Also:** For information about Feedback task flows at runtime, see the "Working with Feedback and the Message Board" chapter in *Using Oracle WebCenter Portal*.

37.1.1.4 Message Board

Message Board provides a means of viewing and posting messages and attachments to Message Boards and Activity Streams.

Two Message Board task flows are available through the Resource Palette:

- Message Board—Provides users with the main view of Message Board messages and a means of adding, viewing, updating, hiding, deleting, and managing your view of messages, and for marking messages as private and sharing private messages (Figure 37–8).

Figure 37–8 Message Board Task Flow

37.1.1.5 Profile

Profile provides users with a variety of views into their own and other users' personal profile information. Such information can include a user's email address, phone number, office location, department, manager, direct reports, and so on. Profile takes the bulk of its information from the back-end identity store that provides your WebCenter Portal application with its users. Additionally, Profile may offer opportunities for altering some of this information and for providing additional data not included in the identity store.

Three Profile task flow are available through the Resource Palette:

- Profile—Exposes a user's profile details, such as a user's email address, phone number, office location, department, manager, direct reports, and so on. It also exposes any personal image a user may have provided and the user's personal status message (Figure 37–10).

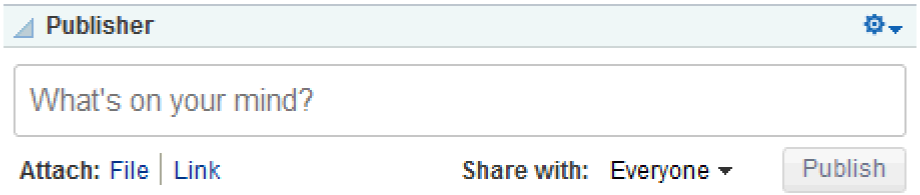
See Also: For information about Profile task flows at runtime, see the "Managing Your Profile" chapter in *Using Oracle WebCenter Portal*.

37.1.1.6 The Publisher Task Flow

The Publisher task flow works in concert with Activity Stream. Users enter content into Publisher, which is then published to the Activity Stream of the user who posted it as well as to the Activity Streams of that user's connections (Figure 37–13).

Figure 37–13 Publisher Task Flow



> **See Also:** For information about the Publisher task flow at runtime, see the "Sharing Messages, Files, and URLs" section in *Using Oracle WebCenter Portal*.

37.1.2 People Connections Service Requirements

For a successful integration of People Connections with your WebCenter Portal Framework application, ensure that the following steps have been taken:

1. Create a WebCenter Portal Framework application (for more information, see Section 6.1, "Creating a New WebCenter Portal Framework Application").
2. Set up the WebCenter schema, and create a database connection to it (for more information, see Chapter 4, "Preparing Your Application for WebCenter Portal Tools and Services").
3. Create a JSF (`.jspx`) page (for more information, see Section 15.2, "Creating Pages in a WebCenter Portal Framework Application").
4. Secure your application and create some test users (for more information, see Chapter 74, "Securing Your WebCenter Portal Framework Application" and Section 22.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File").
5. Drag and drop a People Connections task flow onto your page (for more information, see Section 38.2, "How to Add People Connections Task Flows to a Page").
6. Provide required values for task flow bindings (for more information, see Chapter 39, "People Connections Task Flow Binding Parameters").
7. Run the page.
8. When required, provide the user name and password of a test user you created at Step 4.

37.2 Troubleshooting the People Connections Service

This section provides information to assist you in troubleshooting problems you may encounter while using the People Connections service.

People Connections Task Flows Take Up the Full Browser, Even When Empty

This problem might arise if you are using Internet Explorer, version 8 (IE8). In IE8, go to **Tools**, **Compatibility View Settings**. In the Compatibility View Settings dialog, clear the following check boxes:

- Display intranet sites in Compatibility View
- Display all websites in Compatibility View

New Profile Image is Not Shown

Changes to a Profile image may not be rendered immediately due to a stale WebCenter Database cache. Clicking the **Refresh** icon under the stale image will cause the image to update.

38

Basic Configuration for the People Connections Service

This chapter describes how to work with the People Connections service, including adding People Connections task flows to a page, setting People Connections security, and configuring site-level People Connections settings.

This chapter includes the following topics:

- Section 38.1, "How to Set Up a Database Connection for the People Connections Service"
- Section 38.2, "How to Add People Connections Task Flows to a Page"
- Section 38.3, "Setting Security for the People Connections Service"
- Section 38.4, "Establishing Site-Level Settings for People Connections Features"

38.1 How to Set Up a Database Connection for the People Connections Service

For information about setting up a database connection in support of Oracle WebCenter Portal tools and services, see Section 4.2.2, "Setting Up a Database Connection."

38.2 How to Add People Connections Task Flows to a Page

This section describes how to add a People Connections task flow to an application page. The steps provided here are largely the same for all People Connections task flows. Differences are noted.

To add People Connections task flows to your WebCenter Portal Framework application:

1. Prepare your application as described in Section 37.1.2, "People Connections Service Requirements."
2. Open the page on which to add a People Connections task flow.
3. In the Resource Palette, open **My Catalogs**, then **WebCenter Portal - Services Catalog**, then the **Task Flows** folder.
4. Drag and drop a task flow (for example, Connections - Quick View) onto the JSF (`.jspx`) page.
5. Select **Region** from the resulting context menu.

It may ask whether you want to add the People Connections library to the project. Confirm by clicking **Add Library**.

6. In the Edit Task Flow Binding dialog, specify parameter values for the task flow.

   For example, for Connections - Quick View, the parameter `userid` represents the name of the current user at runtime. You can specify an EL expression for the parameter that will evaluate to the currently logged-in user. For example, for `userid`, enter `#{securityContext.userName}`. For more information, see Chapter 39, "People Connections Task Flow Binding Parameters."

7. Click **OK**.

   The task flow is added to the page, and the ViewController project's libraries are configured to run the task flow.

8. Save and run your page to the browser.

Note: To enable users to upload anything to your ADF-based application at runtime, the page on which you have placed the task flow must have the `usesUpload` attribute set on the form. For example, to enable the upload of a document to the document library or a photo to a profile, add the following to the relevant page:

```
<af:form usesUpload="true">
  …
  <af:region value="#{bindings.profile1.regionModel}"/>
  …
</af:form>
```

Additionally, to enable the upload of a profile snapshot, the task flow binding parameter `photoUploadAllowed` must be set to `true`. For more information, see Chapter 39, "People Connections Task Flow Binding Parameters."

38.3 Setting Security for the People Connections Service

Because People Connections features are centered around users, application security must be set up for successful use of the service. Ideally, test users are also in place to enable you to interact in a meaningful way with each feature. Each feature in the People Connections service can be secured separately.

- ADF security is configured by default when you create your application using the WebCenter Portal Application template. For details about how to implement a basic security solution for your WebCenter Portal application, see Section 74.3, "Configuring ADF Security."

- To create test users, follow the steps outlined in Section 22.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File."

  Once you have added test users, you can add additional user attributes, such as `business_email`, `title`, or `department`:

  1. Open the `jazn-data.xml` file.

     Tip: You will find the `jazn-data.xml` file in the Application Resources panel in the META-INF folder under Descriptors.

  2. Select the tab for **Source** at the bottom of the main content area.

3. Inside the `<user>` node for a selected user, insert the following:

```
<property name="[property-name]" value="[property-value]"/>
```

For example, to add `business_email` as `monty@example.com` for the user `monty`, add:

```
<user>
     <name>monty</name>
     <display-name>monty</display-name>
     <credentials>{903}EfEepsY6I/TrKthpcmjJIsrlP36Ysr/j</credentials>
     <property name="business_email" value="monty@example.com"/>
</user>
```

38.4 Establishing Site-Level Settings for People Connections Features

Two scripts are available to configure and revise People Connections site-level settings:

```
RCUHOME/rcu/integration/webcenter/sql/oracle/settings-insert.sql

RCUHOME/rcu/integration/webcenter/sql/oracle/settings-update.sql
```

The variable *`RCUHOME`* refers to your install location of the Resource Creation Utility (RCU). The RCU may be used in setting up the WebCenter schema and is packaged with the Oracle JDeveloper ship home. `RCUHOME` is the root folder where the RCU is installed.

This section describes the scripts and provides information about the types of settings they control. It includes the following subsections:

- Section 38.4.1, "Understanding the People Connections Site-Level Setting Scripts"
- Section 38.4.2, "Supported Site-Level Settings for People Connections Features"
- Section 38.4.3, "Example: Configuring Connections to Accept Invitations Automatically"

38.4.1 Understanding the People Connections Site-Level Setting Scripts

All site-level settings for People Connections features are stored in the WebCenter schema table `WC_PPL_COMMON_SETTING`. Out-of-the-box, this table does not contain any setting values. In the absence of values, the application assumes default values. To change the value of any setting, the setting must first be inserted into this table and then updated with the desired value. Two SQL scripts enable you to perform these steps in their proper sequence.

This section describes how to prepare and run the People Connections site-level settings scripts. It includes the following subsections:

- Section 38.4.1.1, "Preparing and Running settings-insert.sql"
- Section 38.4.1.2, "Preparing and Running settings-update.sql"

38.4.1.1 Preparing and Running settings-insert.sql

Before you can change People Connections site-level settings, you must run the `settings-insert.sql` script once. The script has `INSERT` statements for all supported settings. All `INSERT` statements are commented out by default. Before you run the script, you must prepare it by uncommenting all the settings you plan to change.

> **See Also:** For an example of the settings-insert.sql script in action, see Section 38.4.3, "Example: Configuring Connections to Accept Invitations Automatically."

To prepare and run the settings-insert.sql script:

1. Open the script in an editor.
2. For the settings you plan to change, uncomment the corresponding INSERT statement.

   > **Tip:** To uncomment an INSERT statement, remove the leading double dash (--) on the lines the statement spans.

3. Once you have uncommented all the INSERT statements for the settings of interest, save and run the script.

   The uncommented settings are populated with default values.

   > **Note:** You can run the settings-insert.sql script only once for a given set of settings on a given schema. If you must run it more than once—for example, if you must update a different set of settings—then the previously uncommented INSERT statements must be commented before you can run the script again. Otherwise, a SQL error is thrown during the re-execution of the INSERT statement.

38.4.1.2 Preparing and Running settings-update.sql

To change People Connections site-level settings, you must run the settings-update.sql script after you run settings-insert.sql once. The settings-update.sql script has UPDATE statements for all supported settings. All UPDATE statements are commented out by default.

You can run the settings-update.sql script as many times as required for a given set of settings on a given schema, provided you have run settings-insert.sql once for those settings.

> **See Also:** For an example of the settings-update.sql script in action, see Section 38.4.3, "Example: Configuring Connections to Accept Invitations Automatically."

To prepare and run the settings-update.sql script:

1. Open the script in an editor.
2. For the settings you plan to change, uncomment the corresponding UPDATE statement.

   > **Tip:** To uncomment an INSERT statement, remove the leading double dash (--) on the lines the statement spans.

3. For each uncommented statement, change the value of the SETTING_KEY column to the desired value.

   For information about settings and values, see Section 38.4.2, "Supported Site-Level Settings for People Connections Features."

4. Once you have revised all UPDATE statements of interest, save and run the script.

The table WC_PPL_COMMON_SETTING is updated with the revised values.

5. If your WebCenter Portal Framework application is running, restart it for the changes to take effect.

38.4.2 Supported Site-Level Settings for People Connections Features

This section lists and describes the supported site-level application settings for the People Connections service. It includes the following subsections:

- Section 38.4.2.1, "Activity Stream Site-Level Settings"
- Section 38.4.2.2, "Connections Site-Level Settings"
- Section 38.4.2.3, "Feedback Site-Level Settings"
- Section 38.4.2.4, "Message Board Site-Level Settings"
- Section 38.4.2.5, "Profile Site-Level Settings"

38.4.2.1 Activity Stream Site-Level Settings

Table 38–1 lists and describes the site-level settings for the People Connections service Activity Stream feature.

The service ID for Activity Stream is `oracle.webcenter.activitystreaming`. For a list of service IDs, see Table G–7.

Table 38–1 Site-Level Settings for Activity Stream

Setting Key	Description	Valid Site-Level Values
`accesscontrol.value.accessControlLevel`	Specifies who can view a user's Activity Stream.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`accesscontrol.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their Activity Stream. This setting is honored only when the application exposes the override control in a user preferences screen.	`+`, `-` +=TRUE -=FALSE

Table 38–1 (Cont.) Site-Level Settings for Activity Stream

Setting Key	Description	Valid Site-Level Values
`connectionsActivities.value`	Specifies whether the Home portal activities of a user's connections are included in the user's Activity Stream. Users can override this setting on a task flow instance.	`NONE`, `ALL` `NONE`=No activities of the user's connections are shown. `ALL`=All activities of the user's connections are shown.
`groupSpaceActivities.value`	Specifies whether any portal activities of a user's connections are included in the user's Activity Stream. Users can override this setting on a task flow instance.	`GSNONE`, `GSALL` `GSNONE`=No portal activities are shown `GSALL`=Activities are shown for all of the portals of which the user is a member and on which the user has view access.
`servicePublishedSettings[`*`serviceId`*`]`	Specifies whether to show activities published by the WebCenter service *`serviceId`* in a user's Activity Stream. A *`serviceId`* is the WebCenter service ID of any service that publishes activities. For a list of service IDs, see Table G–7. For example: `servicePublishedSettings[oracle.webcenter.community]` Users can override this setting on a task flow instance.	`+`, `-` `+`=TRUE `-`=FALSE

38.4.2.2 Connections Site-Level Settings

Table 38–2 lists and describes the site-level settings for the People Connections service Connections feature.

The service ID for Connections is `oracle.webcenter.peopleconnections.connections`. For a list of service IDs, see Table G–7.

Table 38–2 Site-Level Settings for Connections

Setting Key	Description	Valid Site-Level Values
`autoAcceptInvitations`	Specifies that connection invitations are accepted automatically by default. Individual users can override this application-level setting in their own view, provided the application exposes the override control in a user preferences screen.	`+, -` +=TRUE -=FALSE
`connectionsVisibility.accessControlSettings.accessControlLevel`	Specifies who can view a user's Connections.	`SELF, CONNECTIONS, USERS` (that is, authenticated users), `PUBLIC`
`connectionsVisibility.personalizable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their Connections. This setting is honored only when the application exposes the override control in a user preferences screen.	`+, -` +=TRUE -=FALSE

38.4.2.3 Feedback Site-Level Settings

Table 38–3 lists and describes the site-level settings for the People Connections service Feedback feature.

The service ID for Feedback is `oracle.webcenter.peopleconnections.kudos`. For a list of service IDs, see Table G–7.

Table 38–3 Site-Level Settings for Feedback

Setting Key	Description	Valid Site-Level Values
`visibility.accessControlSettings.accessControlLevel`	Specifies who can view a user's received Feedback.	`SELF, CONNECTIONS, USERS` (that is, authenticated users), `PUBLIC`
`visibility.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their received Feedback. This setting is honored only when the application exposes the override control in a user preferences screen.	`+, -` +=TRUE -=FALSE
`addControl.accessControlSettings.accessControlLevel`	Specifies who can give Feedback to a user.	`SELF, CONNECTIONS, USERS` (that is, authenticated users), `PUBLIC`
`addControl.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can give them Feedback. This setting is honored only when the application exposes the override control in a user preferences screen.	`+, -` +=TRUE -=FALSE

Table 38–3 (Cont.) Site-Level Settings for Feedback

Setting Key	Description	Valid Site-Level Values
`miniViewRowCount.value`	Specifies the number of Feedback entries to show in a Feedback - Quick View task flow.	Positive integers
`miniViewRowCount.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for the number of entries to show in a Feedback - Quick View task flow. This setting is honored only when the application exposes the override control in a user preferences screen.	`+, -` +=TRUE -=FALSE
`postedUserActions.delete`	Specifies whether users are allowed to delete the Feedback they leave for other users.	`+, -` +=TRUE -=FALSE

38.4.2.4 Message Board Site-Level Settings

Table 38–4 lists and describes the site-level settings for the People Connections service Message Board feature.

The service ID for Message Board is `oracle.webcenter.peopleconnections.wall`. For a list of service IDs, see Table G–7.

Table 38–4 Site-Level Settings For Message Board

Setting Key	Description	Valid Site-Level Values
`visibility.accessControlSettings.accessControlLevel`	Specifies who can view a user's Message Board.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`visibility.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their Message Board. This setting is honored only when the application exposes the override control in a user preferences screen.	`+, -` +=TRUE -=FALSE
`addControl.accessControlSettings.accessControlLevel`	Specifies who can post to a user's Message Board.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`addControl.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can post to their Message Board. This setting is honored only when the application exposes the override control in a user preferences screen.	`+, -` +=TRUE -=FALSE
`miniViewRowCount.value`	Specifies the number of messages to show in a Message Board - Quick View task flow.	Positive integer

Table 38–4 (Cont.) Site-Level Settings For Message Board

Setting Key	Description	Valid Site-Level Values
`miniViewRowCount.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for the number of messages to show in a Message Board - Quick View task flow. This setting is honored only when the application exposes the override control in a user preferences screen.	+, - +=TRUE -=FALSE
`postedUserActions.edit`	Specifies whether users are allowed to edit the messages they post on other users' Message Boards.	+, - +=TRUE -=FALSE
`postedUserActions.delete`	Specifies whether users are allowed to delete messages they post on other users' Message Boards.	+, - +=TRUE -=FALSE

38.4.2.5 Profile Site-Level Settings

Table 38–5 lists and describes the site-level settings for the People Connections service Profile feature.

The service ID for Profile is `oracle.webcenter.peopleconnections.profile`. For a list of service IDs, see Table G–7.

Note: If Oracle WebCenter Portal is connected to embedded LDAP (the default), you must disable profile editing or users will see an error when they try to edit their profiles.

Table 38–5 Site-Level Settings for Profile

Setting Key	Description	Valid Site-Level Values
`general-profile-settings.logActivity`	Specifies whether profile updates, such as uploading a photo, updating personal status, changing profile attributes, should result in activities getting published in Activity Stream.	`true`, `false`
`general-profile-settings.prersonalWebVisibility`	Specifies who can view a user's Profile Gallery.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`general-profile-settings.pwVisibilityPersonalizable`	Specifies whether individual users can override in their own views the application-level setting for who can view their Profile Gallery. This setting is honored only when the application exposes the override control in a user preferences screen.	`true`, `false`

Table 38–5 (Cont.) Site-Level Settings for Profile

Setting Key	Description	Valid Site-Level Values
`general-profile-settings.view.name.`*`profileSectionName`*`.access-control-level`	Specifies who can view the Profile section identified by *`profileSectionName`*. For example: `general-profile-settings.view.name.personalInfo.access-control-level` For more information, see Table 38–6, " Profile Section Names".	`SELF`, `USERS` (that is, authenticated users), `PUBLIC` **Note:** `CONNECTIONS` is not a valid value for this setting.
`general-profile-settings.view.name.`*`profileSectionName`*`.allow-personalize-visibility`	Specifies whether individual users can override in their own application views the application-level setting for who can view the Profile section identified by *`profileSectionName`* on their profile. This setting is honored only when the application exposes the override control in a user preferences screen. For more information, see Table 38–6, " Profile Section Names".	`true`, `false`
`general-profile-settings.view.name.`*`profileSectionName`*`.allow-user-edit`	Specifies whether users are allowed to edit the Profile section identified by *`profileSectionName`* on their own Profiles. For example: `general-profile-settings.view.name.personalInfo.allow-user-edit` For more information, see Table 38–6, " Profile Section Names".	`true`, `false`
`ootb-view-edit-settings.view.name.`*`profileSectionName`*`.`*`profileFieldName`*`.allow-edit`	Specifies whether users are allowed to update the field identified by *`profileFieldName`* when they edit the Profile section identified by *`profileSectionName`* on their own profile. For example: `ootb-view-edit-settings.view.name.personalInfo.homePhone.allow-edit` For more information, see Table 38–6, " Profile Section Names" and Table 38–7, " Profile Field Names".	`true`, `false`

Table 38–6 Profile Section Names

Section Name	Description
`basic`	Profile summary These details are discoverable in an application search.
`employee`	Employee detail
`businessContact`	Business contact information

Table 38–6 (Cont.) Profile Section Names

Section Name	Description
`personalInfo`	Personal information

Table 38–7 Profile Field Names

Field Name	Description
`email`	Business email address
`displayName`	User display name
`Dept`	Office department
`title`	Job title
`phone`	Business phone number
`timeZone`	Time zone
`photo`	User photo
`persStatNote`	Personal status message
`description`	About me
`empType`	Employee type
`empNo`	Employee number
`prefLang`	User's preferred language
`organization`	Employee's organization
`expertise`	Employee's expertise
`fax`	Fax number
`mobile`	Mobile/cell phone number
`pager`	Page number
`street`	Office address: street
`city`	Office address: city
`state`	Office address: state
`poBox`	Office address: P.O. box
`poCode`	Office address: ZIP/PIN/P.O. code
`country`	Office address: country
`homeAdd`	Home address
`homePhone`	Home phone number
`dob`	Date of birth
`maidenName`	Maiden name/surname before marriage
`doh`	Date of hire

38.4.3 Example: Configuring Connections to Accept Invitations Automatically

By default, when users send invitations to connect, recipients must explicitly accept them. Through site-level settings, the application administrator can configure the application to accept invitations automatically. This setting is identified by the key, `autoAcceptInvitations`, and the service ID, oracle.webcenter.peopleconnections.connections. To change the setting, the administrator performs the following steps:

1. Open the settings-insert.sql script and uncomment the following lines:

   ```
   -- INSERT INTO WC_PPL_COMMON_SETTING (ID, APPLICATION_ID, SCOPE_ID, SERVICE_ID,
   USER_ID, TASKFLOW_INST_ID, SETTING_KEY, SETTING_VALUE)
   --   VALUES ('768e5d1f-a73d-41b4-819d-74be081e1de1', 'webcenter',
   'defaultScope', 'oracle.webcenter.peopleconnections.connections', 'SYSTEM',
   'SITE', 'autoAcceptInvitations', '-')
    -- ;
   ```

   After modification, the lines appear as follows:

   ```
    INSERT INTO WC_PPL_COMMON_SETTING (ID, APPLICATION_ID, SCOPE_ID, SERVICE_ID,
   USER_ID, TASKFLOW_INST_ID, SETTING_KEY, SETTING_VALUE)
      VALUES ('768e5d1f-a73d-41b4-819d-74be081e1de1', 'webcenter', 'defaultScope',
   'oracle.webcenter.peopleconnections.connections', 'SYSTEM', 'SITE',
   'autoAcceptInvitations', '-')
    ;
   ```

2. Save and run the script.

3. Open the settings-update.sql script and uncomment the following lines:

   ```
     -- UPDATE WC_PPL_COMMON_SETTING SET SETTING_VALUE='-'
     --   WHERE APPLICATION_ID='webcenter' AND SCOPE_ID='defaultScope' AND USER_
   ID='SYSTEM' AND TASKFLOW_INST_ID='SITE'
     --   AND SERVICE_ID='oracle.webcenter.peopleconnections.connections' AND
   SETTING_KEY='autoAcceptInvitations'
      -- ;
   ```

   After the modification, the lines appear as follows:

   ```
      UPDATE WC_PPL_COMMON_SETTING SET SETTING_VALUE='-'
        WHERE APPLICATION_ID='webcenter' AND SCOPE_ID='defaultScope' AND USER_
   ID='SYSTEM' AND TASKFLOW_INST_ID='SITE'
        AND SERVICE_ID='oracle.webcenter.peopleconnections.connections' AND
   SETTING_KEY='autoAcceptInvitations'
       ;
   ```

4. Change the value of SETTING_VALUE to a plus sign (+).

   After modification, the lines appear as follows:

   ```
      UPDATE WC_PPL_COMMON_SETTING SET SETTING_VALUE='+'
        WHERE APPLICATION_ID='webcenter' AND SCOPE_ID='defaultScope' AND USER_
   ID='SYSTEM' AND TASKFLOW_INST_ID='SITE'
        AND SERVICE_ID='oracle.webcenter.peopleconnections.connections' AND
   SETTING_KEY='autoAcceptInvitations'
       ;
   ```

5. Save and run the script.

6. If your WebCenter Portal Framework application is running, restart the application.

   After you restart, the setting takes effect. In this example, when a user invites another user to connect, the connection is created automatically.

See Also: For lists and descriptions of People Connections site-level settings, see Section 38.4.2, "Supported Site-Level Settings for People Connections Features."

39

People Connections Task Flow Binding Parameters

This chapter describes how to revise task flow parameter values at design time and provides a table of binding parameters associated with People Connections task flows.

This chapter includes the following topics:

- Section 39.1, "About People Connections Task Flow Binding Parameters"
- Section 39.2, "How to Revise People Connections Task Flow Binding Parameters"
- Section 39.3, "People Connections Task Flow Binding Parameters"
- Section 39.4, "About the Activity Stream Advanced Query Option"

39.1 About People Connections Task Flow Binding Parameters

Each People Connections task flow has a set of required and optional task flow binding parameters that capture information that is useful to the task flow's successful function. For example, all People Connections task flows provide a binding parameter for capturing the ID of the current runtime user. This value (typically `#{securityContext.userName}`) enables the task flow to return People Connections data that is relevant to the current user.

In addition to providing required values for successful task flow rendering, you can use task flow binding parameters to customize the appearance and behavior of a task flow instance. For example, you can use parameter values to determine whether headers and footers are rendered, the number of rows and columns of information to show, whether to apply a filter to returned data, and the like.

You can provide task flow binding parameter values when you drag and drop a task flow onto an application page. Doing so opens the Task Flow Bindings dialog (for more information, see Section 38.2, "How to Add People Connections Task Flows to a Page"). You can also adjust task flow binding parameter values after you have placed a task flow on a page.

39.2 How to Revise People Connections Task Flow Binding Parameters

After you have added a task flow to a page, you might want to customize the instance by revising its binding parameter values. This section describes how to access the Edit Task Flow Binding dialog and change binding parameter values.

To access the Edit Task Flow Binding dialog:

1. Open the application page and set the view to bindings by clicking the **Bindings** tab at the bottom of the page.

2. Under **Executables**, double-click the task flow for which to revise task flow binding parameters (Figure 39–1) to open the Edit Task Flow Binding dialog (Figure 39–2).

   > **Tip:** Task flow names under **Executables** differ from names in design view. For example, Message Board task flows are instead referred to as *wall*, and Feedback task flows are instead referred to as *kudos*.

photoUploadAllowed	
statusUpdateAllowed	

* = Required

3. Revise binding parameter values (for more information, see Section 39.3, "People Connections Task Flow Binding Parameters").

4. Click **OK** to save your changes and exit the dialog.
5. Save and run your page to see the results.

39.3 People Connections Task Flow Binding Parameters

Table 39–1 lists and describes task flow binding parameters applicable to the People Connections service.

Table 39–1 People Connections Service Task Flow Binding Parameters

Parameter	Description
`__followEnforced`	A means of enforcing the follow logic when querying Activity Stream ■ Enter `#{true}` to establish that the user must follow the business object to access streamed activities, even when the object's activities are queried in an advance query clause. The default is true. ■ Enter `#{false}` to omit this requirement. The activities streamed for Fusion business objects are returned as far as required by the advanced query, no matter whether the user follows the objects. This parameter (for Fusion application business objects) is used in conjunction with the `advancedQuery` parameter. This parameter is associated with the Activity Stream task flow.
`__objectExtHandlerEnabled`	A means of using the object extension handler to process Fusion application business objects ■ Enter `#{true}` to use the object extension handler to process business objects. ■ Enter `#{false}` to omit using the object extension handler. False is the default. When you enter `#{true}`, then, before querying activities for the business objects, the Activity Stream uses the object extension handler to process the business objects. The handler checks whether the user has permission to access the business object. If the user does not have permission, the object is removed from the list, and, none activities are retrieved from this object. This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View
`__objects`	A comma separated list of objects for which to show activities Enter objects in the format `object-id;object-type;service-id`. Typically used only for followed objects. This parameter is associated with the Activity Stream task flow.
`__objectSecured`	A means of enforcing a security check on a Fusion application business object ■ Enter `#{true}` to enforce the security check. ■ Enter `#{false}` to omit the security check. False is the default. The security check is performed by the resource authorizer that is implemented by the Fusion application. If a user has no permission on a business object, the activities related to that business object are filtered out. This parameter is associated with the Activity Stream task flow. This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`advancedQuery`	A field for specifying a custom query to filter streamed items For more information, see Section 39.4, "About the Activity Stream Advanced Query Option." This parameter is associated with the Activity Stream task flow.
`connectionListName`	The name of a connections list This parameter is associated with the task flow Connections - Card.
`currentView`	The view to display by default Valid values include: ■ `connections`—(the default value) a list of connections ■ `receivedInvitations`—a list of connections invitations you received ■ `sentInvitations`—a list of connections invitations you sent ■ `people`—a search field for finding people with whom to connect When users access the task flow instance, the view specified here is the first one they see. All selections, except `people`, provide controls for navigating to the application default view (`connections`). Selecting `people` provides search and select controls for inviting other users to connect. This parameter is associated with the Connections task flow.
`displayCount`	The number of items to show in the task flow For example, enter `5` to specify that a maximum of five items can appear in the task flow. In quick views, a **More** link appears at the bottom of the task flow when there are more items than the specified number of items. Users click **More** to open the main view of the task flow where all items are accessible. In main views, **Previous** and **Next** links are shown. Users click these to page through entries. This parameter appears in the component properties for the following task flows: ■ Feedback ■ Feedback - Quick View ■ Message Board ■ Message Board - Quick View
`displayMessageSize`	The number of characters to show for each feedback message Messages exceeding the specified value are truncated, and an ellipse (…) is appended to the end. This parameter is associated with the task flow Feedback - Quick View.
`display_maxConnections`	The maximum number of connections to show in the task flow For example, enter `5` to specify that a maximum of five connections can appear in the task flow. A **More** link appears at the bottom of the task flow when there are more connections than the specified number of connections. Users click More to open the main view of the task flow where all connections are show. The value entered for this parameter is honored only when values for `display_numberOfRows` and `display_numberOfColumns` have not both been specified. If values for both of these parameters have been specified, then **Previous** and **Next** links appear when there are more connections than can fit into the specified numbers of rows and columns. This parameter is associated with the following task flows: ■ Connections - Card ■ Connections - Quick View

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`display_numberOfColumns`	The number of columns to show in the task flow For example, in a Connections - Card task flow that shows six connections, a value of `2` means those connections are shown in two columns with three rows (see also `display_numberOfRows` and `display_maxConnections`). This parameter is associated with the following task flows: - Connections - Card - Connections - Quick View
`display_numberOfRows`	The number of rows to show in the task flow For example, in a Connections - Card task flow that shows six connections and a value of `2` for `display_numberOfColumns`, a value of `2` for this parameter means connections are shown in two columns with two rows. That is, four connections are shown. A **More** link appears at the bottom of the task flow when there are more connections than can be fit in the specified number of columns and rows. Users click More to open the main view of the task flow where all connections are shown. See also `display_maxConnections`. This parameter is associated with the following task flows: - Connections - Card - Connections - Quick View
`display_profileFormat`	The default layout style for the task flow Enter one of the following: - `vcard`—displays a connection's photo and status message. - `iconic`—displays a connection's photo and user name. - `list`—displays connections in a list, with each list row showing the profile photo, user name (linked to a summary profile view), mail address, job title, status message, and actions icons and links. - `tiled`—renders the connection's personal Profile photo and shows the user name and job title beside the photo. In all layouts, the name links to a summary view of the user's Profile. This parameter is associated with the task flow Connections - Card.
`display_removalAllowed`	A means of showing or hiding the **Remove** action on the task flow Enter `true` to show the Remove action. Enter `false` to hide the Remove action. The default value (`true`) is applied if the input is invalid. This parameter is associated with the task flow Connections - Card.
`display_sortedBy`	The connections sort order Enter `LAST_ACTIVITY_TIME` to sort connections in descending date/time order. Leave this field blank to sort connections alphabetically by name. This parameter is associated with the task flow Connections - Card.
`editMode`	A means of enabling an edit mode on a Profile task flow instance Enter `#{true}` to enable an edit mode. Enter `#{false}` to disable it. This parameter is associated with the Profile task flow.

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`enableContextInf0`	A means of showing or omitting detailed information about the object in the current context (that is, in a popup or other contextual instrument) ■ Enter `#{true}` to enable Activity Stream to display the `af:contextInfo` component (a small, red dot). Users can click this dot to view object detail information. ■ Enter `#{false}` to omit object detail information. When this parameter is true and the `contextInfoTaskflowId` in the service definition is defined, the activity from the service displays the `af:contextInfo`. Otherwise, no context information is shown. This parameter is associated with the Activity Stream task flow.
`filterPattern`	A filter against task flow content For example, enter `pat` to show only those connections named *pat* (including *patrick* or *sripathy*). This parameter is associated with the task flow Connections - Card.
`fromDate`	The start date of a date range within which to show feedback messages Enter dates in the format `YYYY-MM-DD`. See also `toDate`. This parameter is associated with the following task flows: ■ Feedback ■ Feedback - Quick View ■ Message Board
`hideActions`	A means of hiding the actions normally associated with a Feedback or Message Board entry, such as Edit, Private, Hide, and Delete ■ Enter `#{true}` to hide actions associated with a Feedback or Message Board entry. ■ Enter `#{false}` to show such actions. When no value is entered, `false` is the default. This parameter appears in the component properties for the following task flows: ■ Feedback – Quick View ■ Message Board – Quick View
`hideAttach`	Specifies whether the **Attach: File | Link** option is shown or hidden ■ Check for `#{true}` to hide the **Attach: File | Link** option. ■ Clear for `#{false}` to show the **Attach: File | Link** option. This parameter is associated with the Publisher task flow.
`hideComments`	A means of showing or hiding the Comments feature on streamed activities Enter `true` to hide the Comments feature. Enter `false` to show it. This parameter is associated with the Activity Stream task flow
`hideConfigure`	A means of hiding the personalization option on the task flow instance This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`hideDocumentUploader`	A means of showing or hiding the Publisher task flow's document uploader Enter `#{true}` to hide the Publisher task flow's document uploader. Enter `#{false}` to show it. This parameter is associated with the Publisher task flow.
`hideFooter`	A means of showing or hiding the task flow footer The task flow footer contains the **More** link that appears at the bottom of a task flow when there are more items to show than can be accommodated in the current view. Hiding the footer hides the **More** link. Hiding the footer does not affect **Previous** and **Next** links that may also appear at the bottom of a task flow. Enter `true` to hide the footer. Enter `false` (default) to show the footer. This parameter is associated with the following task flows: ■ Activity Stream - Quick View ■ Connections - Card ■ Connections - Quick View ■ Feedback - Quick View ■ Message Board - Quick View
`hideGiven`	A means of showing or hiding feedback given to a user Enter true to allow the rendering of given feedback. Enter false to prohibit it. This parameter is associated with the following task flows: ■ Feedback ■ Feedback - Quick View
`hideHeader`	A means of showing or hiding the task flow header Enter `true` to hide the task flow header. Enter `false` (default) to show the task flow header. This parameter is associated with the following task flows: ■ Activity Stream - Quick View ■ Connections - Quick View ■ Feedback ■ Feedback - Quick View ■ Message Board ■ Message Board - Quick View
`hideInlinePreview`	A means of allowing or omitting an inline preview of files attached to streamed activities Enter `true` to omit a file preview. Enter `false` to show it. This parameter is associated with the Activity Stream task flow.
`hideLike`	A means of showing or hiding the Like link on a streamed activity Enter true to hide the Like link. Enter false to show it. This parameter is associated with the Activity Stream task flow
`hideName`	A means of showing or hiding the user name for a connection Enter true to hide the name. Enter false to show it. This parameter is associated with the Connections - Card task flow

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`hidePublisher`	A means of showing or hiding the message entry field and the upload file and URL controls (the Publisher) ■ Enter `#{true}` to disable the display of the message entry field in a given task flow instance. ■ Enter `#{false}` to allow the display of the message entry field in a given task flow instance. This parameter is associated with the following task flows: ■ Message Board ■ Message Board - Quick View
`hideScopePicker`	Specifies whether the **Share something with** option is shown or hidden ■ Check for `#{true}` to hide the **Share something with** option. ■ Clear for `#{false}` to show the Share something with option. This parameter is associated with the Publisher task flow.
`hideShare`	A means of showing or hiding the Share link on a streamed activity Enter true to hide the Share link. Enter false to show it. This parameter is associated with the Activity Stream task flow
`hideSpacesUI`	Specifies whether to show the Portals UI in the Activity Stream and Activity Stream - Quick View Configuration dialogs. The Portals UI enables users to specify whether to show activities from all portals, the portals of which they are a member, no portals, or just the portal on which the task flow is placed. ■ Enter `#{true}` to show the Portals UI. This is the default. ■ Enter `#{false}` to hide the Portals UI. This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View
`hintsTextKey`	Specifies the resource bundle class and message key for hint text Use the format `key[,RBClass]`. `__EMPTY__` as the predefined key for no hint text. This is the default value. This parameter is associated with the Publisher task flow.
`imageSize`	The display size of the profile photo Enter one of the following values: ■ `ORIGINAL` ■ `LARGE` ■ `MEDIUM` ■ `SMALL` This parameter is associated with the Profile - Snapshot task flow.
`isUpdateStatus`	A means of dedicating the task flow instance to updating the current user's Profile status message Enter `#{true}` to devote the task flow instance to updating user status messages. Enter `#{false}` to omit publishing messages to the current user's Profile status message. This parameter is associated with the Publisher task flow.

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`keepOpenAfterPublish`	Specifies whether the text box remains active after a user clicks the **Publish** button ■ Enter `#{true}` to keep the text box open after a message is published. ■ Enter `#{false}` to close the text box after a message is published. This parameter is associated with the Publisher task flow.
`launchStyle`	Specifies the profile launch style. This parameter is considered only if Profile Launched On Selection is selected. Enter one of the following: ■ `snapshot`—displays a user's profile snapshot when the user's name is clicked. ■ `profile`—displays user's Profile page when the user's name is clicked. This parameter is associated with the task flow Connections - Card.
`messageType`	Types of messages to display. Applicable only if viewing own's messageboard. Specifies the types of messages to display. Enter one of the following: ■ `all`—displays both public and private messages. This is the default. ■ `private`—displays only private messages. ■ `public`—displays only public messages. This parameter is associated with the following task flows: ■ Message Board ■ Message Board - Quick View
`numberOfRows_list`	The number of rows to show when the Connections task flow instance is set to list view This parameter is associated with the Connections task flow.
`objectId`	The ID of an object to associate with a published message This parameter is associated with the Publisher task flow.
`objectType`	The type of an object to associate with a published message This parameter is associated with the Publisher task flow.
`orgBreadCrumbsShown`	A means of showing or omitting organization breadcrumbs on a user profile that renders a management chain that is linked to each member up the chain Enter `#{true}` to show organizational breadcrumbs. Enter `#{false}` to omit them. This parameter is associated with the Profile - Snapshot task flow.
`pageSize`	The number of items to stream in a given task flow instance This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`pagination`	The form of pagination to use on a multipage stream ■ Enter `#{true}` to show Previous and Next links. ■ Enter `#{false}` hide to omit Previous and Next links. Instead, a more link is rendered, enabling users to navigate to a fuller view of the task flow where all streamed activities are shown. This parameter is associated with the Activity Stream task flow.
`photoUploadAllowed`	A means of allowing a photo upload from the profile screen Enter `true` (default) to allow users to upload a photo to their profile. Enter `false` to prevent users from uploading a photo. This parameter is associated with the task flow Profile - Snapshot.
`profileEditLinkShown`	A means of showing or omitting an Edit link on a Profile - Snapshot task flow Enter `#{true}` to show the Edit link. Enter `#{false}` to hide it. This parameter is associated with the Profile - Snapshot task flow.
`profileLaunchedOnSelection`	A means of launching a user Profile when the user name is clicked Enter `true` to launch a user Profile when the user name is clicked. Enter `false` to prevent launching a user Profile This parameter is associated with the task flow Connections - Card
`profileOnly`	A means of streaming activities only from user profiles ■ Enter `true` to stream only those activities associated with user profiles. ■ Enter `false` to stream other types of activities along with those associated with user profiles. This parameter is associated with the Activity Stream task flow.
`profileUserId`	ID of the user from whom to stream activity This parameter is associated with the Activity Steam - Quick View task flow.
`resourceId`	The current user ID Enter `#{securityContext.userName}` to return the current user. This parameter is associated with the following task flows: ■ Activity Stream ■ Connections ■ Feedback ■ Message Board ■ Profile ■ Profile Gallery
`scopeId`	The ID of the scope to which to publish This property value assists in generating a link for use in navigating to the published object. It is not necessary to provide a value, unless you plan to do so using an EL expression. For information about EL expressions, seeAppendix G, "Expression Language Expressions." This parameter is associated with the Publisher task flow.

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`sectionWiseEditEnabled`	A means of enabling or disabling section-by-section edit capability on the task flow - Enter `#{true}` to enable section-by-section editing. An **Edit** control is shown on each editable Profile section. - Enter `#{false}` to disable section-by-section editing. This parameter is associated with the Profile task flow.

`serviceCategories`	A field for entering a comma-separated list of names of services from which to stream activities
	Use this parameter to limit the display of streamed activities to only those associated with the specified service or services. Enter one or more service IDs, for example:
	`oracle.webcenter.collab.announcement,`
	`oracle.webcenter.collab.forum`
	For a list of valid service ID, see Table G–7, " Service and Tool IDs". Note that all listed service IDs cannot be used because all services do not stream items to the Activity Stream. For example, the RSS service does not stream any activities.
	This parameter is associated with the Activity Stream task flow.

`serviceId`	The service ID of the service to which the object associated with a published message belongs For a list of service IDs, see Table G–7, " Service and Tool IDs". This parameter is associated with the Publisher task flow.
`showViewListOfAll`	Specifies whether the footer includes a **See all your connections** link. If this parameter is enabled, the task flows shows no pagination. - Enter `#{true}` to show the **See all your connections** link. - Enter `#{false}` to hide the **See all your connections** link. This parameter is associated with the task flow Connections - Card.
`spaceName`	The portal to which to publish messages If your application does not support portals, do not provide a value for this parameter. This parameter is associated with the following task flows: - Message Board - Message Board - Quick View - Publisher
`spaces`	A comma-separated list of names or GUIDs of portals from which to stream activities Use this parameter to limit the display of streamed activities to only those associated with the specified portal or portals. If your application does not support portals, do not provide a value for this parameter. This parameter is associated with the Activity Stream task flow.
`statusUpdateAllowed`	A boolean value representing whether a control is available on the task flow for updating a profile status message Enter either `true` or `false`. This parameter appears in the component properties for the Profile - Snapshot task flow.

Table 39–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`toDate`	The end date of a date range within which to show feedback messages Enter dates in the format `YYYY-MM-DD`. See also `fromDate`. This parameter is associated with the following task flows: ■ Feedback ■ Feedback - Quick View ■ Message Board
`uploadDocumentOnly`	A means of limiting the Publisher task flow to its document upload feature Enter #{true} to limit the Publisher task flow to be only a document uploader. Enter `#{false}` to expose all Publisher features. This parameter is associated with the Publisher task flow.
`userId`	The current user ID Enter `#{securityContext.userName}` to return the current user. This parameter is associated with the following task flows: ■ Connections - Card ■ Connections - Quick View ■ Feedback - Quick View ■ Message Board - Quick View ■ Profile - Snapshot
`userName`	The name of the user to whom to publish messages This value is supplied by default. We recommend that you do not change the default value, `#{o_w_w_i_v_b_resourceViewerBean.username}`. This parameter is associated with the Publisher task flow.
`viaUser`	The user name of the person who provided the object the current user is sharing For example, John is sharing a document with everyone that Jane originally shared with him. In this case, Jane is the via user. This parameter is associated with the Publisher task flow.

39.4 About the Activity Stream Advanced Query Option

Use `Advanced Query` to create filters against streamed activities in an Activity Stream task flow. Create filters for user names, service IDs, and object details, such as a document's display name. You can use SQL syntax for parameter values. Additionally you can place EL expressions within the SQL.

You can construct queries against specific database objects, which are represented by aliases that are prefixed to the inquiry. Table 39–2 lists and describes the types of database objects against which you can construct a query and provides their alias prefixes.

> **See Also:** In many cases, you can use EL expressions to obtain the value you require for the supported fields and columns listed in Table 39–2. For more information, see Appendix G, "Expression Language Expressions."

Table 39–2 Supported Database Objects for Constructing a SQL WHERE Clause

Database Object	Alias Prefix	Supported Fields/Columns
ACTIVITY	AE	■ `SCOPE_ID`—The GUID of the scope (you can use an EL to return this value, for example, `#{serviceCtx.scope.GUID}`). ■ `SERVICE_ID`—The service ID of the service to track. See Table G–7 for a list of service IDs. ■ `ACTIVITY_TIME`—The time the activity occurs. Use the datetime format that is supported in the SQL or target database. You can also use Oracle database SQL constructs, such as `to_date()`. ■ `ACTIVITY_TYPE`—The type of activity to track For a list of valid activity type names, see Table 39–3.
ACTIVITY (ACTOR)	AD	`ACTOR_NAME`—The user name of the person performing the activity.
ACTIVITY (OBJECT)	OD	■ `SERVICE_ID`—The service ID of the service from which the tracked object issues. See Table G–7 for a list of service IDs. ■ `OBJECT_ID`—The GUID of the object. ■ `DISPLAY_NAME`—The object display name. ■ `OBJECT_TYPE`—The object type. Object type names for use with Advanced Query include: ■ `event` ■ `announcement` ■ `forum` ■ `topic` ■ `bookmark` ■ `list` ■ `page` ■ `blog` ■ `document` ■ `wiki`

Table 39–3 Activity Type Names for Advanced Query

Service	Activity Type Name
Events	■ `createEvent` ■ `updateEvent`
Announcements	■ `createAnnouncement` ■ `updateAnnouncement`
Discussions	■ `createForum` ■ `createTopic` ■ `replyTopic`
Tags	■ `updateBookmark`
Lists	■ `createList` ■ `editList`

Table 39–3 (Cont.) Activity Type Names for Advanced Query

Service	Activity Type Name
Page	■ `createPage` ■ `editPage`
Documents	■ `create-blog` ■ `update-blog` ■ `create-document` ■ `create-wiki` ■ `update-document` ■ `update-wiki`
People Connections (Profile)	■ `updateStatus` ■ `updateProfile` ■ `updatePhoto`
People Connections (Message Board)	■ `postScope` ■ `postself` ■ `post` ■ `sharescope` ■ `shareself` ■ `share` ■ `shareobjectscope` ■ `shareobjectself` ■ `shareobject` ■ `updatescope` ■ `updateself` ■ `update`
People Connections (Connections)	■ `connect` ■ `inviteForConnection`
People Connections (Feedback)	■ `post`

The SQL string that is passed as the advanced query parameter complies with SQL standards. That is, it supports SQL constructs, such as `AND`, `OR`, `IN`, and the like. Note, however, that it does not support `INSERT`, `UPDATE`, `DELETE`, `SELECT`, `JOIN` constructs. The syntax of the advanced query must contain only the `WHERE` clause portion of a SQL query. Because `SELECT` is not supported, the `WHERE` clause cannot have nested queries or subqueries.

The `Advanced Query` parameter also supports EL expressions, which can be embedded in the `WHERE` clause or used to generate the whole `WHERE` clause.

All the literals in the query must be escaped by prepending a backward slash (\); otherwise, such characters generate syntax errors (see Table 39–4 for examples).

The advanced query `WHERE` clause is always `AND`ed to the internal query that is generated by Activity Stream based on the current user, portal membership, connection list, and the like. This is to prevent a user from viewing activities to which he or she does not have access.

Table 39–4 lists examples of advanced queries.

Table 39–4 Examples of Advanced Queries for Use with Activity Stream

Use Case	Query Syntax
Stream only document creation activities.	`AE.SERVICE_ID = \'oracle.webcenter.doclib\'`
Stream activities only from an object or current portal.	`OD.OBJECT_ID = \'objectA\' OR AE.SCOPE_ID = \'#{serviceCtx.scope.GUID}\'`
Stream activities only about wikis created by the current user.	`OD.OBJECT_TYPE = \'Wiki\' AND AD.ACTOR_NAME = \'#{securityContext.userName}\'`
Stream activities for documents and discussions, but only create activities or all activities for the current user.	`(AE.SERVICE_ID IN (\'oracle.webcenter.doclib\', \'oracle.webcenter.collab.forum\') AND AE.ACTIVITY_TYPE IN (\'createDocument\', \'createTopic\')) OR AD.ACTOR_NAME = \'#{securityContext.userName}\'`

40

Using People Connections Data Controls and Java APIs

This chapter describes how to use People Connections service data controls and Java APIs. It provides details about each data control, including how to add a data control to a project and where to find additional information.

This chapter includes the following topics:

- Section 40.1, "Using People Connections Data Controls"
- Section 40.2, "People Connections Service Java APIs"

40.1 Using People Connections Data Controls

The People Connections service provides data controls that enable you to create your own visualization of the People Connections functionality. This section provides an overview of the following data controls and lists and describes their supported methods, attributes, and classes:

- People Connections Management Data Control
- Kudos Service Data Control
- Profile Data Control

This section also includes the following subsections:

- Section 40.1.1, "Adding a Data Control to Your Project"
- Section 40.1.2, "Working with People Connections Management Data Control"
- Section 40.1.3, "Working with Profile Data Control"

40.1.1 Adding a Data Control to Your Project

You add a data control to your project by right-clicking it in the Resource Palette and selecting **Add to Project** from the resulting context menu. Once added, you can browse the data control's methods and attributes by expanding it in the Data Controls panel in the Application Navigator.

You add a data control to an application page by dragging it onto the page from the Data Controls panel. Once placed, a context menu opens with options for selecting the type of component to which to bind the data, such as a button or a text box.

To implement a People Connections Data Control:

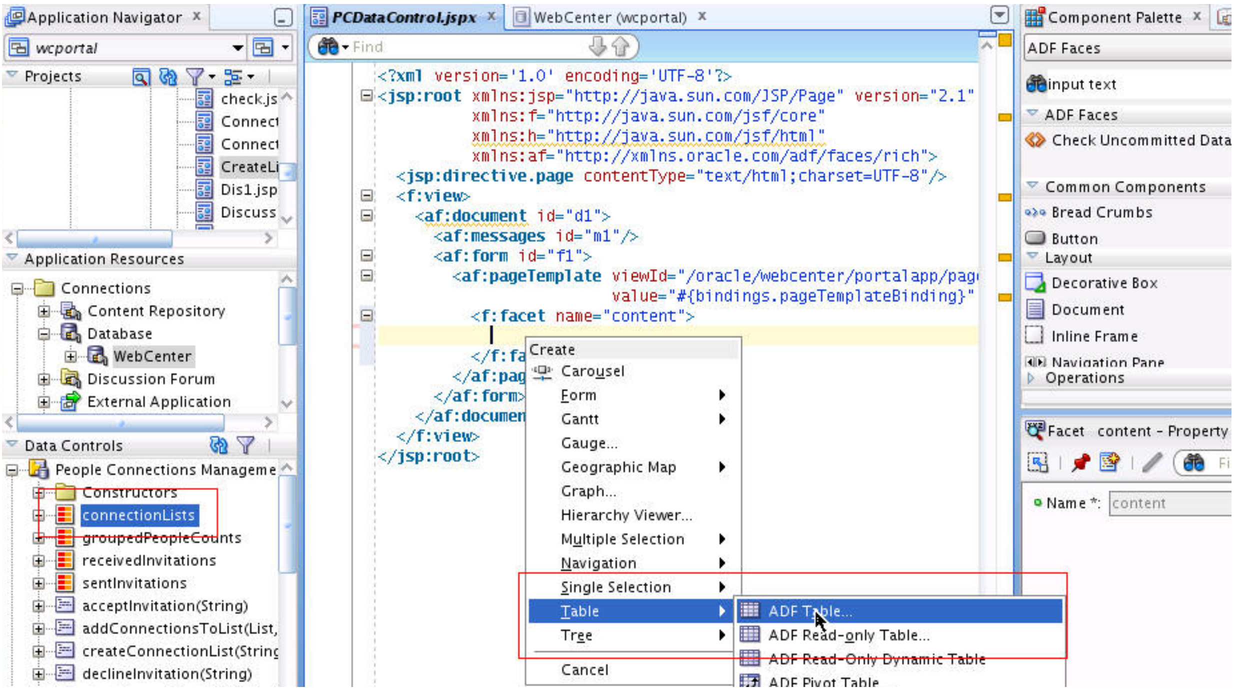
1. Create a WebCenter Portal Framework application in JDeveloper.

2. In your WebCenter portal application, navigate to **Resource Catalog** > **Services Catalog** > **Data Controls**.
3. Select a People Connection Data Control and right-click the control.
4. Click **Add to Project** in the context menu.

   The Data Controls appear in the Application Navigator Projects Data Controls folder.
5. Expand the Data Controls folder.

   On expanding, the Data Control objects and their corresponding Java methods appear.
6. Drag and drop the data control object on to the `.jspx` page and select the **ADF Table** option in the drop-down **Table** menu list, shown in Figure 40–1.

Figure 40–1 The Data Control Object Dragged and Dropped on to a .jspx Page With ADF Table Selected

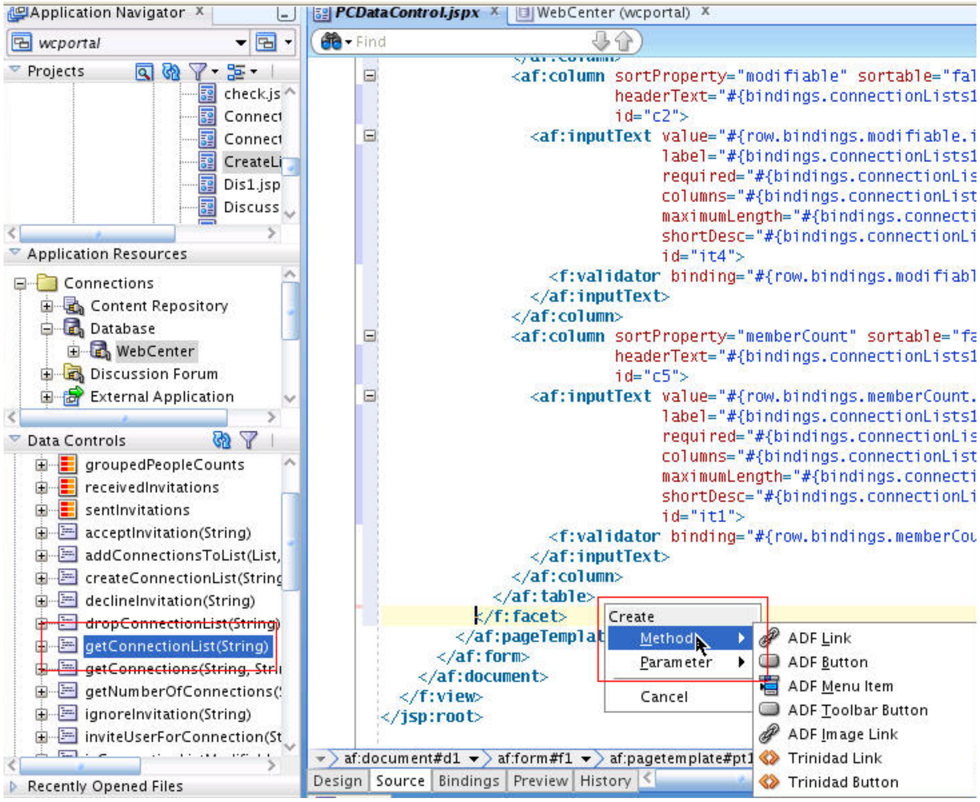


```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <f:view>
    <af:document id="d1">
      <af:messages id="m1"/>
      <af:form id="f1">
        <af:pageTemplate viewId="/oracle/webcenter/portalapp/pag
                         value="#{bindings.pageTemplateBinding}"
          <f:facet name="content">

          </f:fa
        </af:pag
      </af:form>
    </af:documen
  </f:view>
</jsp:root>
```

7. To use the available Java methods, drag the methods to the .jspx page and select the **Method** item in the **Create** menu list, as shown in Figure 40–2, and bind it to the data in your project to achieve the desired functionality.

Figure 40–2 Dragging and Dropping Java Methods to the .jspx Page and Selecting Method in the Create Menu List



```
            </af:column>
            <af:column sortProperty="modifiable" sortable="fal
                       headerText="#{bindings.connectionLists1
                       id="c2">
              <af:inputText value="#{row.bindings.modifiable.i
                            label="#{bindings.connectionLists1
                            required="#{bindings.connectionLis
                            columns="#{bindings.connectionList
                            maximumLength="#{bindings.connecti
                            shortDesc="#{bindings.connectionLi
                            id="it4">
                <f:validator binding="#{row.bindings.modifiabl
              </af:inputText>
            </af:column>
            <af:column sortProperty="memberCount" sortable="fa
                       headerText="#{bindings.connectionLists1
                       id="c5">
              <af:inputText value="#{row.bindings.memberCount.
                            label="#{bindings.connectionLists1
                            required="#{bindings.connectionLis
                            columns="#{bindings.connectionList
                            maximumLength="#{bindings.connecti
                            shortDesc="#{bindings.connectionLi
                            id="it1">
                <f:validator binding="#{row.bindings.memberCou
              </af:inputText>
            </af:column>
          </af:table>
        </f:facet>
      </af:pageTemplat
    </af:form>
  </af:document>
</f:view>
</jsp:root>
```

See Also: For more information about using data controls in a WebCenter Portal Framework application, see Section 4.1.3, "Using WebCenter Portal Data Controls."

40.1.2 Working with People Connections Management Data Control

The People Connections Management Data Control provides methods for adding and managing connections and connections lists. The primary methods exposed include:

- connectionLists
- groupedPeopleCounts
- receivedInvitations
- sentInvitations
- acceptInvitation(String invitationId)
- addConnectionsToList(List userids, String listName)
- createConnectionList(String listName)
- declineInvitation(String invitationId)
- dropConnectionList(String listName)
- getConnectionList(String connectionListName)
- getConnections(String userid, String connectionListName, String filterPattern, String sortBy, int startIndex, int fetchSize)

- getNumberOfConnections(String userid, String connectionListName, String filterPattern)
- ignoreInvitation(String invitationId)
- inviteUserForConnection(String userid, String invitationMessage, Collection connectionListNames)
- isConnectionListModifiable(String listName)
- isConnectionPartOfUnmodifiableList(String connecteeGuid)
- removeConnection(String userid, boolean fromListOnly, String listName)
- searchUsers(String filterPattern, int startIndex, int fetchSize)
- updateConnectionListsMembership(String member, Collection addListIds, Collection removeListIds)

The subsections in this section list and describe the methods associated with the People Connections Management Data Control.

40.1.2.1 connectionLists

A collection of details about connections lists, including the list ID, name, localized name, number of members, whether or not the list is modifiable, and member user IDs. Table 40–1 lists and describes the attributes associated with this method.

Table 40–1 Attributes of the Method connectionLists

Attribute	Description
id	The connections lists IDs
listName	The names of connections lists
localizedName	The localized names of connections lists
memberCount	The number of members on each named connections list
modifiable	Information about whether a named connections list can be modified
memberUserIds	The user IDs of members on each named connections list

40.1.2.2 groupedPeopleCounts

The number of connections contained in each connections group.

40.1.2.3 receivedInvitations

A collection of details about a received invitation to connect, including when the invitation was sent and received, the invitation's GUID, the invitation message, and the user IDs of the user who sent the invitation and who received it. Table 40–2 lists and describes the attributes associated with this method.

Table 40–2 Attributes of the Method receivedInvitations

Attribute	Description
dateFormattedAsReceived	The date the invitation was received according to the recipient's time stamp
dateFormattedAsSent	The date the invitation was sent according to the sender's time stamp.
id	The GUID of the received invitation

Table 40–2 (Cont.) Attributes of the Method receivedInvitations

Attribute	Description
`invitationMessage`	The invitation message
`inviteeUserid`	The user ID of the person who received the invitation
`invitorUserid`	The user ID of the person who sent the invitation
`sentDate`	The date the invitation was sent according to the system time stamp

40.1.2.4 sentInvitations

A collection of details about a sent invitation to connect, including when the invitation was sent and received, the invitation's GUID, the invitation message, and the user IDs of the user who sent the invitation and who received it. Table 40–3 lists and describes the attributes associated with this method.

Table 40–3 Attributes of the Method sentInvitations

Attribute	Description
`dateFormattedAsReceived`	The date the invitation was received according to the recipient's time stamp
`dateFormattedAsSent`	The date the invitation was sent according to the sender's time stamp
`id`	The unique GUID of the received invitation
`invitationMessage`	The invitation message
`inviteeUserid`	The user ID of the person who received the invitation
`invitorUserid`	The user ID of the person who sent the invitation
`sentDate`	The date the invitation was sent according to the system time stamp

40.1.2.5 acceptInvitation(String invitationId)

A method for accepting invitations to connect. Table 40–4 lists and describes the parameters associated with this method.

Table 40–4 Parameters of the Method acceptInvitations

Parameter	Description
`invitationId`	The GUID of the invitation to connect to be accepted

40.1.2.6 addConnectionsToList(List userids, String listName)

A method for adding identified users to a named connections list. Table 40–5 lists and describes the parameters associated with this method.

Table 40–5 Parameters of the Method addConnectionsToList

Parameter	Description
`userids`	The user names of the users to add to the named connections list
`listName`	The name of the connections list to which to add identified users

40.1.2.7 createConnectionList(String listName)

A method for creating a connections list. Table 40–6 lists and describes the parameters associated with this method.

Table 40–6 Parameters of the Method createConnectionList

Parameter	Description
`listName`	The name to give the new connections list

40.1.2.8 declineInvitation(String invitationId)

A method for declining an invitation to connect. Table 40–7 lists and describes the parameters associated with this method.

Table 40–7 Parameters of the Method declineInvitation

Parameter	Description
`invitationId`	The unique GUID of the declined invitation

40.1.2.9 dropConnectionList(String listName)

Method for deleting a connections list. Table 40–8 lists and describes the parameters associated with this method.

Table 40–8 Parameters of the Method dropConnectionList

Parameter	Description
`listName`	The name of the connections list to delete

40.1.2.10 getConnectionList(String connectionListName)

Returns an object that represents a Connections List. This object provides details about a connections list acquired for the given connection list name. Table 40–9 lists and describes the parameters associated with this method. Table 40–10 lists and describes the attributes associated with this method.

Table 40–9 Parameters of the Method getConnectionList

Parameter	Description
connectionListName	The name of the connections list for which to return the following attributes (see Table 40–10): ■ `id` ■ `listName` ■ `localizedName` ■ `memberCount` ■ `modifiable` ■ `memberUserIds`

Table 40–10 Attributes of the Method getConnectionList

Attribute	Description
`id`	The unique GUID of the connections list to return
`listName`	The name of the connections list to return
`localizedName`	The localized name of the connections list to return

Table 40–10 (Cont.) Attributes of the Method getConnectionList

Attribute	Description
memberCount	The number of members on the connections list to return
modifiable	An indicator of whether the returned connections list can be modified
memberUserIds	The user IDs of the members of a returned connections list

40.1.2.11 getConnections(String userid, String connectionListName, String filterPattern, String sortBy, int startIndex, int fetchSize)

Returns the `Connection` object, which provides details about the connection, including the connection's user ID, the connections lists on which the connection is a member, and details from a connection's profile. Table 40–11 lists and describes the parameters associated with this method. Table 40–12 lists and describes the attributes associated with this method.

Table 40–11 Parameters of the Method getConnections

Parameter	Description
userid	The user ID for each returned connection
connectionListName	The name of the connection list from which to obtain connections
filterPattern	A filter to use against returned connections, such as "co," which returns `condoleezza` as well as `nicole`
sortBy	The order by which to sort connections Enter `LAST_ACTIVITY_TIME` to sort connections in descending date/time order. Leave blank to sort alphabetically by name.
startIndex	The point from which to start fetching results This is used for pagination. For example, the search can return 50 matching records, and only 10 are needed, starting from 1. Set `startIndex` to 1 and `fetchSize` to 10.
fetchSize	The number of results to return (see `startIndex`)

Table 40–12 Attributes of the Method getConnections

Attribute	Description
connecteeUserId	The user ID of a connection
connectionListsMembershipList	The names of connections lists of which the connection is a member
connecteeUserProfile	The connectee's Profile details

40.1.2.12 getNumberOfConnections(String userid, String connectionListName, String filterPattern)

Returns the number of users (`int`) connected to the identified user. Table 40–13 lists and describes the parameters associated with this method. Table 40–14 lists and describes the attributes associated with this method.

Table 40–13 Parameters of the Method getNumberOfConnections

Parameter	Description
`userid`	The user ID for whom to return the number of connections
`connectionListName`	The name of the connection list from which to obtain a count
`filterPattern`	A filter to use against returned connections, such as "co," which returns `condoleezza` as well as `nicole`

Table 40–14 Attributes of the Method getNumberOfConnections

Attribute	Description
`Int`	The number of connections to return

40.1.2.13 ignoreInvitation(String invitationId)

Specifies that the invitation with the specified ID should be ignored. Table 40–15 lists and describes the parameters associated with this method.

Table 40–15 Parameters of the Method ignoreInvitation

Parameter	Description
`invitationId`	The GUID of the connection invitation to ignore

40.1.2.14 inviteUserForConnection(String userid, String invitationMessage, Collection connectionListNames)

A means of inviting the user with the specified user ID to connect. Includes the invitation message, such as, "I would like you to be my connection." Also includes one or more connection list names to which to add the invitee once the invitation is accepted. Table 40–16 lists and describes the parameters associated with this method.

Table 40–16 Parameters of the Method inviteUserForConnection

Parameter	Description
`userid`	User ID of the invitee
`invitationMessage`	Connection message, such as, "Let's connect!"
`connectionListNames`	The names of the connections lists to add the invitee to once the invitation is accepted

40.1.2.15 isConnectionListModifiable(String listName)

Returns true or false (`boolean`) as to whether the named connections list can be modified. Table 40–17 lists and describes the parameters associated with this method. Table 40–18 lists and describes the attributes associated with this method.

Table 40–17 Parameters of the Method isConnectionListModifiable

Parameter	Description
`listName`	The name of the connections list for which to determine whether it can be modified

Table 40–18 Attributes of the Method isConnecitonListModifiable

Attribute	Description
`boolean`	True or false, depending on whether the named connections list can be modified

40.1.2.16 isConnectionPartOfUnmodifiableList(String connecteeGuid)

Returns true or false (`boolean`) as to whether the identified user is a member of a connections list that cannot be modified. Table 40–19 lists and describes the parameters associated with this method. Table 40–20 lists and describes the attributes associated with this method.

Table 40–19 Parameters of the Method isConnectionPartOfUnmodifiableList

Parameter	Description
`connecteeGuid`	The GUID of the connection for whom to determine whether this connection is a member of a connections list that cannot be modified

Table 40–20 Attributes of the Method isConnecitonPartOfUnmodifiableLIst

Attribute	Description
`boolean`	True or false, depending on whether the user is a member of a connections list that cannot be modified

40.1.2.17 removeConnection(String userid, boolean fromListOnly, String listName)

A method for removing the identified connection either as a connection or from a connections list. Table 40–21 lists and describes the parameters associated with this method.

Table 40–21 Parameters of the Method removeConnection

Parameter	Description
`userid`	The user name of the connection to remove from the specified list
`fromListsOnly`	A flag (true or false) indicating whether to remove the user as a connection or remove the user only from the specified connections list
`listName`	The name of the connections list from which to remove the specified user

40.1.2.18 searchUsers(String filterPattern, int startIndex, int fetchSize)

Returns the object `Users`, which is a collection of details about returned users, including the user's relational attributes, GUID, and profile details. Table 40–22 lists and describes the parameters associated with this method. Table 40–23 lists and describes the attributes associated with this method.

Table 40–22 Parameters of the Method searchUsers

Parameter	Description
`filterPattern`	A filter to use against returned search terms, such as "co," which returns `condoleezza` as well as `nicole`

Table 40–22 (Cont.) Parameters of the Method searchUsers

Parameter	Description
`startIndex`	The point from which to start fetching results This is used for pagination. For example, the search can return 50 matching records, and only 10 are needed, starting from 1. Set `startIndex` to 1 and `fetchSize` to 10.
`fetchSize`	The number of results to return (see `startIndex`)

Table 40–23 Attributes of the Method searchUsers

Attribute	Description
`relationalAttributes`	—
`userGuid`	The user's unique GUID
`userProfile`	The user's Profile details

40.1.2.19 updateConnectionListsMembership(String member, Collection addListIds, Collection removeListIds)

Provides a means of updating an identified connection's list membership by adding the connection to identified connections lists and removing the connection from identified connections lists. Table 40–24 lists and describes the parameters associated with this method.

Table 40–24 Parameters of the updateConnectionListsMembership Method

Parameter	Description
`member`	The user name of the member whose connections list membership to manage
`addListIds`	The names of the connections lists to which to add the identified user
`removeListIds`	The names of the connections lists from which to remove the identified user

40.1.3 Working with Profile Data Control

The Profile Data Control provides methods for returning and updating Profile details.

The subsections in this section list and describe the methods associated with the Profile Data Control.

40.1.3.1 Method: getProfile(String userId)

A method for returning the `WCUserProfile` object, which is a collection of user Profile details. Table 40–25 lists and describes the parameters associated with this method.

Table 40–25 Parameters for the getProfile Method

Parameter	Description
`userID`	The ID of the user for whom to return Profile details

> **Tip:** To see the attributes associated with the `WCUserProfile` object, expand the `WCUserProfile` node under the `getProfile` method on the Data Controls panel in the Application Navigator.

40.1.3.2 Method: getProfileForUpdate(String userId)

A method for updating the `WCUserProfile` object, which is a collection of user Profile details. Table 40–26 lists and describes the parameters associated with this method.

Table 40–26 Parameters for the getProfileForUpdate Method

Parameter	Description
`userID`	The ID of the user for whom to update Profile details

> **Tip:** To see the attributes associated with the `WCUserProfile` object, expand the `WCUserProfile` node under the `getProfileForUpdate` method on the Data Controls panel in the Application Navigator.

40.2 People Connections Service Java APIs

The People Connections service has associated Java APIs that you can use to work with service features. These include:

- `oracle.webcenter.peopleconnections.connections`
- `oracle.webcenter.peopleconnections.wall`
- `oracle.webcenter.activitystreaming`

For more information, see the *Java API Reference for Oracle WebCenter Portal*.

41

Integrating Worklists

This chapter describes how to integrate worklists into your application. Worklists enable users to view and take action on all tasks and notifications from a BPEL (Business Process Execution Language) server all in one place.

This chapter includes the following topics:

- Section 41.1, "Introduction to Worklists"
- Section 41.2, "Roadmap - Configuring Worklists for Portal Framework Applications"
- Section 41.3, "Basic Configuration for Worklists"
- Section 41.4, "Advanced Information for Worklists"

For information about managing and using worklists, see:

- the "Managing Worklists" chapter in *Administering Oracle WebCenter Portal*
- the "Adding Worklists to a Portal" chapter in *Building Portals with Oracle WebCenter Portal*
- the "Exploring Your Worklists" chapter in *Using Oracle WebCenter Portal*

41.1 Introduction to Worklists

Worklists enable you to show Business Process Execution Language (BPEL) Worklist items assigned to the currently authenticated user. The BPEL Worklist items are open BPEL tasks from one or more BPEL Worklist Repositories to which your application is connected. The Worklist displays BPEL Worklist items that are a result of a task invoked as part of a BPEL Workflow process, or are a result of a message being sent to the Worklist channel on the Oracle User Messaging Service.

This section contains the following subsections:

- Section 41.1.1, "Understanding Worklists"
- Section 41.1.2, "Requirements for Worklists"
- Section 41.1.3, "What Happens at Runtime"

41.1.1 Understanding Worklists

Worklists provide a personal, at-a-glance view of business processes that require your users' attention. These can include a request for document review or other types of business processes that come directly from your enterprise applications.

Worklist items come from a variety of sources. Some worklist items are kicked off by events that are associated with an externally defined workflow. A workflow maps the route an item follows once an event kicks off. This type of workflow is defined in a worklist BPEL server, such as Oracle BPM Worklist.

Messages, alerts, and notifications might also come from the User Messaging Service (UMS). The Worklist task flow includes a control for accessing messaging preferences on this server. Use these controls to specify the channels over which to receive Oracle User Messaging Service messages and to define messaging filters.

41.1.2 Requirements for Worklists

To use worklists, you must have a BPEL server installed. For information on installing BPEL for worklists, see the "Back-End Requirements for Worklists" in the *Installation Guide for Oracle WebCenter Portal*.

For a worklist to properly function, it must reside on a secured page, as it uses the currently authenticated user to access the BPEL server. If the page or application that contains the worklist is not secured, you will encounter exception errors.

41.1.3 What Happens at Runtime

At runtime, the Worklist task flow fetches latest worklist workflow items from BPEL workflows configured in the BPEL server. For more information, see the "Exploring Your Worklists" chapter in *Using Oracle WebCenter Portal*.

To get a list of the items assigned to a user, worklists uses the WebService access function of the public BPM client API. Worklists uses SAML authentication to authorize the logged-in user to fetch the list of latest items from the BPEL repository. Worklists fetches the 25 most recent items for each worklist connection and determines the order of these items by using a predicate on the `TaskQueryService` API. For more information, see "Building a Custom Worklist Client" in *Developer's Guide for Oracle SOA Suite*.

Figure 41–1 shows worklists at runtime.

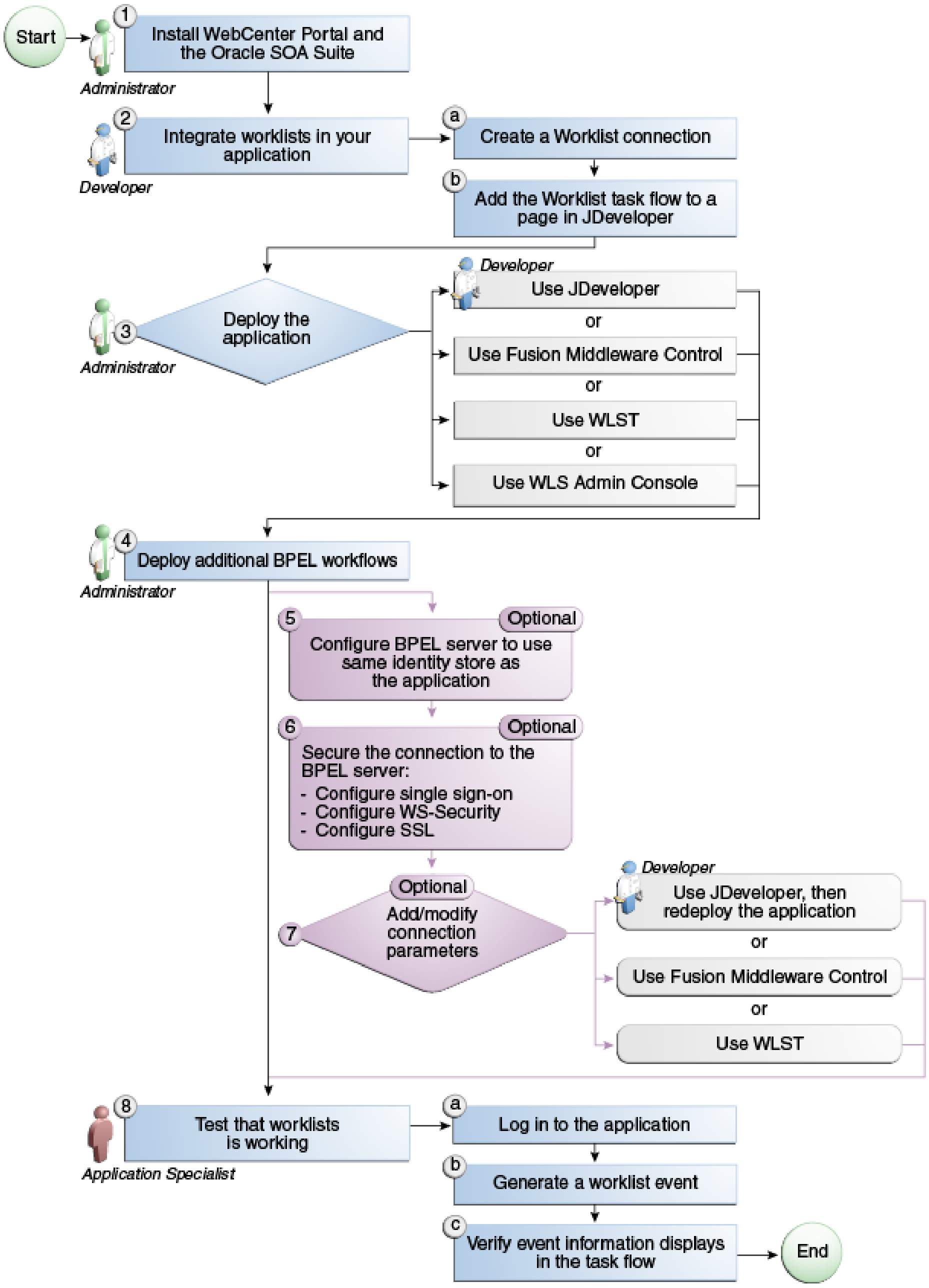
41.2 Roadmap - Configuring Worklists for Portal Framework Applications

Figure 41–2 and Table 41–1 in this section provide an overview of the prerequisites and tasks required to get worklists working in Portal Framework applications.

Figure 41–2 Configuring Worklists for Portal Framework Applications



Start
1
Install WebCenter Portal and the Oracle SOA Suite
Administrator
2
Integrate worklists in your application
Developer
a
Create a Worklist connection
b
Add the Worklist task flow to a page in JDeveloper
Developer
Use JDeveloper
or
Use Fusion Middleware Control
or
Use WLST
or
Use WLS Admin Console
3
Deploy the application
Administrator
4
Deploy additional BPEL workflows
Administrator
5
Optional
Configure BPEL server to use same identity store as the application
6
Optional
Secure the connection to the BPEL server:
- Configure single sign-on
- Configure WS-Security
- Configure SSL
7
Optional
Add/modify connection parameters
Developer
Use JDeveloper, then redeploy the application
or
Use Fusion Middleware Control
or
Use WLST
8
Test that worklists is working
Application Specialist
a
Log in to the application
b
Generate a worklist event
c
Verify event information displays in the task flow
End

Table 41–1 Configuring the Worklist for Portal Framework Applications

Actor	Task	Sub-Task
Administrator	**1.** Install Oracle WebCenter Portal and the Oracle SOA Suite	
Developer	**2.** Integrate worklist in your Portal Framework application	**2.a** Create a Worklist connection **2.b** Add the Worklist task flow to a page in JDeveloper

Table 41–1 (Cont.) Configuring the Worklist for Portal Framework Applications

Actor	Task	Sub-Task
Developer/Administrator	**3.** Deploy the application using one of the following tools: ■ JDeveloper (Developer) ■ Fusion Middleware Control (Administrator) ■ WLST (Administrator) ■ WLS Admin Console (Administrator)	
Administrator	**4.** Deploy additional BPEL workflows using the Oracle BPM Worklist application (see "Deploying and Managing SOA Composite Applications" in *Administrator's Guide for Oracle SOA Suite and Oracle Business Process Management Suite*)	
Administrator	**5.** (Optional): Configure BPEL server to use same identity store as the application	
Administrator	**6.** (Optional): Secure the connection to the BPEL server	**6.a** Configure single sign-on **6.b** Configure WS-Security **6.c** Configure SSL
Developer/Administrator	**7.** (Optional): Add/modify connection parameters using one of the following tools: ■ JDeveloper, then redeploy the application (Developer) ■ Fusion Middleware Control (Administrator) ■ WLST (Administrator)	
End User	**8.** Test that worklists functionality is working	**8.a** Log in to the Portal Framework application **8.b** Generate a worklist event **8.c** Verify event information displays in the task flow

41.3 Basic Configuration for Worklists

This section describes how to set up a connection for worklists and add the task flow to your Portal Framework application.

This section contains the following subsections:

- Section 41.3.1, "Setting up Connections for Worklists"
- Section 41.3.2, "Adding Worklists Functionality at Design Time"
- Section 41.3.3, "Setting Security for Worklists"

41.3.1 Setting up Connections for Worklists

To use worklists, you must establish a connection to one or more BPEL servers. This section describes these connections and how to create them in a Portal Framework application.

41.3.1.1 Worklist Connections

Worklist rely on a BPEL server. After you create a connection using the Create Worklist Connection dialog, the connection is registered in your application's `connections.xml` and referenced in your application's `adf-config.xml`. You can see the connections to your BPEL Worklist Repositories in the Application Resources pane.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Fusion Middleware Control. For more information, see the *Administering Oracle WebCenter Portal*.

41.3.1.2 How to Set Up Connections for Worklists

You can add the Worklist task flow to your application at design time or at runtime. Before you can run the task flow, you must create a connection from your application to a BPEL server.

> **See Also:** Chapter 4, "Preparing Your Application for WebCenter Portal Tools and Services"

To set up the connection for worklists:

1. In the Application Resources panel for your application, right-click **Connections**, then choose **New Connection> Worklist**.
2. In the Create Worklist Connection dialog, choose whether to create the connection in the Application Resources (only the current application can use this connection) or IDE Connections (other applications you create can use the same connection).
3. In the **Connection Name** field, enter a name for your connection. This name will be used as the display name of the Worklist server.

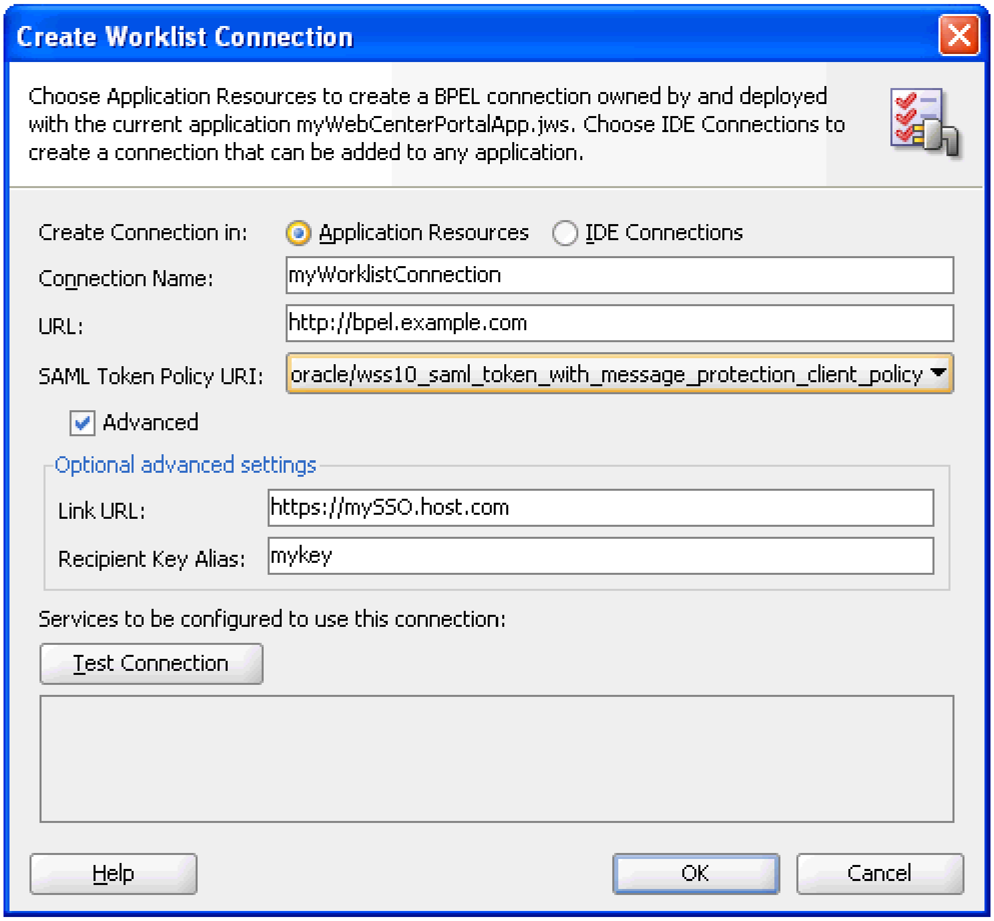
> **Note:** At runtime, when users view their worklist items, they can choose to group the items by "Worklist Server." The Worklist Server name used is the name you enter in the Connection Name field.

4. In the **URL** field, enter the location of your BPEL/SOA server, such as `http://bpel.example.com`. This is the URL for the managed server running the SOA processes.
5. Select the **SAML Token Policy URI** to use for this server (Figure 41–3).

   SAML (Security Assertion Markup Language) is an XML-based standard for passing security tokens defining authentication and authorization rights. An attesting entity (that already has trust relationship with the receiver) vouches for the verification of the subject by method called sender-vouches. Options available are:

- SAML Token Client Policy (**oracle/wss10_saml_token_client_policy**) - Select to verify your basic configuration without any additional security. This is the default setting.
- SAML Token With Message Client Policy (**oracle/wss10_saml_token_with_message_protection_client_policy**) - Select to increase the security using SAML-based BPEL Web Services. If selected, you must configure keys stores both in your Portal Framework application and in the BPEL application. For more information about this configuration, see the "Configuring Policies" section in the *Security and Administrator's Guide for Web Services*.

Figure 41–3 Create Worklist Connection Dialog



Create Worklist Connection

Choose Application Resources to create a BPEL connection owned by and deployed with the current application myWebCenterPortalApp.jws. Choose IDE Connections to create a connection that can be added to any application.

Create Connection in: ● Application Resources ○ IDE Connections

Connection Name: myWorklistConnection

URL: http://bpel.example.com

SAML Token Policy URI: oracle/wss10_saml_token_with_message_protection_client_policy

☑ Advanced

Optional advanced settings

Link URL: https://mySSO.host.com

Recipient Key Alias: mykey

Services to be configured to use this connection:

6. To enable advanced settings, select **Advanced**:

   - In the **Link URL** field, specify the URL used to link to the BPEL server. Only required if it is different to the BPEL SOAP URL, for example, when SSO or HTTPS is configured. Use the format: `protocol://host:port`.

     For example, `http://mySSO.host.com:7777`.

     This URL is used to build SSO- or HTTPS-enabled URL links to worklist items, whereas the URL property for worklists is used to access the BPEL Task Query Service, which for performance reasons does not need to go through HTTPS or an SSO server.

   - In the **Recipient Key Alias** field, enter the recipient key alias to be used for message protected SAML policy authentication. Only required when the BPEL server connection is using a SAML token policy for authentication and the application is using multiple BPEL server connections. For information about working with recipient key alias and WS-security, see the chapter "Configuring WS-Security" in *Administering Oracle WebCenter Portal*.

7. Click **Test Connection** to validate the URL.
8. Click **OK**.

   The new connection displays in the Application Resources panel under **Connections**.

41.3.2 Adding Worklists Functionality at Design Time

This section describes the Worklist task flow and how to add it to your application.

41.3.2.1 Worklist Task Flow

The Worklist task flow is found in the WebCenter Portal - Services Catalog in the Resource Palette.

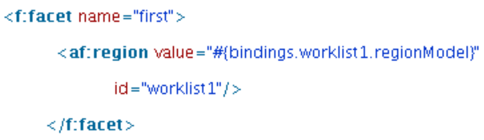
41.3.2.2 How to Add the Worklists Functionality to your Application

You can add worklists functionality to your application before or after you have created your connection. However, you must set up your connection before you run the application.

To add the Worklist task flow to your application:

1. Follow the steps in Section 4.2.1, "How to Prepare Your Application to Consume Tools and Services" to implement security and create a customizable page in your application.
2. Open the page where you wish to add the Worklist task flow.
3. In the Resource Palette, in the My Catalogs pane, open the **WebCenter Portal - Services Catalog**, then open the **Task Flows** folder.
4. Drag the Worklist task flow onto the desired region on the page, then choose **Region** from the pop-up list. The task flow displays on the page. For example, in the Source view, you will see Figure 41–4.

Figure 41–4 Worklist Task Flow in the Page Source



```
<f:facet name="first">
    <af:region value="#{bindings.worklist1.regionModel}"
        id="worklist1"/>
  </f:facet>
```

5. Save your project, then run your page to a browser. The worklist displays in your browser.

41.3.3 Setting Security for Worklists

Worklists display the tasks for the currently authenticated user. So, for users to store and retrieve worklist tasks on the BPEL server from your application, you must set up security on the application (as described in Section 4.2.1.1, "Implementing Security for Tools and Services"). The user names need to either exist in a shared user directory (LDAP), or set up similarly (same user name) on both the Portal Framework application and the BPEL Server. For example, if the user `rsmith` needs to use worklists in your Portal Framework application to store and retrieve tasks from the BPEL server, then you must ensure that the user `rsmith` exists on both the BPEL server and within your application.

To enable users to perform actions on assigned worklist tasks, you can configure SSO. If you do not configure SSO, the users will be prompted to log into the Worklist Task Details page on the BPEL server. For more information, see the *Securing Applications with Oracle Platform Security Services*.

Only authenticated users can view worklist tasks on the BPEL server to which they have permissions to view. If the application end user does not supply appropriate credentials, or if the page containing the worklist is not secured, she will not see any worklist items stored on the BPEL server and exception errors may occur.

41.4 Advanced Information for Worklists

Worklists collate all the worklist items for the authenticated user from all connections in your application defined for the worklists. You can use the create connection method described in Section 41.3.1.2, "How to Set Up Connections for Worklists" to create additional connections, or right-click the connection name in the Application Resources list and choose **Delete** to remove a connection.

42

Using the People Connections REST APIs

This chapter describes the REST APIs associated with People Connections.

This chapter includes the following topics:

- Section 42.1, "Activity Stream REST API"
- Section 42.2, "Connections and Profile REST API"
- Section 42.3, "Feedback REST API"
- Section 42.4, "Message Board REST API"
- Section 42.5, "Creating an Invitation"

> **See Also:** For an introduction to the REST APIs, see Chapter 53, "Using Oracle WebCenter Portal REST APIs."

42.1 Activity Stream REST API

Use the Activity Stream REST API to browse user application activities in an activity stream. This section provides information about the REST API methods you can use to perform this action.

This section includes the following subsections:

- Section 42.1.1, "Activity Stream Entry Point"
- Section 42.1.2, "Activity Stream Resource Type Taxonomy"
- Section 42.1.3, "Activity Stream Security Considerations"
- Section 42.1.4, "Activity Stream Resource Types"

> **Note:** Because the REST API can be configured in many different ways, it's possible that not all of a user's activities will be returned, allowing the REST client to customize how the Activity Stream behaves separately from the Framework application.

42.1.1 Activity Stream Entry Point

Each REST service has a link element within the Resource Index that provides the entry point for that service. For People Connections, each feature has its own link element. For example, to find the entry point for the People Connections' Activity Stream feature, find the link elements with a `resourceType` of:

```
urn:oracle:webcenter:activities:stream
```

The corresponding `href` or `template` element provides the URI entry point, which retrieves application activities for the current user from the Activity Stream. The client sends HTTP requests to this entry point to work with the People Connections' Activity Stream feature.

> **See Also:** For more information about the Resource Index, see Section 53.5.1, "Using the Resource Index."
>
> For more information about resource types, see Section 53.5.2.1, "Resource Type."

42.1.2 Activity Stream Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 42.1.4, "Activity Stream Resource Types."

The resource type taxonomy for the People Connections' Activity Stream feature is:

```
urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:activity
```

42.1.3 Activity Stream Security Considerations

You must be logged into the REST service to access any of the People Connections REST APIs. After that, the underlying service handles permission checking and the like.

> **See Also:** For general security considerations, see Section 53.8, "Security Considerations for WebCenter Portal REST APIs."

42.1.4 Activity Stream Resource Types

This section provides you with all the information you need to know about each resource type. It includes the following subsections:

- "urn:oracle:webcenter:activities:stream"
- "urn:oracle:webcenter:activities:activity"

urn:oracle:webcenter:activities:stream

The `stream` response contains URIs for use in retrieving activities from the Activity Stream.

You can retrieve the activities from a user's stream or activities from a user's connections' streams. To have even greater control over which activities to retrieve, use the activity stream query filter. With the query filter, you can:

- Specify the user to query
- Include the user's connections' activities in the results
- Include activities from portals, including the Home portal, in the results
- Restrict the results to activities from specific services

The options available to you depend on the path you take to get to the `stream` resource and the `rel` of the link that you use. For example, the activity stream query filter is available only from links with a `rel` attribute of urn:oracle:webcenter:activities:stream. If you access the activity stream query filter from the person resource, the personGuid parameter is prefilled.

Table 42–1 shows the activities returned depending on the rel element of the link.

Table 42–1 Activities Returned by stream

rel	Returns
urn:oracle:webcenter:activities:stream:person	Activities from the user's stream (*GUID*/@self)[1]
urn:oracle:webcenter:activities:stream:connections	Activities from the user's connections' streams (*GUID*/@connections)[1]
urn:oracle:webcenter:activities:stream	Activities determined by the activity stream query filter
urn:oracle:webcenter:activities:stream:space	Activities from the portal activity stream
urn:oracle:webcenter:activities:stream:list	Activities from the portal activity list

[1] *GUID* can be any valid user GUID or @me.

Navigation Paths to stream

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceIndex
   stream (rel="urn:oracle:webcenter:activities:stream:person" or
               "urn:oracle:webcenter:activities:stream")

resourceIndex
   person
      stream (rel="urn:oracle:webcenter:activities:stream:person" or
                  "urn:oracle:webcenter:activities:stream:connections" or
                  "urn:oracle:webcenter:activities:stream")

resourceIndex
   person
      list
         stream

resourceIndex
   space
      stream

stream
   activity
      param
         stream (rel="urn:oracle:webcenter:activities:stream:space")

personReference
   stream
```

Supported Methods for stream

The following method is supported by the stream resource:

- GET
  - **request—Parameters:**

- startIndex, itemsPerPage

See Also: For information about REST API parameters, such as startIndex and itemsPerPage, see "Common Request Query Parameters".

The following additional parameters are available for the query filter URI:

- fromDate – Specifies activities start date (yyyy-mm-dd).
- toDate – Specifies activities end date, (yyyy-mm-dd).
- data – Returns specified data only (for more information, see "Common Request Query Parameters"). For the stream resource, if you specify the constant 'data' as the data parameter, all of the basic information about the resource is returned except "comments" and "likes" summaries. If you want to return comments or likes, specify the data parameter value 'commentsSummary' or 'likesSummary'.

Note: You can specify multiple data values as a comma separated list. For example, data=data, commentsSummary.

- personGuid – (Required) Retrieves activities from the stream for the specified user. **Valid values:** any valid user GUID or @me.
- serviceIds – Retrieves activities only for the specified services. **Valid values:** An asterisk (*) returns all services. If null or empty, uses the user preference settings for service filters (from the settings link in the top bar).
- personal – Includes the specified user's activities in the Home portal. **Valid values:** true or false. **Default value:** false.
- connections – Includes activities from the streams of the specified user's connections. **Valid values:** true or false. **Default value:** false.
- groupSpaces – Includes activities from all portals of which the specified user is a member. **Valid values:** true or false. **Default value:** false.
- connectionListIds – A comma separated list of connection list names that specifies the connection lists used to show activities.
- groupSpaceGuids – A comma separated list of portal GUIDs used to show activities.
- userGroupSpaceActivities – Specifies whether or not to show the user's activities in their portal. **Valid values:** true or false. **Default value:** false.
- followedObjects – Specifies whether or not to show all activities for followed objects that both the current user and the specified user follow. **Valid values:** true or false. **Default value:** false.
- followedObjectsUserActivities – Specifies whether or not to show the specified user's activities for followed objects that both the current user and the specified user follow. **Valid values:** true or false. **Default value:** false.
- advancedQuery – Specifies filters against streamed activities. Create filters for user names, service IDs, and object details, such as a document's display name.

Note: You must plug actual values into the `advancedQuery` parameter. You cannot pass EL expressions directly into the parameter. Typically, the REST API client handles an EL transformation manually and inserts the actual object data value into the REST URL. See the example below, and see also Section 39.4, "About the Activity Stream Advanced Query Option."

For example, the following URI returns activities from the current user's activity stream, for all services that the user has configured in their personal preference settings for service filters. It returns activities from the user's Home portal and from the streams of the user's connections:

```
http://host:port/rest/api/activities?personal=true&connections=true&personG
uid=@me&token=utoken
```

The following URI returns only the user's personal profile and connections activities:

```
http://host:port/rest/api/activities?serviceIds=oracle.webcenter.peopleconn
ections.profile,oracle.webcenter.peopleconnections.connections&personal=
true&personGuid=@me&token=utoken
```

This next example illustrates how to use the `advancedQuery` parameter. As explained previously, you cannot pass an EL expression to `advancedQuery`. The REST API client must first obtain the actual data object value, and that value can then be passed to `advancedQuery`. For example, to filter activities for a particular portal, you can pass the GUID of the portal's scope to `advancedQuery`:

```
http://host:port/rest/api/activities?personGuid=@me&advancedQuery=AE.SCOPE_
ID%20%3D%20\%27s8bba98ff_4cbb_40b8_beee_296c916a23ed\%27&ttoken=token
```

where `s8bba98ff_4cbb_40b8_beee_296c916a23ed` is the GUID of the portal. Note that the query string must be encoded with the appropriate escape codes. For a list of EL expressions that can be used to obtain values for `advancedQuery`, see Section 39.4, "About the Activity Stream Advanced Query Option."

– **response—Body:** 0 or more activities

Note: Because the `stream` resource includes activity items, the response may also return resource links for the objects referenced in the activity.

Resource Types Linked to From stream

Table 42–2 lists the resource types that the client can link to from the `stream` resource.

Table 42–2 Related Resource Types for stream

rel	resourceType
self urn:oracle:webcenter:activities:stream:person	urn:oracle:webcenter:activities:stream urn:oracle:webcenter:activities:activity

urn:oracle:webcenter:activities:activity

The `activity` response contains the data for activities and URIs for use in retrieving all the data you need from an activity that is included in an Activity Stream.

Navigation Paths to activity

This section shows how the client can navigate through the hypermedia to access the `activity` resource:

```
resourceIndex
   stream
      activity

resourceIndex
   person
      stream
         activity

resourceIndex
   space
      stream
         activity
```

Supported Methods for activity

No methods are supported for `activity`. Activities are currently available only from the `stream` resource type.

Resource Types Linked to from activity

Table 42–3 lists the resource types that the client can link to from this resource.

Table 42–3 Related Resource Types for urn:oracle:webcenter:activities:activity

rel	resourceType
self	`urn:oracle:webcenter:activities:activity`
icon	`urn:oracle:webcenter:activities:activity:icon`

Read-only Elements for activity

Table 42–4 lists the read-only elements for the `activity` resource.

> **See Also:** For information about `projection`, see "Common Request Query Parameters".

> **Note:** The activity will also return a link to an activity icon in the links section of the response, if an icon is available. See urn:oracle:webcenter:activities:activity:icon.

Table 42–4 Read-Only Elements for activity

Element	Type	Description
`activityType`	String	Activity type Unique within the service. For example, Discussions can return the `activityType` `createForum`.

Table 42–4 (Cont.) Read-Only Elements for activity

Element	Type	Description
`commentsCount`	String	If you specify `commentsSummary` in the data parameter, then the `commentsCount` parameter will be returned.
`createdDate`	Date (String)[1]	Date the activity was created.
`description`	String	The description of the activity.
`detail`	String	Detail information for the activity, if available. For example, this might return the contents of a message, the file name of a document, and the like. Similar to `detailURL`. Both, either, or neither can be used. The detailURL will be available when creating wiki and blog in a portal.
`detailURL`	String	detailURL is available when creating wikis and blogs in a portal. In a Web-based WebCenter Portal, the user can click this URL and open a wiki or blog page in a portal. Similar to `detail`. Both, either, or neither can be used.
`displayDescription`	String	A pre-formatted, internationalized description.
`displayMessage`	String	A pre-formatted, internationalized message (does not include template information).
`groupSpace`	groupSpaceReference	Information about the portal in which the activity was performed **Note:** This reference is not present for activities that did not happen in a portal (for example, activities that happened in the Home portal). Also, because creation of a portal happens in a Home portal, that activity does not have this element either.
`id`	String	Unique ID of the message
`isSummary`	true or false	Indicates whether or not this activity is a summary of other activities.
`likesCount`	String	If you specify `likesSummary` in the data parameter, then the `likesCount` parameter will be returned.
`message`	String	Localized string for this activity This may contain replacement strings within curly braces ({}).
`permission`	PRIVATE SHARED PUBLIC	Permission level of this activity

Table 42–4 (Cont.) Read-Only Elements for activity

Element	Type	Description
`scope`	String	Scope of the activity This might return a portal, like the Home portal. For example, for a portal, it returns a string similar to the following: `s8bba98ff_4cbb_40b8_beee_296c916a23ed`
`serviceId`	String	Unique ID of the service that created the activity **Note:** For a list of WebCenter Portal tools and services IDs, see Table G–7, " Service and Tool IDs".

`sharedLink_url`	String	Can be used to render a navigation link by the REST client as shown in the example below:
		`<param resourceType="urn:oracle:webcenter:activities:parameter">`
		`<links>`
		`<link href="http://www.google.com" />`
		`</links>`
		`<displayName>http://www.google.com</displayName>`
		`<key>_sharedLink_url</key>`
		`<type>custom</type>`
		`</param> "`
		Note that this parameter cannot be used in a message template (for example: `{actor[0]}` has created the portal {object[0]}).

`templateParams`	urn:oracle:webcenter:activities:parameter	A list of `param` elements that capture data related to an activity. A key provided with each `templateParam` <param> element allows you to plug one or more data items into a parameterized activity message. See "Understanding the templateParams Element".
`custom`	Param	The custom parameter includes a `displayName`, `key`, and `type`, and may or may not have a URL.

[1] Data types, such as `DATE` and `BOOLEAN`, are stored in the API as `STRING`. The `DATE` data type returns a Java standard date format, for example, `2009-08-21T14:43:11.0013-0700`, with `0700` representing the time zone.

Understanding the templateParams Element

Suppose you want to display the most recent messages for a user named Carl. You want to display information like this: "Carl created the portal Customer Feedback". The `templateParams` element helps you solve this problem.

The `templateParams` element is returned in objects of type `oracle:webcenter:activities:activity`. This element captures a lot of data related to an activity. For example, if a user creates a new portal, the `templateParams` element for that activity captures information about the user and about the portal. Keys are provided that allow you to perform string substitutions in a parameterized message string related to the activity.

For example, if the user creates a portal, the returned activity object contains a `<message>` item that is parameterized like this:

```
<message>{actor[0]} has created the portal {object[0]}</message>
```

By parsing the `templateParams` element for the activity, you can find the available keys that allow you to perform string substitutions as well as appropriate data to display, like the name of the user and the activity.

For a detailed example showing how you might code a UI using `templateParams` to display information about an activity, see Section 53.13.2, "Displaying Activity Stream Data."

The `templateParams` element also provides links to `comments`, `likes`, `commentsSummary`, and `likesSummary` objects, if they are requested using the `data` parameter. These links let you query for all the comments or likes for an object or post a new comment or like. The summary links returns the comments or likes count and several recent comments or likes. See also "Understanding Comments and Likes".

The links returned with the `templateParams` element vary depending on what kind of object is returned, like a user, document, portal, or custom object. For more information, see "urn:oracle:webcenter:activities:parameter".

> **Note:** The `templateParams` element can sometimes contain elements that are not directly referenced in the message.

If a `rel` link is marked "via," this means it is a link to the underlying REST object–for instance, the document not the parameter. If a `rel` link is marked "alternate" and type "text/html," it is a link to the HTML page for that object. Portal objects include an activity stream link for portals. Users have icon and activity stream links. Other objects can have an `alt` link to the tagged item, as well as the related tagged items list, if tagging is enabled for that object. If a regular object supports comments or likes, it can include the comments/commentsSummary and likes/likesSummary, as explained previously.

Understanding Comments and Likes

Hyperlinks to `comments`, `commentsSummary`, `likes` and `likesSummary` are included by default (you can expand the `commentsSummary` and `likesSummary` by specifying `data=data,commentsSummary,likesSummary`). Comments and likes can be associated with the object referenced by the activity or the activity itself. For example, if you edit a document, then the comments will be associated with the document. If you add comments on an edit document activity on the activity stream page, then comments will be associated with the edit document activity.

The links associated with comments and likes are:

- `comments` – The `comments` link lets you query for all the comments for an object. This link also lets you POST a new comment. For a `comments` POST, the `text` field is required. For example, for body data you would use:

  JSON:

  ```
  {
    "text" : "REST Comment"
  }
  ```

XML:

```
<text>REST Comment</text>
```

- `commentsSummary` – The `commentsSummary` link returns the comments count and several recent comments.
- `likes` – The `likes` link lets you query for all the likes for an object. This link also lets you POST a new like. There are no required fields for a `likes` POST.
- `likesSummary` – The `likesSummary` link returns the likes count and the current user's like (if available).

> **Note:** `Like` objects themselves only support DELETE, not GET. The `likesCount` and `commentsCount` items return the number of likes or comments for the current object.

The following URLs show examples of `GET` requests for `comments`, `commentSummary`, `likes` and `likesSummary` for a document object:

```
"http://example.com:8892/rest/api/activities/services/oracle.webcenter.doclib/obje
ctTypes/document/objects/(<document_object_
id>)/comments?startIndex=0&amp;itemsPerPage=10&amp;utoken=FCvY3qQSBh0eAByLdxugV-lU
gFO3_w**"

"http://example.com:8892/rest/api/activities/services/oracle.webcenter.doclib/obje
ctTypes/document/objects/(<document_object_
id>)/commentsSummary?utoken=FCvY3qQSBh0eAByLdxugV-lUgFO3_w**"

"http://example.com:8892/rest/api/activities/services/oracle.webcenter.doclib/obje
ctTypes/document/objects/(<document_object_
id>)/likes?startIndex=0&amp;itemsPerPage=10&amp;utoken=FCvY3qQSBh0eAByLdxugV-lUgFO
3_w**"

"http://example.com:8892/rest/api/activities/services/oracle.webcenter.doclib/obje
ctTypes/document/objects/(<document_object_
id>)/likesSummary?utoken=FCvY3qQSBh0eAByLdxugV-lUgFO3_w**"
```

Where <document_object_id> is the document object ID.

The following URLs show examples of `GET` requests for `comments`, `commentSummary`, `likes` and `likesSummary` for a create document activity:

```
"http://example.com:8892/rest/api/activities/ffa9a9f0-d02f-4e30-8c58-8a41b7a6e8a3/
comments?startIndex=0&amp;itemsPerPage=10&amp;utoken=FCvY3qQSBh0eAByLdxugV-lUgFO3_
w**"

"http://example.com:8892/rest/api/activities/ffa9a9f0-d02f-4e30-8c58-8a41b7a6e8a3/
commentsSummary?utoken=FCvY3qQSBh0eAByLdxugV-lUgFO3_w**"

"http://example.com:8892/rest/api/activities/ffa9a9f0-d02f-4e30-8c58-8a41b7a6e8a3/
likes?startIndex=0&amp;itemsPerPage=10&amp;utoken=FCvY3qQSBh0eAByLdxugV-lUgFO3_
w**"

"http://example.com:8892/rest/api/activities/ffa9a9f0-d02f-4e30-8c58-8a41b7a6e8a3/
likesSummary?utoken=FCvY3qQSBh0eAByLdxugV-lUgFO3_w**"
```

urn:oracle:webcenter:activities:parameter

The templateParams element returns a set of param elements. The param elements return data specific to the type of activity object returned. The possible types of param elements include:

- user – Returns the displayName, guid, id, key, primaryId, and type.
- document – Returns the displayName, iconUrl, id, key, primaryId, and type.
- custom – Returns displayName, key, and type, and may or may not have a URL.

A param can also be a variable reference or key of the general form {prefix[index].variable}.

urn:oracle:webcenter:activities:activity:icon

Use this resource type to get the icon of the activity, if available (GET).

Navigation Paths to activities:activity:icon

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   activities
      activity
         icon
```

Supported Methods for icon

The following methods are supported by this resource:

- GET – Returns the icon used for the named activity.

Resource Types Linked to from icon

Table 42–5 lists the resource types that the client can link to from this resource.

Table 42–5 Related Resource Types for urn:oracle:webcenter:activities:activity:icon

rel	resourceType
self	urn:oracle:webcenter:activities:activity:icon
urn:oracle:webcenter:parent	urn:oracle:webcenter:activities:activity

42.2 Connections and Profile REST API

Use the Connections and Profile REST API to browse a profile or a connections list, manage connections lists, add or remove connections, send invitations to connect, and update a profile status message. This section provides information about the REST API methods to use to perform these actions.

This section includes the following subsections:

- Section 42.2.1, "Connections and Profile Entry Point"
- Section 42.2.2, "Connections and Profile Resource Type Taxonomy"
- Section 42.2.3, "Connections and Profile Security Considerations"
- Section 42.2.4, "Connections and Profile Resource Types"

42.2.1 Connections and Profile Entry Point

Each REST service has a link element within the Resource Index that provides the entry point for that service. For People Connections, each feature has its own link element. For example, to find the entry points for the People Connections' Connections and Profile features, find the link elements with a `resourceType` of:

`urn:oracle:webcenter:people` (returns the current user profile)

`urn:oracle:webcenter:people:person` (enables you to query for a user)

`urn:oracle:webcenter:people:invitations` (returns invitations sent or received by the current user)

> **Note:** The `people:person` and `people:invitations` resource types have a `template` but not an `href`.

The corresponding `href` or `template` element provides the URI entry point, which returns a list of people (`people`) or an individual user (`people:person`). The client sends HTTP requests to this entry point to work with the People Connections' Connections and Profile features.

> **See Also:** For more information about the Resource Index, see Section 53.5.1, "Using the Resource Index."
>
> For more information about resource types, see Section 53.5.2.1, "Resource Type."

42.2.2 Connections and Profile Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 42.2.4, "Connections and Profile Resource Types."

The resource type taxonomy for the People Connections' Connections and Profile features is:

```
urn:oracle:webcenter:people
   urn:oracle:webcenter:people:person
   urn:oracle:webcenter:people:icon
   urn:oracle:webcenter:people:person:list
      urn:oracle:webcenter:people:person:listNames
      urn:oracle:webcenter:people:person:listName
      urn:oracle:webcenter:people:person:list:member
      urn:oracle:webcenter:people:person:status
   urn:oracle:webcenter:people:invitations
      urn:oracle:webcenter:people:invitation
```

42.2.3 Connections and Profile Security Considerations

You must be logged in to the REST service to access any of the People Connections REST APIs. After that, the underlying service handles permission checking and the like.

> **See Also:** For general security considerations, see Section 53.8, "Security Considerations for WebCenter Portal REST APIs."

42.2.4 Connections and Profile Resource Types

This section provides you with all the information you need to know about each resource type. It includes the following subsections:

- "urn:oracle:webcenter:people"
- "urn:oracle:webcenter:people:person"
- "urn:oracle:webcenter:people:person:list"
- "urn:oracle:webcenter:people:person:listNames"
- "urn:oracle:webcenter:people:person:listName"
- "urn:oracle:webcenter:people:person:list:member"
- "urn:oracle:webcenter:people:person:status"
- "urn:oracle:webcenter:people:invitations"
- "urn:oracle:webcenter:people:invitation"

urn:oracle:webcenter:people

The `people` response contains URIs for use in retrieving the profile of one or more users.

Navigation Paths to people

This section shows how the client can navigate through the hypermedia to access the `people` resource:

```
resourceIndex
   people
```

Supported Methods for people

The following method is supported by the `people` resource:

- GET
  - **request—Parameters:**
    - * `startIndex` – See "Common Request Query Parameters."
    - * `itemsPerPage` – See "Common Request Query Parameters."
    - * `projection` – See "Common Request Query Parameters."
    - * `data` – The data parameter is a comma separated list that controls which data will be returned in the response. The predefined set `basic` is equivalent to `data=guid,id,displayName`. The predefined set `data` is a standard set that returns all the data for the user, but does not include `status`, `manager`, `reportees`, or `photos`. The full list of possible values includes the predefined sets `basic` and `data`, as well as the following individual data values: `guid`, `id`, `displayName`, `birthday`, `language`, `timeZone`, `name`, `addresses`, `organizations`, `workEmail`, `phoneNumbers`, `manager`, `reportees`, `photos`, and `status`.

      If you specify the constant `'data'` as the `data` parameter, all the basic information will be returned for the resource. If both the `projection` and `data` query string parameters are present, the `data` parameter will be used to determine which data to return.

The data parameter can also take any of the following values comma-separated values to return the corresponding data: guid, id, displayName, birthday, language, timeZone, name, addresses, organizations, workEmail, phoneNumbers, manager, reportees, photos, and/or status.

> **Note:** The data parameter can accept a predefined set, a collection of values, or a mix of sets and values. For example, to get the basic data plus the user's birthday, you can specify data=basic,birthday.

- links – The links parameter is a comma-separated list that controls which links will be returned in the response. This parameter can accept predefined sets, individual data values, or a combination of predefined sets and individual data values. The predefined sets are basic, data, activitiesSet, connectionsSet, and feedbackSet. These predefined sets are described in "Predefined Sets for the links Parameter".

  The individual values for the links parameter are: person, profile, icon, status, messageBoard, activities, personActivities, connectionActivities, connections, listNames, invitation, givenFeedback, receivedFeedback, userGivenFeedback, manager, reportees, member.

  If both the projection and links query string parameters are present, the links parameter will be used to determine which links to return.

– **response—Body:** One or more person objects.

Predefined Sets for the links Parameter

The following items are predefined sets that can be returned in the links parameter. For example, if you specify links=basic, it is the equivalent of specifying data=person,profile,icon. You can also specify additional parameters as needed. For example, you could specify data=basic,birthday.

> **Note:** Links that are not currently available will not be returned even if they are specified in the links parameter.

- basic – A standard set that returns the basic information for the profile and includes person, profile, and icon.
- data – A standard set that returns all the basic links for the response plus the connections list, status, and activity stream template.
- activitiesSet – Includes activities, personActivities, and connectionActivities.
- connectionsSet – Includes connections, listNames, and invitation.
- feedbackSet – Includes givenFeedback, receivedFeedback, and userGivenFeedback.

Resource Types Linked to from people

Table 42–6 lists the resource types that the client can link to from the people resource.

Table 42–6 Related Resource Types for people

rel	resourceType
urn:oracle:webcenter:people:icon	urn:oracle:webcenter:people:person
urn:oracle:webcenter:people:person:list:connections	urn:oracle:webcenter:people:person:list
urn:oracle:webcenter:activities:stream:person	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream:connections	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:feedback:all-received	urn:oracle:webcenter:feedback
urn:oracle:webcenter:feedback:all-given	urn:oracle:webcenter:feedback
self	urn:oracle:webcenter:people:person:status
urn:oracle:webcenter:people:person:list:list	urn:oracle:webcenter:people:person:list
self	urn:oracle:webcenter:people:person:listName
urn:oracle:webcenter:activities:stream:list	urn:oracle:webcenter:activities:stream

urn:oracle:webcenter:people:icon

Use this resource type to get the icon used for the named profile (`GET`).

Navigation Paths to people:icon

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   people
      icon
```

Supported Methods for icon

The following methods are supported by this resource:

- `GET` – Returns the icon used for the named profile.

> **Note:** This resource includes a template that lets you choose the size of the profile icon to use. The `size` template parameter can be set to `small`, `medium`, or `large`.

Resource Types Linked to from icon

Table 42–7 lists the resource types that the client can link to from this resource.

Table 42–7 Related Resource Types for urn:oracle:webcenter:people:icon

rel	resourceType
self	`urn:oracle:webcenter:people:icon`

Table 42–7 (Cont.) Related Resource Types for urn:oracle:webcenter:people:icon

rel	resourceType
urn:oracle:webcenter:parent	`urn:oracle:webcenter:people`

urn:oracle:webcenter:people:person

The `person` response contains profile data and the URIs for use in retrieving a user profile.

Navigation Paths to person

This section shows how the client can navigate through the hypermedia to access the `person` resource:

```
resourceIndex
   people

resourceIndex
   people
      person

resourceIndex
   person

author
   person

resourceIndex
   activities:stream
      person
```

Supported Methods for person

The following method is supported by the `person` resource:

- GET
  - **request—Parameters:** `q`

    To retrieve a specified person, the format of `q` is:

    ```
    q=[loginid:equals:username]
    Or
    q=[guid:equals:guid]
    Or
    q=[email:equals:email]
    ```

    Note: The parameter `q` is only on the `resourceIndex` template for `person`.

  - **response—Body:** `message`

    See Also: For information about the response `message`, see "Read-only Elements for person".

Read-only Elements for person

Table 42–8 lists the read-only elements for the `person` resource.

Note: The elements present in a person response depend on how the user repository is configured and the elements it supports. Additionally, several of the pieces of data represented in Table 42–8, such as address, emails, photos, phoneNumbers, and organization, can have multiple instances.

See Also: Some of the elements listed in Table 42–8 can be returned in predefined sets described in "Predefined Sets for the links Parameter".

Table 42–8 Read-Only Elements for person

Element	Type	Description
guid	String	Unique GUID of the person
id	String	Unique login ID of the person (that is, the user name, for example, pat_coi)
displayName	String	Display name of the person (the user's name, for example, Pat Coi). This may have the same value as id, depending on the repository configuration.
birthday	Date (String)[1]	Birth date of the person
connected	Boolean (String)1	Whether or not this person is connected to the current user
language	String	Preferred language of the person
timeZone	String	Time zone of the person
name	name	Name information for the person name is a portable contact type. For more information, see Section 53.10.2.1, "name Portable Contact Type."
address	address	Address information for the person address is a portable contact type. For more information, see Section 53.10.2.2, "address Portable Contact Type."
emails	value	Emails for the person emails is derived from the value portable contact type. For more information, see Section 53.10.2.4, "value Portable Contact Type."
photos	value	Profile photos for the person photos is derived from the value portable contact type. For more information, see Section 53.10.2.4, "value Portable Contact Type."
phoneNumbers	value	Phone numbers for the person phoneNumber is derived from the value portable contact type. For more information, see Section 53.10.2.4, "value Portable Contact Type."
organizations	organization	Organization information for the person organization is a portable contact type. For more information, see Section 53.10.2.3, "organization Portable Contact Type."
manager	personReference	Manager of this person
reportees	personReference	Direct reports of this person
status	urn:oracle:webcenter:people:person:status	Person's profile status message

[1] Data types, such as DATE and BOOLEAN, are stored in the API as STRING.

Resource Types Linked to from person

Table 42–9 lists the resource types that the client can link to from the `person` resource.

Table 42–9 Related Resource Types for person

rel	resourceType
self	urn:oracle:webcenter:people:person
alternate	urn:oracle:webcenter:spaces:profile (HTML)
urn:oracle:webcenter:people:person:list:connections	urn:oracle:webcenter:people:person:list urn:oracle:webcenter:people:person:listNames urn:oracle:webcenter:people:person:status
urn:oracle:webcenter:activities:stream:person	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream:connections	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream	urn:oracle:webcenter:activities:stream urn:oracle:webcenter:messageBoard
urn:oracle:webcenter:feedback:all-given	urn:oracle:webcenter:feedback
urn:oracle:webcenter:feedback:all-received	urn:oracle:webcenter:feedback

urn:oracle:webcenter:people:person:list

The `list` response contains URIs for use in retrieving all the profiles on a connections list (`GET`), inviting a user to be a connection or adding a connection to a connections list (`POST`), and removing a connections list (`DELETE`).

Navigation Paths to list

This section shows how the client can navigate through the hypermedia to access the `list` resource:

```
resourceIndex
   person
      listNames
         list

resourceIndex
   person
      list (rel="urn:oracle:webcenter:people:person:list:connections")
```

Supported Methods for list

The following methods are supported by the `list` resource:

- `GET`
  - **request—Parameters:** `startIndex`, `itemsPerPage`, `projection`

    See Also: For information about REST API parameters, such as `startIndex` and `itemsPerPage`, see "Common Request Query Parameters".

  - **response—Body:** 0 or more `person` items
- `POST`
  - **request—Body:** `member`
  - **response—Body:** `member`

See Also: For information about member in the request and response elements, see "urn:oracle:webcenter:people:person:list:member".

- DELETE
  - **request**

Resource Types Linked to from list

Table 42–10 lists the resource types that the client can link to from the list resource.

Table 42–10 Related Resource Types for list

rel	resourceType
self urn:oracle:webcenter:people:person:list[1]	urn:oracle:webcenter:people:person:list
urn:oracle:webcenter:activities:stream	urn:oracle:webcenter:activities:stream

[1] self rel currently includes "urn:oracle:webcenter:people:person:list:list" instead of the correct "urn:oracle:webcenter:people:person:list". For the @connections default list, it currently includes "urn:oracle:webcenter:people:person:list:connections".

urn:oracle:webcenter:people:person:listNames

The listNames response contains the names of existing connections lists as well as the URIs for use in retrieving the lists (GET) and creating connections lists (POST).

Navigation Paths to listNames

This section shows how the client can navigate through the hypermedia to access the listNames resource:

```
resourceIndex
   person
      listNames
```

Supported Methods for listNames

The following methods are supported by the listNames resource:

- GET
  - **request**
  - **response**: **Body:** 0 or more listName items
- POST
  - **request—Body:** listName
  - **response—Body:** listName

See Also: For information about listName, see "urn:oracle:webcenter:people:person:listName".

Resource Types Linked to from listNames

Table 42–11 lists the resource types that the client can link to from the listNames resource.

Table 42–11 Related Resource Types for listNames

rel	resourceType
self	urn:oracle:webcenter:people:person:listNames

urn:oracle:webcenter:people:person:listName

The `listName` response contains the names of connections lists and URIs for use in accessing the connections lists. See also "urn:oracle:webcenter:people:person:listNames".

Navigation Paths to listName

This section shows how the client can navigate through the hypermedia to access the `listName` resource:

```
resourceIndex
   person
      listNames
         listName
```

Supported Methods for listName

The following method is supported by the `listName` resource:

- `DELETE`
  - **request**

Writable Elements for listName

Table 42–12 lists the writable elements for the `listName` resource.

Table 42–12 Writable Elements for listName

Element	Type	Required	Constraints	Description
`name`	String	Yes	1 or more characters	A single list name

Resource Types Linked to from listName

Table 42–13 lists the resource types that the client can link to from the `listName` resource.

Table 42–13 Related Resource Types for listName

rel	resourceType
self urn:oracle:webcenter:people:person:list	urn:oracle:webcenter:people:person:list
urn:oracle:webcenter:activities:stream:list	urn:oracle:webcenter:activities:stream

urn:oracle:webcenter:people:person:list:member

The `member` response contains URIs for use in deleting a connection from a connections list.

Navigation Paths to member

This section shows how the client can navigate through the hypermedia to access the `member` resource:

```
resourceIndex
   person
      list
         member
```

Supported Methods for member

The following method is supported by the `member` resource:

- DELETE
  - **request**

Writable Elements for member

Table 42–14 lists the writable elements for the `member` resource. Writable elements for `member` are used when you add a connection to a list or invite a user to be a connection. The `member` resource itself is for deleting connections, and does not use writable elements.

Table 42–14 Writable Elements for member

Element	Type	Required	Constraints	Description
`guid`	String	Yes	1 or more characters	GUID of the user
`message`	String	No	0 or more characters	Invitation message Use this only when inviting users to be connections (that is POSTing to the `@connections` list, not to user-created connections lists).

urn:oracle:webcenter:people:person:status

The `status` response contains URIs for use in retrieving (`GET`) and updating (`PUT`) the profile status message of a specified user.

Navigation Paths to status

This section shows how the client can navigate through the hypermedia to access the `status` resource:

```
resourceIndex
   people
      person
         status
```

Supported Methods for status

The following methods are supported by the `status` resource:

- GET
  - **request**
  - **response—Body:** `status`
- PUT
  - **request—Body:** `status`
  - **response—Body:** `status`

Writable Elements for status

Table 42–15 lists the writable elements for the `status` resource.

Table 42–15 Writable Elements for status

Element	Type	Required	Constraints	Description
`note`	String	Yes	1 or more characters	Content of status message

Resource Types Linked to from status

Table 42–16 lists the resource types that the client can link to from the `status` resource.

Table 42–16 Related Resource Types for status

rel	resourceType
self	urn:oracle:webcenter:people:person:status

urn:oracle:webcenter:people:invitations

The `invitations` response contains URIs for use in retrieving invitations (`GET`). You can also send an invitation (`POST`) to another user.

Navigation Paths to invitations

This section shows how the client can navigate through the hypermedia to access the `invitations` resource:

```
resourceIndex
   invitations
```

If you are not already connected to a user, you can also navigate to the invitations resource from that user's profile in order to invite them to connect. This path is only used for POSTing.

```
resourceIndex
   person
      invitations
```

Supported Methods for invitations

The following methods are supported by the `invitations` resource:

- `GET`
  - **Request—Parameters:** `q`

    To retrieve invitations sent to the current user, the format of `q` is:

    ```
    q=[invitee:equals:@me]
    ```

    To retrieve invitations sent from the current user, the format of `q` is:

    ```
    q=[invitor:equals:@me]
    ```

  - **Response—Body:** 1 or more invitations
- `POST`
  - **Request—Body:** `invitation`
  - **Response—Body:** `invitation`

Writable Elements for invitations

Table 42–17 lists the writable elements for the `invitations` resource.

Table 42–17 Writable Elements for invitations

Element	Type	Required	Constraints	Description
`message`	String	No	1 or more characters	Message attached to the invitation

Resource Types Linked to from invitations

Table 42–18 lists the resource types that the client can link to from the `invitations` resource:

Table 42–18 Related Resource Types for invitations

rel	resourceType
self	urn:oracle:webcenter:people:invitation

urn:oracle:webcenter:people:invitation

The `invitation` response contains URIs for use in deleting (`DELETE`) invitations you have sent, or deleting (`DELETE`) or updating (`PUT`) invitations you have received.

Navigation Paths to invitation

This section shows how the client can navigate through the hypermedia to access the `invitation` resource:

```
resourceIndex
   invitations
      invitation
```

Supported Methods for invitation

The following methods are supported by the `invitation` resource:

- `PUT`
  - **Request—Body:** `invitation`
  - **Response—Body:** `invitation`
- `DELETE`
  - **Request**

Writable Elements for invitation

Table 42–19 lists the writable elements for the `invitation` resource.

Table 42–19 Writable Elements for invitation

Element	Type	Required	Constraints	Description
`status`	String	Yes (PUT)	ACCEPTED IGNORED	The status of the invitation. **Note:** When you accept or ignore an invitation, it is removed from your list of invitations.

Read-only Elements for invitation

Table 42–20 lists the read-only elements for the `invitation` resource.

Table 42–20 Read-only Elements for invitation

Element	Type	Description
`id`	String	Unique ID of the invitation
`invitee`	personReference	User to whom the invitation is sent
`invitor`	personReference	User from whom the invitation is sent

Table 42–20 (Cont.) Read-only Elements for invitation

Element	Type	Description
`sentDate`	Date (String)[1]	Date the invitation was sent

[1] Data types, such as `DATE` and `BOOLEAN`, are stored in the API as `STRING`.

Resource Types Linked to from invitation

Table 42–21 lists the resource types that the client can link to from the `invitation` response.

Table 42–21 Related Resource Types for invitations

rel	resourceType
self	urn:oracle:webcenter:people:invitation

42.3 Feedback REST API

Use the Feedback REST API to read and delete feedback. This section provides information about the REST API methods to use to perform these actions.

This section includes the following subsections:

- Section 42.3.1, "Feedback Entry Point"
- Section 42.3.2, "Feedback Resource Type Taxonomy"
- Section 42.3.3, "Feedback Security Considerations"
- Section 42.3.4, "Feedback Resource Types"

42.3.1 Feedback Entry Point

Each REST service has a link element within the Resource Index that provides the entry point for that service. For People Connections, each feature has its own `link` element. To find the entry points for the People Connections' Feedback feature, find the `link` elements with a `resourceType` of:

```
urn:oracle:webcenter:feedback
```

The corresponding `href` or `template` element provides the URI entry point, which returns all received feedback for the current user. The client sends HTTP requests to this entry point to work with the People Connections' Feedback feature.

> **See Also:** For more information about the Resource Index, see Section 53.5.1, "Using the Resource Index."
>
> For more information about resource types, see Section 53.5.2.1, "Resource Type."

42.3.2 Feedback Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 42.3.4, "Feedback Resource Types."

The resource type taxonomy for the People Connections' Feedback feature is:

```
urn:oracle:webcenter:feedback
   urn:oracle:webcenter:feedback:message
```

42.3.3 Feedback Security Considerations

You must be logged into the REST service to access any of the People Connections REST APIs. After that, the underlying service handles permission checking and the like.

> **See Also:** For general security considerations, see Section 53.8, "Security Considerations for WebCenter Portal REST APIs."

42.3.4 Feedback Resource Types

This section provides you with all the information you need to know about each resource type. It includes the following subsections:

- "urn:oracle:webcenter:feedback"
- "urn:oracle:webcenter:feedback:message"

urn:oracle:webcenter:feedback

The `feedback` response contains URIs for use in reading Feedback messages.

Navigation Paths to feedback

This section shows how the client can navigate through the hypermedia to access the `feedback` resource:

```
resourceIndex
   feedback

resourceIndex
   person
      feedback
```

Supported Methods for feedback

The following methods are supported by the `feedback` resource:

- `GET`
  - **request—Parameters:** `startIndex`, `itemsPerPage`

    > **See Also:** For information about REST API parameters, such as `startIndex` and `itemsPerPage`, see "Common Request Query Parameters".

  - **response—Body:** `message`

    > **See Also:** For information about `message`, see "urn:oracle:webcenter:feedback:message".

- `POST` – If permitted, lets you add feedback for a target user. This method is only available if the current user is connected to and has permission to add feedback for the target user.
  - **request - body**: feedback

```
<message resourceType="urn:oracle:webcenter:feedback:message">
    <body>test from REST API</body>
    <receivedUser>
    <guid>4F16DD80393611DFBF895F177662C511</guid>
    </receivedUser>
```

```
</message>
```

Resource Types Linked to from feedback

Table 42–22 lists the resource types that the client can link to from the `feedback` resource.

Table 42–22 Related Resource Types for feedback

rel	resourceType
self urn:oracle:webcenter:feedback:all-received	urn:oracle:webcenter:feedback
self urn:oracle:webcenter:feedback:all-given	urn:oracle:webcenter:feedback
	urn:oracle:webcenter:feedback:message

urn:oracle:webcenter:feedback:message

The `message` response contains the feedback message data and URIs for use in deleting a Feedback message.

Navigation Paths to message

This section shows how the client can navigate through the hypermedia to access the `message` resource:

```
resourceIndex
   feedback
      message

resourceIndex
   person
      feedback
         message
```

Supported Methods from message

The following method is supported by the `message` resource:

- `DELETE`
  - **request**

Read-only Elements for message

Table 42–23 lists the read-only elements for the `message` resource.

Table 42–23 Read-only Elements for message

Element	Type	Description
`body`	String	Message content
`id`	String	Unique ID of the message
`author`	personReference	User who created the message
`created`	Date (String)[1]	Date the message was created
receivedUser	**personReference**	A person reference to the user who received the feedback

[1] Data types, such as `DATE` and `BOOLEAN`, are stored in the API as `STRING`.

Resource Types Linked to from feedback

Table 42–24 lists the resource types that the client can link to from the `feedback` resource.

Table 42–24 Related Resource Types for message

rel	resourceType
self	urn:oracle:webcenter:feedback:message

42.4 Message Board REST API

Use the Message Board REST API to post, read, and delete messages to a user's or a portal message board. This section provides information about the REST API methods to use to perform these actions.

This section includes the following subsections:

- Section 42.4.1, "Message Board Entry Point"
- Section 42.4.2, "Message Board Resource Type Taxonomy"
- Section 42.4.3, "Message Board Security Considerations"
- Section 42.4.4, "Message Board Resource Types"
- Section 42.4.5, "Filtering Messages Based on Visibility"

42.4.1 Message Board Entry Point

Each REST service has a `link` element within the Resource Index that provides the entry point for that service. For People Connections, each feature has its own `link` element. To find the entry points for the People Connections' Message Board feature, find the `link` elements with a `resourceType` of:

```
urn:oracle:webcenter:messageBoard
```

Note: As well as an entry point from the Resource Index, to navigate to an individual user's message board, the Message Board feature also has an entry point from a portal response for the portal message board.

The corresponding `href` or `template` element provides the URI entry point, which returns the Message Board for the current user. The client sends HTTP requests to this entry point to work with People Connections' Message Board feature.

See Also: For more information about the Resource Index, see Section 53.5.1, "Using the Resource Index."

For more information about resource types, see Section 53.5.2.1, "Resource Type."

42.4.2 Message Board Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 42.4.4, "Message Board Resource Types."

The resource type taxonomy for the Message Board feature for People Connections is:

```
urn:oracle:webcenter:messageBoard
   urn:oracle:webcenter:messageBoard:message
```

42.4.3 Message Board Security Considerations

You must be logged into the REST service to access any of the People Connections REST APIs. After that, the underlying service handles permission checking and the like.

> **See Also:** For general security considerations, see Section 53.8, "Security Considerations for WebCenter Portal REST APIs."

42.4.4 Message Board Resource Types

This section provides you with all the information you need to know about each resource type. It includes the following subsections:

- "urn:oracle:webcenter:messageBoard"
- "urn:oracle:webcenter:messageBoard:message"

urn:oracle:webcenter:messageBoard

The `messageBoard` response contains URIs for use in reading (`GET`) and posting (`POST`) portal and individual user Message Board messages.

Navigation Paths to messageBoard

This section shows how the client can navigate through the hypermedia to access the `messageBoard` resource:

```
resourceIndex
   messageBoard

resourceIndex
   person
      messageBoard

resourceIndex
   spaces
      space
         messageBoard
```

Supported Methods for messageBoard

The following methods are supported by the `messageBoard` resource:

- GET
  - **request—Parameters:** `startIndex`, `itemsPerPage`

    > **See Also:** For information about REST API parameters, such as `startIndex` and `itemsPerPage`, see "Common Request Query Parameters".

  - **response—Body:** message

Note: The REST GET command for reading (retrieving) messages retrieves all shown messages by default. You can also retrieve messages that are private or hidden through the application user interface as described in Section 42.4.5, "Filtering Messages Based on Visibility." For information about hiding and showing messages, see the "Adding Messages and Feedback to a Portal" chapter in *Building Portals with Oracle WebCenter Portal*.

- POST
  - **request—Body:** message

    The POST for messages supports including a link URL in the message.

    See Also: For information about message, see "urn:oracle:webcenter:messageBoard:message".

Read-only Elements for messageBoard

Table 42–25 lists the read-only elements for the messageBoard resource.

Table 42–25 Read-only Elements for message

Element	Type	Description
messageType	String	Returns link if the message has a link. Otherwise, returns null.
link	String	Contains link data for messages with links: name, url, icon, description, mimeType, objectId, objectType, serviceId.

Resource Types Linked to from messageBoard

Table 42–26 lists the resource types that the client can link to from the messageBoard resource.

Table 42–26 Related Resource Types for messageBoard

rel	resourceType
self	urn:oracle:webcenter:messageBoard
	urn:oracle:webcenter:messageBoard:message

urn:oracle:webcenter:messageBoard:message

The message response contains the Message Board message data and URIs for use in reading (GET), revising (PUT), and deleting (DELETE) a portal or individual user Message Board message.

Navigation Paths to message

This section shows how the client can navigate through the hypermedia to access the message resource:

```
resourceIndex
   messageBoard
      message

resourceIndex
   person
```

```
        messageBoard
          message

resourceIndex
  spaces
    space
      messageBoard
        message
```

Supported Methods for message

The following methods are supported by the `message` resource:

- `GET`
  - **request**
  - **response—Body:** `message`
- `PUT`
  - **request—Body:** `message`
  - **response—Body:** `message`
- `DELETE`
  - **request**

Writable Elements for message

Table 42–27 lists the writable elements for the `message` resource.

Table 42–27 Writable Elements for message

Element	Type	Required	Constraints	Description
`body`	String	Yes	1 or more characters	message content

Read-only Elements for message

Table 42–28 lists the read-only elements for the `message` resource.

Table 42–28 Read-only Elements for message

Element	Type	Description
`id`	String	Unique ID of the message
`author`	personReference	User who created the message
`created`	Date (String)[1]	Date the message was created

[1] Data types, such as `DATE` and `BOOLEAN`, are stored in the API as `STRING`.

Resource Types Linked to from message

Table 42–29 lists the resource types that the client can link to from the `message` resource.

Table 42–29 Related Resource Types for message

rel	resourceType
self	urn:oracle:webcenter:messageBoard:message

42.4.5 Filtering Messages Based on Visibility

Although the REST `GET` command for retrieving messages retrieves all shown messages by default, you can also retrieve messages that are private or hidden through the application user interface using a set of visibility filters.

Messages posted on message boards can have the following visibility criteria:

- Public
- Private
- Hidden
- Public and hidden
- Private and hidden

By default, messages are public.

Private Messages:

A person owning a message board can mark any message as private. When a message is marked as private, that message will not be visible to anyone other than the owner of the message unless the owner chooses to send a private message to someone else. Otherwise, other people viewing a message board with private messages will see only public messages.

Hidden Messages:

A person owning a message board can mark any message as hidden. When a message is marked as hidden, that message will not be visible to the owner of the message board, but will remain visible to other people viewing the message board.

REST URLs for Message Boards:

The context for message board URL filters is:

```
rest/api/messageBoards/<BOARD-TYPE>/<GUID>/<FILTER-TYPE>
```

Where:

- `<BOARD-TYPE>` is either `person` or `space`
- `<GUID >` is either `@me`, the `person <GUID>` (if `<BOARD-TYPE>` is person) or the `space <GUID>` (if `<BOARD-TYPE>` is `portal`)
- `<FILTER-TYPE>` is applicable only for the `person <BOARD-TYPE>` and can be one of:
  - `null` - (default) shows all messages
  - `private` - shows private messages
  - `public` - shows public messages
  - `hidden` - shows hidden and public messages
  - `private_hidden` - shows private and hidden messages

Available filters in the context of the applicable HTML methods are shown below.

`GET`

- `@me`
  - all
    `rest/api/messageBoards/person/@me`

  - private
    `rest/api/messageBoards/person/@me/private`
  - public
    `rest/api/messageBoards/person/@me/public`
  - hidden and public
    `rest/api/messageBoards/person/@me/hidden`
  - private and hidden
    `rest/api/messageBoards/person/@me/private_hidden`

- `person`

  `rest/api/messageBoards/person/<GUID>`

  If the GUID matches that of the logged in user then the same filtering as for @me applies. If the GUID is different, then no filtering is available.

- `space`

  `rest/api/messageBoards/space/<GUID>`

  No filtering based on visibility is available.

POST

- `@me`
  - all
    rest/api/messageBoards/person/@me
  - private

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "private"}
    ```

  - public

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "public"}
    ```

  - hidden and public

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "hidden"}
    ```

  - private and hidden

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "private_hidden"}
    ```

- `person`
  `rest/api/messageBoards/person/<GUID>`

  If the GUID is the same as the logged in user, then the filters for GET apply. If the users are different, then the following filters apply:

  - public

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "public"}
    ```

  - private

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "private"}
    ```

- `space`

  `rest/api/messageBoards/space/<GUID>`

  No filtering based on visibility is available.

`PUT`

- `@me`
  - all
    est/api/messageBoards/person/@me/messages/<msg guid>
  - private

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "private"}
    ```

  - public

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "public"}
    ```

  - hidden and public

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "hidden"}
    ```

  - private and hidden

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "private_hidden"}
    ```
- `person`
  `rest/api/messageBoards/person/<GUID>/messages/<msg guid>`

  If the GUID is the same as the logged in user, then the filters for GET apply. If the users are different, then the following filters apply:

  - public

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "public"}
    ```

  - private

    ```
    {"body" : "<BODY_CONTENT>",
     "visibilityType" : "private"}
    ```

- `space`

  `rest/api/messageBoards/space/<GUID>/messages/<msg guid>`

  No filtering based on visibility is available.

42.5 Creating an Invitation

This section illustrates how to invite another user to join your connections list using the People Connections Service REST API. After the invitation is made, the invitee is given the option to accept or not. This example also illustrates how to delete an invitation.

This section includes the following subsections:

- Section 42.5.1, "Creating an Invitation"

- Section 42.5.2, "Accepting an Invitation"
- Section 42.5.3, "Deleting an Invitation"

42.5.1 Creating an Invitation

1. The first step, as always with REST API methods, is to retrieve the resource index:

   ```
   GET http://<host:port>/rest/api/resourceIndex
   ```

2. Next, find the person to whom you want to connect. To do this:

   a. In the resource index listing, scan for the link with the following resource type:

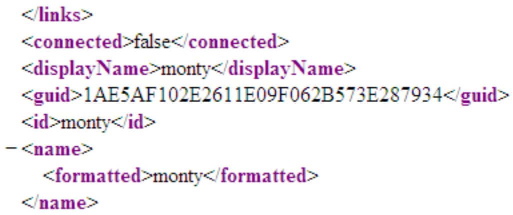
      ```
      urn:oracle:webcenter:people:person
      ```

   b. Execute a search for the user who you wish to invite. In this example, the user is named Monty.

      ```
      GET http://<host:port>/rest/api/people?q=loginid:equals:monty&utoken=ASDF
      ```

   c. Locate Monty's GUID in the response, as shown in Figure 42–1.

Figure 42–1 Response With User's GUID



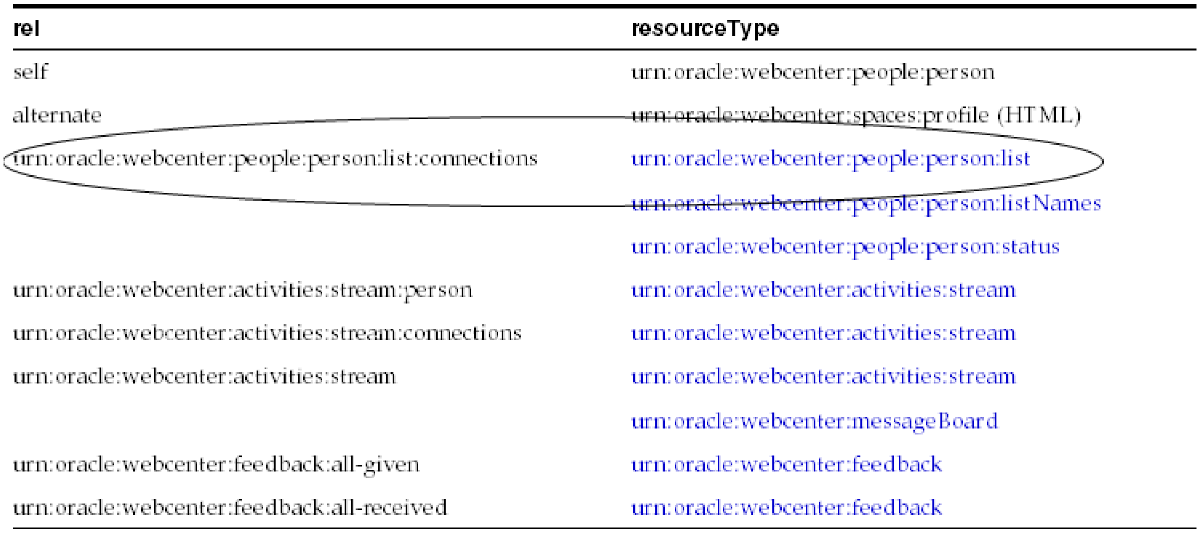
```
  </links>
  <connected>false</connected>
  <displayName>monty</displayName>
  <guid>1AE5AF102E2611E09F062B573E287934</guid>
  <id>monty</id>
- <name>
    <formatted>monty</formatted>
  </name>
```

   d. Save the GUID so that you can use it to connect to the user.

3. Now that you have the invitee's GUID, you must find the resource to which you would like to add him. In this case, you want to add him to your own `connections` list.

   To find your `connections` list, first, scan the People Connections documentation (this chapter) for "`connections`." You will discover in Table 42–9, " Related Resource Types for person" that `connections` are linked to from the `person` resource. For convenience, this table is shown in Figure 42–2.

Figure 42–2 Finding the connections Link



rel	resourceType
self	urn:oracle:webcenter:people:person
alternate	urn:oracle:webcenter:spaces:profile (HTML)
urn:oracle:webcenter:people:person:list:connections	urn:oracle:webcenter:people:person:list
	urn:oracle:webcenter:people:person:listNames
	urn:oracle:webcenter:people:person:status
urn:oracle:webcenter:activities:stream:person	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream:connections	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream	urn:oracle:webcenter:activities:stream
	urn:oracle:webcenter:messageBoard
urn:oracle:webcenter:feedback:all-given	urn:oracle:webcenter:feedback
urn:oracle:webcenter:feedback:all-received	urn:oracle:webcenter:feedback

Now that you know that `connections` are linked to from the `person` resource, you need to find the `person` resource. As the URN indicates, you get to the `person` resource from the `people` resource, as described in the following steps.

4. Return to the resource index (or use a cached version of the `resourceIndex` from your previous visit):

```
GET http://<host:port>/rest/api/resourceIndex
```

5. Scan for the `people` resource, and you will find:

```
urn:oracle:webcenter:people
```

6. Use the link in the `people` resource to access *your* lists:

```
GET http://<host:port>/rest/api/people/@me/lists/@self?utoken=ASDF
```

7. Scan the returned links for the `resourceType` and `rel` listed in Table 42–9:

```
resourceType="urn:oracle:webcenter:people:person:list
rel="urn:oracle:webcenter:people:person:list:connections
```

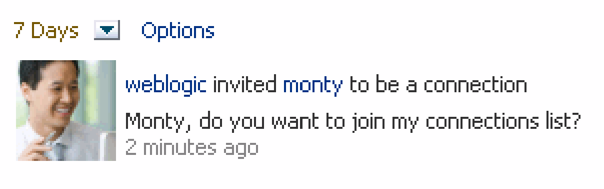
8. Make the invitation by using the URI to your `connections` list to execute a `POST`:

```
POST http://<host:port>/rest/api/people/@me/lists/@connections?utoken=ASDF

Headers --  Accept:application/json, Content-Type:application/json
Body -- {"message":"Monty, do you want to join my connections
list?","guid":"1AE5AF102E2611E09F062B573E287934"}
```

9. Now, if you log in to Monty's account and you can see the invitation has been added, as shown in Figure 42–3.

Figure 42–3 Activity Stream Showing Invitation



7 Days ▾ Options

weblogic invited monty to be a connection

Monty, do you want to join my connections list?

2 minutes ago

42.5.2 Accepting an Invitation

After an invitation has been sent, the next step is for the invitee (Monty) to accept the invitation.

1. Using a second REST client, retrieve the resource index:

```
GET http://<host:port>/rest/api/resourceIndex
```

2. Login as Monty.

3. List all the invitations sent to Monty by making the following request:

```
GET
http://<host:port>/rest/api/people/invitations?q=invitee:equals:@me&utoken=ASDF
```

Each invitation element listed in the response contains a link that supports the UPDATE operation and that looks something like this:

```
<links>
<link capabilities="urn:oracle:webcenter:delete urn:oracle:webcenter:update"
href="http://<host:port>/rest/api/people/invitations/<invitationid>?utoken=ASDF
"
rel="self" resourceType="urn:oracle:webcenter:people:invitation"/>
</links>
<id><invitationid></id>
```

4. To accept the invitation, make the following request:

```
PUT http://<host:port>/rest/api/people/invitations/<invitationid>?utoken=ASDF

Headers
  Accept -> application/xml
  Content-Type -> application/xml

Body
  <invitation>
      <id><invitationid></id>
      <status>accepted</status>
  </invitation>
```

42.5.3 Deleting an Invitation

After you initiate an invitation, you can view the invitation from your account by specifying `invitor:equals:@me`. For example:

```
GET
http://<host:port>/rest/api/people/invitations?q=invitor:equals:@me&utoken=ASDF
```

Each invitation element listed in the response contains a link that supports the DELETE operation and that looks something like this:

```
<links>
```

```
<link resourceType="urn:oracle:webcenter:people:invitation"
rel="self"
href="http://host_name:port_name/rest/api/people/invitations/
     e9073cdb-56ab-423d-8b1f-1220c802bdd4?
     utoken="FN0SEFwX42OCntwtx9a1dSbhqocO_w**"
     capabilities="urn:oracle:webcenter:delete"/>
</links>
```

The invitee can also delete an invitation from his or her own account. The invitee can get a list of his or her invitations by specifying:

```
GET
http://<host:port>/rest/api/people/invitations?q=invitee:equals:@me&utoken=ASDF
```

Note that the response from a DELETE is simply a status code of 204.

Part VII

Helping Users Find Content

Part VII contains the following chapters:

43 Integrating Links

This chapter explains how to integrate links functionality in a Portal Framework application at design time.

This chapter includes the following topics:

- Section 43.1, "Introduction to Links"
- Section 43.2, "Basic Configuration for Links"
- Section 43.3, "Advanced Information for Links"

For more information about managing and including links, see:

- the "Setting up Database Connections" chapter in *Administering Oracle WebCenter Portal*
- the "Working with the Links Component" chapter in *Building Portals with Oracle WebCenter Portal*
- the "Linking Information in WebCenter Portal" chapter in *Using Oracle WebCenter Portal*

43.1 Introduction to Links

This section provides overview information about links functionality and requirements. It includes the following subsections:

- Section 43.1.1, "Understanding Links"
- Section 43.1.2, "Requirements for Links"
- Section 43.1.3, "What Happens at Runtime"

43.1.1 Understanding Links
